B Cells

Novel aspects of B cell response to vaccination and viral infection

*Batista, F. Gaya, M, Martinez, N.
Ragon Institute*

B lymphocytes form an integral part of the immune system via the production of specific antibodies and by establishing immunological memory enabling a swift and effective response to pathogenic assault. To fully understand the processes whereby this is achieved, it is essential to gain a comprehensive understanding of the events involved in B cell activation and antibody production. This is initiated by the encounter with and acquisition of cognate antigen by the B cell receptor (BCR); processes occurring primarily in secondary lymph nodes (SLOs) such as the lymph node (LN) and which are regulated by complex systems. The functionality of these systems is strictly dependent on maintaining the architecture of the SLOs. During this talk I will describe how the LN structure enables the early encounter of B cells with antigen. Antigenic properties such as the size and nature of the pathogen affect the specialized lymph node antigen delivery systems that exist in readiness to deliver pathogen-derived antigen to B cells. This variability in the types of encounter enables the most appropriate response for that particular antigen to occur, giving the maximal protection to the host. Lastly, the consequences of the disruption of the LN architecture, and the help provided by other cells such as iNKTs, on the immune response will also be described. Their critical role in the immune response is evident following infection, which causes a temporary disruption in the cellular organization of lymphoid organs and lack of essential cytokines leading to a reduction in immune responses.

Tolerance & Transplantation

Immunoregulation in Transplantation

*Wood, K., Bushell, A., Harden, P., Issa, F., Hester, J.
University of Oxford*

Immune regulation is fundamental to any immune response to ensure that it is appropriate for the perceived threat to the host. Strategies for the induction of specific unresponsiveness to donor alloantigens currently under investigation in the clinic take advantage of two of the major mechanisms for the induction of tolerance to self antigens – deletion and immunoregulation/suppression. We have demonstrated that human regulatory T cells expanded *ex vivo* can protect human allografts (skin, islets and vessels) from rejection. Treg migrate to the allograft and function *in situ*. Donor alloantigen reactive Treg are more effective on a per cell basis than polyclonal Treg. Together with other leukocyte populations, including regulatory T cells,

B cells and macrophages as well as myeloid derived suppressor cells and dendritic cells, Treg contribute to the regulation of immune responses *in vivo* after organ transplantation. The identification and characterisation of Treg that can control immune responsiveness to alloantigens has opened up exciting opportunities for new therapies in transplantation. Phase 1/2a clinical trials are in progress – www.onestudy.org.

A new approach to GVHD based on biomarkers

*Ferrara, J.
Icahn School of Medicine at Mount Sinai*

Acute graft versus host disease (GVHD) is the major toxicity of allogeneic bone marrow transplantation. Recent research has identified and validated unexpected biomarkers that predict outcomes. This session will review the use of large and informative biorepositories to create biomarker signatures that predict severe GVHD prior to its clinical onset and that can guide preemptive GVHD therapy. This session will also review mechanistic studies that have illuminated unexpected interactions between the innate and adaptive immune systems in the GI tract that have led to both conceptual breakthroughs and the discovery of novel therapeutic approaches.

Cancer Immunotherapy

Immunotherapy for persisting viral infection and associated cancer

*Frazer, I.¹, Mattarollo, S.¹, Leggatt, G.¹, Wells, J.¹, Tuong, K.¹, Kuo, P.¹, Jazayeri, S.¹, Lambert, P.², Chandra, J.^{1,3}
¹The University of Queensland, Australia, ²The University of Madison, Wisconsin, ³Admedus Immunotherapies*

While vaccines have proven effective at preventing virus infections, immunotherapy for persisting cancer associated viral infections and their associated cancers has proven less tractable. Using a model where a viral antigen, the E7 protein of human papillomavirus (HPV)16, is expressed in grafted mouse skin, we have determined mechanisms preventing effective immunotherapy of persisting HPV infection. In this model, the effector functions of vaccine induced cytotoxic T cells are locally inhibited by multiple mechanisms initiated by hyper-proliferative epithelium associated with HPV infection, and mediated via inflammasome activation, IL-18 and IFN γ . Intra-dermal delivery of an E7 specific polynucleotide vaccine encoding ubiquitin conjugated viral proteins can overcome inhibition of effector T cell function in this model. A herpes virus (HSV) glycoprotein D immunotherapy using the same strategy has, in clinical trial, induced a cell mediated immune response, and is currently under evaluation in persistently HSV-2 infected subjects.

Autoimmunity

Type 1 diabetes is the result of the destruction of pancreatic beta cells by autoreactive T cells. Proinsulin as an autoantigen with beta cell-restricted expression triggers and sustains the autoimmune CD4+ and CD8+ T cell response and islet inflammation. We hypothesized that insulin-degrading enzyme (IDE), a protease genetically associated with type 2 diabetes possessing very high insulin affinity, might be involved in proinsulin processing and presentation. We find high expression of IDE and an increased number of autoantigenic insulin B chain fragments in IDE-deficient beta cells of non-obese diabetic (NOD) mice, and normal to increased stimulation of insulin-specific CD8 and CD4 T cells by IDE-deficient islets. This suggests that IDE physiologically degrades (pro)insulin in beta cells. However, surprisingly, IDE-deficient NOD mice are more resistant to diabetes transfer by T cells specific for insulin but not for another key autoantigen, harbor fewer diabetogenic splenocytes and display strongly reduced diabetes incidence. Moreover, IDE-deficient islet grafts are more resistant to autoimmune rejection. Seeking to explain the apparent paradox between normal to increased insulin presentation and resistance to the diabetogenic action of insulin-specific T cells, we find that IDE deficiency results in upregulated beta cell regeneration in response to autoimmune inflammation. Diabetes protection in IDE-deficient mice most likely result from moderately increased beta cell stress recently shown to induce beta cell proliferation. Thus IDE acts both in processing of the key autoantigen in murine type 1 diabetes and as a regulator of beta cell stress, ultimately enhancing autoimmune pathology and diabetes.

Redemption or Revolt of Forbidden Clones: Mutations, Autoantibodies and CTLA4-Ig Therapy

Goodnow, C.¹, Reed, J.¹, Burnett, D.¹, Brink, R.¹, Christ, D.¹, Schofield, P.¹, Perotti, S.², Enders, A.², Ziegler, J.³, Wainstein, B.³, Roscioli, T.^{1,3}, Gray, P.³

Many B cells in the pre-immune repertoire carry antibodies that bind to self-antigens. Some are deleted before these antibodies can be tested for binding foreign antigens, but others are

carried on anergic B cells. Tolerance by B cell clonal anergy is enigmatic since the B cells exist in a potentially reversible state, balanced between activation and apoptosis, posing the risk of autoimmunity. Here I will describe a clinical case of LRBA deficiency resulting in life-threatening autoimmune cytopenias that rapidly resolved by treatment with CTLA4-Ig (Abatacept) following diagnosis by whole genome sequencing. By producing a mouse avatar of the case, we confirm that LRBA-deficiency leads selectively to low CTLA4 on Tregs and other T cells. Autoantibody secretion in LRBA or CTLA4 deficiency may be explained by our earlier findings that failure to dampen CD86 expression on anergic B cells allows them to escape FasL-mediated killing by helper T cells and be reactivated to form huge numbers of plasma cells. I will present evidence that physiological reactivation of anergic cells in humans and mice yields precursors for germinal centre cells that hypermutate their antibody variable segments away from self-reactivity. This represents a mechanism for actively acquired tolerance that has been hypothesised in the past but not taken seriously. IgD, which is the main antigen receptor displayed on anergic B cells before any reactivation, helps to keep anergic cells alive in the pre-immunerepertoire by attenuating their response to self-antigens.

Transcription Factors

2131

The dual role of Bcl6 in the regulation of the differentiation and function of follicular cytotoxic T cells

Chen, Y.¹, Leong, Y.A.¹, Man, K.², Ong, H.¹, Wu, D.³, Kallies, A.², Yu, D.¹

¹Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ²Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ³University of North Carolina, Chapel Hill, United States

Follicular helper T (T_{fh}) cells are a subset of CD4⁺ helper T cells that express the chemokine receptor CXCR5 and migrate into B-cell follicles. T_{fh} cells support germinal centre response for antibody affinity maturation and memory formation. As the master transcription factor for T_{fh} differentiation, Bcl6 is required for CXCR5 expression on CD4⁺ T cells. Recently, my lab identified a subset of CD8⁺ cytotoxic T cells that express CXCR5 and localize to B-cell follicles in a model of viral infection. CXCR5⁺ CD8⁺ T cells are required to control the infection of T_{fh} cells and termed follicular cytotoxic T (T_{fc}) cells. As in T_{fh} cells, we found Bcl6 was also upregulated in T_{fc} cells. The loss of Bcl6 led to the defects of T_{fc} differentiation while overexpression of Bcl6 promoted the differentiation of T_{fc} cells. Importantly, we also found Bcl6 suppresses the cytotoxic function by inhibiting the expression of genes that encode cytotoxic molecules such as Granzyme B. In HIV infections, T_{fh} cells serve as the major CD4 T cell compartment for HIV-1 infection, replication, and production. The discovery of the dual role of Bcl6 in the regulation of T_{fc} differentiation and function might provide an explanation why CD8⁺ T cells are less effective to control the infection of T_{fh} cells in B-cell follicles than non-T_{fh} cells in T-cell zone.

Mapping regulatory networks in human regulatory T cells by chromatin conformation capture

Sadlon, T.^{1,2}, Bandara, V.¹, Brown, C.¹, Beyer, M.³, Schultze, J.³, Bent, S.¹, Forrest, A.⁴, Barry, S.²

¹Molecular Immunology, Robinson Research Institute, Adelaide, Australia, ²Women's and Children's Health Network, Gastroenterology, Adelaide, Australia, ³LIMES, University of Bonn, Bonn, Germany, ⁴Henry Perkins Institute for Medical Research, Genomics, Perth, Australia

Regulatory T cells (T_{reg}) play a key role in tolerance and immune homeostasis. Our research has revealed that T_{reg} function and stability is orchestrated by gene networks regulated by FOXP3 and microRNAs. It is now evident that coordinated gene regulation occurs in a cell specific manner to bring together regulatory elements and coding regions, and this is conformation dependant. While bioinformatics can

predict targets of transcription factors with some accuracy, and genomics datasets can now identify functional motifs in chromatin, such as super enhancers and lncRNAs, the targets of these regions cannot be predicted by linear annotation models. Conformation capture can determine which non coding elements interact with T_{reg} specific genes, and we can superimpose on this our FOXP3 binding site data. This analysis will reveal the conformation dependant transcriptional regulation of T_{reg} genes, and will also allow for the first time annotation of SNPs from autoimmune diseases to functional targets. As proof of principle we have used SATB1, a key FOXP3 repressed gene in T_{reg} (1), as a conformation capture target. Using 4Cseq we have identified a T cell specific activation induced FOXP3 responsive super enhancer over 300Kb upstream, and this region includes 5 enhancer elements. We now confirm that this enhancer is T cell activation dependant, is repressed by FOXP3, and overlaps a number of IBD/Colitis SNPs from GWAS datasets, confirming the power of this approach. The functional impact of autoimmune SNPs on SATB1 expression is now under investigation

A combinatorial threshold model for effector differentiation of CD8⁺ T cells mediated by Blimp-1 and T-bet

Masson, F.^{1,2,3}, Xin, A.^{2,3}, Liao, Y.^{2,3}, Preston, S.^{2,3}, Guan, T.⁴, Gloury, R.^{2,3}, Olshansky, M.^{2,5}, Lin, J.-X.⁶, Li, P.⁶, Speed, T.P.^{2,7}, Smyth, G.K.^{2,7}, Ernst, M.^{1,8}, Leonard, W.J.⁶, Pellegrini, M.^{2,3}, Kaech, S.^{4,9}, Nutt, S.L.^{2,3}, Shi, W.^{2,7}, Belz, G.T.^{2,3}, Kallies, A.^{2,3}

¹Olivia Newton-John Cancer Research Institute, Cancer Inflammation Laboratory, Heidelberg, Australia, ²Walter & Eliza Hall Institute, Parkville, Australia, ³University of Melbourne, Department of Medical Biology, Parkville, Australia, ⁴Yale University School of Medicine, Department of Immunobiology, New Haven, United States, ⁵University of Melbourne, Department of Computing and Information Systems, Parkville, Australia, ⁶National Heart, Lung and Blood Institute, NIH, Bethesda, United States, ⁷University of Melbourne, Department of Mathematics and Statistics, Parkville, Australia, ⁸La Trobe University, School of Cancer Medicine, Heidelberg, Australia, ⁹Howard Hughes Medical Institute, Chavry Chase, United States

T cell responses are guided by cytokines that induce transcriptional regulators, which ultimately control the differentiation of effector and memory T cells. However, it is unknown how their activities are coordinated and integrated during this process. In the present study, we used broad transcriptional profiling of antigen-specific CD8⁺ T cells to systematically dissect the relative contributions and interdependency of two major drivers of CD8⁺ effector T cell differentiation, Blimp-1 and T-bet. Furthermore, we unraveled how IL-2 impacts on transcriptional changes during effector cell differentiation *in vivo*. We showed that Blimp-1 acts as a signal integration node for IL-2 and pro-inflammatory cytokines, in particular IL-12, which overlap to initiate effector differentiation. Moreover, while deficiency in either Blimp-1 or T-bet left effector function partially intact, combined ablation of both factors resulted in loss of expression of effector molecules and an inability to control systemic viral infection. Importantly,

T-bet/Blimp1 double-deficiency resulted in the derepression of several molecules usually associated with IL-17 producing CD8⁺ T (Tc17) cells and severe immune pathology. Overall, our data reveal two major pathways of effector differentiation governed by the availability of Blimp-1 and T-bet and suggest a model for cytokine-induced transcriptional changes that combine quantitatively and qualitatively to promote robust effector CD8⁺ T-cell differentiation.

757

The role of SATB1 in virus-specific CD8⁺ T cell mediated immunity

Nuessing, S., Russ, B.E., Grant, E.J., Kedzierska, K., Turner, S.J. University of Melbourne, Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia

CD8⁺ T cells are a critical component of the immune response to viral infection such as the influenza virus. Upon virus recognition immunologically naïve T cells undergo a program of proliferation and functional differentiation resulting in a large pool of effector cells secreting cytotoxic molecules and pro-inflammatory cytokines required for viral clearance. Importantly, a long-lived pool of virus-specific memory T cells survives after resolution of the infection and responds more readily following re-infection, allowing faster viral clearance and providing the basis of protective T cell-mediated immunity.

Changes to the structure of DNA-protein complexes, within responding T cells underpin the differences in gene transcription that confer the functional and phenotypic differences between naïve, effector, and memory T cells. SATB1 is a master regulator of chromatin structure, and as such, a key regulator of transcription. We have shown that *Satb1* is expressed in naïve T cells, down-regulated as naïve cells differentiate to effector and then memory, in both mice and human. Additionally, characterization of mice bearing a dysfunctional *Satb1* gene revealed a depletion of T cells bearing the CD44^{hi} signature, a gene up-regulated after T cell activation. On this basis, we hypothesize that SATB1 regulates CD8⁺ T cell differentiation. To address this hypothesis, we use next generation sequencing methods to characterize the genome-wide distribution of SATB1 binding at each stage of T cell differentiation. Combining these data with transcriptomic analyses of the wild-type and *Satb1* mutant mice will provide insights into the role of SATB1 in mediating virus-specific CD8⁺ T cell differentiation.

Transcriptional networks that establish B cell identity

Ikawa, T.¹, Miyai, T.¹, Kawamoto, H.²

¹RIKEN Center for Integrative Medical Sciences, Yokohama, Japan,

²Kyoto University, Institute for Frontier Medical Sciences, Kyoto, Japan

B lymphocytes are generated from hematopoietic stem cells (HSCs) through a successive series of lineage restriction processes. Although many transcription factors (TFs) and epigenetic regulators have been implicated in controlling the B cell fate specification, exact mechanisms remain elusive. We have recently established a culture system that can

examine gene regulatory networks of HSCs differentiating into B cell lineage (Ikawa et al. 2015). We overexpressed Id3 protein fused with ERT2 (Estrogen receptor) protein whose nuclear translocation is induced by 4-hydroxytamoxifen (4-OHT) in hematopoietic progenitors and cultured them in B cell differentiation condition. B cell development of Id3-transduced cells was blocked at an early developmental stage and the cells grew enormously with maintaining multipotency in the presence of 4-OHT. Virtually all cells became CD19⁺ B cells by simply withdrawing 4-OHT within 7 days. We then performed RNA-Seq analysis at multiple time points in this system. The expressions of “master” TFs such as Ebf1 and Pax5 were dramatically upregulated after 48hrs of induction. Notably, the sequential upregulation of TFs before the onset of the key TF program was found. The earliest responding TFs such as Egr1 and Klf4 had a peak at 0.5-2hrs followed by a continuous stream of TFs within 24hrs. Knockdown of these genes led to the defected B cell generation both in vivo and in vitro. Taken together, our findings identified a genome-wide view of the dynamic transcriptional waves in B cell fate determination.

1387

Hierarchical regulation of enhancer establishment and gene expression by transcription factors during mononuclear phagocyte development

Kurotaki, D.¹, Nakabayashi, J.², Nishiyama, A.¹, Sasaki, H.¹, Kaneko, N.¹, Ozato, K.³, Suzuki, Y.⁴, Tamura, T.¹

¹Yokohama City University Graduate School of Medicine, Department of Immunology, Yokohama, Japan, ²Yokohama City University, Advanced Medical Research Center, Yokohama, Japan, ³NICHD, NIH, Bethesda, United States, ⁴Graduate School of Frontier Sciences, University of Tokyo, Department of Computational Biology, Chiba, Japan

Monocytes and dendritic cells (DCs) are mononuclear phagocytes essential for innate and adaptive immunity. These phagocytes develop from hematopoietic stem cells via intermediate progenitors, such as granulocyte-monocyte progenitors (GMPs), monocyte-DC progenitors (MDPs), and common monocyte progenitors (cMoPs) or common DC progenitors (CDPs). However, the molecular mechanism underlying their differentiation potential remains incompletely understood. Recent studies suggest that promoter-distal enhancers are key for cell fate decision. In this study, we performed chromatin immunoprecipitation-sequencing (ChIP-seq) analysis of enhancer-related histone modifications (H3K4me1 and H3K27ac) in GMPs, MDPs, cMoPs, CDPs, monocytes, DCs, and neutrophils. We found that monocyte- and DC-specific enhancers were gradually established at progenitor stages prior to gene expression. DNA motif analysis implicated that these enhancers were regulated by combinations of lineage-determining transcription factors such as PU.1, RUNX, C/EBP, and IRF. Interestingly, the motifs specifically enriched in the mononuclear phagocyte lineage were the IRF binding motifs. Among IRFs, IRF8 is known to be highly expressed from the MDP stage and necessary for MDP-to-CDP and cMoP-to-monocyte transitions. Somewhat unexpectedly, however, global gene expression patterns were comparable

between the remaining *Irf8*^{-/-} progenitors and their wild-type counterparts. Nevertheless, the enhancer landscapes of *Irf8*^{-/-} progenitors were significantly distinct from those of wild-type cells, with the enhancer landscapes of *Irf8*^{-/-} GMPs, MDPs, and cMoPs all remaining similar to that of wild-type GMPs. IRF8 was required particularly for the establishment of enhancers common in monocytes and DCs. These results illustrate that enhancer establishment and gene expression are dynamically and hierarchically regulated by transcription factors during mononuclear phagocyte development.

1506

Batf2/Irf1 induces inflammatory responses in classically activated macrophages, lipopolysaccharides, and mycobacterial infection

Roy, S.^{1,2}, Guler, R.^{3,4}, Parihar, S.P.^{3,4}, Schmeier, S.⁵, Kaczowski, B.^{1,2}, Nishimura, H.^{1,2}, Shin, J.W.^{1,2}, Negishi, Y.^{1,2}, Ozturk, M.^{3,4}, Hurdoyal, R.^{3,4}, Kubosaki, A.¹, Kimura, Y.¹, de Hoon, M.J.L.^{1,2}, Hayashizaki, Y.^{2,6}, Brombacher, F.^{3,4}, Suzuki, H.^{1,2}

¹RIKEN Center for Life Science Technologies, Yokohama, Japan, ²Riken Omics Science Center, Yokohama, Japan, ³University of Cape Town/Institute of Infectious Disease and Molecular Medicine (IDM), Division of Immunology, Cape Town, South Africa, ⁴International Centre for Genetic Engineering and Biotechnology (ICGEB), Cape Town Component, Cape Town, South Africa, ⁵Massey University, Institute of Natural and Mathematical Sciences, North Shore City, New Zealand, ⁶Riken Preventive Medicine and Diagnosis Innovation Program (PMI), Yokohama, Japan

Basic leucine zipper transcription factor Batf2 is poorly described, whereas Batf and Batf3 have been shown to play essential roles in dendritic cell, T cell, and B cell development and regulation. Batf2 was drastically induced in IFN- γ -activated classical macrophages (M1) compared with unstimulated or IL-4-activated alternative macrophages (M2). Batf2 knockdown experiments from IFN- γ -activated macrophages and subsequent expression profiling demonstrated important roles for regulation of immune responses, inducing inflammatory and host-protective genes *Tnf*, *Ccl5*, and *Nos2*. *Mycobacterium tuberculosis* (Beijing strain HN878)-infected macrophages further induced Batf2 and augmented host-protective Batf2-dependent genes, particularly in M1, whose mechanism was suggested to be mediated through both TLR2 and TLR4 by LPS and heat-killed HN878 (HKTb) stimulation experiments. *Irf1* binding motif was enriched in the promoters of Batf2-regulated genes. Coimmunoprecipitation study demonstrated Batf2 association with *Irf1*. Furthermore, *Irf1* knockdown showed downregulation of IFN- γ - or LPS/HKTb-activated host-protective genes *Tnf*, *Ccl5*, *Il12b*, and *Nos2*. Batf2 deficiency in mice resulted in resistance to *M. tuberculosis* infection with reduced immunopathology. Conclusively, Batf2 is an activation marker gene for M1 involved in gene regulation of IFN- γ -activated classical macrophages, as well as LPS/HKTb-induced macrophage stimulation, possibly by Batf2/*Irf1* gene induction. Taken together, these results underline the role of Batf2/*Irf1* in inducing inflammatory responses in *M. tuberculosis* infection.

2879

The effects of transgenic expression of a T-box molecule, eomesodermin, in naive T cells on their activation and exhaustion status

Eshima, K., Misawa, K., Noma, H., Iwabuchi, K.
Kitasato University School of Medicine, Department of Immunology, Sagami-hara, Japan

A T-box family transcription molecule, Eomesodermin (Eomes), controls effector function of CD8⁺ CTLs. Eomes is expressed in effector or memory CD8⁺ T-cells, but is also found in "exhausted" cells, although its precise roles there remain to be fully delineated. In order to determine the relevance of Eomes in T-cell activation statuses, we developed Eomes-transgenic mouse using human CD2 promoter/enhancer. In Eomes-Tg mouse, the number of peripheral T-cells was smaller than that in wild type mice. This was accompanied with decreased expression of CD127 and Bcl-2 in Tg mature T-cells, which is frequently observed in exhausted T-cells. It was also noticed that higher proportion of peripheral CD8⁺ T-cells in Eomes-Tg mice expressed some of exhausted T-cells markers, such as, PD-1, LAG-3, or TIM-3, suggesting that part of exhausted T-cell phenotypes may result from higher expression of Eomes. As for other activation markers, expression of CD44, CD122, Ly-6C was also up-regulated on Eomes-Tg CD8⁺ T-cells. By utilizing Tg-TCR, it was suggested that optimal expression of many of these markers, except for CD122, still requires TCR-stimulation. Transgenic expression of Eomes alone may not be adequate for provision of functional activity to CD8⁺ T-cells, either, since CD44^{lo+} CD8⁺ T-cells from Eomes-Tg did not produce IFN- γ or exert cytotoxicity until antigenically primed. Collectively, these results imply that Eomes induction alone may be insufficient for proper CTL differentiation and that Eomes expression without TCR stimulation might induce exhausted phenotypes.

2692

Deciphering the importance of H3K27me3 demethylation during early CD8⁺ T cell responses against influenza A virus

Li, J., Olshansky, M., Turner, S.
University of Melbourne, Department of Microbiology & Immunology, Melbourne, Australia

The acquisition and maintenance of cytotoxic CD8⁺ T cell (CTL) function in response to influenza virus infection is partly regulated by co-ordinated changes in chromatin structure, histone modifications and binding of transcription factors. Developmental or lineage-defining genes in stem cells and CD4⁺ T cells are bivalently marked by the repressive trimethylated lysine 27 (H3K27me3) and activating trimethylated lysine 4 (H3K4me3) on the H3 histone. In naive CD8⁺ T cells, we have also shown that a number of bivalent genes rapidly resolve to a transcriptionally permissive state when differentiated into virus-specific effector and memory T cells (Russ *et al.*, 2014). To understand how the early removal of the repressive mark, H3K27me3, defines immediate transcriptional responses of bivalent genes, naive CD8⁺ T cells were stimulated with the SIINFEKL peptide for 3, 5 and 24hrs. Whole-genome H3K27me3 chromatin-immunoprecipitation-sequencing (ChIP-seq) and

RNA-seq at each time point showed that distinct cohorts of gene expression, including bivalently marked genes, *Tbx21* (encoding T-bet) and *Irf4*, are transcribed as early as 3hrs post-activation. Importantly, inhibition of H3K27me3 demethylation perturbed the immediate expression of these transcription factors along with early activation markers *i.e.* CD62L and CD69. Therefore, the timely resolution of chromatin bivalency by H3K27me3 demethylation, significantly shapes early CTL gene expression programs through the activation of these transcription factors. These molecular signatures potentially represents a novel regulatory step involved in the formation of effector and memory CD8⁺ T cells.

Emerging Technologies

1831

Next-generation detection of antigen-responsive T cells using DNA barcode-labeled peptide-major histocompatibility complex I multimers

Bentzen, A.K.¹, Marquard, A.M.², Lyngaa, R.¹, Saini, S.K.¹, Andersen, S.R.¹, Donia, M.³, Svane, I.M.³, Thor Straten, P.³, Szallasi, Z.², Jakobsen, S.N.⁴, Eklund, A.C.², Hadrup, S.R.¹

¹Section for Immunology and Vaccinology, Technical University of Denmark, Frederiksberg, Denmark, ²Center for Biological Sequence Analysis, Technical University of Denmark, Lyngby, Denmark, ³Center for Cancer Immune Therapy, Copenhagen University Hospital, Herlev, Denmark, ⁴Immudex, Copenhagen, Denmark

Identification of antigenic peptides recognized by T cells is important for understanding and treating immune related diseases. Current cytometry-based approaches are limited to simultaneous screening of T cell reactivity towards 10-100 distinct peptide specificities, which poorly match the large diversity of T cell recognition in humans. Consequently it has been impossible to comprehensively analyze T cell responsiveness in cancer, infectious and autoimmune diseases. We present and validate a novel technology that enables parallel detection of numerous different peptide-MHC responsive T cells in a single sample using >1000 different peptide-MHC multimers labeled with individual DNA barcodes. After isolation of MHC multimer binding T cells their recognition are revealed by amplification and sequencing of the MHC multimer-associated DNA barcodes. The relative frequency of the sequenced DNA barcodes originating from a given peptide-MHC motif relates to the size of the antigen-responsive T cell population. We have demonstrated the use of large panels of >1000 DNA barcoded MHC multimers for detection of rare

T cell populations of virus and cancer-restricted origin in various tissues and compared with combinatorial encoding of fluorescent-labeled MHC multimers. Finally, we have demonstrated that this technology can be applied for multiplex T cell detection both in limited biological samples, such as uncultured tumor material, and for simultaneous assessment of target recognition and functional capability of T cells. This technology enables true high-throughput detection of antigen-responsive

T cells and will advance our understanding of immune recognition from model antigens to genome-wide immune

assessments on a personalized basis.

Multiplexed spatially resolved protein detection from FFPE samples for oncology and immunotherapy

Rhodes, M.¹, Warren, S.¹, Jung, J.¹, Merritt, C.¹, Webster, P.¹, Dunaway, D.¹, Mills, G.², Tumei, P.³, Beechem, J.¹

¹NanoString Technologies, Seattle, United States, ²MD Anderson Cancer Center, Houston, United States, ³University of California, Los Angeles, Los Angeles, United States

Traditional immunohistochemistry approaches to staining proteins within FFPE tissue are suboptimal because they only evaluate a few targets simultaneously, rely on signal amplification, and require subjective assessment of staining intensity. NanoString has developed a method for determining abundance and localization of a large number of proteins (potentially up to 800-plex) from FFPE samples using non-amplified digital counting. Tissue sections are stained with antibodies conjugated to UV-cleavable barcodes and proteins are enumerated by counting UV-released barcodes with the the nCounter® Analysis System. This allows the quantification of proteins from either a whole slide (to facilitate biomarker development in highly reproducible format) or from small regions of interest within the tumor (to permit the discovery of novel biology).

Here, we present two applications of the technology. First, breast cancer samples are stained with a oncocktail of barcode labeled antibodies including HER2, ER, PR, EGFR, histone, and others. Regions of interest are selected and barcodes from the cocktail of antibodies quantified. The robustness of the system is demonstrated by digital counts which are proportional to the illuminated area and strong concordance between visual intensity of HER2 staining and the HER2 digital counts. In the second example, a 30+ cocktail of antibodies recognizing immunologically relevant targets (including cell lineage markers and immune checkpoints) are used to stain tumors and elucidate patterns of immune cell distribution and activation states.

This new technology enables highly multiplexed characterization of protein expression and localization on both tumor and infiltrating immune cells and facilitates the development of novel biomarkers.

2351

Proof of concept for MHC allelic replacement by CRISPR-Cas9 assisted cassette exchange

Kelton, W., Waindok, A., Pogson, M., Parola, C., Reddy, S.
ETH Zürich, BSSE, Basel, Switzerland

Allogeneic cellular transplantation is widely employed to treat various genetic diseases and hematological malignancies. Locating suitable donors for these procedures is often challenging, as MHC/HLA gene alleles need to be matched in order to prevent transplant rejection. We report here a proof of concept study for an ex-vivo CRISPR-Cas9-based approach for the precise exchange of MHC alleles (~5kb) at the native genomic locus. For initial evaluation, the method was performed

on immortalized mouse antigen-presenting cells (RAW264.7 macrophages) expressing high levels of surface MHC (H2-Kd). Genomic exchange at the H2-K locus was achieved via co-transfection of cells with a plasmid carrying Cas9 and guide RNA targeting the H2-Kd locus and a homology donor repair template encoding an alternate MHC allele (H2-Kb). Following homology directed repair, modified cells were isolated by flow cytometry based on expression of new MHC. Engineered cells expressing the alternate H2-Kb allele were able to present a model antigen peptide (OVA-SINFEKLL) and activate a cognate T cell hybridoma line, demonstrating they were active for downstream immune functions. We envision this approach could be used in the future to improve MHC/HLA matching in cellular transplantation.

Editing the genome in cells and mice using CRISPR/Cas9 technology

Herold, M.J.^{1,2}, Aubrey, B.J.^{1,2,3}, Kelly, G.L.^{1,2}, Kueh, A.J.^{1,2}, Brennan, M.S.^{1,2}, O'Connor, L.^{1,2}, Milla, L.^{1,2}, Wilcox, S.^{1,2}, Tai, L.¹, Strasser, A.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ²Melbourne University, Department of Medical Biology, Melbourne, Australia, ³Royal Melbourne Hospital, Department of Clinical Haematology, Melbourne, Australia

CRISPR/Cas9 mediated genome engineering provides an easy and rapid way to edit genes *in vitro* and *in vivo*. Initial experimental strategies utilised proved to have a low efficiency and were not broadly applicable to all cell types. In order to overcome this hurdle and to allow for efficient modification of genes in the haematopoietic system, we have developed a novel drug-inducible lentiviral system to deliver the CRISPR/Cas9 platform to cells permitting efficient genome engineering *in vitro* and *in vivo*. Additionally we have recently also implemented the CRISPR/Cas9 technology for producing genetically modified mice and to use it as a screening tool for the identification of novel cell death regulators.

Cancer-specific T cell receptor isolation by single cell PCR for cancer immunotherapy

Hibbert, L., Teng, M., Ryan, R., Baker, D., Clark, V., Williams, L., Conlon, L., Hale, K., Davis, S., Weigand, L., Paston, S., Molloy, P., Vuidepot, A., Hassan, N., Jakobsen, B.

Immunocore Ltd, Abingdon, United Kingdom

Malignant cells may be recognised by T cells binding cell surface Class I HLA (Human Leukocyte Antigen)-peptide complexes presenting disease-associated epitopes. Many cancer patients have been shown to generate CD8 cytotoxic T cell responses to tumour-associated antigens. However this is often insufficient for the immune system to clear tumours, resulting in progression of cancer. This is in part due to the low avidity of these T cells as well as the ability of cancer cells to develop escape mechanisms to avoid destruction by T cells. To overcome these issues, we have engineered novel, bi-functional protein therapeutics

termed ImmTACs (Immune mobilising monoclonal TCR Against Cancer) which re-direct the immune system to target and destroy tumour cells with a high degree of potency and specificity. An ImmTAC comprises a high affinity 'monoclonal' T cell Receptor (mTCR) targeting a cancer-associated HLA-peptide complex, fused to an anti-CD3 scFv domain which activates an anti-tumour T cell response.

In order to produce ImmTACs, we have developed an integrated in-house process leading to the isolation of TCRs specific for validated cancer epitopes. High affinity ImmTACs are then generated through affinity maturation by phage display. We have developed a method of rapidly identifying TCR chains from T cell clones using targeted amplification from single cells. We describe the steps leading to cloning of wild type TCRs with single cell PCR. We present data to illustrate the successful isolation of TCRs as a result of this procedure.

956

A scalable multiplex assay enabling assessment of TCR specificity to hundreds of self- and pathogen-derived antigens

Klinger, M., Taniguchi, R., Hu, J., Hayes, T., Wittkop, T., Asbury, T., Moorhead, M., Emerson, R., Sherwood, A., Robins, H., Faham, M. Adaptive Biotechnologies Corp, South San Francisco, United States

Monitoring antigen-specific T-cells is critical for the study of immune responses and development of biomarkers and immunotherapeutics. We developed and validated a novel multiplex assay (MIRA, or Multiplexed Identification of TCR Antigen specificity) that combines conventional immune monitoring techniques and TCR repertoire sequencing to assess T-cell specificity to large numbers of query antigens. MIRA is a sensitive assay enabling detection of antigen-specific TCR clonotypes well below the limit of detection of conventional immune monitoring assays including flow cytometry and ELISPOT. Here we report the results from a scaled-up version of the assay using 270 different query peptide antigens (159 self- and 111 pathogen-derived). We identified >500 TCR clonotypes at frequencies as low as 1 per million T-cells that were specific to 41 query antigens from 6 healthy HLA-A*02-positive individuals. Most of the antigen-specific TCRs identified recognized one of 27 different peptides derived from a variety of pathogens including CMV, EBV, Flu, Rotavirus, HSV, mTB, WNV and HIV. A subset of antigen-specific TCRs recognized one of 14 different peptides derived from self including MART1, RCC, BCL-2, MAGE, STEAP1, KLK4, CAMEL and MOG. These data support the notion that escape and survival of self antigen-specific T-cells occurs without causing overt autoimmunity in healthy individuals. We show MIRA can be used to assess TCR specificities to hundreds of query antigens simultaneously. The assay is highly scalable and easily modified to accommodate thousands of additional query antigens. This technology may be used to monitor T-cell specificity to antigens relevant to infection, autoimmunity and cancer.

3224**Small airway-on-a-chip: a novel microphysiological system to study human lung inflammation *in vitro***

Hajipouran Benam, K.¹, Villenave, R.¹, Lucchesi, C.¹, Hubeau, C.², Varone, A.¹, Ferrante, T.C.¹, Weaver, J.C.¹, Bahinski, A.¹, Hamilton, G.A.¹, Ingber, D.E.¹

¹Harvard University, Wyss Institute for Biologically Inspired Engineering, Boston, United States, ²Pfizer Inc, Cambridge, United States

Development of new therapeutics for lung inflammatory and infectious diseases, such as chronic obstructive pulmonary disease (COPD) and respiratory viral infections, which are associated with significant morbidity and mortality, has been hindered by challenges to study organ-level complexities of lung inflammation *in vitro*.

Here, we applied a microengineering technological approach known as 'organ-on-a-chip' to create a human lung small airway-on-a-chip that supports full differentiation of a pseudostratified mucociliary bronchiolar epithelium composed of cells isolated from normal or diseased donors underlined by a functional microvascular endothelium, which experiences continuous blood-like fluid flow. Airway chips lined with well-differentiated COPD epithelia recapitulated features of the disease including selective cytokine hypersecretion, increased neutrophil recruitment, and clinical exacerbations by exposure to pathogen-mimetic compounds. Using this robust *in vitro* method for modeling human lung inflammatory disorders, it was possible to detect synergistic effects of lung endothelium and epithelium on cytokine secretion, identify new biomarkers of disease exacerbation, and measure responses to anti-inflammatory compounds that inhibit cytokine-induced recruitment of circulating neutrophils under physiological vascular shear. Importantly, the 'synthetic biology' nature of our tissue engineering approach allowed us to independently control and vary key system parameters that influence organ-level lung mucosal inflammation.

Thus, the human small airway-on-a-chip offers a powerful complement to animal models for both analyzing human pathophysiology and carrying out preclinical drug evaluation.

1127**The GARD assay for potency assessment of skin sensitizing chemicals**

Forreryd, A., Zeller, K., Lindberg, T., Albrekt, A.-S., Chawade, A., Lindstedt, M.

Lund University, Department of Immunotechnology, Medicin Village, Lund, Sweden

Allergic Contact Dermatitis (ACD) is caused by adverse immune reactions in the skin and develops upon repeated exposure to chemical haptens. To reduce exposure, efforts are being made to develop assays for identification of such compounds. We have previously developed an assay (GARD) based on a biomarker signature of 200 mRNAs, identified by transcriptomics of a myeloid cell-line stimulated with reference chemicals (n=38). GARD classifies unknown compounds binary, as either skin sensitizers or non-sensitizers, with an accuracy estimated to

89% (on 39 test chemicals). The aim of the current study is to broaden applicability domain of GARD to include also potency assessments.

We utilized the versatility of analyzing complete transcriptomes of cells, divided reference samples into potency groups, (CLP-labeling: no cat, weak=1B, strong=1A) and identified an alternative signature for prediction of sensitizing potency, using Random Forest (RF). To shed additional light into the molecular mechanisms, we also performed a pathway analysis.

A signature comprising 30 genes was identified. The performance of the signature was validated by cross-validation and estimated to an accuracy of 85% (no cat), 83% (1A) and 79% (1B). We also found a correlation between metabolic and cell-cycle associated pathways and sensitizing potency.

Combining the original and new signature, we present a testing strategy with an ability not only to identify sensitizing chemicals, but rather to perform a more complete risk assessment. Ongoing work focuses on expanding reference chemicals with an additional 50 chemicals to improve predictive performance, and to elucidate molecular mechanism involved in sensitization potency.

1711 **α HER2/CD3 bifunctional RNA engineered human T cells specifically eliminate HER2+ gastric cancer**

Luo, F., Qian, J., Yang, J., Deng, Y., Zheng, X., Liu, J., Chu, Y.
Fudan University, Shanghai, China

Genetically engineered T cells therapy is a promising strategy in cancer immunotherapy. One successful strategy is chimeric antigen receptor (CAR)-T cells therapy, but CARs-restricted on cell surface and side effects of retrovirus are partial limitations for CAR-T therapy. An alternative strategy is bispecific T cell engager (BiTE), but the therapeutic potential of BiTEs is still limited by the short half-life of antibodies, the lack of endogenous effector T cells in patients with advanced cancer, and severe adverse effects. In this study, we developed a novel secretable human epidermal growth factor receptor 2 (HER2)-targeting BiTE, α HER2/CD3. These α HER2/CD3 RNA engineered human T cells persistently secreted α HER2/CD3 fusion proteins, which were released to help engineered T cell to exhibit HER2-specific activity, or redirect bystander T cells to HER2+ cancer cells and even inhibit HER2+ cancer cells proliferation directly. Additionally, HER2+ tumor-bearing mice treated with the secretable α HER2/CD3 RNA engineered T cells got a significant tumor growth inhibition and prolonged survival without observed adverse effect. Thus, the secretable α HER2/CD3 T cells have the characteristics of high potency, long term and low toxicity, which might offer an attractive HER2-targeting immunotherapy for solid tumors.

Nr4a receptors promote completion of Treg cell developmental program and prevent conversion of labile Treg precursors into pathogenic cells

Sekiya, T., Yoshimura, A.

Keio University School of Medicine, Department of Microbiology and Immunology, Tokyo, Japan

Recently, our group reported that Nr4a family of nuclear orphan receptors plays crucial roles in Treg cell development. In this study, we investigated molecular mechanisms for Treg cell development in the thymus, by focusing on the roles mediated by Nr4a. First, we tried to distinguish Nr4a-dependent and -independent Treg cell developmental programs. As a result, we found that several Treg cell-developmental programs were strictly dependent on Nr4a, including suppression of majority of inflammatory cytokine genes, and induction of *Ikzf4* (Eos). On the other hand, induction of many genes in the Treg-signature gene set, including *Ctla4* and *Ii2ra*, were revealed to be independent of Nr4a function. Even Foxp3 was induced, albeit at a reduced level, in Nr4a-deficient Treg precursor (preTreg) cells. However, the Foxp3 expression in Nr4a-deficient preTreg cells was so transient and unstable, that the expression disappeared within one day, even under a supporting condition for Foxp3 expression. Next, we analyzed cooperation between Nr4a and other Treg-developmental factors, including IL-2/CD25 and TNF superfamily (TNFSF)/TNF receptor super family (TNFRSF). By an in vitro system, we revealed that Nr4a were indispensable for IL2/CD25- and TNFSF/TNFRSF-mediated conversion of Treg precursor into Tregs. On the other hand, it was also suggested that Nr4a alone could not induce Tregs, but requires cooperation with IL2/CD25 and TNFSF/TNFRSF. Finally, we found that Nr4a-deficient preTreg cells have a potential to induce autoimmunity. Reflecting the diverse spectrum of self-reactive TCR repertoire of Tregs, Nr4a-deficient preTreg cells elicited autoimmunity against diverse array of self-antigens, including both ubiquitous and tissue-specific ones.

Antibody responses to most infectious and food protein

antigens depend on help to B cells from specialised T follicular helper (Tfh) cells. A subset of Foxp3+ regulatory T cells (Tregs) has been described in mice, with a prominent role in repressing germinal center reactions that are critical for memory B cell formation and long-lived antibody responses. These specialised Tregs co-opt the Bcl-6-dependent Tfh differentiation pathway in order to access the B cell-rich follicles and have therefore been designated as T follicular regulatory (Tfr) cells. Little is known about the ontogeny or function of human Tfr cells. Here we identify a unique Bcl-6-expressing follicular regulatory T cell in human secondary lymphoid tissue, that lacks Foxp3 expression and the thymic-imprinted Foxp3 methylation pattern, but shares expression of key Treg molecules. These cells, designated Tfr2 cells, are the predominant source of T cell-derived IL-10 in human tonsil. Whereas IL-10 alone promotes B cell terminal differentiation into plasma cells, IL-10-producing Tfr2 cells suppress human B cell differentiation and profoundly limit IgE production. Intriguingly, Tfr2 cells only exert their effects in the presence of Tfr2 cells, at least in part through repressing Tfh-derived IL-21 and CD40L. Tfr2 cells are enriched at human oral-associated lymphoid tissues; continuous exposure to food antigens at these sites make Tfr2 cells an ideal candidate to suppress food allergies.

3642

Selective control of regulatory T cells through TCR signaling molecule

Tanaka, A.¹, Nishikawa, H.¹, Noguchi, S.^{1,2}, Morikawa, H.¹, Takahashi, N.², Sakaguchi, N.¹, Sakaguchi, S.¹

¹Osaka University, Immunology Frontier Research Center, Suita, Japan, ²Akita University, Department of Hematology, Nephrology, and Rheumatology, Akita, Japan

Regulatory T (Treg) cells are essential for the active maintenance of immunological self-tolerance and homeostasis. On the other hand, Treg cells infiltrate tumors and hinder effective anti-tumor immune responses in patients, requiring a method to selectively control Treg cells in tumors without eliciting autoimmunity. Here we show that in Treg cells, proximal TCR signaling molecules including Lck and ZAP-70 are regulated specifically to maintain low levels of gene expression and/or basal kinase activity. This Treg-specific repression renders Tregs, especially terminally differentiated and highly suppressive Foxp3+ effector Treg (eTreg) cells, vulnerable to inhibition of Lck and leads to selective depletion of eTreg cells in humans. Imatinib, a tyrosine kinase inhibitor of the oncogenic BCR-ABL fusion protein specifically expressed in chronic myelogenous leukemia (CML) cells, inhibits tyrosine phosphorylation of Lck, as an off-target effect. Long-term imatinib-treated CML patients in complete molecular remission showed selective depletion of eTreg cells whereas those failed in molecular remission did not. The former concurrently exhibited a general increase in the number of effector- or memory-type CD8+ T cells producing multiple cytokines. In vitro, imatinib induced apoptosis predominantly in eTreg cells, augmenting CD8+ T-cell responses against various tumor antigens in healthy individuals and cancer patients. Imatinib is, therefore, able to attenuate TCR signaling intensity more profoundly in eTreg cells than in other T cells, rendering

the former more susceptible to signal-deprived apoptotic cell death. Thus, small molecules that can selectively deplete eTreg cells via exploiting Treg-specific functions are instrumental in augmenting anti-tumor immunity in various cancers.

Pharmacological inhibition of acid sphingomyelinase or genetic ablation enhances CD4⁺ Foxp3⁺ regulatory T cell activity

Hollmann, C.¹, Reuter, D.¹, Werner, S.¹, Avota, E.¹, Müller, N.¹, Japtok, L.², Kleuser, B.², Becker, K.A.³, Gulbins, E.³, Schneider-Schaulies, J.¹, Beyersdorf, N.¹

¹University of Wuerzburg, Institute for Virology and Immunobiology, Wuerzburg, Germany, ²University of Potsdam, Institute of Nutritional Science, Nuthetal, Germany, ³University of Duisburg-Essen, Institute for Molecular Biology, Essen, Germany

The acid sphingomyelinase (human: ASM, mouse: Asm) hydrolyses sphingomyelin into phosphocholine and ceramide which generates signalling platforms and affects viral pathogenicity. CD4⁺ Foxp3⁺ regulatory T (Treg) cells depend on CD28 signalling for their survival and function, a receptor that has previously been shown to activate the Asm/ASM. In line with these findings we observed that Treg cells of wild-type (wt) mice displayed higher basal and CD28-induced Asm activity and, thus, contained more ceramide than conventional CD4⁺ T (Tconv) cells. Investigating Asm-deficient mice we could show that the frequency of Treg cells among CD4⁺ T cells is increased and their suppressive activity is enhanced compared to wt mice - at least partially due to a higher turnover of the effector molecule CTLA-4. Similar to anti-CD28 antibody-mediated expansion of Treg cells in wt mice, these changes in Treg cell frequencies and/ or function in the Asm-deficient mice were associated with more infected neurons using a CNS infection model with recombinant measles virus. Of clinical importance, pharmacological inhibition of Asm in mouse splenocytes *in vitro* and in mice *in vivo* led to higher frequencies of Treg cells among CD4⁺ T cells, as did ASM inhibition in primary human peripheral blood mononuclear cells (PBMC). ASM inhibitors should, thus, be considered as potential immunomodulatory agents for the therapy of inflammatory and autoimmune disorders. This study was supported by a grant from the DFG (FOR2123/P02).

TCR signal strength regulates Akt substrate specificity to induce alternate Th and Treg differentiation programs

Morel, P.A.¹, Hawse, W.F.¹, Sheehan, R.P.², Boggess, W.C.³, Faeder, J.R.²

¹University of Pittsburgh, Immunology, Pittsburgh, United States, ²University of Pittsburgh, Computational and Systems Biology, Pittsburgh, United States, ³University of Notre Dame, Notre Dame, United States

T regulatory (Treg) cells are induced following stimulation of naïve CD4 T cells with low dose antigen to an extent that is negatively correlated with signaling via the Akt/mTOR pathway. Strong TCR signals induce high levels of Akt activity that inhibit

development of Treg by poorly understood mechanisms. Here, we show that high dose stimulation of T cells results in the phosphorylation of Akt on two regulatory sites, Serine (S) 473 and Threonine (T) 308, whereas low dose stimulation results in only T308 phosphorylation. Mathematical modeling shows that the dual phosphorylation of Akt on S473 and T308 is controlled by a feedback loop involving PTEN, mTORC2 and the transcription factor FoxO1 that creates a sharp activation threshold with respect to antigen dose and stimulus duration. Using mass spectrometry to analyze phosphorylated Akt substrates at different levels of stimulation, we find profound differences in the substrates phosphorylated, suggesting that a switch in substrate specificity coupled to the phosphorylation status of Akt may lead to alternative cell fates. Proteins differentially phosphorylated by these two states of Akt include RNA splicing factors, and we find changes in the splice variant expression levels of key TCR signaling proteins, such as CD3 ζ and CD45 that correlate with the observed differences in cell fate. Knockdown of specific splicing factors changed the ratios of Th versus Treg cells induced. Together, this work demonstrates that alternative splicing can affect the outcome of T cell fate decisions and identifies alternate Akt-mediated signaling networks that drive CD4⁺ T cell differentiation.

1532

Evaluation of Galectin-9 blocking mono-clonal antibodies as novel immune-checkpoint inhibitors via the targeting of regulatory T cells in cancer

Mustapha, R.¹, Mrizak, D.¹, Renaud, S.¹, Barjeon, C.², de Launoit, Y.¹, Pancré, V.¹, Moralès, O.¹, Busson, P.², Delhem, N.¹

¹CNRS, UMR 8161, Institut de Biologie de Lille, Lille, France,

²Université Paris-sud, CNRS UMR 8126 and Institut Gustave Roussy, Villejuif, France

The immune system has the potential to recognize and eliminate cancer cells but is held back by certain inhibitory pathways. Regulatory T cells (Tregs) are key players in these pathways. They are a subpopulation of T lymphocytes whose role is to inhibit the immune response in order to maintain immunological homeostasis. However, the Treg population is often upregulated in cancer patients where it promotes tumor. This has made Tregs an appealing target for immunotherapeutic approaches such as anti-CTLA-4 and anti-PD-1. Galectin-9 (Gal-9) a b-galactoside binding lectin has been described as an immunosuppressive molecule which is expressed by both cancer cells and Tregs in order to suppress the anti-tumoral immune response. In this study we first aimed to confirm the role of Gal-9 in Treg-mediated-immuno-suppression. Then we tested the effects of Gal-9 blocking on Treg function and subsequently the anti-tumoral immune response. Following Treg isolation from healthy donors, we have proven via QPCR, ELISA and flow cytometry that Gal-9 is highly expressed and secreted by Tregs with respect to conventional T cells. Moreover, the anti-Gal-9 antibody significantly inhibited the immuno-suppressive function of Tregs in mixed leukocyte reaction proliferation tests. We have also demonstrated that Gal-9 blocking in PBMC culture promotes the secretion of Th1 cytokines TNF-a and IFN-g. Finally, we successfully used the anti-Gal-9 antibody to inhibit

the suppressive function of human nasopharyngeal carcinoma (hNPC) derived exosomes and to significantly limit the growth of xeno-transplanted hNPC tumors in immuno-deficient mice that were previously reconstituted with a human immune system.

1582

Toll-like receptor 9 is required for the maintenance of CD25⁺FoxP3⁺CD4⁺T_{reg} cells during *Listeria monocytogenes* infection

Dolina, J., Lee, J., Schoenberger, S.

La Jolla Institute for Allergy and Immunology, San Diego, United States

It has long been appreciated, but not understood, that the CD8⁺ cytotoxic T lymphocyte (CTL) dependence on CD4⁺ T cell help (T_h) is conditional; needed for some immunogens but not others. One explanation for this phenomenon envisions T_h requirement as an intrinsic property of the pathogen itself rather than its introduction to the immune system. Here we show that dependence of the optimal CD8⁺

T cell response to *Listeria monocytogenes* (*Lm*) on CD4⁺ T cells is a function of the immunogen dose used for priming, with low dose *Lm* (LD; 50 or 10³ CFU WT or Δ ActA, respectively) inducing a primary antigen-specific CTL response profoundly dependent on CD4⁺ T_h cells while that induced by high dose *Lm* (HD; 4×10³ or 10⁶ CFU WT or Δ ActA, respectively) is significantly inhibited by CD4⁺CD25⁺FoxP3⁺ regulatory T cells (T_{reg}). The T_h-independence of HD immunization is not overcome by additional antigen but instead involves the inflammatory response to more bacteria. Evaluation of various TLR pathways as the relevant sensing mechanism showed that TLR2 is required for CTL responses to LD immunization, and that HD immunization in the absence of TLR9 results in a simultaneous loss of CD25⁺FoxP3⁺CD4⁺ T_{reg} cells and increase in conventional CD4⁺ T_h cells and CTLs. Our data thus reveal that the CTL response to the same pathogen is determined by distinct roles for CD4⁺ T cells as helpers versus regulators based on immunogen dose and demonstrate a previously undescribed role for TLR9 in the regulation of CD4⁺ T_h and T_{reg} cells.

High-content cytotoxic assays reveal the biological activity of pathological and therapeutical cytotoxic T lymphocytes

Guipouy, D.^{1,2,3,4}, Gertner-Dardenne, J.⁴, Belmonte, N.⁴, Dupré, L.^{1,2,3}

¹Centre de Physiopathologie de Toulouse Purpan, Inserm UMR 1043, Toulouse, France, ²Université Toulouse III Paul Sabatier, Toulouse, France, ³CNRS, UMR 5282, Toulouse, France, ⁴TxCell, Valbonne-Sophia Antipolis, France

The killing efficiency of cytotoxic T cells is usually evaluated by measuring the percentage of dead target cells resulting from a 4-hr incubation with an excess of cytotoxic T cells. However, the conventional assays fail to capture the ability of these cells to sustain killing over prolonged time. We have recently developed a combination of flow cytometry- and microscopy-based assays to provide kinetic measurements of target cell elimination by human CD8⁺ T cells (Vasconcelos *et al.*, Cell Rep. 2015,11:1474). We here developed these assays further to assess in depth the

cytotoxic activity of

T cells in two clinically-relevant settings: i) CD8⁺ T cells isolated from Wiskott-Aldrich syndrome (WAS) patients, ii) antigen-specific type-1 regulatory CD4⁺ T cells (Ovasave[®], TxCell), which are currently tested in refractory Crohn's Disease patients (Phase IIb). Although WAS CD8⁺

T cells were able to kill target cells in 4hr, their ability to sustain killing over 24hr was strongly impaired. The defect of WAS CD8⁺ T cells to control target cells over time was linked to an inability to assemble stable synapses, resulting from abnormal actin cytoskeleton organization and LFA-1 activation. Our assays also revealed that a potential mechanism of action of therapeutic regulatory T cells relied on the elimination of myeloid cell via a cytotoxic mechanism. Interestingly, these unconventional cytotoxic

T cells developed a robust cumulative killing activity over 24hr. Our study highlights the advantage of applying flow cytometry- and microscopy-based assays to characterize, with high sensitivity, the kinetics of the cytotoxic activity of clinically-relevant T lymphocytes.

The Nedd4-2-Ndfip1 axis is essential to curtail mast cell-dependent IgE-mediated anaphylaxis *in vivo*

Yip, K.H.¹, Kolesnikoff, N.¹, Hauschild, N.¹, Lopez, A.F.^{1,2}, Galli, S.J.³, Kumar, S.^{1,2}, Grimbaldston, M.A.^{1,2}

¹Centre for Cancer Biology, University of South Australia and SA Pathology, Adelaide, Australia, ²University of Adelaide, School of Medicine, Adelaide, Australia, ³Stanford University, Departments of Pathology and of Microbiology and Immunology, Stanford, United States

Cross-linkage of the IgE receptor (FcεRI) by specific antigen ligation on mast cells (MCs) plays a critical role in the pathological process of IgE-dependent allergic disorders, such as anaphylaxis and asthma. Restraint of intracellular signal transduction pathways that promote release of MC-derived pro-inflammatory mediators is necessary to dampen activation and restore homeostasis. In the course of studying the molecular basis regulating IgE-mediated MC function, we discovered that the ubiquitin ligase, Nedd4-2, is a major gatekeeper of MC activation and the adapter molecule Ndfip1 (Nedd4 family interacting protein 1) has a role in this process.

Herein, we show that loss of Nedd4-2 or Ndfip1 activity in MCs causes an increase in the magnitude and duration of IgE-induced pro-inflammatory mediator release *in vitro*. A closer inspection of the signalsome activities of FcεRI engagement in *Nedd4-2^{-/-}* and *Ndfip1^{-/-}* MCs compared to the wild-type counterparts, revealed that p-Syk polyubiquitination by Nedd4-2/Ndfip1 proximal to FcεRI aggregation was disrupted, leading to exacerbated calcium mobilization and prolonged propagation of multiple downstream signaling events including those of the ERK1/2 and NF-κB pathways. The biological significance of these investigations is highlighted further in an IgE-mediated MC-dependent passive cutaneous anaphylaxis mouse model that employed the adoptive transfer of *Nedd4-2^{-/-}* and *Ndfip1^{-/-}* MCs

into conditional MC-deficient *Cpa3-Cre; Mcl-1^{fl/fl}* mice. In this *in vivo* setting, loss of MC-Nedd4-2 or -Ndfip1 resulted in a striking sustained inflammatory influx at the reaction site. Collectively, our findings reveal a previously unknown negative regulatory mechanism whereby Nedd4-2 and Ndfip1 are essential to restrain MC function.

Humanized allergic NOD-SCID IL-2R γ ^{-/-} mice as *in vivo* model for novel allergy vaccines

Vizzardelli, C.¹, Nagl, B.¹, Neunkirchner, A.², Zimmann, F.¹, Kitzmüller, C.¹, Jahn-Schmid, B.¹, Pickl, W.F.², Bohle, B.¹

¹Medical University Vienna, Department of Pathophysiology and Allergy Research, Vienna, Austria, ²Medical University Vienna, Institute of Immunology, Vienna, Austria

Birch pollen allergy affects around 100 million people worldwide. The only treatment curing IgE-mediated allergy with long-term benefit is allergen-specific immunotherapy (AIT). Unfortunately, AIT is not successful in all treated patients. Therefore, one major focus of allergy research is the development of AIT vaccines with improved efficacy. To study such vaccines in an *in vivo* model imitating the human allergic response we humanized NOD-SCID IL-2R γ ^{-/-} (NSG) mice with cells from birch pollen-allergic patients. Briefly, PBMC were injected intraperitoneally (i.p.) together with birch pollen extract (BPE). After seven days, mice were boosted once i.p. with BPE. In addition, mice were humanized with BPE-specific T cell lines (TCL) expanded from PBMC of birch pollen-allergic patients. NSG-mice were challenged thrice intranasally (i.n.) with BPE or PBS. Thereafter, airway hyperresponsiveness (AHR) and lung inflammation was monitored. Human CD45⁺ cells were assessed in lungs and spleens by flowcytometry.

Mice humanized with PBMC and BPE-specific TCL and challenged with BPE showed significantly higher AHR and higher numbers of eosinophils, neutrophils, and basophils, in bronchoalveolar-lavage-fluids (BALF) than mice challenged with PBS. Human CD45⁺ cells were detected in lungs and spleens in both humanization conditions. As expected, higher percentages of CD4⁺T cells were found in mice humanized with BPE-specific TCL. NSG-mice humanized with cells from birch pollen-allergic donors developed allergic lung inflammation to birch pollen. We will now use this *in vivo* model for testing of novel vaccines for birch pollen allergy developed in our laboratory.

Role of interleukin-36 γ in regulating lung inflammation

Tay, H., Yang, M., Hsu, A., Nguyen, T.-H., Plank, M., Maltby, S., Bartlett, N., Hansbro, P., Foster, P.

The University of Newcastle, Immunology & Microbiology, Newcastle, Australia

Respiratory infections are thought to be one of the major risk factors that trigger the steroid resistant asthma exacerbations. In these patients innate inflammatory mediators and cells are

linked to pathogenesis and disease severity. Our investigations have identified novel roles of interleukin (IL)-36 family cytokines in regulating airway inflammation and alterations in lung function during infection and pathogen-induced exacerbation of asthma. We found that the expression of IL-36 γ was significantly increased by pathogen-associated molecular patterns derived from bacteria and viruses in macrophages. Administration of recombinant IL-36 γ *in vivo* leads to increase inflammatory genes expression (gene profiling) and recruitment of innate immune cells that are linked to asthma pathogenesis. We next sought to determine the importance of IL-36 γ in asthma using a well-characterised murine model of allergic airway disease. Mice were sensitised and challenged with ovalbumin (OVA) to induce hallmark features of asthma. During allergen challenge, recombinant IL-36 γ was administered intranasally and pulmonary function was assessed. Mice treated with IL-36 γ became insensitive to corticosteroid therapy. In conclusion, we show that infections that trigger asthma exacerbations are linked to IL-36 production and that delivery of this cytokine to the airways results in steroid-resistant airway hyperresponsiveness and neutrophilic inflammation. Our results suggest that IL-36 γ could be a potential therapeutic target for neutrophilic and severe asthmatics.

Background: Inhalation of aerosolized fish allergens and fish matrix components is often associated with severe IgE-mediated reactions in sensitized individuals. We explored interactions of bronchial epithelial cells with the major codfish allergen Gad m 1 and the cod food matrix.

Methods: We used the human bronchial epithelial cell line 16HBE14o-. Polarized cells were treated with natural Gad m 1 with or without the codfish-derived food matrix. Fluorescently labelled allergen was detected by confocal microscopy. mRNA levels of IL-6 and CCL2 were determined by qRT-PCR. Concentration of cytokines in the basolateral cell culture medium was measured by the Luminex assay.

Results: Apical exposure of the cells to Gad m 1 resulted in binding of the allergen to the lateral membrane domain (below ZO-1 level). The allergen was not internalized by the cells nor detected in the basolateral medium. IL-6 mRNA and protein levels were increased by 30% after treatment with codfish matrix but not with the allergen alone. The CCL2 concentration was 50% higher in the basolateral medium of samples treated with Gad m 1 compared to fish matrix-treated samples and the negative control.

Conclusion: The major codfish allergen Gad m 1 interacts with the plasma membrane of bronchial epithelial cells. This interaction leads to changes in gene and protein expression

of IL-6 and CCL2, which are further modulated by food matrix components and may play a role in allergic reactions to fish via inhalation. Supported by the Austrian Science Fund doctoral program W1248-B1 and grants SFB 4608 and 4613.

The ORMDL3-ceramide axis may be a novel therapeutic target for the control of allergic airway disease

Sturgill, J.¹, Oyeniran, C.², Conrad, D.³, Spiegel, S.²

¹Virginia Commonwealth University, Family and Community Health, Richmond, United States, ²Virginia Commonwealth University, Biochemistry, Richmond, United States, ³Virginia Commonwealth University, Microbiology and Immunology, Richmond, United States

Asthma, defined as a chronic inflammatory condition characterized by episodic shortness of breath with expiratory wheezing and cough, is a serious health concern. The WHO estimates that asthma affects more than 230 million people worldwide. There is a strong genetic component to asthma and numerous genome-wide association studies have identified ORM (yeast)-like protein isoform 3 (ORMDL3) as an asthma associated gene. Surprisingly however, the mechanism by which ORMDL3 contributes to asthma pathogenesis is not well understood. The yeast ortholog of ORMDL3 is a negative regulator of serine palmitoyltransferase (SPT), the rate limiting step in de novo ceramide synthesis, yet elevations of ceramide rather than its reduction have been linked to lung inflammation. Thus, we examined the role of ORMDL3 in asthma immunopathology. Consistent with its role in yeast, we show that decreasing expression of ORMDL3 in lung epithelial cells and macrophages increases ceramide and conversely, modest increases in ORMDL3 decrease ceramide levels. In a house dust mite (HDM) mouse model of allergic airway disease, allergen challenge induced expression of ORMDL3 and resulted in a concomitant increase in lung ceramide. Intriguingly, the use of specific drugs, which inhibit ceramide synthesis, prevented HDM-induced airway hyperreactivity (AHR) and suppressed airway inflammation. Nasal administration of the orally available FDA approved prodrug FTY720/fingolimod reduced both ORMDL3 expression and ceramide production while mitigating airway inflammation, hyperreactivity, and mucus hypersecretion in HDM challenged mice. Thus the ORMDL3-ceramide pathway may be a novel therapeutic target for the control of allergic asthma.

Effect of CTLA4-Ig on steroid resistant asthma model

Kouyama, S.¹, Yamaguchi, M.¹, Ohtomo-Abe, A.¹, Kamide, Y.¹, Hayashi, H.¹, Watai, K.¹, Mitsui, C.¹, Sekiya, K.¹, Tsuburai, T.¹, Fukutomi, Y.¹, Taniguchi, M.¹, Ohtomo, T.², Kaminuma, O.³, Mori, A.¹

¹National Hospital Organization, Sagami-hara National Hospital, Clinical Research Center, Sagami-hara, Japan, ²National Hospital Organization, Sagami-hara National Hospital/Tokyo University of Pharmacy and Life Science, Department of Pharmacotherapeutics, Hachioji, Japan, ³University of Yamanashi, The Center for Life Science Research, Chuo, Japan

Rationale: To investigate the role of helper T (Th) cells in steroid resistant (SR) asthma, steroid sensitive (SS) and SR Th clones were selected *in vitro*, and adoptively transferred into unprimed mice. Effect of CTLA4-Ig was analyzed both *in vitro* and *in vivo*.

Methods: For *in vitro* evaluation, ovalbumin (OVA) reactive Th clones were cultured with antigen presenting cells and OVA in the presence of various concentrations of dexamethasone (DEX). Proliferative responses of Th clones were measured by ³H-thymidine incorporation. For *in vivo* assessments, unprimed BALB/c mice were transferred with Th clones, challenged with OVA, and administered with DEX subcutaneously. Bronchoalveolar lavage fluid (BALF) was obtained 48 hr after challenge, and the number of infiltrating cells was differentially counted. CTLA4-Ig was administered through nasal inhalation or venous injection.

Results: SS and SR clones were selected based on the effect of DEX on the proliferative responses of antigen-stimulated Th clones. Airway infiltration of eosinophils and lymphocytes of mice transferred with SS clones were effectively inhibited by the administration of DEX. In contrast, those of mice transferred with SR clones were not significantly inhibited by DEX. Administration of CTLA4-Ig significantly suppressed the proliferation of DEX-treated SR clones *in vitro*, and eosinophil infiltration of SR asthma model transferred with SR clones *in vivo*.

Conclusions: Steroid sensitivity of Th clones assessed *in vitro* was consistent with that of adoptively transferred asthma model assessed *in vivo*. Costimulatory signal mediated through CD28 is crucial for the induction of steroid resistance both *in vitro* and *in vivo*.

Are house dust mites (HDM) potential carriers of bacteria responsible for the induction of sensitisation to microbial "allergens"?

Dzoro, S.¹, Mittermann, I.¹, Nehr, M.², Hirschl, A.², Wikberg, G.³, Johansson, C.⁴, Lundeberg, L.³, Scheynius, A.⁵, Valenta, R.¹

¹Medical University of Vienna, Department of Pathophysiology and Allergy Research, Vienna, Austria, ²Medical University of Vienna, Division of Clinical Microbiology, Clinical Institute of Laboratory Medicine, Vienna, Austria, ³Karolinska University Hospital, Dermatology and Venereology Unit, Stockholm, Sweden, ⁴Karolinska Institute and Karolinska University Hospital, Translational Immunology Unit, Department of Medicine, Solna, Stockholm, Sweden, ⁵Karolinska Institute and Karolinska University Hospital, Translational Immunology Unit, Department of Medicine Solna, Stockholm, Sweden

Introduction: IgE reactivity to various *Staphylococcus aureus* and *Escherichia coli* antigens can be found in up to 25% of atopic dermatitis (AD) patients. A genomic analysis recently described *S. aureus* and *E. coli* species as abundant bacteria within the house dust mite (HDM) microbiome. We therefore investigated the role of mites as potential carriers for IgE sensitisation to microbial elements in AD patients.

Materials and methods: Sera from 179 AD patients, was analysed for IgE reactivity to a comprehensive panel of HDM allergens by chip analysis, and to *S. aureus* and *E. coli* by immunoblotting. Selected sera were additionally tested on the

mite ImmunoCAP. Inhibition experiments were conducted by pre-incubating patient sera with bacterial extracts, prior to HDM immunoblot or ImmunoCAP assay. Rabbit antibodies raised against *S. aureus* and *E. coli* antigens were tested for reactivity to blotted HDM extract.

Results: The frequency of IgE sensitisation to bacterial antigens was significantly higher in HDM allergic patients compared to allergic subjects without HDM allergy. Specific antibody probes detected *S.aureus* and *E.coli* antigens in immune-blotted HDM extract. Furthermore, pre-incubation of sera from HDM allergic patients with bacterial extract, inhibited IgE binding to bands in blotted HDM extract, and reduced IgE binding to HDM extracts in ImmunoCAP measurements.

Conclusion: House dust mites are potential carriers of bacteria responsible for the induction of IgE sensitisation to microbial antigens.

Virus infected human mast cells have a unique and potent type 1 interferon response and selectively respond to interferon activation

Portales, L.¹, Oldford, S.², Haidl, I.D.¹, Marshall, J.S.¹

¹Dalhousie University, Microbiology and Immunology, Halifax, Canada, ²Dalhousie University, Medicine, Halifax, Canada

Mast cells are frequent at mucosal surfaces and have a sentinel role in infection. They have been implicated in the pathogenesis of asthma where viral infections are associated with disease exacerbation. Type 1 interferons (IFNs) are critical for the early response to viral infection. We therefore examined human mast cell production of, and response to, type 1 IFNs.

Using reovirus, which infects multiple cell types, we analyzed the IFN response of cord blood derived human mast cells and structural cells. Mast cells expressed a wide range of IFNs including IFN β , IFN α 1, IFN α 2, IFN α 4, IFN α 6 and IFN α 8 upon infection. In contrast, structural cells, such as normal lung fibroblasts had a highly restricted pattern of IFN expression. When peripheral blood NK cells were treated with supernatants from virus activated mast cells they demonstrated significantly greater CD69 expression and cytotoxicity than those treated with uninfected mast cell supernatants. These responses were dependent on type 1 IFNs. *In vivo*, virus infected mast cells also significantly enhanced both NK cell activation and recruitment. Human mast cell responses to IFN α 2 were also examined. Significant production of several cytokines was observed following IFN treatment, including VEGF-A and IL-1 receptor antagonist, in the absence of mast cell degranulation.

These data suggest that mast cells contribute substantially to the IFN response to viral infection at mucosal surfaces, and that such responses activate NK cells. The subsequent mast cell response to IFNs might potentially aid in tissue remodeling and regulation of inflammation.

The effect of early postnatal colonisation of newborns by probiotic vaccine Colinfant New Born on allergy incidence and immune system characteristics

Hrdy, J.¹, Sukenikova, L.¹, Novotna, O.¹, Petraskova, P.¹, Borakova, K.², Prokesova, L.¹

¹First Faculty of Medicine, Charles University in Prague, Institute of Immunology and Microbiology, Prague, Czech Republic, ²Institut for the Care of Mother and Child, Paediatric Unit, Prague, Czech Republic

Allergies belong to the most common diseases with steadily increasing incidence. Probiotics are believed to prevent or reduce allergy development. Nevertheless, the mechanism of their beneficial effect is poorly understood. Decreased allergy incidence was observed 5, 10, 20 years after initial supplementation of newborns with Colinfant New Born (*E. coli* O83:K24:H31). To reveal the mechanism of the action, immune characteristics of peripheral blood regulatory T cells (Tregs) of probiotic colonized and noncolonized children of allergic mothers (high risk children) and noncolonized children of healthy mothers were compared by flow cytometry. The capacity of *E. coli* O83:K24:H31 to promote maturation of dendritic cells (DC) and induce immune responses was tested in vitro by coculture of probiotic primed DC derived from cord blood precursors with naive CD4+. Functional characteristics of Tregs (MFI of FoxP3, intracellular presence of regulatory cytokines IL-10, TGF- β) were decreased in the allergic group. Probiotic colonized children have increased regulatory potency of Tregs (MFI of FoxP3, regulatory cytokines) in comparison to noncolonized children. *E. coli* O83:K24:H31 promotes maturation of cord blood derived DC. The beneficial effect of probiotics on newborn immature immune system could be, at least partially, explained by the modulating immune function of Tregs. Although we detected increased proportion of Tregs in peripheral blood of allergic children, their functional properties were decreased in comparison with Tregs of healthy children. We suggest increased proportion of Tregs in allergic children reflects an effort to compensate impaired function of Tregs. This work was supported by AZV CR15-26877A and PRVOUK P25/LF1/2.

Soluble CD52 binds the damage-associated molecular pattern protein HMGB1 to mediate T-cell suppression through the Siglec-10 receptor

Bandala-Sanchez, E.¹, Ngui, K.¹, Stone, N.L.¹, Pearce, L.A.², Adams, T.A.², Harrison, L.C.¹

¹Walter and Eliza Hall Institute of Medical Research, Population Health and Immunity Division, Parkville, Australia, ²Commonwealth Scientific and Industrial Research Organisation (CSIRO), Materials Science & Engineering, Melbourne, Australia

Introduction: Activated T cells release the GPI-anchored glycopeptide CD52, which suppresses bystander T cells by binding the inhibitory receptor, sialic acid binding Ig-like lectin-10 (Siglec-10) (1). Siglec-10 was reported to bind another

GPI glycoprotein, CD24, in the presence of the damage-associated molecular pattern (DAMP) protein, high-mobility group box 1 (HMGB1) (2).

Objective: To determine the role of HMGB1 in Siglec-10 binding and action of CD52.

Methods: Binding of recombinant CD52-Fc to HMGB1 and Siglec-10-Fc proteins was performed in microtiter plates and by surface plasmon resonance. Native proteins associated with CD52-Fc were analysed by immunoprecipitation and Western blotting of lysed human Jurkat line and human blood CD4⁺ T cells.

Results: T-cell suppression by CD52-Fc *in vitro* depended on the presence of native HMGB1 in serum and did not occur in serum-free medium. Intact HMGB1 or its cytokine-inducing Box B domain, but not its anti-inflammatory Box A domain, bound to soluble CD52 with a K_d of ~70nM. Binding to HMGB1 significantly enhanced binding of CD52 to Siglec-10. This interaction impaired phosphorylation of T-cell receptor (TCR)-associated tyrosine kinases Lck and Zap70, after TCR crosslinking by anti-CD3 monoclonal antibody. CD52-Fc was recovered from T cells in a complex with HMGB1 and Siglec-10, and the SH2 domain-containing tyrosine phosphatase SHP1.

Conclusion: CD52 exerts a concerted immunosuppressive effect first by capturing HMGB1, abrogating its pro-inflammatory effect, followed by binding to the Siglec-10 receptor to inhibit TCR phosphorylation.

Role of Galectin-3 in influenza virus infection by regulating host immune responses and IL-1 β production

Chen, Y.-J.¹, Wang, S.-F.², Chen, H.-Y.^{1,3}, Liu, F.-T.^{1,3}

¹IBMS, Academia Sinica, Taipei, Taiwan, Republic of China,

²Kaohsiung Medical University, Department of Medical Laboratory Science and Biotechnology, Kaohsiung, Taiwan, Republic of China,

³UC Davis Medical Center, Department of Dermatology, Sacramento, United States

H5N1 Virus induces cytokine production and excessive inflammatory responses that contribute to the pathogenesis of human H5N1 disease. Galectin-3 is a β -galactoside-binding animal lectin and has been reported to participate in the host response to microbial infections. Here we investigated the role of endogenous galectin-3 in H5N1 virus-induced host immune responses. We observed that galectin-3 knockout (Gal3KO) mice were less susceptible to H5N1 infection compared to wild-type (WT) mice, whereas the viral loads in the lungs were comparable between the two genotypes. Moreover, we found that H5N1-infected Gal3KO mice exhibited a lower degree of lung inflammation, including neutrophil infiltration. In addition, the levels of the proinflammatory cytokine IL-1 β in both bronchoalveolar lavage fluid and lungs were significantly reduced in H5N1-infected Gal3KO mice. It has been reported that influenza virus induces IL-1 β production through the NLRP3 inflammasome pathway. We showed that NLRP3 and IL-1 β mRNA levels and NLRP3 inflammasome components and pro-IL-1 β protein levels were comparable between Gal3KO and WT bone marrow-derived macrophages (BMMs) infected

with H5N1. However, IL-1 β secretion and ASC oligomerization, an indicator of inflammasome activation, were decreased in Gal3KO BMMs compared to WT BMMs, in response to H5N1 infection. In addition, the presence of galectin-3 enhanced the IL-1 β processing in HEK293T cells containing reconstituted NLRP3 inflammasome complex and thus autonomously secreting IL-1 β . Combined, our results suggest that galectin-3 may enhance the pathological effects of H5N1 virus infection by promoting the host inflammatory response and that galectin-3 may positively regulate IL-1 β production by promoting NLRP3 inflammasome activation.

Themis regulates cytokine signals in mature CD8⁺ T cells

Brzostek, J., Zhao, X., Mehta, M., Gascoigne, N.

National University of Singapore, Department of Microbiology and Immunology, Singapore, Singapore

Themis plays a critical role in regulation of T cell receptor (TCR) signal strength during thymic development, through interaction with phosphatase Shp1¹. Germline deletion of Themis leads to severe perturbation of mature T cell numbers and phenotype, but this is likely to result from the abnormal thymic development. We have developed a conditional knockout mouse to investigate the role of Themis in peripheral T cells.

Post-selection deletion of Themis reduces CD8⁺ T cell numbers in the periphery. Themis-deficient lymphocytes show unimpaired responses to TCR stimulation. However, Themis-deficient CD8⁺ T cells show reduction in proliferative responses to common γ chain cytokines. Since Themis interacts with Shp1, a negative regulator of IL-4 signalling in peripheral T cells², we investigated the role Shp1 in controlling common γ chain cytokine responses in CD8⁺ T cells. T-cell specific deletion of Shp1 enhances CD8⁺ T cell responses to common γ chain cytokines. This opposing effect of Themis and Shp1 deficiency on cytokine responses suggests that Themis acts as a positive regulator of cytokine signals, though binding to and sequestering the negative regulator Shp1 from the cytokine signalling networks. We are currently investigating this proposed molecular mechanism and the physiological significance of Themis-dependent regulation of cytokine signals the context of T cell responses to bacterial infections.

Interactomics and structure-function analysis of the RLTPR protein underpin its essential role for costimulation via CD28 in mouse and human T cells

Malissen, M., Roncagalli, R., Cucchetti, M., Bergot, E., Jarmuzynski, N., Gregoire, C., Goncalves Menoita, M., Liang, Y., Malissen, B. CIML, Marseille, France

RLTPR comprises concatenated leucine-rich repeats (LRR) and mice harboring a mutation - called *Basilic* - in one of those repeats mimicked fully a CD28 deficiency.

The lymphoid lineage-specific actin-uncapping protein RLTPR is essential for costimulation via CD28 and the development of regulatory T cells. RLTPR colocalizes with CD28 at the immune synapse and couples CD28 to the Carma1 cytosolic effectors. However, the precise molecular function of RLTPR in CD28 costimulation and role in humans remains elusive. We have used quantitative mass spectrometry and T cells from mice in which a tag for affinity purification was knocked in the *Rltpr* gene to determine the composition and dynamics of the signaling complex that formed around RLTPR following T cell stimulation. We demonstrated that a physical association existed between RLTPR and upstream (CD28) and downstream (CARMA1) components of the CD28 pathway. Proteins not associated before with the CD28 pathway were also identified in the RLTPR interactome. By developing RLTPR deficient mice, we showed that the *Basilic* mutation corresponded to a null mutation, thereby establishing the functional importance of the LRR domain. Using Crispr-Cas9-based gene editing of Jurkat T-cell line, we demonstrated that RLTPR is also essential in human for costimulation via CD28. Our findings underpin the similar role exerted by RLTPR in human and mouse T cells and point in a new direction regarding its mode of action during CD28 costimulation.

"Microsynapse" composed of focal adhesion molecules surrounding TCR microcluster is essential for T cell activation

Saito, T.^{1,2}, Hashimoto-Tane, A.¹

¹RIKEN Center for Integrative Medical Sciences, Laboratory for Cell Signaling, Yokohama, Japan, ²Osaka University, WPI Immunology Frontier Research Center, Suita, Japan

Immunological synapse (IS) formed at the interface between T cells and antigen-presenting cells represent hallmark of initiation of acquired immunity. T cell activation is initiated at T cell receptor (TCR) microclusters (MCs), in which TCR and signaling molecules assemble at the interface prior to IS formation. We found that each TCR-MC was transiently bordered by a ring structure made of integrin and focal adhesion molecule in early phase of activation, which is similar structure to mature immunological synapse (IS) in micro-scale and we named "Microsynapse". The micro adhesion-ring in the microsynapse is composed of LFA-1, focal adhesion molecules such as paxillin and Pyk2, and myosin II (MyoII), and is supported by F-actin core and MyoII activity through LFA-1 outside-in signals. The formation of microsynapse and the adhesion-ring was transient and especially sustained upon weak TCR stimulation to recruit LAT and SLP76. Perturbation of the microsynapse induced impairment of TCR-MC development and resulted in impaired cellular signaling and T cell activation and functions. Thus, the microsynapse composed of the core TCR-MC and surrounding micro adhesion-ring is a critical structure for initial T cell activation through integrin outside-in signals.

TRAF adaptors limit IL-6 receptor signaling through an unexpected binding to the signaling transducer receptor gp130

So, T.¹, Nagashima, H.¹, Okuyama, Y.¹, Hayahi, T.¹, Asao, A.¹, Kawabe, T.¹, Yamaki, S.¹, Nakano, H.², Croft, M.³, Ishii, N.¹

¹Tohoku University Graduate School of Medicine, Microbiology and Immunology, Sendai, Japan, ²Toho University School of Medicine, Biochemistry, Tokyo, Japan, ³La Jolla Institute for Allergy and Immunology, Immune Regulation, La Jolla, United States

There is growing evidence that TNF receptor-associated factors (TRAFs) are recruited to unconventional cytokine receptors and control their key signaling pathways in lymphocytes. We have found that TRAF5 expressed in CD4⁺ T cells constitutively binds to a cytoplasmic region of the signal transducing receptor gp130 through its C-terminal TRAF domain and inhibits the recruitment and activation of STAT3 mediated by IL-6. This function of TRAF5 significantly impacts IL-6-driven Th17 cell differentiation. However, it is not clear how TRAF5 inhibits the gp130-STAT3 signaling axis and whether other TRAF family molecules contribute to this process. We found that amino acid residues 774-798 in gp130, which contain TRAF-binding consensus motifs, were critical not only for association with TRAF5 but also with TRAF2. gp130 expressed on naive CD4⁺ T cells gradually decreased after T cell activation and its expression reached a minimum level at 48 h. Whereas TRAF5 rapidly disappeared from activated naive T cells within 4 h, TRAF2 was stably expressed in primed T cells during the course of Th17 development. These results demonstrate that both TRAF2 and TRAF5 inhibit the early signaling activity of the IL-6 receptor complex in naive CD4⁺ T cells and that TRAF2 works as a negative regulator even in the later stage of Th17 development. Accordingly, shRNA-mediated *Traf2*-knockdown in differentiating *Traf5*^{-/-} CD4⁺ T cells strongly promoted IL-6-driven Th17 differentiation. We propose a novel signaling mechanism of Th17-lineage commitment that is spatiotemporally regulated by the adaptor proteins TRAF2 and TRAF5.

3633

A structured pathway for T cell receptor signal transmission through the membrane

Krshnan, L.^{1,2}, Park, S.³, Im, W.³, Call, M.^{1,2}, Call, M.^{1,2}

¹Walter & Eliza Hall Institute of Medical Research, Structural Biology, Parkville, Australia, ²The University of Melbourne, Parkville, Australia, ³University of Kansas, Department of Molecular Biosciences and Center for Computational Biology, Lawrence, United States

The octameric T cell receptor (TCR)-CD3 complex signals the recognition of antigenic peptide:MHC ligands on target cells by initiating a cascade of intracellular biochemical events beginning with phosphorylation of immunoreceptor tyrosine-based activation motifs (ITAMs) on CD3 and ζ cytoplasmic tails by the src-family kinase Ick. How ligand-sensing is communicated across the cell membrane is an important unresolved problem in T cell biology, and a lack of structural information on the intact receptor complex stands as a major

barrier to the development of specific mechanistic models. Both extracellular and intracellular structural transitions have been implicated in TCR "triggering," but little is known about whether specific structures within the transmembrane (TM) regions of the receptor complex are required to support the coupling of these events through the lipid bilayer. We have recently shown that the TCR $\alpha\beta$ TM domains form a closely associated coiled-coil interface that provides a structured core for the TCR $\alpha\beta$ -CD3 $\delta\epsilon$ -CD3 $\gamma\epsilon$ - $\zeta\zeta$ complex in the membrane. This interface is mediated by a network of inter-helical hydrogen bonds between TM sequences that are absolutely conserved across vertebrate evolution and in both $\alpha\beta$ and $\gamma\delta$ forms of the TCR. Receptors with mutations at the key polar residues were expressed normally but exhibited a severe defect in antigen-triggered IL-2 production. These data support a model in which extracellular alterations propagate through the structured TCR/CD3 TM domains to initiate intracellular signalling and provide a structural rationale for the ability of T cells to respond to a single antigenic peptide:MHC ligand through a receptor-intrinsic conformational mechanism.

Quantitative analysis of Vav1 signalosome in primary CD4 T cells identify several new Vav1 partners including CD226

Gaud, G.¹, Roncagalli, R.², Gonzalez De Pedro, A.³, Malissen, B.², SAOUDI, A.¹

¹INSERM U 1043, CNRS UMR 5282, Toulouse, France, ²CIML, Marseille, France, ³IPBS, Toulouse, France

A tightly controlled balance of immune cell signaling is necessary for proper immunity. A dysfunction of this balance has been observed in several immune mediated diseases. Vav1 is a signaling molecule involved in T cell development and functions. Recently, our team showed that Vav1 is involved in several auto-immune diseases such as multiple sclerosis and myasthenia gravis. However, the molecular mechanisms by which Vav1 controls these phenotypes are still poorly understood.

In the present study, we analyzed the composition and dynamic of Vav1 signalosome in primary CD4

T cells by generating a novel animal model where Vav1 was tagged at its C-terminus with OneStrepTag (Vav1OST). Following *in vitro* stimulation of primary CD4 T lymphocytes, Vav1 was pull-down at different time-points, and its interactome was analyzed by mass spectrometry, allowing the characterization of Vav1 interactors and their binding kinetics following stimulation. This approach allowed us to describe the first spatial and temporal vav1 interactome and to identify numerous new Vav1 partners. We analyzed the major biological processes of these interactors and as expected most of them are involved in TCR signaling. This proteomic study also leads us to identify 4 co-receptors involved in immunological synapse formation. Among them, CD226 is involved in CD4 T cell proliferation and differentiation. We demonstrate here for the first time that Vav1 is a crucial effector of CD226 signaling in CD4 T cells.

3964

Engagement of TCR with foreign and self antigens trigger distinct signaling pathways to generate different T cell responses

Shiokawa, M.¹, Ishikawa, E.¹, Ogata, M.², Saito, T.³, Yamasaki, S.¹

¹Division of Molecular Immunology, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan, ²Department of Biochemistry and Proteomics, Mie University Graduate School of Medicine, Tsu, Japan, ³Laboratory for Cell Signaling, RIKEN Center for IMS, Yokohama, Japan

Mature T cells are activated by recognizing foreign antigens (Ags) through T cell receptor (TCR). Although it was widely believed that endogenous self Ags do not activate mature T cells, recent studies have demonstrated that they can induce T cell maintenance in the periphery. However, it remains unclear how these distinct responses are generated through the same receptor. To address this issue, we compared the contribution of Erk, a pivotal MAP kinase for cell growth and survival, to these distinct responses. By establishing mature T cell-specific Erk1/2-deficient mice, we found that mature T cells could survive in the periphery without Erk. Moreover, homeostatic T cell proliferation was observed in the absence of Erk, suggesting that Erk is not essential for T cell maintenance induced by self Ags. In contrast, OVA-specific responses, such as proliferation or cytokines production, were abrogated by loss of Erk. Thus, T cell responses induced by self/foreign Ags are regulated differentially, at least concerning the requirement of Erk. Next, to examine the correlation of peptide affinity and Erk dependency, OT-I TCR Tg T cells transferred into TAP-deficient mice were stimulated with peptides with different affinities and examined T cell responses. High-affinity peptide SIINFEKL could induce vigorous proliferation *in vivo*, whereas low-affinity peptides induced survival without proliferation. Again, we found that the former response was largely dependent on Erk. Collectively, these results suggest that the strength of TCR signal may determine different mature T cell responses through distinct signaling pathways.

Rogue germinal center B cells: unconventional lymphocytes released by FAS inactivation that drive IgE and autoantibody production

Butt, D.¹, Chan, T.¹, Bourne, K.¹, Hermes, J.¹, Strasser, A.², Tangye, S.¹, Phan, T.¹, Rao, V.K.³, Brink, R.¹

¹Garvan Institute of Medical Research, Sydney, Australia, ²The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ³National Institute of Allergy and Infectious Diseases, NIH, Bethesda, United States

The mechanistic links between genetic variation and autoantibody production in autoimmune disease remain obscure. Inactivating mutations in the death receptor FAS or its ligand (FASL) cause Autoimmune Lymphoproliferative Syndrome (ALPS) and lupus-like autoimmune diseases. FAS is thought to safeguard against autoantibody production by

delivering death signals to self-reactive B cells that arise in the germinal centre (GC). Nevertheless, studies performed over the past two decades to elucidate a role for FAS in the regulation of GC B cell selection, differentiation and self-tolerance have yielded conflicting results. To definitively address the role of FAS in regulating GC B cell responses, we utilised a high resolution *in vivo* mouse model, specifically the adoptive transfer and challenge of anti-hen egg lysozyme (SW_{HEL}) B cells lacking expression of FAS. Surprisingly, the results indicated that FAS was in fact not required for the deletion of self-reactive B cells that arise in the GC reaction. Instead, it was discovered that FAS functions by preventing the development of a previously unrecognized lymphocyte population designated "rogue" GC (GCr) B cells. GCr B cells somatically mutate and survive despite losing antigen reactivity and differentiate into large populations of plasma cells with unconventional specificities, including autoantibody-secreting clones. Significantly, IgE⁺ plasma cells were particularly increased, leading us to identify a major cohort of ALPS patients with a hyper-IgE phenotype. Data presented will reveal that GCr B cells are a major driver of autoantibody production and provide a mechanistic explanation for the linked production of IgE and autoantibodies in autoimmune disease.

ES-62, an immunomodulator secreted by the filarial nematode *Acanthocheilonema viteae* resets the effector:regulatory B cell balance in the MRL/Lpr model of systemic lupus erythematosus

Harnett, M.M.¹, Rodgers, D.T.¹, Pineda, M.A.¹, Mc Grath, M.A.¹, Al-Riyami, L.², Harnett, W.²

¹University of Glasgow, Glasgow, United Kingdom, ²University of Strathclyde, Glasgow, United Kingdom

Systemic lupus erythematosus (SLE) is an autoimmune condition characterized by high titers of anti-nuclear antibodies (ANA) where deposition of the resulting immune complexes (IC) initiates inflammatory pathologies with the kidneys, joints and skin commonly affected. Existing therapies rely heavily on generalised immunosuppression with recent disappointing trials of B cell-targeting biologics underscoring the urgent need for safer, effective therapies. The striking inverse relationship between active filarial nematode infection and SLE recently reported in an endemic area of India is consistent with that observed between parasitic worm infection and autoimmune disease, globally. This has been proposed to reflect the actions of immunomodulators that are secreted by parasitic worms to promote their survival by dampening inflammation but without seriously immunocompromising the host. Interest has therefore now focused on exploiting worm-derived immunomodulators to develop therapies for such inflammatory disorders. We have shown one such immunomodulator, ES-62, to protect against kidney and joint damage in the MRL/Lpr model of SLE. In particular, ES-62 suppresses the production of ANA and consequent IC-mediated development of proteinuria. Such protection correlates with induction of a hypo-responsive phenotype of effector B cell and an increase in the levels of IL-10-producing MZP-like "regulatory" B cells, and can be mimicked by the adoptive transfer of B cells from ES-62-treated MRL/Lpr mice.

Successful suppression of collagen-induced arthritis, a model of rheumatoid arthritis, is also associated with ES-62 resetting the effector:regulatory B cell balance, suggesting that this provides a unifying homeostatic mechanism for the therapeutic actions of this immunomodulator in autoimmune disease.

Pathogenicity of anti-HMGCR auto-antibodies in necrotizing autoimmune myopathy

Bergua, C.¹, Chiavelli, H.¹, Drouot, L.¹, Jouen, F.^{1,2}, Benveniste, O.^{3,4}, Boyer, O.^{1,2}

¹Normandy University, Inserm U 905, Rouen, France, ²Rouen University Hospital, Department of Immunology, Rouen, France,

³Pitie-Salpetriere University Hospital, Department of Internal Medicine, Paris, France, ⁴UPMC, Inserm U 974, Paris, France

Background and objective: Necrotizing autoimmune myopathies (NAM) are a newly recognized group of severe acquired myopathies characterized by prominent myofiber necrosis with little inflammation. NAM may be associated to auto-antibodies (aAbs) against the statins target 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR). Since its expression is ubiquitous rather than muscle-specific, the role of anti-HMGCR aAbs in NAM remains elusive. We investigated the pathogenic role of anti-HMGCR aAbs in a new *in vivo* mouse model.

Methods: Recombinant human rhHMGCR was coupled to fluorescent beads and anti-HLMGCR aAb level were assayed by Luminex. IgGs purified from anti-HMGCR aAb-positive patients were transferred to C57BL/6 or Rag-/- mice. Alternatively, mice were immunized with rhHMGCR plus adjuvant. The requirement for complement was studied using C3-/- mice.

Results: Injection of anti-HMGCR positive IgGs resulted in significant decrease in muscle strength. This was associated with moderate myofiber necrosis with myophagocytosis, fetal myosin re-expression and hIgG deposits. The muscle holoproteome (day 8 post-transfer) was profoundly modified, with increase in muscle regeneration- and metabolism-related proteins. The effect was transient in immunocompetent mice and prolonged in immunodeficient animals. Immunization with rhHMGCR led to reduced muscle strength. In complement-deficient mice, anti-HMGCR positive IgGs did not transfer disease.

Conclusion: Anti-HMGCR aAbs are directly involved in disease pathogenesis. IgG deposits and absence of disease in C3-/- mice indicate a role for the classical pathway of complement. These results support further evaluation of plasma exchange and/or B cell-targeted therapy in anti-HMGCR-associated NAM.

MHC class II allelic polymorphisms are strongly associated with susceptibility to many autoimmune diseases. In addition, abnormal MHC class II molecules are often observed in autoimmune-diseased tissues. However, it has remained unclear how MHC class II genes control susceptibility to autoimmune diseases. Recently, we found that MHC class II molecules function as a molecular chaperon to transport cellular misfolded ER proteins to the cell surface intact, without processing to peptides, by associating with them via their peptide-binding groove.

Here, we show that sera from patients of autoimmune diseases such as rheumatoid arthritis (RA) contain autoantibodies specific to misfolded proteins complexed with MHC class II molecules. A strong correlation between autoantibody binding to misfolded proteins complexed with certain HLA-DR alleles and the odds ratio for that allele's association with RA was observed ($r = 0.81$; $P = 4.6 \times 10^{-5}$). Indeed, association of autoantigens with aberrantly expressed MHC class II molecules was detected in autoimmune diseased tissues but not in normal tissues. Similarly, we found that β 2-glycoprotein I (β 2GPI) complexed with MHC class II molecules is a major target for autoantibodies in antiphospholipid syndrome (APS).

These findings suggest that misfolded proteins complexed with MHC class II molecules are involved in autoimmune diseases as targets for autoantibodies. Because cellular misfolded proteins are promptly degraded in the cells, immune cells might not be tolerized with the cellular misfolded proteins. Therefore, cellular misfolded proteins rescued from degradation by aberrantly expressed MHC class II molecules might induce autoantibody production, which results in autoimmune diseases.

Targeting KCa1.1 channels inhibits the invasiveness of fibroblast-like synoviocytes and attenuates models of rheumatoid arthritis

Tanner, M.R.¹, Huq, R.¹, Tajhya, R.B.¹, Pennington, M.W.², Laragione, T.³, Gulko, P.S.³, Beeton, C.¹

¹Baylor College of Medicine, Molecular Physiology and Biophysics, Houston, United States, ²Peptides International, Inc., Louisville, United States, ³Icahn School of Medicine at Mt. Sinai, Medicine / Rheumatology, New York, United States

Highly-invasive fibroblast-like synoviocyte (FLS) play a central role in the pathogenesis of rheumatoid arthritis (RA). Currently, no RA therapy has been developed to specifically target FLS.

We have found that highly-invasive FLS from patients with RA and from rats with the pristane-induced and collagen-induced arthritis models of RA express higher levels of the KCa1.1 potassium channel at their plasma membrane when compared to FLS from patients with osteoarthritis or from healthy rats, respectively. Selectively blocking this channel inhibits RA-FLS, including decreasing proliferation and release of cytokines,

chemokines, angiogenic factors, and proteases. Importantly, we have found that the presence and activity of KCa1.1 at the plasma membrane of RA-FLS is both necessary and sufficient to regulate the *ex vivo* invasiveness of RA-FLS. This is accomplished through the role of KCa1.1 as a regulator of calcium homeostasis in RA-FLS, with downstream effects on Akt activity and the plasma membrane expression and activation of β_1 integrins.

Pharmacological inhibition of KCa1.1 after onset of clinical signs of arthritis significantly reduces joint inflammation, bone and cartilage damage, and synovial hyperplasia in both the collagen-induced and pristane-induced rat models of RA. FLS from blocker-treated animals also have reduced *ex vivo* invasiveness and proliferation compared to those from vehicle-treated animals.

These studies indicate the importance of KCa1.1 as a novel target for RA and emphasize the potential efficacy of directly inhibiting FLS in reducing the severity of this debilitating disease.

Glycerophospholipids regulate immunity and inflammation via induction of myeloid-derived suppressor cells

Singh, R.^{1,2,3}, Prasad, P.¹, Tran, C.¹, Halder, R.¹

¹UCLA, Medicine / Rheumatology / Autoimmunity and Tolerance Laboratory, Los Angeles, United States, ²UCLA, Jonsson Comprehensive Cancer Center, Los Angeles, United States, ³UCLA, Pathology and Laboratory Medicine, Los Angeles, United States

CD1d presents lipid antigens to T-cells. Glycosphingolipid (GSL) antigens such as β GluCer, and glycerophospholipid (GPL) antigens such as phosphatidic acid (PA), phosphatidylcholine (PC), phosphatidylethanolamine (PE), phosphatidylinositol (PI), and phosphatidylserine (PS), have been eluted and identified by mass spectrometry as natural human CD1d ligands, and PC and PE have been eluted from murine CD1d. Here, we report that the normal immune repertoire contains $\alpha\beta$ T-cells that recognize abundant self-GPLs in a CD1d-restricted manner. CD1d-tetramers loaded with GPLs, including PA, PC, PI, PS, phosphatidylethanolamine (PE), and BMP (bis(monoacylglycero)phosphate), identify 0.4-4% T-cells in the lymphoid organs of wild-type and iNKT-deficient Ja18^{-/-} mice but not in CD1d^{-/-} mice. GPL-reactive T-cells don't recognize GSL-loaded tetramers and don't respond to α GalCer, suggesting that GPL-reactive T-cells are distinct from iNKT cells. GPL-reactive T-cells expand, express CD69, and produce cytokines upon *in vivo* priming. However, self-GPL antigens potently inhibited the proliferation and cytokine production by invariant natural killer T-cells via induction of monocytic myeloid-derived suppressor cells (M-MDSC) that inhibited invariant natural killer T-cells in an IL-10-dependent manner. Treatment with a GPL as well as adoptive transfer of GPL-modified M-MDSC ameliorated liver inflammation in the Con A hepatitis model, whereas it reversed the iNKT cell-mediated protection against tumor in the melanoma lung metastasis model. These observations support a new role for self-GPLs to help maintain homeostasis between the diverse populations of lipid-reactive T-cells. These observations have important implications for immune pathogenesis and intervention in conditions associated with altered lipid metabolism and inflammation.

Role of the TNF-family cytokine TL1A and its receptor DR3 in systemic autoimmunity and glomerulonephritis*Meylan, F., Hayes, E., Ferdinand, J., Farley, T., Richoz, N., Gabay, O., Siegel, R.**NIH/NIAMS, Immunoregulation Group, Bethesda, United States*

DR3 (Tnfrsf25) is a death domain-containing tumor necrosis factor receptor found primarily on activated T cells and innate lymphocytes. Interaction with its ligand the TNF-family cytokine TL1A plays critical roles in diverse autoimmune disease models in facilitating T cell accumulation at the site of inflammation while the systemic response was unaffected. To determine whether DR3 could play a role in systemic autoimmunity, we studied the role of DR3 in the MRL/lpr mouse model of lupus. lpr mice have a mutation in the TNF family receptor Fas (CD95, Tnfrsf6) that impair its expression, causing a systemic autoimmune disease that mimics systemic lupus erythematosus (SLE) observed in humans. DR3 deficient lpr mice developed identical degrees of lymphadenopathy, splenomegaly compared to control littermates. Accumulation of autoantibodies was also not dependent on DR3. However, DR3 deficiency significantly protected MRL/lpr mice from IgG and C3 glomerular immune complex deposition and DR3 deficient kidneys had decreased medullary T cell accumulation, decreased periglomerular and medullary macrophage infiltrates, reduced proteinuria and reduced renal pathology. In addition, DR3-deficient CD4+ T cell transfer in a chronic graft-versus-host disease (GVHD) model showed similar levels of autoantibodies and immunoglobulin class switching than with wild-type CD4+ T cells but decreased proteinuria and reduced renal pathology. These findings show that DR3 specifically promotes renal pathology in the MRL/lpr mouse model of lupus nephritis and in chronic GVHD without affecting systemic autoimmunity. Blockade of TL1A-DR3 interactions may be a novel strategy to counter nephritis and other organ damage in human SLE.

Inflammatory circuit of Th17 cells, fibroblast-like synoviocytes, and ILCs in the development of autoimmune arthritis*Hirota, K.^{1,2}, Ito, Y.¹, Hashimoto, M.³, Watanabe, H.¹, Kondoh, G.¹, Tanaka, A.², Yasuda, K.², Kopf, M.⁴, Potocnik, A.J.⁵, Stockinger, B.⁶, Sakaguchi, N.², Sakaguchi, S.^{1,2}**¹Institute for Frontier Medical Science, Kyoto University, Kyoto, Japan, ²iFReC, Osaka University, Osaka, Japan, ³Kyoto University, Kyoto, Japan, ⁴Institute of Integrative Biology, Zurich, Switzerland, ⁵Institute of Immunology and Infection, University of Edinburgh, Edinburgh, United Kingdom, ⁶Francis Crick Institute, Mill Hill Laboratory, London, United Kingdom*

Proinflammatory cytokine and cellular networks at sites of inflammation play a pivotal role in immune-mediated diseases such as rheumatoid arthritis. Yet, inflammatory cascades in target tissues downstream of Th17-mediated autoimmune responses remain largely obscure. Here, we show in an animal model of rheumatoid arthritis, SKG mice, that GM-CSF from fibroblast-like synoviocytes (FLS), but not from Th17 cells is a key inflammatory

mediator downstream of arthritogenic Th17 responses to initiate autoimmune arthritis. The effector cytokine IL-17, but not GM-CSF from Th17 cells led to induction of an inflammatory profile and drove GM-CSF production in FLS. Intriguingly, synovial tissue inflammation expands innate lymphoid cells (ILCs) which produce large amounts of inflammatory cytokines in inflamed joints and the selective depletion of ILCs significantly ameliorated the severity of autoimmune arthritis, demonstrating that synovial ILCs contribute to the tissue inflammation. Fate mapping of synovial ILCs using IL-17-iCre R26ReYFP SKG mice revealed that inflammatory synovial ILCs were not derived from the group 3 ILCs which are generally associated with Th17 immunity. Together, these data indicate that arthritogenic Th17 cells orchestrate a cellular network and inflammatory mediators in the development of autoimmune arthritis.

TLR induced IL-1beta production in monocytes and dendritic cells in T1D patients*Sediva, A.¹, Kayyserova, J.¹, Zentsova, I.¹, Paračková, Z.¹, Hromádková, H.¹, Katina, S.², Šumník, Z.³, Koloušková, S.³, Štechová, K.⁴
¹Motol University Hospital, Department of Immunology, Prague, Czech Republic, ²Masaryk University, Institute of Mathematics and Statistics, Brno, Czech Republic, ³Motol University Hospital, Department of Pediatrics, Prague, Czech Republic, ⁴Motol University Hospital, Department of Internal Medicine, Prague, Czech Republic*

Background: IL-1 is a cytokine with an important role in a pathogenesis of type1 diabetes (T1D) with a direct damaging effect on pancreatic beta cells. IL-1 signature is typical particularly for recent onset T1D and IL-1 blockade for T1D was tested in clinical trials. However, the initial event leading to an increased IL-1 secretion in T1D is not precisely known.

Methods: The IL-1 production in peripheral blood mononuclear cells (PBMCs) upon stimulation with TLR 3,4,7,9 ligands (LPS, polyI:C, ssRNA and CpG 2216) was tested in a cohort of 70 patients with recent onset T1D, 25 with long term T1D, 65 their relatives and 68 healthy controls. We have further specified the cellular source of IL-1 secretion within PBMC population.

Results: In comparison to controls, T1D patients and relatives, but particularly long-term patients, secreted increased amount of IL-1beta upon stimulation with TLR ligands. While monocytes are a dominant source of LPS induced IL-1beta in controls, both myeloid (mDCs) and plasmacytoid dendritic cells (pDCs) contributed significantly to IL-1 beta production in T1D (increase of IL-1beta producing cells upon LPS stimulation p 0.015 for mDCs, 0.0016 for pDCs). Such increase of IL-1beta production is surprising particularly for pDCs as LPS induced notable IL-1 production in pDCs despite their weak TLR4 expression.

Conclusion: The pattern of IL-1 beta secretion is different in T1D patients compared to controls. TLR ligands 4, 7 and 9 induced significantly more IL-1 beta production in T1D patients. Additionally, TLR stimulation alone was sufficient for IL-1beta production by blood DCs.

Malaria is a deadly disease that causes more than 600,000 deaths each year with the majority being children below the age of five. Tissue resident memory T cells (T_{RM}) are a recently discovered subset of non-circulating memory T cells that reside permanently in peripheral tissues after the resolution of infection and can accelerate the clearance of pathogens upon reinfection. Recently, our laboratory has identified a population of T_{RM} in the liver after immunization with irradiated *Plasmodium berghei* ANKA (PbA) sporozoites, an effective form of vaccination. We then asked whether liver T_{RM} could be efficiently generated through the use of a novel vaccination strategy termed “prime and trap”: a two-stage approach that involves activation of plasmodium-specific CD8⁺ T cells in the spleen using Clec9A-targeted antigen (prime), followed by trapping in the liver through local antigen expression using adeno-associated virus vector (trap). By tracking responses of PbA-specific TCR transgenic CD8⁺ PbT-I cells, the prime-and-trap vaccination strategy was shown to form large numbers of liver T_{RM} and to elicit high level of sterile protection that persisted for more than 6 months. Follow-up studies have extended this work to natural malaria antigens and endogenous T cells, revealing protective immune response against malaria. Our findings describe a highly promising novel vaccination approach that confers protection against murine malaria.

Influenza virus infection of neonates poses a major health concern, often resulting in severe disease and hospitalization. Compounding this issue is the lack of vaccines for this at-risk population. Thus, development of an effective vaccine is an urgent need. To address this, we have tested a novel TLR 7/8 agonist (R848) conjugated influenza virus vaccine. The use of the intact virion represents a step forward in conjugate vaccine design as it provides multiple antigenic targets allowing for elicitation of a broad immune response. Immunogenicity and efficacy were tested in a nonhuman primate neonate, a model which is highly relevant for human infants with regard to immune development, TLR function, and physiology. Our results show that this vaccine induces high level virus-specific antibody and cell mediated immune responses in neonates. These responses promote increased virus clearance and reduced lung pathology following challenge compared to a non-adjuvanted virus vaccine. Surprisingly, the addition of a second TLR agonist (flagellin) did not enhance vaccine protection, suggesting combinations of TLR that provide increased efficacy must be determined empirically. These data support further exploration of this new virus conjugate vaccine approach as a platform for use in the at-risk neonate population to induce protection against influenza as well as other viral diseases.

Protective efficacy of tuberculosis-specific T Cell immunity in the lung after aerosol delivery of adenoviral vaccines in nonhuman primates

Darrah, P.¹, Roederer, M.¹, Flynn, J.², Scanga, C.², Coleman, M.T.², DiFazio, R.², Lin, P.², Evans, T.³, Laddy, D.³, Anantha, R.³, Limbach, M.P.³, Temmerman, S.⁴, Demoitie, M.-A.⁴, Seder, R.¹

¹NIH, Vaccine Research Center, NIAID, Bethesda, United States, ²University of Pittsburgh School of Medicine, Pittsburgh, United States, ³Aeras, Rockville, United States, ⁴GlaxoSmithKline, Rixensart, Belgium

The magnitude, quality, breadth, and location of T cell responses are critical factors in determining protection against infections such as HIV, malaria, and tuberculosis (TB). For TB, developing a vaccine that prevents pulmonary infection may require an immunization route that elicits a high frequency of T cells directly in the lung. Accordingly, simultaneous intramuscular and aerosol (IM/AE) rAd5-TB (a recombinant adenovirus serotype 5 expressing *Mycobacterium tuberculosis* [Mtb] antigens) was delivered to BCG-primed rhesus macaques. Intradermal BCG priming induced low-level TB-specific CD4 T cell cytokine responses in blood and BAL. IM/AE boosting with rAd5-TB generated robust TB-specific CD4 and CD8 effector T cells in BAL that produced primarily IFN- γ , with subsets that also produced TNF and/or IL-2. Twelve weeks post-boost, animals were challenged intrabronchially with a low dose

(~10 CFU) of Mtb Erdman, monitored non-invasively using PET/CT scanning, and evaluated for pathology and bacterial burdens at a 6-month end point. Remarkably, the presence of a high frequency of TB-specific effector T cells in the lung after IM/AE rAd5-TB immunization did not improve outcome measures after challenge compared to animals that received only BCG. These data show that while IM/AE immunization was an effective approach for inducing T cells directly in the lung (and periphery), rAd5 vectors with the tested TB antigens were not sufficient to enhance protection over BCG alone in rhesus macaques. Studies are underway to determine mechanisms for the limited efficacy of rAd5-TB vaccines in this model.

Characterising the lymphatic immune responses induced by sub-cutaneous and intramuscular injection of the human vaccine adjuvant AS01

de Veer, M.¹, Neeland, M.², Collignon, C.³, Didierlaurent, A.³

¹Monash University, Physiology, Clayton, Australia, ²Murdoch Childrens Research Institute, Parkville, Australia, ³GSK Vaccines, Rixensart, Belgium

AS01 is a liposome-based Adjuvant System incorporating the immunostimulant 3-O-desacyl-4'-monophosphoryl lipid A (MPL) and the saponin QS-21. AS01 is included in two candidate vaccines that have demonstrated clinical efficacy, i.e. the RTS,S malaria vaccine and the herpes zoster vaccine. AS01 has been shown to enhance adaptive immunity via activation of the innate immune system, however the respective contribution of the injection site and the draining lymph node remain unclear. We report the development of an ovine lymphatic cannulation model to investigate the *in vivo* trafficking of cells within the lymphatic network following intramuscular administration of an AS01-adjuvanted vaccine. Injections were given to sheep using a vaccine dose and volume comparable to that administered in humans. We show that AS01 induced the transient migration of neutrophils into the tissue draining lymph and out of the lymph node that rapidly resolved within 24 hours. This was followed by the recruitment of antigen-positive monocytes and MHCII^{high} dendritic cells into muscle-draining afferent lymph within 48 hours of vaccination. This initial innate response correlated with the generation of an adaptive response in the local lymph node, characterised by the production of blast cells, IFN γ -producing T cells and antigen-specific antibodies in efferent lymph within 5 days of vaccination. This study reports the development a surgical cannulation model that was used to quantitate lymphatic cellular migration following intramuscular or subcutaneous vaccination with AS01. It adds to our understanding of the immunogenic function of AS01 for the development of safe and effective human vaccine formulations.

¹Monash University, Clayton Campus, Chemical Engineering, Clayton, Australia, ²Monash University Central Clinical School,

Melbourne, Australia, ³National Key Laboratory of Biochemical Engineering, Institute of Process Engineering, Chinese Academy of Sciences, Beijing, China

Nanoparticles have been widely used in vaccine design as both adjuvants and antigen delivery vehicles. In a seminal study, 40-50 nm nanoparticles with conjugated antigen were shown to induce high antibody titers and IFN- γ production in mice but with no added inflammatory stimuli. Subsequent research has shown that similar levels of immunogenicity can be achieved via the co-injection of naked 40-50 nm nanoparticles adjuvants and larger 500 nm nanoparticles with conjugated antigen. Furthermore, recent works indicate that particle shape can also influence the immune response. As such, we investigate the influence of surface morphology using 40-50 nm smooth and rough surfaced nanoparticle adjuvants and report their differential immunogenicity via ELISA, ELISpot and flow cytometry. Further, we determine the biodistribution of fluorescent 40-50 nm nanoparticle adjuvants with smooth and rough surfaces and larger 500 nm nanoparticles. Nanoparticle size is shown to be a discriminating factor in lymph node drainage, using a Carestream FX PRO *in vivo* imaging system and fluorescence microscopy of lymph nodes sectioned *ex vivo*. To elucidate the safety profile of this vaccine construct, we also investigate the biodistribution of nanoparticles within the major organs. The outcomes from this study provide key design criteria in the development of novel nanoparticle immunotherapeutics for the treatment of disease.

3016

Modulation of host immune responses using influenza viruses expressing functional miR-150

Xia, Y., Izzard, L., Ye, S., Stambas, J.

Deakin University, School of Medicine, Geelong, Australia

Current influenza vaccines offer considerable protection for the majority of the population. However, vaccine efficacy amongst high risk populations, such as the elderly, is variable. Novel approaches are therefore required to improve vaccine efficiency in these susceptible populations. MicroRNAs (miRNAs) play important roles in the regulation of immune responses by modulating gene expression. Our work describes the generation and delivery of engineered influenza viruses with the ability to express defined Immunomodulatory miRNAs. MicroRNA-150 (miR-150) has been shown to be involved in the development of T cell and B cell. Furthermore, evidence suggests that circulating miR-150 can be actively transported to target cells where it can influence gene expression. In this study, we first investigated the ability of recombinant influenza viruses to deliver immunomodulatory miR-150, and alter cytokine production *in vitro*. miR-150 was inserted into an artificial intron between the NS1 and NEP genes of the PR8 H1N1 (PR8-150) and X31 H3N2 (X31-150) influenza A viruses and was rescued using reverse genetics. Mature miR-150 expression was confirmed using qPCR and by knockdown of its target gene, c-Myb, using dual-luciferase. Moreover, cytokine mRNA expression levels (IL-6, IFN- β , CXCL10 and CCL5) were enhanced following infection with PR8-150 in A549 cells. Mice infected intranasally

with recombinant X31-150 virus showed significantly higher numbers of neutrophils, macrophages and influenza specific CD8+ T cells post infection compared to X31 wild type controls. These results demonstrate that recombinant influenza viruses can be used to deliver functional miRNAs with the ability to modulate immunity both *in vitro* and *in vivo*.

Novel mannose- α (1 \rightarrow 2)-mannose decorated liposomes for dendritic cell targeted nanovaccines: strong humoral and cell immune response against *Brucella ovis*

Pappalardo, J.S.¹, Chodilef, M.M.¹, Mignaqui, A.C.¹, Marcellino, R.¹, Zamit, A.L.², Salmaso, S.³, Levchenko, T.S.⁴, Torchilin, V.P.⁴, Robles, C.A.¹

¹National Institute for Agricultural Technology (INTA), Bariloche Research Station (EEA Bariloche) - Animal Health Group (GSA), Bariloche, Argentina, ²National Institute for Agricultural Technology (INTA), Agribusiness Research Center (CIA), Hurlingham, Argentina, ³University of Padova, Department of Pharmaceutical and Pharmacological Sciences, Padova, Italy, ⁴Northeastern University, Center for Pharmaceutical Biotechnology and Nanomedicine, Boston, United States

Dendritic Cells (DC), are the only professional antigen-presenting cells due to their unique ability to activate naïve T lymphocytes, thus initiating the adaptive immune response. DC-targeted vaccination is a promising strategy for the prevention of certain infectious diseases and cancer. The activation of DC for this purpose is attractive because of their ability to present epitopes through the MHC class I and II, and to activate the cytotoxic CD8+ T cell responses, among others.

Mannose is a saccharide that belongs to the pathogen-associated molecular patterns which can be exploited to decorate nanovehicles such as liposomes to target their cargo to DC.

Brucella ovis is a pathogen that generates big losses in the sheep industry. To overcome *B. ovis* infection, it is necessary to generate a strong humoral and cell mediated immune response.

Here we report the use of a liposomal formulation decorated with Mannose- α (1 \rightarrow 2)-Mannose through a PEG spacer and afterwards loaded with *B. ovis* antigens as a novel vaccine against *B. ovis* infection. The experimental vaccine was able to trigger a strong humoral response in mice and rams up to 6 months post vaccination. In addition, it was able to generate specific IFN γ secretion 12 months after vaccination in rams.

These results show that the liposomal platform targeted to DC using Mannose- α (1 \rightarrow 2)-Mannose is a promising nanovaccine to elicit a strong humoral and cell response. For this reason, it can be considered as a strategy to be explored for DC-targeted vaccination with a variety of antigens, for veterinary and human applications.

Quercetin exhibits enhanced Th1/Th2 immune response and CD11c⁺ dendritic cell infiltration in peritoneum of ovalbumin immunized mice

Singh, D., Tanwar, H.

Defence Institute of Physiology and Allied Sciences, Immunomodulation, New Delhi, India

Quercetin, one of the most abundant of plant flavonoids, has been studied with a great deal of attention over the last several decades mainly for its properties in inflammation and allergy. In this study, we are reporting for the first time the *in vivo* immunostimulatory activity of quercetin in ovalbumin immunized Balb/c mice. Administration of quercetin (50mg/kg body weight) along with ovalbumin antigen showed increased ova specific serum IgG antibody titres in comparison to the control group ($p < 0.05$). Quercetin administration not only showed predominance of Th2 immune response by increasing the IgG1 antibody titres, but also increased the infiltration of CD11c⁺ dendritic cells in the mouse peritoneum and also increased LPS activated IL-1 β and nitric oxide (NO) production by peritoneal macrophages. Expression of Oct-2, Tbx21 and GATA-3 proteins also increased in splenocytes of quercetin administered mice. Quercetin also did not cause any haemolysis in human RBCs. Overall; our findings strongly demonstrate the novel *in vivo* immunostimulatory and adjuvant potentials of quercetin.

Keywords: Quercetin, Flavonoids, Immunomodulators, Dendritic cells, Antibody titre.

Single shot booster vaccination against diphtheria does not induce sufficient long-term protection, particularly in elderly people

Grasse, M., Weinberger, B., Meryk, A., Grubeck-Loebenstern, B.

University of Innsbruck/Institute for Biomedical Aging Research, Immunological Division, Innsbruck, Austria

Immunization is one of the most successful health intervention against infectious diseases. However, the efficacy of vaccination is reduced in old age. Our study analyzed specific immune responses following a booster vaccination containing tetanus and diphtheria toxoid in healthy elderly (>60y; n=87) and young volunteers (25-40y; n=46). Long term protection was evaluated for 27 elderly and 17 young adults 5 years later. In addition, antigen-specific T-cells producing a panel of cytokines were quantified.

Before the vaccination 9% of the older and none of the young individuals had tetanus-specific antibody levels below the protective limit. The booster induced sufficient protection in both age groups for the following 5 years. The protection against diphtheria was almost equal before the vaccination (52% for the elderly and 48% for the young donors). Antibody concentrations increased significantly 4 weeks after vaccination, but dropped substantially over 5 years leaving again 54% (elderly) and 24% (young) below protective antibody levels. Thus, compared to the elderly young adults have a significantly better, but still insufficient maintenance of diphtheria-specific

antibodies. We found correlations between diphtheria-specific antibodies and diphtheria-specific T-cells producing different cytokines. Among those were GM-CSF-producing T-cells which we detected in a lower frequency in elderly compared to young adults.

In conclusion, our findings demonstrate that a booster vaccination induce long-lasting immunity against tetanus but not diphtheria, particularly in elderly people. GM-CSF might be useful as an adjuvant to improve diphtheria vaccination. We set up a mouse model to further investigate this question.

Increasing antitumor efficacy of checkpoint blockade by targeting to the tumor microenvironment

Ingram, J., Dougan, M., Rashidian, M., Linnebacher, A., Ploegh, H. Whitehead Institute for Biomedical Research, Cambridge, United States

Disruption of immune checkpoint interactions by antibodies has delivered on its promise: first in treating metastatic melanomas, and now also in non-small cell lung cancer. Not all tumors respond to treatment and therefore diagnostic tools to predict responsiveness are an important goal, especially with the severe immune side effects of checkpoint blockade. To address these challenges, we developed VHHs--variable region domains derived from camelid heavy chain-only antibodies--that serve as modular binding agents, not only to image PD-L1 and CTLA-4 non-invasively, but also to counteract their inhibitory activity *in vivo*. We exploit the modifiability of VHHs to direct therapeutic payloads to the tumor microenvironment through linkage to anti-PD-L1, achieving enhanced antitumor efficacy. High affinity anti-PD-L1 VHHs hold promise as a tool to re-engineer the tumor microenvironment.

828

Induction of stem cell-like memory T cells by cancer vaccine correlates to enhanced antitumor effect

Wu, S., Peng, Y., Wang, L., Zhu, W., Wu, J., Xie, J., Celis, E., He, Y. Augusta University (formerly Georgia Regents University, Medicine and Cancer Center, Augusta, United States

To understand why cancer vaccine-activated immune responses often failed to generate antitumor effect, we studied the antitumor effects of two alpha fetoprotein (AFP) epitope (AFP₂₁₂- and AFP₄₉₉-) specific CD8 T cells recently identified in our lab. We found that both T cells could recognize AFP+ tumor cells. However, while the AFP₄₉₉-specific CD8 T cells can be re-activated *in vitro* to generate potent CTL activity against AFP+ tumor cells, the AFP₂₁₂-specific CD8 T cells activated by the same vaccine in the same mouse have a very limited CTL activity after *in vitro* stimulation. Importantly, only the AFP₄₉₉-specific, but not the AFP₂₁₂-specific, CD8 T cells can prevent AFP+ tumor challenge *in vivo*. Mechanistically, majority of the AFP₂₁₂-specific CD8 T cells were dead or undergoing apoptosis after persistent *in vitro* AFP₂₁₂ peptide stimulation, a scenario

existed in the tumor microenvironment. However, the AFP₄₉₉-specific CD8 T cells were enriched by AFP₄₉₉ peptide stimulation and maintain their killing activity while the AFP₂₁₂-specific CD8 T cells were eliminated and functionally suppressed by long-term Ag stimulation. Surprisingly, only the AFP₄₉₉-specific CD8 T cells contain a population of cells that resemble to the newly discovered stem-like memory T cells. We propose that the stem-like memory T cells may provide the constant source for generating functional fresh and young effector cells to generate antitumor effect. The possible reasons and mechanism for generating stem-like memory T cells by cancer vaccines will be discussed, providing new clues and rationale for designing more effective cancer vaccines to achieve antitumor effect.

Effector regulatory T cells are associated with disease-free survival in colorectal cancer

Ward Hartstonge, K.¹, McCulloch, T.¹, Kamps, A.¹, Cretney, E.², Munro, F.³, McCall, J.³, Kemp, R.¹

¹University of Otago, Microbiology and Immunology, Dunedin, New Zealand, ²Walter & Eliza Hall Institute, Melbourne, Australia, ³University of Otago, Department of Surgical Sciences, Dunedin, New Zealand

Analysis of tumour infiltrating T cells in colorectal cancer is superior to the current staging at predicting disease-free survival. The Immunoscore has been proposed as a way to incorporate T cell infiltrates into the current staging by measuring CD3+ and CD8+ T cells. Unlike in many cancers, high tumour infiltrating regulatory T cells (Tregs) are associated with good patient outcomes in colorectal cancer. Effector Tregs are potently suppressive in mice. Effector Tregs are present in human colorectal cancer but their role in patient outcome is not known.

Immunofluorescence was used to analyse immune cell infiltrates in early stage (II) colorectal cancer patients and to compare those with recurrent and non-recurrent disease (n=33). CD3 and CD8 were used for the Immunoscore. FoxP3, Blimp-1 and CD3 were used to identify effector regulatory T cells.

Patients with a high Immunoscore (high T cell infiltrate) had increased disease-free survival than patients with a low Immunoscore (low T cell infiltrate, Log-rank test p>0.001). The ability to predict patient outcome was improved by measuring the infiltrate of CD4+FoxP3+Blimp-1+ cells (effector regulatory T cells, Log-rank test p>0.001). Patients with a low Immunoscore but high infiltrate of CD4+FoxP3+Blimp-1+ cells at the invasive margin had increased disease-free survival than those with a low Immunoscore and a low infiltrate of CD4+FoxP3+Blimp-1+ cells.

These results indicate that effector Tregs may play an important role in patient outcome in colorectal cancer. Incorporation of effector Tregs into the Immunoscore may help to identify patients at high risk of recurrent disease.

3898**Antigen-specific regulatory T cell suppression of the CD4+ T cell anti-tumour response**

Terry, A., Bolton, H., Guy, T., Fazekas de St Groth, B., Shklovskaya, E. Centenary Institute, University of Sydney, T Cell Biology, Camperdown, Australia

Regulatory T cells (Tregs) play a dominant role in suppression of anti-tumour responses, evident by the promising results seen in patients treated with immunotherapies targeting Tregs (eg. Ipilimumab). The exact cell targets and mechanism by which Tregs suppress anti-tumour responses have yet to be fully established. We have developed a model to study the effect of tumour-specific Tregs on the anti-tumour responses of CD4 T cells and the tumour microenvironment.

B16.F10 tumours expressing a model neoantigen (HELMCC) grew rapidly in immunodeficient mice but were rapidly rejected after adoptive transfer of naive MCC-specific CD4 T cells. Co-transfer of MCC-specific Tregs but not polyclonal Tregs prevented rejection of tumours. Suppression of the CD4 T cell response was associated with a significant reduction in DC costimulation, T cell proliferation and cytokine production. Depletion of MCC-specific Tregs (derived from FoxP3.DTR mice) rescued the T cell response only when performed early after co-transfer (day 3 post transfer), before T cells had differentiated.

In order to establish the effect of Tregs on the CD4 T cell response in immunosufficient mice, FoxP3.DTR mice were used as tumour hosts. Only when MCC-specific T cells were transferred into Treg-depleted hosts when Treg number was at the lowest and DC costimulation was highest were T cells able to mount an effective response, expressing IFN γ +TNF α +IL-2+, controlling tumour growth and even inducing endogenous host CD4 T cell cytokine production.

In summary, CD4 T cells can mount potent anti-tumour responses but only if priming occurs under Treg-deficient conditions. This is therefore relevant to the design of adoptive-cell immunotherapeutics.

1528**Dysregulated repair processes in inflammation and colorectal cancer: pathogenic regulatory T cells to blame?**

Franchini, F.^{1,2}, West, N.^{1,2}, Royston, D.J.³, Powrie, F.M.^{1,2}

¹Kennedy Institute of Rheumatology, University of Oxford, Oxford, United Kingdom, ²Translational Gastroenterology Unit, Nuffield Department of Clinical Medicine, Oxford, United Kingdom,

³University of Oxford, Department of Cellular Pathology, Oxford, United Kingdom

There is now abundant evidence that chronic inflammation can promote tumorigenesis and patients with inflammatory bowel disease have an increased risk of developing colitis-associated cancer (CAC). Although inflammatory pathways that drive colitis are well-described much less is known about the cellular and molecular mechanisms that induce and sustain cancerous lesions in the intestine.

Transfer of regulatory T cells (Tregs) from spleens of 129.IL-10^{-/-} mice accelerated and increased the tumorigenesis in 129.RAG^{-/-} recipients infected with *Helicobacter hepaticus*, while

transfer of WT Tregs led to no phenotype. In less than 3 months, mice transferred with IL10^{-/-} Tregs showed macroscopic tumour lesions in the colon and invasive carcinomas were confirmed by histological analysis. This project focuses on deciphering the molecular pathway by which a defective Treg response driven by a microbial insult promotes tumorigenesis.

Amphiregulin (AREG) is a key member of the EGF family we show that interleukin-10 deficient Tregs upregulate AREG as well as TGF- β at the transcriptional level compared to WT Tregs, which lead us to hypothesize that IL10^{-/-} Tregs could promote cancer development through a dysregulated repair response. In addition, we showed that transcripts for tissue remodelling factors as well as Sox4,

a master regulator of epithelial-mesenchymal transition (EMT), are upregulated in tumour tissue compared to inflamed tissue controls.

Altogether, the results of this study may lead to the identification of key pathways involved in tumorigenesis, which could be relevant for novel therapeutic targets.

3258**The effects of targeting both PD-1 and CD96 on tumour immunity, autoimmunity and immune homeostasis**

Harjunpaa, H.M.^{1,2}, Blake, S.J.¹, Liu, J.^{1,2}, Allen, S.¹, Smyth, M.J.^{1,2}, Teng, M.W.L.^{1,2}

¹QIMR Berghofer Medical Research Institute, Brisbane, Australia,

²University of Queensland, Brisbane, Australia

Tumour cells have developed multiple mechanisms to suppress anti-tumour immunity. One important mechanism is delivered via immune checkpoint receptors. Indeed, immunotherapy targeting immune checkpoint receptors, particularly PD-1 has shown significant efficacy and durable responses against a variety of different cancers. Given that anti-PD-1 will be used as the backbone in combination therapies due to its efficacy and safety, there is a search to determine which other pathways can synergize with anti-PD-1 to increase anti-tumour efficacy. CD96 is the least known member of immune checkpoint receptors and binds ligands of the nectin and nectin-like family. It is expressed on T cells and NK cells following activation and has been shown to suppress NK cell activity. This study aims to characterize the effects of targeting both PD-1 and CD96 on tumour immunity, development of autoimmunity and immune homeostasis. For this purpose, a novel PD-1/CD96 double knock-out (DKO) mouse was generated in our laboratory. Differences in frequencies and numbers of NK cells and Tregs in the PD-1/CD96 DKO mouse were observed compared to wild type or either PD-1 or CD96 single knock-out mouse. From our results, PD-1/CD96 DKO mice displayed improved anti-tumour efficacy compared to wild type, PD-1 or CD96 single knock-out mice in some tumour models. Importantly, PD-1/CD96 DKO mice that were aged for more than a year did not develop any overt signs of autoimmunity. Our findings suggest targeting PD-1 and CD96 in combination will be a safe and effective strategy to improve anti-tumour efficacy.

1718**Alpha fetoprotein immune modulation via DC and NK cells***Butterfield, L.¹, Santos, P.¹, Shi, J.¹, Vujanovic, L.¹, Delgoffe, G.²**¹University of Pittsburgh, Medicine, Surgery and Immunology, Pittsburgh, United States, ²University of Pittsburgh, Immunology, Pittsburgh, United States*

Alpha fetoprotein (AFP) is an oncofetal antigen expressed by over 50% of hepatocellular carcinoma (HCC) tumors. Previous studies proposed an immunoregulatory role for AFP. To examine the effects of AFP on dendritic cell (DC) and NK cell differentiation and function, peripheral blood cells were cultured in the presence of cord blood-derived "normal" AFP (nAFP) or HCC "tumor"-derived AFP (tAFP), and cellular phenotype and function were assessed. We have previously shown that monocytes cultured in vitro with tAFP differentiated into DC that retained a monocytic morphology, were phenotypically immature and failed to induce robust T cell proliferative responses. Here, we further examine nAFP and tAFP-induced effects on: 1) CD1 family surface expression; 2) cytokine and chemokine production; 3) glycolysis and oxidative phosphorylation metabolism; and 4) viability. In DC, we show that surface expression of CD1a, CD1b, CD1c and CD1d are reduced by nAFP and are further reduced by tAFP. TAFP-DC had decreased secretion of chemokines CCL1, CCL2, CCL3, CCL4, CCL17, CCL20 and CCL22 and we observe a significant defect in mitochondrial oxidative phosphorylation in both nAFP and tAFP-DC as early as 1 day after tAFP exposure. In NK cells, we show that these cells also take up AFP, show a short term skewed activation and cytokine secretion profile, but over time, have decreased viability. These DC and NK cell effects appear to be mediated by both AFP protein and a LMW binding partner. Together, these data implicate AFP as a key mediator of immune modulation and suppression.

2714**Treating cancer one interferon at a time***Buzzqai, A.¹, Foley, B.¹, Hart, P.¹, Robinson, B.², Fear, V.², Waithman, J.^{1,2}**¹Telethon Kids Institute, University of Western Australia, Perth, Australia, ²National Centre of Asbestos Related Disease, University of Western of Australia, Perth, Australia*

Why our bodies produce 14 subtypes of type I interferons (IFNs) is poorly understood. Only the IFN- α 2 subtype has been investigated as a possible treatment option for certain cancers. We investigated if other individual subtypes have the potential to arrest tumour growth and/or enhance anti-tumour immunity. We transduced the murine melanoma cell line B16 with five individual IFN subtypes (B16_{IFN_v}, B16_{IFN_w}, B16_{IFN_x}, B16_{IFN_y}, B16_{IFN_z}) and grafted them onto mice. We found that wild-type mice inoculated with B16_{IFN_v} or B16_{IFN_w} have significant delayed tumour growth. When mice lacking the receptor for IFN (IFNAR^{0/0}) are inoculated with B16_{IFN_v} or B16_{IFN_w} tumours grow at the same rate as B16 control cells. This result provides strong evidence that type I IFNs indirectly mediate tumour control by harnessing anti-tumour immunity.

Strikingly, cohorts of either wild-type or IFNAR^{0/0} mice inoculated with B16_{IFN_x}, B16_{IFN_y} or B16_{IFN_z} cells never develop a palpable tumour. This

intriguing result suggests that these IFNs can directly exert their effect on tumour cells through a yet undefined mechanism.

In conclusion, our data provides compelling evidence that the family of 14 type I IFNs did not evolve solely to coordinate efficient immunity as the literature currently suggests. Instead, we postulate that multiple type I IFN subtypes exist to enable an individual to confront malignancies, such as cancer, through at least two distinct pathways:

- 1) either indirectly through immune modulation or
- 2) directly by arresting development and growth.

2858**Intravital visualization of brain metastasis immune surveillance reveals organ-specific regulation by the neuronal chemokine fractalkine***Nwajei, F.¹, Shanmugasundaram, M.¹, Zal, M.A.¹, Gabrusiewicz, K.², Wu, W.¹, Heimberger, A.², Zal, T.¹**¹University of Texas MD Anderson Cancer Center, Department of Immunology, Houston, United States, ²University of Texas MD Anderson Cancer Center, Department of Neurosurgery, Houston, United States*

Behind the blood-brain barrier, brain and other central nervous system (CNS) tissues are typically excluded from the immune surveillance by lymphocytes. As such, the CNS has been considered as immune privileged. Longitudinal intravital multiphoton microscopy via thinned skull windows revealed that single cell micrometastases of otherwise lethal MCA cancer progressed within the brains of syngeneic immune competent mice initially, but then became infiltrated by myeloid and T cell subsets followed by immune-mediated regression. In contrast, MCA brain metastases progressed lethally when the adaptive immunity was compromised such as by Rag deficiency or CD8 depletion. Interestingly, the neuronal chemokine fractalkine, which is uniquely recognized by the CX3CR1 chemokine receptor expressed by the microglia and various immune cell subsets, was highly upregulated around brain tumor borders, and brain MCA tumors were not rejected in CX3CR1-deficient mice. The contextual tracking of T cell motility patterns and cell subset depletion experiments revealed that T cell surveillance of brain metastases was cancer type-dependent and that it was organized largely by the CD11c⁺ CX3CR1⁺ monocytic dendritic cell (DC) subset rather than by the brain-resident CX3CR1-high microglia. Our results show that the blood-brain barrier is easily breached for T cell surveillance of brain invading cancers in a manner that is organ-specific such as through the recruitment of monocytic DC by the neuronal chemokine fractalkine. In extension, our study suggests that the phenomenon of organ specificity of tumor metastasis that is explained by the "seed and soil" concept should be re-considered as also involving organ-dependent immune regulation.

IFN-lambda production of CD8 cDCs in response to DNA-viruses, transfected dsDNA or cyclic-di-nucleotides depends on STING

Lauterbach, H.¹, Bathke, B.¹, Sanos, S.¹, Chaplin, P.¹, Suter, M.², O'Keefe, M.³, Hochrein, H.¹

¹Bavarian Nordic, Research Immunology, Martinsried, Germany,

²University of Zurich, Zurich, Switzerland, ³Monash University, Department Biochemistry & Molecular Biology, Melbourne, Australia

CD8 α ⁺ conventional dendritic cells (CD8 cDCs) and plasmacytoid dendritic cells (pDC) are major producers of IFN-lambda (IL-28/29). Previously, we have shown that upon stimulation with dsRNA murine CD8 cDCs were the exclusive source of IFN-lambda *in vivo* and *in vitro* via a TLR3/TRIF dependent recognition pathway. A finding confirmed for the human equivalent cDCs expressing CD141 (BDCA3). In contrast, pDCs ignored dsRNA but produced large amounts of IFN-lambda in response to TLR7 or TLR9 stimuli via MyD88.

Here, we demonstrate that both, the CD8 cDCs and pDCs, are able to produce IFN-lambda in response to DNA viruses such as HSV-1 or poxviruses. Our analysis of the pattern recognition receptors or adaptor molecules involved revealed that pDCs mainly use TLR9 and MyD88 for the detection of DNA viruses, whereas CD8 cDCs depend on the adaptor molecule STING but not on MyD88. The transfection of CD8 cDCs with different forms of dsDNA or cyclic-di-nucleotides such as c-di-GMP or c-GAMP induced, similar to the infection with DNA viruses, large amounts of IFN-lambda in a STING dependent way.

Thus, the immune system produces IFN-lambda in response to DNA via two different DC subsets (CD8 cDCs and pDCs), different pattern recognition receptors (cytoplasmic DNA receptors and TLR9) and adaptor molecules (STING and MyD88) as well as downstream signaling components (IRF3 and IRF7). We hypothesize, that this widespread redundancy counteracts viral or other pathogen encoded inhibitory mechanisms, possibly acting on the specific DC subsets, the pattern recognition receptors and adaptor molecules or other signaling components.

Type I interferon signalling suppresses anti-parasitic CD4⁺ T cell responses during visceral leishmaniasis

Kumar, R.^{1,2,3}, Bunn, P.², Singh, N.³, Sundar, S.³, Engwerda, C.²

¹Netaji Subhas Institute of Technology (University of Delhi), Div. of Biotechnology, Delhi, India, ²QIMR Berghofer Medical Research Institute, Immunology & Infection Lab, Brisbane, Australia,

³Banaras Hindu University, Dept. of Medicine, Varanasi, India

Many pathogens, including viruses, bacteria, and protozoan parasites, suppress cell mediated immune responses through activation of type I Interferon (IFN-1) signalling. However the role of IFN-1 during *Leishmania donovani* infection causing visceral leishmaniasis (VL) is not well known. Here we report that IFN-1 play an important role in the pathogenesis of VL by

impairing parasite clearance and suppressing pro-inflammatory cytokine production. Mice lacking type-1 IFN signalling (B6. IFNAR1^{-/-} mice) had enhanced pro-inflammatory cytokine production and better control of parasite burden in liver as well as spleen compared to wild type C57BL/6 mice. IFN-1 signalling suppressed the CD4⁺ derived IFN- γ production and prevented Th1 response from controlling parasite replication. Experiment using bone marrow chimeric mice revealed that IFN-1 did not suppress CD4⁺ T via directly acting to this cell type. Using conventional dendritic cell (cDC) specific IFN-1 deficient mice (CD11c Cre-IFNAR^{fl/fl}), we observed that IFN-1 hampered CD4⁺ T cells response acting via dendritic cells. Studies in VL patients supported these findings and showed enhanced accumulation of mRNA encoding type I IFN signature genes in peripheral blood mononuclear cells (PBMCs) that were reduced following successful drug therapy. Critically, we also showed, using a whole blood assay, that blockade of type-1 IFN signalling enhanced antigen specific IFN- γ production, and that this response was HLA-II restricted. Together, these results identify type-1 IFN signalling pathways as a potential therapeutic target to treat VL by stimulating anti-parasitic CD4⁺ T cell responses.

2867

MKP5 regulates RIG-I and STING mediated IRF3-type I interferon response in response to virus infection

James, S.J.¹, Jiao, H.¹, Teh, H.-Y.¹, Takahashi, H.¹, Yamamoto, N.¹, Dong, C.², Zhang, Y.¹

¹National University of Singapore, Microbiology & Immunology, Singapore, Singapore, ²Tsinghua University School of Medicine, Beijing, China

Detection of cytosolic nucleic acids from viral pathogens induces the production of type I interferons (IFNs) including IFN α and IFN β , which are critical for immune response to virus infection. Cytosolic RNA sensor RIG-I is important for recognition of RNA viruses including Sendai virus and influenza virus leading to IRF3 activation and type I IFN expression. Cytosolic DNA sensor STING, on the other hand, is essential for the induction of type I IFNs in response to cytosolic DNA of pathogen- and self-origin. However, how RIG-I and STING mediated IRF3-type I IFN response is negatively regulated is unclear. MAPK phosphatases (MKPs), also known as dual-specificity phosphatase (DUSPs), are cysteine-based protein tyrosine phosphatases that dephosphorylate phosphotyrosine, phosphothreonine, and phosphoserine residues in their substrates. They are originally identified as negative regulator of MAP kinases. It has been shown that members of this protein family also target other important signalling molecules such as FOXO1 and STATs. In this study, we demonstrate that RIG-I and STING stimulation induce the expression of MKP5. MKP5 protein interacts with RIG-I-MAVS-IRF3 or STING-MAVS-IRF3 signaling complexes to inhibit IRF3 activation by dephosphorylation of IRF3 in response to RNA virus or DNA virus infection. Our study reveals a critical function of MKP5 in negative regulation of IRF3-type I IFN axis in response to virus infection, which may be explored by viruses to evade host immunity. This function of MKP5 may also be important for the host to regulate the intensity of antiviral immune response to avoid uncontrolled immunopathology.

In vivo visualizing the IFN- β response required for tumor growth control in a therapeutic model of poly A:U administration

Maccioni, M.¹, Brinkmann, M.², Araya, P.¹, Jablonska, J.², Roselli, E.¹, Nocera, D.A.¹, Nuñez, N.¹, Lienenklaus, S.², Kröger, A.², Weiss, S.²
¹CIBICI-CONICET, Departamento de Bioquímica Clínica. Facultad de Ciencias Químicas. Universidad Nacional de Córdoba, Córdoba, Argentina, ²Molecular Immunology, Helmholtz Centre for Infection Research, HZI, Braunschweig, Germany

The crucial role that endogenously produced IFN- β plays in eliciting an immune response against cancer has recently started to be elucidated. Endogenous IFN- β has an important role in immune surveillance and control of tumor development. Accordingly, the role of TLR agonists as cancer therapeutic agents are being revisited via the strategy of intra/peritumoral injection with the idea of stimulating the production of endogenous type I IFN inside the tumor. Polyadenylic-polyuridylic acid (poly A:U) is a dsRNA mimetic explored empirically in cancer immunotherapy long time ago with little knowledge regarding its mechanisms of action. In this work, we have in vivo visualized the IFN- β required for the anti-tumor immune response elicited in a therapeutic model of poly A:U administration. Here, we have identified the role of host type I IFNs, cell populations that are sources of IFN- β in the tumor microenvironment and other host requirements for tumor control in this model. One single peritumoral dose of poly A:U was sufficient to induce IFN- β , readily visualized in vivo. IFN- β production relied mainly on the activation of the transcription factor IRF3 and the molecule UNC93B1, indicating that TLR3 is required for recognizing poly A:U. CD11c+ cells were an important, but not the only source of IFN- β . Host type I IFN signaling was absolutely required for the reduced tumor growth, prolonged mice survival and the strong anti-tumor specific immune response elicited upon poly A:U administration. These findings add new perspectives to the use of IFN- β inducing compounds in tumor therapy.

Serum interleukin 38 is associated with disease severity and organ involvement in systemic lupus erythematosus

Rudloff, L.^{1,2}, Godsell, J.³, Nold-Petry, C.A.^{1,2}, Harris, J.³, Hoi, A.³, Morand, E.F.³, Nold, M.F.^{1,2}
¹Hudson Institute of Medical Research, Ritchie Centre, Clayton, Australia, ²Monash University, Department of Paediatrics, Melbourne, Australia, ³Monash University, Centre for Inflammatory Diseases, Monash Medical Centre, Melbourne, Australia

Aims: Interleukin (IL)-38 is an IL-1 cytokine family member. Gene polymorphisms in IL-38 are associated with inflammatory diseases, and recombinant IL-38 inhibits IL-17 and IL-22. Intriguingly, both IL-17 and IL22 play a role in systemic lupus erythematosus (SLE), a severe autoimmune disease. We therefore set out to investigate IL-38 in SLE.

Methods: IL-38 and IL-10 were quantified in serum from SLE patients at admission (baseline, 142 patients) and two subsequent clinic visits (115/142). Serum of 28 healthy donors served as controls. Moreover, we silenced IL-38 in PBMC from

healthy volunteers by siRNA (siIL-38) and measured IL-6.

Results: IL-38 was detectable in 59 out of 345 patient samples (17.1%). IL-38 abundance in SLE samples was significantly higher compared to controls. Patients with active disease had 18.4-fold higher serum IL-38 than patients with non-active disease. Importantly, IL-38 was associated with increased risk of renal and CNS disease, and when IL-38 was detectable at baseline, patients had a 1.7-fold increased risk of developing persistently active disease. Remarkably, siIL-38-treated PBMC from healthy volunteers produced up to 30-fold more IL-6 than control-transfected cells when stimulated with CpG or imiquimod. Similarly, in SLE patients, the anti-inflammatory IL-10 was 5-fold higher when IL-38 was detectable, suggesting that IL-38 may be protective in SLE.

Conclusions: This study is the first to demonstrate the anti-inflammatory activity of endogenous IL-38. We reveal IL-38 as the first mediator that exhibits an association with markers of SLE disease activity, renal and CNS involvement; IL-38 may thus become the first biomarker for SLE.

A new function for TRAF1 in regulation of TLR signaling underlies the role of TRAF1 in rheumatic disease

Abdul Sater, A.¹, Edilova, M.¹, Clouthier, D.¹, Mbanwi, A.¹, Kremmer, E.², Watts, T.¹
¹University of Toronto, Immunology, Toronto, Canada, ²Institut für Molekulare Immunologie, Deutsches Forschungszentrum für Gesundheit und Umwelt (GmbH), München, Germany

TNF receptor (TNFR) associated factor 1 (TRAF1) is a signaling adaptor known for its role in TNFR-induced cell survival. Here we show that monocytes from healthy donors with a rheumatoid arthritis-associated SNP in the TRAF1 gene express less TRAF1 protein but produce higher levels of inflammatory cytokines in response to LPS. TRAF1, via its MATH domain, binds to HOIP and HOIL1, components of the linear ubiquitination (LUBAC) complex, to interfere with the recruitment and linear ubiquitination of NF- κ B essential modifier (NEMO). This results in decreased NF- κ B activation and cytokine production, independently of TNF- α . Consistently, TRAF1^{-/-} mice show increased susceptibility to endotoxin-induced septic shock. These findings reveal an unexpected role for TRAF1 in regulation of TLR signaling, providing an explanation for increased inflammation associated with a disease associated TRAF1 SNP.

1355

Elevated pressure promotes EndoMT-induced fibrosis via a caveolin-1 dependent mechanism

Shihata, W.A.^{1,2}, Andrews, K.L.¹, Sampson, A.K.¹, Fang, L.¹, Murphy, A.J.¹, Kaye, D.M.¹, Chin-Dusting, J.P.F.¹
¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Monash University, Melbourne, Australia

Introduction: A major risk-factor for cardiac fibrosis is high blood pressure, which we have previously shown to induce endothelial activation *via* a caveolin-1 (cav-1) dependent mechanism. Endothelial-to-mesenchymal transition (EndoMT)

is a key player in the development of cardiac fibrosis. Here, we examine the hypothesis that increased pressure promotes EndoMT-induced fibrosis via a cav-1 dependent mechanism.

Methods: Human umbilical vein endothelial cells (HUVECs) or cav-1 knockdown (cav-1 KD) cells were treated with TGF β 1 (10ng/mL) and TGF β 2 (10ng/mL), known inducers of EndoMT, or pressurised to 120 mmHg for up to 5 days. Wild-type and cav-1^{-/-} mice were used to confirm our findings *in vivo*.

Results: TGF β 1/2-treated HUVECs had increased expression of fibroblast genes, vimentin and alpha-smooth muscle actin (α SMA), and decrease of the endothelial gene, CD31. A similar pattern was observed when HUVECs were exposed to a hypertensive pressure (120mmHg), suggesting that exposure to increased pressure promotes EndoMT. This was also accompanied by an increase in both MMP2 and MMP9 activity, consistent with the premise that pressure induces the breakdown of collagen type IV, essential for the progression of EndoMT. Interestingly, cav-1 KD cells were protected from these pressure-induced changes. In angiotensin II (AngII) and noradrenaline (NA) mouse models of hypertension, we found that Cav-1^{-/-} mice compared to WT mice were protected from perivascular fibrosis and cardiac hypertrophy and failed to increase vimentin and α SMA gene expression.

Conclusions: Hypertension induces EndoMT via a cav-1 dependent mechanism and may be responsible for the end-organ fibrosis observed in the context of high blood pressure.

1989

Targeting IL-4 receptor alpha mediated signaling to treat fibroproliferative diseases: the case of chronic schistosomiasis

*Nono Komgwep, J., Ndlovu, H., Brombacher, F.
University of Cape Town/Institute of Infectious Disease and
Molecular Medicine, Cape Town, South Africa*

Fibroproliferative diseases represent a leading cause of mortality. Despite their pathophysiological differences, this group of diseases associates with activation of myofibroblast, deposition of collagen and fibrosis, a cascade of events that can be initiated and amplified by type 2 cytokines. Central to the production of type-2 cytokines is the host signaling via the IL-4 receptor alpha (IL-4Ra). A pathogenic role has therefore been suggested for the signaling via IL-4Ra, principally mediated by IL-13 and poorly IL-4 in fibroproliferative diseases like allergy and schistosomiasis. However, the therapeutic value of targeting IL-4Ra has only been successfully addressed in the former but not the latter disease. Utilizing a new and tractable murine model of inducible cessation of IL-4Ra mediated signaling, we now report that cessation of IL-4Ra mediated signaling abrogates already initiated type-2 immune responses in murine models of helminth infections uncovering an unprecedented role for IL-4Ra mediated signaling in the maintenance of type-2 immune responses. Importantly, in the advanced fibrotic model of chronic schistosomiasis, cessation of IL-4Ra mediated signaling considerably reduced the egg-surrounding collagen as well as the total collagen content in the liver without affecting the viability of the infected animals. Overall, our data indicate that targeting IL-4Ra could be a viable option for the mitigation of

type-2 immunopathologies and the treatment of associated morbidities like fibrosis. Since our findings could prove equally attractive for the management of other fibroproliferative diseases, further avenues of investigation on the wide anti-fibroproliferative potential of our approach will be discussed.

Autocrine and paracrine IL-2 signals collaborate to regulate distinct phases of CD8 T cell memory

Yuzefpolskiy, Y.¹, Penny, L.A.², Baumann, F.M.², Smith, K.A.³, Sarkar, S.^{4,5}, Kalia, V.^{4,5}

¹Penn State University, Seattle, United States, ²Penn State University, University Park, United States, ³Weill Cornell Medical College, New York, United States, ⁴University of Washington School of Medicine, Seattle, United States, ⁵Seattle Children's Research Institute, Seattle, United States

Proliferation is a defining feature of clonal cytotoxic T lymphocyte (CTL) responses upon activation. However, how proliferative events during primary expansion relate to divergent CD8 T cell fate outcomes remains poorly defined. Emerging evidence from our laboratory and others in the field suggest that death-fated effectors undergo more pronounced proliferation compared to memory-fated cells during antigen-driven T cell expansion. Adoptive transfer of activated CD8 T cell-subsets, purified based on their extent of proliferation, showed that *in vivo* differentiation of CD8 T cells and memory fate are linked to proliferation. We found that the less-divided effector CTL subset preferentially contributed to the central memory lineage. Interestingly, these less-divided memory precursor cells were also programmed to produce more IL-2 compared to their more-divided terminal effector counterparts. How do memory-fated cells that make their own IL-2 (a pro-proliferative cytokine) proliferate less and how does this make them better fit for the long-lived memory lineage? To answer this question, we generated CD8 T cells that could be conditionally ablated for *il2*. We ablated IL-2 specifically in antigen-specific CD8 T cells, during distinct phases of effector and memory differentiation. Our data showed that while paracrine IL-2 is critical for driving the early *in vivo* proliferative burst, the programmed life-long autochthonous IL-2 in memory-fated cells was necessary for antigen-independent maintenance, and robust secondary expansion of memory cells. Thus, autocrine and paracrine IL-2 signals collaborate during distinct stages of T cell differentiation to direct diverse CTL lineages through effects on proliferation.

Th Differentiation

Molecular mechanisms of human T helper cell differentiation

Lahesmaa, R.

University of Turku

Regulation of the immune response is central for human health. In healthy individuals there is an appropriate balance between the adaptive and innate arms of the immune response. T cells, in particular, orchestrate the adaptive arm of the immune system and are required for key immune functions. T helper (Th) cell subsets with distinct cytokine secretion profiles and function play a crucial role in host defense. Pathological imbalances in these lymphocyte subsets contribute to allergy, chronic inflammatory and autoimmune diseases as well as in cancer. Effector cell functions are suppressed by natural or induced T regulatory cells (Treg and iTreg, respectively). Understanding the gene regulatory pathways controlling T-cell differentiation into functionally distinct subsets is important to understand the pathogenesis of immune-mediated diseases and to develop better therapies. Our efforts have focused on the detailed studies of transcriptional and epigenetic regulation of the early stages of primary human Th cell differentiation. Genome wide systems level approaches followed by functional studies have revealed new factors and molecular mechanisms contributing to the regulation of Th cell lineage specification in human. Our recent results will be presented and discussed.

Dendritic Cells

Toward an integrative biology of T cells and dendritic cells

Malissen, M., Roncagalli, R., Henri, S., Dalod M., Luche, H.

Centre d'Immunologie de Marseille-Luminy

T cells probe the surface of dendritic cells (DCs) in search of cues reflecting the antigenic and inflammatory status of the body tissues. It remains a daunting task to understand how T cell activation is regulated through the summation of a multitude of positive and negative inputs and how their integration contributes to the unfolding of appropriate T cell responses. One of our major objectives is to understand how mutations that reduce TCR signaling output paradoxically lead to severe immune pathologies in both the mouse and human species. More specifically, we would like to elucidate the mechanisms through which during physiological, antigen-driven T cell responses some signaling "hub" used by the TCR leads first to activation of intracellular signaling pathways and then exerts with a temporal delay a feedback inhibition that leads to rapid attenuation of the whole TCR signaling pathway. In the absence of such negative feedback, T cell responses evolves into chronic pro-inflammatory T cell responses that perpetuate themselves

in a TCR-independent manner and induce the production of massive amounts of autoantibodies. After giving an overview of the major actors of T cell activation, we will present some recent genetic and proteomic approaches that we have developed to tackle the complexity of T cell activation under physiological conditions and at the systemic levels.

Innate Lymphoid Cells

Regulatory mechanisms for ILC2 functions in allergic inflammation

Koyasu, S.¹, Kabata, H.², Koga, S.¹, Moro, K.¹

¹RIKEN Center for Integrative Medical Sciences, ²Keio University School of Medicine

Innate lymphoid cells (ILC) are classified into three groups, ILC1, ILC2 and ILC3 based on their ability to produce distinct sets of cytokines. We have identified a previously unidentified lymphocyte population producing large amounts of type 2 cytokines, which we named Natural Helper (NH) cells. We identified NH cells in lymphoid clusters in adipose tissues, which we termed fat-associated lymphoid cluster (FALC). NH cells produce Th2 cytokines constitutively without any stimulation, and support the self-renewal of B1 cells and IgA production by B cells. Stimulation by IL-33 or helminth infection activates NH cells to produce large amounts of IL-5 and IL-13, which induce eosinophilia and goblet cell hyperplasia, both of which play an important role in anti-helminth immunity and pathophysiology of allergic diseases. NH cells are now considered to be a member of group 2 innate lymphoid cells (ILC2) that are tissue-resident lymphoid cells present in various tissues. We have shown that NH cells are involved in the steroid resistance of allergic airway inflammation. Steroid resistance is induced by thymic stromal lymphopoietin (TSLP) through Stat5-dependent signals. In addition, we have identified interferon- α/β , interferon- γ and IL-27 as negative regulators of NH cell functions in vivo. These cytokines suppress NH cell proliferation and functions through Stat1-dependent signals. Thus, NH cell functions are differentially controlled by distinct sets of Stat proteins. We will present our recent work on the regulatory mechanisms of NH cells in allergic inflammation.

Roles of iNKT and dendritic cells in myometrium for the induction of miscarriages by α -galactosylceramide

Negishi, Y.^{1,2}, Ichikawa, T.^{1,2}, Shimizu, M.¹, Takeshita, T.², Takahashi, H.¹

¹Nippon Medical School, Microbiology and Immunology, Tokyo, Japan, ²Nippon Medical School, Obstetrics and Gynecology, Tokyo, Japan

Innate immunity plays a crucial role in the control of pregnancy. When IL-12 (0.2 μ g/mouse) was administered to syngeneic-mated pregnant mice (C57BL/6 (♀ x ♂)) on day 7.5 of gestation (Gd 7.5), significant fetal loss was observed. Such IL-12 generally secreted by innate DEC-205+ dendritic cells (DCs) and invariant natural killer T (iNKT) cells expressing IL-12-receptor can be activated by the externally added IL-12. In addition, intraperitoneal (i.p.) administration of 2 μ g of α -galactosylceramide (α -GalCer), known to activate iNKT cells, on Gd 7.5 induced miscarriages in both syngeneic-mated pregnant C57BL/6 mice and allogeneic-mated pregnant mice (C57BL/6 (♀) x BALB/c (♂)). On the other hand, miscarriages were not induced in iNKT cells-deficient Ja18-/- mice by the IL-12 or α -GalCer treatment. Surprisingly, the percentage of both DEC-205+ DCs and CD1d-restricted NK1.1+ iNKT cells was far higher in the myometrium of pregnant mice treated i.p. with α -GalCer than it was in the decidua. The IL-12 secreted from α -GalCer-activated DEC-205+ DCs then stimulates the secretion of various cytokines including IL-2, IL-4, IFN- γ , TNF- α , perforin, and granzyme B from the NK1.1+ iNKT cells, leading to miscarriages in the pregnant mice. These findings may provide a new notion about the importance of myometrium rather than decidua in the regulation of pregnancy as well as the mechanism for miscarriages through activated innate DEC-205+ DCs and NK1.1+ iNKT cells in the myometrium of pregnant mice.

Protection of mother and fetus against bacterial infection induced complications via prophylactic treatment during pregnancy with a microbial-derived immunomodulator

Scott, N.M.¹, Jones, A.C.¹, Lauzon-Joset, J.-F.¹, Mincham, K.T.¹, Troy, N.M.¹, Prescott, S.L.^{1,2}, Robertson, S.A.³, Bosco, A.¹, Holt, P.G.¹, Strickland, D.H.¹

¹Telethon Kids Institute, The University of Western Australia, Subiaco, Australia, ²The University of Western Australia, School of Pediatrics and Child Health, West Perth, Australia, ³Robinson Research Institute, University of Adelaide, Adelaide, Australia

Maternal bacterial infection can be linked to serious pregnancy complications, including increased mortality and morbidity for mother and child, fetal growth restriction, and preterm delivery. These outcomes are also associated with a detrimental impact on child growth and development during early life, and significantly increase risk of non-communicable disease during

adulthood.

Safe effective novel treatments to protect against infection and inflammation induced complications could provide exciting opportunities for improving pregnancy outcomes. Pro-biotics, and other agents classified generally as immunomodulators have shown great promise for prevention of inflammatory diseases. OM-85, a cocktail lysate of several heat-killed respiratory bacterial antigens is one such compound, which is currently in use for attenuation of infection-associated airway inflammatory symptoms in human infants.

Using a pregnant mouse model with LPS as an inflammatory bacterial challenge, we have demonstrated that OM-85 markedly reduces risk for fetal loss and growth restriction. Here, we have conducted RNASeq analysis of gestational tissues, which has revealed that OM-85 treatment attenuates the LPS-driven activation of TNF and IL1 driven pro-inflammatory gene networks in maternal gestational tissues, but preserves interferon-mediated networks.

These results suggest that OM-85 has potential as a novel, safe, effective treatment strategy to protect against bacterial infection-induced inflammatory complications during pregnancy.

Vitamin-D and fetomaternal immunity: effects on uterine natural killer cells

Jeffery, L.¹, Tamblin, J.^{1,2}, Susarla, R.¹, Moss, P.³, Hewison, M.¹, Kilby, M.²

¹University of Birmingham Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, Birmingham, United Kingdom, ²Birmingham Women's Foundation Hospital, Edgbaston, Birmingham, United Kingdom, ³University of Birmingham, Institute of Immunology and Immunotherapy, College of Medical and Dental Sciences, Birmingham, United Kingdom

Vitamin-D deficiency is prevalent in pregnant women. Active vitamin-D (1,25(OH)₂D₃) exerts important non-classical immune-regulatory effects and the maternal placenta (decidua) appears a potential target. CD56+ uterine natural killer cells (uNKs) are the most prominent decidual immune cell during early pregnancy. Given their critical role in fetal implantation and placentation, we hypothesised uNKs are a local source of 1,25(OH)₂D₃ and a pivotal immunomodulatory target for vitamin-D.

CD56+ NK cells were isolated from 1st trimester decidua (uNKs) and matched maternal peripheral blood (pNKs), and stimulated with IL-2, IL-15, and IL-12 with or without 1,25(OH)₂D₃ or 25(OH)D₃. At 24-hours, regulators of vitamin-D signalling and metabolism: 1- α -hydroxylase (CYP27B1), 24-hydroxylase (CYP24A1), vitamin-D-receptor (VDR), were measured by qPCR and IFN- γ , a marker of NK function, by qPCR, flow-cytometry and ELISA. 1,25(OH)₂D₃ was measured by liquid-chromatography-tandem-mass-spectrometry (LC-MS/MS).

Both uNKs and pNKs expressed an intracrine vitamin-D metabolic system, characterised by CYP27B1, CYP24A1 and VDR. Cytokine stimulation up-regulated vitamin-D-activating CYP27B1 and VDR in both subsets (p < 0.05), whilst vitamin-D-deactivating CYP24A1 remained unchanged. Detection of 1,25(OH)₂D₃ in 25(OH)D₃-treated stimulation cultures further confirmed the

functional induction of the system upon stimulation. Feedback regulation was also observed as 1,25(OH)₂D₃ increased CYP24A1 (~44-fold(uNKs), 85-fold(pNKs)).

In NK function studies, 1,25(OH)₂D₃ reduced IFN-γ expression by uNK cells only, suggesting differential vitamin-D sensitivity in the NK subsets. Overall, these data show that uNKs have a functional vitamin-D system, and may be more sensitive to 1,25(OH)₂D₃ than their peripheral counterparts. Vitamin-D metabolism by uNKs and their response to it is a possible mechanism through which vitamin-D affects pregnancy outcomes.

Antigen-specific protective immunity in *Chlamydia trachomatis* genital infection is dependent on effector cell microRNAs

Arulanandam, B.P., Gupta, R., Arkatkar, T., Keck, J.P., Castillo, K., Yu, J.J., Chambers, J.P., Guentzel, M.N.
University of Texas at San Antonio, South Texas Center for Emerging Infectious Disease and Center of Excellence in Infection Genomics, San Antonio, United States

Anti-chlamydial immunity involves efficient presentation of chlamydial antigens (Ag) to effector cell populations resulting in Ag-specific immune responses. There is however, limited information on inherent underlying mechanisms that regulate these events. Previous reports from our laboratory have established that selected microRNAs (miRs) function as molecular regulators of immunity and contribute to disease pathogenesis following intravaginal (i.vag) *Chlamydia trachomatis* (Ct) infection. In the current study, we investigated immune cell type-specific miRs and the role in Ag-specific immune responses. We observed significant up-regulation of a cohort of miRs in Ct infected antigen presenting cells (APC) and Ag-specific CD4⁺ T-cells isolated from Cm infected mice. *Ex vivo* co-cultures of miR-agonist and antagonist treated APC and Ag-specific CD4⁺ T-cells resulted in significant regulation of Ct-specific IFN-γ production. *In vivo* miR depletion studies in Ct infected mice demonstrated a role for regulation of Ag-specific immune responses, IFN-γ production and disease pathogenesis. Additionally, these miRs were significantly regulated in intranasally vaccinated mice protected against a genital Ct infection and in cohorts of Ct-infected women with inflammation and reproductive pathology. Taken together, our data indicates a role for a cohort of miRs in immune effector cells, namely APC and CD4⁺ T cells in regulating Ag-specific protective immunity in Ct infected mice and the translational relevance in human cohorts. Since Ag-specific CD4⁺ T cells and IFN-γ are critical for protection against genital Ct, we are currently using 'omics-level' approaches to determine involved targets and pathways regulated by these miRs.

Maternal asthma exacerbation before mating offers strong protection against offspring asthma

Dähling, S.¹, Blois, S.M.¹, Klopffleisch, R.², Conrad, M.L.¹

¹Charité Medical University, Berlin, Germany, ²Free University Berlin, Berlin, Germany

Background: Prenatal environmental exposures during critical developmental time points can influence allergy susceptibility later in life. Mouse models demonstrate that placental transfer of antibodies from sensitized mothers protects against offspring asthma. Moreover, maternal asthma exacerbation over the entirety of pregnancy results in protective effects against offspring asthma severity. It is not known, however, which gestational time points are important for offspring asthma protection.

Methods: To examine the importance of particular gestational time points with regard to offspring asthma susceptibility, mother mice were sensitized with PBS or casein then challenged at one of the following time points: before mating, gestation day (gd) 11.5-13.5 or gd 14.5-16.5. Experimental asthma was subsequently induced in four week old offspring using the antigen ovalbumin. Offspring asthma severity was assessed by bronchoalveolar lavage (BAL) differential cell counts and cytokines, lung inflammation and mucous production, and serum ovalbumin specific antibodies.

Results: The strongest protective effects against asthma were observed in offspring from mothers challenged before mating, followed by mothers challenged from gd 14.5-16.5. Allergic offspring from these mothers had significantly fewer BAL leukocytes; due to significantly fewer eosinophils and lymphocytes, and significantly less IL-4, IL-13, IL-12p40, IL-12p70, GM-CSF, KC and eotaxin than allergic offspring from control mothers. No difference was seen in OVA specific antibodies. No differences were observed in offspring lung inflammation or mucous production, likely due to the short length of the maternal challenge.

Conclusion: Significant protection against asthma was observed in offspring from allergic mothers challenged before mating or from day 14.5-16.5 of gestation.

3862

Repeated priming with male seminal fluid expands regulatory T cell populations to build pregnancy tolerance in mice

Robertson, S.A., Zhang, B., Wahid, H.H., Moldenhauer, L.M.

University of Adelaide, Robinson Research Institute, Adelaide, Australia

Female tolerance of the semi-allogeneic fetus in pregnancy requires regulatory T (Treg) cells and is maximised when populations of paternal alloantigen-reactive peripheral Treg cells are expanded by contact with seminal fluid from the conceiving male partner at conception. Here, we investigated whether repeated exposure to seminal fluid can sequentially expand the Treg cell pool. Female C57Bl/6 (B6) female mice were mated once or four times to B6 males, Balb/c or Balb/b males, followed by low dose RU486 administration to prevent pregnancy. Uterus

and para-aortic lymph nodes were recovered at day 3.5 post-coitum (pc) after the final mating. Using immunohistochemistry and flow cytometry for the Treg cell transcription factor Foxp3, we demonstrated the expansion in uterine Treg cells was 6-fold greater at day 3.5 pc after 4 prior exposures compared to a single exposure to Balb/c males, and similar increases were evident in lymph nodes. In contrast, no increase was induced by repeated mating with B6 or Balb/b males, indicating requirement for MHC alloantigens. Seminal fluid, as opposed to neuroendocrine or physical responses to mating were necessary, since mating to males surgically rendered deficient in sperm and/or seminal plasma failed to elicit a Treg cell increase. Collectively, these data provide evidence that repeated seminal fluid contact acts to expand the Treg cell pool during early pregnancy, and that sperm-associated or plasma constituents of seminal fluid elicit the Treg cell response. These data provide a mechanistic explanation for the link between duration of sexual cohabitation and protection from pregnancy complications in women.

1306

Effect of TGF- β treatment on Treg cells in adverse pregnancy caused by *Toxoplasma gondii* infection

Hu, X.¹, Zhan, S.¹, Zhang, H.¹, Li, Z.¹, Zhao, M.², Liu, X.¹, Zhan, R.², Liu, Z.²

¹Binzhou Medical University, Department of Immunology, Yantai, China, ²Binzhou Medical University, Department of Medicine & Pharmacy Research Center, Yantai, China

Aims: To examine the effect of TGF- β treatment on the differentiation and function of Treg cells and to improve adverse pregnancy caused by *T. gondii* infection.

Methods: *T. gondii*-infected pregnant mouse was treated with TGF- β or TGF- β -neutralizing antibodies, sacrificed on gestational day (gd) 7 and pregnancy outcomes were observed. Treg cell number, and the expression of pSmad3, CTLA-4 and PD-1 were analyzed by flow cytometry. Histopathological changes of placentas were assessed using HE staining. IL-10 and TNF- α levels in placenta were measured using ELISA.

Results: TGF- β treatment improved *T. gondii*-induced adverse pregnancy outcomes, while TGF- β neutralization demonstrated more serious adverse pregnancy outcomes compared with infected controls. TGF- β treatment increased Treg cell number, while TGF- β neutralization decreased Treg cell number. Pathological histology revealed that TGF- β treatment alleviated hemorrhage and partly restored the uterine spiral arteries of the placenta, while TGF- β neutralization led to serious hemorrhage and more dilated uterine spiral arteries of placenta compared with infected controls. pSmad3 expression in CD4⁺ cells and CTLA-4 and PD-1 levels on Treg cells were up-regulated by TGF- β treatment but down-regulated by TGF- β neutralization. IL-10 levels increased, TNF- α levels decreased, and ratio of IL-10/TNF- α increased after TGF- β treatment, while IL-10 levels decreased, TNF- α levels increased, and ratio of IL-10/TNF- α decreased after TGF- β neutralization.

Conclusion: Our data indicated that TGF- β treatment could up-regulate the differentiation and function of Treg cells through TGF- β /Smad3 signaling pathway and could improve adverse pregnancy outcomes caused by *T. gondii* infection.

Keywords: TGF- β , pSmad3, CTLA-4, PD-1, CD4⁺Foxp3⁺Treg cells, *Toxoplasma gondii*, pregnancy outcome

Circulating blood macrophages transmit *Chlamydia* infection to the testis

Bryan, E.R.¹, Kollipara, A.¹, Armitage, C.W.¹, Redgrove, K.A.², McLaughlin, E.A.², Carey, A.J.¹, Beagley, K.W.¹

¹Queensland University of Technology, Institute of Health and Biomedical Innovation, Brisbane, Australia, ²University of Newcastle, Faculty of Science and IT, Newcastle, Australia

Introduction: *Chlamydia* research has focused almost entirely on females and this has resulted in male disease being underestimated and understudied. The purpose of this study was to determine the mechanism of *Chlamydia* transmission from the lower to the upper male reproductive tract and the impact of *Chlamydia* colonisation of the upper tract leading to deregulation of spermatogenesis and infertility.

Methods/results: We infected 6 week old, male, BALB/c mice that had either undergone vasectomy or not. We found that two weeks post-infection, *Chlamydia* was detected by PCR in the testes and whole blood of all mice. There were histological changes to testes and epididymis, with pathological tubular destruction occurring in infected mice. To determine if macrophages served as a source of testicular infection we showed that isolated primary macrophages were susceptible to infection for up to 4 hours and produced viable progeny. Co-culture of *Chlamydia*-infected RAW264.7 macrophages with TM3 Leydig, TM4 Sertoli and GC-1 Germ cells showed that progeny from macrophages were able to infect each of these cell types, which all contained fragmented DNA resultant from infection.

Conclusion: The presence of *Chlamydia* in the testes of vasectomised mice indicates an alternate route of ascending infection to the classical urethral-epididymal-testicular route. Further investigation is required to establish if infected macrophages home to the testes or travel to many distant sites. Regardless, this is a probable route of transmission of *Chlamydia* to the testes. The consequential testicular infection compromises male infertility through damage to spermatogenesis support cells and tubule structure.

3616

Uterine regulatory T cells prepare a tolerogenic environment for embryo implantation and imprint maternal-fetal tolerance during early gestation

Florez, L.M.¹, Ruocco, M.G.¹, Courau, T.¹, Fourcade, G.¹, Nehar-Belaid, D.¹, Klatzmann, D.^{1,2}

¹Sorbonne Universités, UPMC Univ Paris 06, INSERM, Immunology-Immunopathology-Immunotherapy, Paris, France, ²AP-HP, Hôpital Pitié-Salpêtrière, Biotherapy (CIC-BTi) and Inflammation-Immunopathology-Biotherapy Department (i2B), Paris, France

Regulatory T cells (Tregs) are a key component to successful gestation. Indeed, depletion of Tregs leads to rejection of allogeneic fetuses in mice and correlative human studies

revealed low Treg numbers associated with recurrent spontaneous abortion in women. However, the role of Tregs at the maternal-fetal interface remains poorly understood.

In this work, we combine flow cytometry, transcriptomics and confocal as well as intravital two-photon imaging to study the phenotype and function of uterine Tregs (uTregs).

We found that in the non-pregnant uterus uTregs localize in close proximity to the uterine glands and increase in proportion during the estrus cycle preparing the uterus for fecundation. Moreover, we show a spatio-temporal regulation of uTregs during pregnancy that re-localize in the pregnant uterus and interact with cells of the innate and adaptive immune system. Indeed, the proportion of uTregs significantly increases as early as 2 days after embryo implantation. Our data indicate that effector CD4 and CD8 cells also increase in numbers in the pregnant uterus towards mid-gestation. However, uTregs present a strikingly activated phenotype suggesting that they are able to mediate local immune suppression in order to protect the fetus of the effector T cells. Furthermore, contrasting with the well-described pro-inflammatory role of mast cells, our results reveal mast cells as important mediators in the Treg-dependent establishment of maternal-fetal tolerance.

Together, these results outline another adaptive/innate cells cross-talk selected during evolution of the mammalian adaptive immune system to protect the developing semi-allogenic fetus.

4101

Characterization and functionality of MAIT cells at the fetomaternal interface

Solders, M.^{1,2}, Gorchs, L.¹, Erkers, T.¹, Nava, S.¹, Ringdén, O.¹, Magalhaes, I.³, Kaipe, H.^{1,4}

¹Karolinska Institutet, Laboratory Medicine, Stockholm, Sweden,

²Karolinska University Hospital, Center for Allogeneic Stem Cell Transplantation, Stockholm, Sweden,

³Karolinska Institutet,

⁴Karolinska University Hospital, Clinical Immunology and Transfusion Medicine, Stockholm, Sweden

During pregnancy, the maternal immune system must tolerate the allogeneic fetus while maintaining immunity against pathogens. We investigated the presence, distribution, phenotype and functionality of the innate-like mucosal-associated invariant T (MAIT) cells at the fetomaternal interface. After uncomplicated term deliveries through caesarian sections, paired samples of lymphocytes were isolated from peripheral blood (PB), intervillous blood (IVB), decidua parietalis (DP), and umbilical cord blood (UCB) (n=8).

The proportion of MAIT cells within the CD3+ T-cell population was significantly higher in IVB (median 5.4%, range 2.7-19.2) compared to PB (1.7%, 0.7-7.7), DP (0.7%, 0.5-7.8), and UCB (0.1%, 0.1-10.4). The expression of Ki-67 in MAIT cells was low in IVB, suggesting that MAIT cells are recruited rather than locally proliferating. MAIT cells with an effector memory phenotype (CD45RA⁺CCR7⁻) were enriched in IVB compared to PB, DP, and UCB. MAIT cells from DP expressed significantly higher levels of both activation and exhaustion markers (CD69, CD25, HLA-DR, PD-1) compared to both PB and IVB. Upon *E. coli* stimulation, MAIT cells from IVB showed a significantly higher expression

of interferon- γ and granzyme B compared to PB, DP, and UCB. Unstimulated MAIT cells in IVB had a higher endogenous expression of perforin compared to PB.

To conclude, we show that MAIT cells are present in the placenta and in cord blood, and that they are enriched in placental blood. The increased frequency of highly reactive MAIT cells in the IVB may be a physiological way to maintain bacterial immunity in the immunosuppressed environment at the fetomaternal interface.

Computational Immunology & Systems Biology

The earliest lineage priming regulators leading to the dendritic cell subtypes

Schreuder, J.¹, Kocovski, N.¹, Tran, J.¹, Tian, L.¹, Ritchie, M.¹, Naik, S.^{2,3}

¹The Walter and Eliza Hall Institute of Medical Research, Molecular Medicine, Melbourne, Australia, ²The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ³The University of Melbourne, Medical Biology, Melbourne, Australia

The different dendritic cell subtypes are pivotal players in the recognition of pathogens and activation of the adaptive immune response and include plasmacytoid DCs (pDCs) and the two conventional DCs (cDC); cDC1 and cDC2. They are derived from hematopoietic progenitors. However, prior evidence has demonstrated that, at the single cell level, these progenitors are heterogeneous in their fate and biased towards certain DC subtypes. These findings raise the question as to whether 'lineage bias' occurs either stochastically, or through environmental mechanisms, or alternatively through undefined intrinsic molecular programs. For the latter hypothesis, one cannot both assess the transcriptome of a single progenitor and test its fate - as one test necessarily destroys the chance to test the other. To overcome this, we performed clone-splitting experiments where the daughters of a single progenitor early during expansion stage were separated in three: some daughters for testing fate in duplicate, and others for RNA-seq. By computationally comparing the transcriptome to fate, per clone, for dozens of clones, we made several findings:

- 1) DC fate bias is pre-existing and intrinsic to most proposed 'multipotent' progenitors,
- 2) fate bias was the norm, not the exception, and
- 3) we identified novel molecular programs by linear regression models that correlated gene expression with fate bias.

These included known factors, as well as novel transcription factors and epigenetic regulators. These findings have important implications as to how stem and progenitor cells generate fate diversity, and at which point (and through which mechanisms) in the developmental pathway these arise.

267

Characterisation of the T cell receptor repertoire following immunisation*Chain, B.¹, Best, K.², Cinelli, M.¹, Friedman, N.³, Mark, M.³, Reich-Zeliger, S.³, Sun, Y.⁴, Shave-Taylor, J.⁴, Shifrut, E.³*¹*UCL, Infection and Immunity, London, United Kingdom, ²UCL, CoMPLEX, London, United Kingdom, ³Weizmann Institute, Immunology, Rehovot, Israel, ⁴UCL, Computer Sciences, London, United Kingdom*

The T cell repertoire consists of an ensemble of alpha and beta T cell receptor (TCR) sequences which characterise a blood or tissue sample at a particular time. We understand in detail the molecular interaction between an individual T cell receptor and its cognate peptide/MHC antigen target, but the impact of antigen exposure on the repertoire as a whole is less well understood. The problem is compounded because the stochastic nature of TCR generation results in different repertoires between individuals. We approach the problem from the perspective of classification of repertoires after immunisation with different antigens in a space indexed by all possible TCRs (we focus on CDR3 (complementarity determining region 3) sequences, which play a major role in antigen recognition). We reduce dimensionality by decomposing each CDR3 into sets of short amino acid motifs. From a biophysical perspective, these motifs may capture conserved contact points between TCR and MHC/peptide complex. The frequency of each motif in a sample of TCRs after immunisation with a given antigen defines the repertoire in a new feature space. Finally, we use support vector machines and other “weak learner” algorithms to identify sets of features which correctly classify repertoires from different immunisations. The results suggest that immunisation induces widespread changes in the TCR repertoire which are distributed over a large number of individual TCRs, and are mainly private and differ between individuals immunised with the same antigen.

1155

Analysis of antigen-specific responses by high throughput sequencing of the T cell receptor repertoire*Oakes, T.¹, Popple, A.L.², Heather, J.¹, Singleton, H.², Best, K.¹, Williams, J.³, Dearman, R.J.², Kimber, I.², Chain, B.¹*¹*University College London, London, United Kingdom, ²University of Manchester, Manchester, United Kingdom, ³Salford Royal NHS Foundation Trust, Salford, United Kingdom*

Probing the T cell receptor (TCR) repertoire can provide a snapshot of a person's immune status, providing information on the clonality of T cells, and may therefore be a useful biomarker to monitor immune responses.

We have developed a reliable and economical amplification protocol that can be used to characterise the TCR repertoire using high-throughput sequencing and pipeline for the downstream analysis. Introduction of barcodes, which label every cDNA molecule before amplification allow for correction of PCR bias, and PCR and sequencing error. The protocol can be used to sequence TCR repertoires of diverse types of samples; including whole or FACS fractionated blood or tissue and *in vitro* cultured cells.

We were able to identify putative antigen-specific T cells in patients with allergic contact dermatitis after comparing the *ex vivo* TCR repertoire to allergen-stimulated *in vitro* samples (12/NW/0602). Longitudinal blood samples from alopecia patients treated with DCP to stimulate hair growth, before and after sensitisation, were also analysed to identify DCP-reactive T cells (14/EE/1067). The frequencies of allergen-specific clones will be used to parametrise mathematical models of skin sensitisation to improve our ability to predict safe levels of human exposure to chemical allergens.

We have been able to show that our protocol and analysis pipeline to study the TCR repertoire is robust and that we are able to identify putative antigen-specific T cells from different sets of samples. Crucially, we show the importance of single molecule barcodes to allow quantitative as well as qualitative information on the TCR repertoire.

Persisting fetal clonotypes influence the structure and overlap of adult human TCR repertoires*Pogorelyy, M.¹, Elhanati, Y.², Marcou, Q.², Sycheva, A.¹, Komech, E.¹, Britanova, O.^{3,4,5}, Chudakov, D.^{3,4,5}, Mamedov, I.¹, Lebedev, Y.¹, Mora, T.⁶, Walczak, A.²*¹*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Laboratory of Comparative and Functional Genomics, Moscow, Russian Federation, ²Ecole Normale Supérieure, Laboratoire de Physique Théorique, Paris, France, ³Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Laboratory of Genomics of Adaptive Immunity, Moscow, Russian Federation, ⁴Pirogov Russian National Research Medical University, Moscow, Russian Federation, ⁵Masaryk University, Central European Institute of Technology, Brno, Czech Republic, ⁶Ecole Normale Supérieure, Laboratoire de Physique Statistique, Paris, France*

To ensure protection against the large diversity of pathogens, the adaptive immune system maintains a large set of diverse T-cell receptors. This diversity is generated through the stochastic process of V(D)J-recombination, which makes the independent production of the same sequence twice relatively rare. Yet, unrelated individuals do share a substantial fraction of their receptors. These common receptors, which make up the “public” repertoire, and usually correspond to large clonotypes. Although convergent recombination has been proposed to explain these public clones, the origin of their large sizes is debated. The formation of the TCR repertoire starts in prenatal development, during which the enzyme inserting random nucleotides is initially absent, producing a subset of T-cells with limited diversity. Here, by analysing deep sequencing T-cell repertoire data from monozygotic twins, who share blood cells during pregnancy, and comparing to unrelated individuals and to data-driven models of stochastic recombination, we show that T-cell clones generated before birth can survive and maintain high abundances in adult organism for decades. By profiling the T-cell repertoire in the umbilical cord and in peripheral blood of individuals of various ages, combining deep sequencing with advanced statistical methods, we show the number of clones with no inserted nucleotides is high at birth, and decays slowly with age. Taken together, our results suggest that large,

low diversity public clones are created during pregnancy, and survive over long periods, providing the basis of a robust public repertoire.

Regulatory T cells suppress effector T cell proliferation by limiting division destiny

Dowling, M.R., Hawkins, E.D., Marchingo, J.M., Heinzl, S., Hodgkin, P.D. The Walter and Eliza Hall Institute of Medical Research, Immunology, Parkville, Australia

CD4+CD25+FOXP3+ regulatory T cells (Tregs) play a critical role in immune homeostasis, however the precise mechanisms by which they exert their regulatory function remains contentious. Many different mechanisms of Treg suppression have been demonstrated including stimulatory cytokine deprivation, inhibitory cytokine production, direct cell-contact dependent mechanisms, and limiting access to antigen-presenting cells. The relative importance of different mechanisms remains unclear. Recent work has established the Cyton model as a quantitative framework for understanding the kinetics of effector T cell proliferation, revealing a role for independent regulation of division times, death times, and cessation of division ('division destiny'). Furthermore, using this quantitative approach, independent signals through the T cell receptor, costimulatory signals and cytokines have been shown to sum independently to determine the size of the T cell response (Marchingo et al Science 2014).

We used this mathematical modeling approach to study the effect of Tregs on the kinetics of effector CD4+ T cell (Teff) proliferation. No effect on division times or the rate of death was observed, instead we demonstrate that T regs exhibit their inhibitory function by reducing division destiny. We then compared this quantitative kinetic effect of Tregs to the effect of various interventions aimed at mimicking proposed mechanisms of Treg action. We found that the effect of Tregs on effector T cells was most closely reproduced by blocking interleukin-2, supporting a mechanism where Tregs reduce cytokine availability to Teffs. Thus, mathematical modeling can provide novel mechanistic insights into lymphocyte signal integration in the presence of multiple competing pathways.

Computer model analysis of the difference between F759 and wild type mice in rheumatoid-like arthritis emergence

Yamada, S.¹, Yoshimura, A.², Atsumi, T.³, Murakami, M.³

¹Okayama University of Science, Department of Intelligent Mechanical Engineering, Okayama, Japan, ²Keio University School of Medicine, Tokyo, Japan, ³Hokkaido University, Sapporo, Japan

Rheumatoid arthritis (RA) is a common autoimmune disease characterized by chronic inflammation in joints. In order to analyze the RA emergence, we developed its computer model by using F759 mice. F759 mouse is an IL-6-mediated RA model dependent on excess activation of NFκB in synovial fibroblasts. These mice have an amino acid substitution, Y759F, in gp130.

Because phosphorylated Y759 is the binding site of SOCS3, which creates a negative feedback loop in the IL-6 signaling pathway, IL-6-mediated STAT3 activation is enhanced in F759 mice and is followed by the spontaneous development of a RA-like disease with age.

The model contains the activation of NFκB and JAK/STAT signaling pathway in the synovial cells in joints and the cytokine production by the infiltrated Th-17 and macrophages. The reactions to mimic the RA-like disease in the model are described in the differential equations, and are solved mathematically by using Runge-Kutta-Gill method.

F759 joint synovial cells show an enhanced activation of NFκB in the presence of IL-17 and IL-6 followed by excess expressions of chemokines, IL-6 and epregrin in the joints, which are considered to be essential to emerge the RA-like disease. The effects of several types of antibodies and inhibitors were reproduced by this computer model. The sensitivity analysis showed that the IL-6-STAT3 signaling was more important than the NFκB signaling. We will investigate the RA emergence by comparing simulation results with experimental results. This work is supported by JSPS KAKENHI Grant Number 25330356.

Utilization of SWIFT cluster templates to register (normalize) fluorescence intensity in flow cytometry data at two levels of resolution

Mosmann, T.¹, Rebhahn, J.¹, Quataert, S.¹, Sharma, G.²

¹University of Rochester Medical Center, Center for Vaccine Biology and Immunology, Rochester, United States, ²University of Rochester, Electrical and Computer Engineering, Rochester, United States

Variation in flow cytometry data can result from technical issues (drift in cytometer settings or staining protocols), or from true biological diversity. Technical variation often obscures subtle biological differences in datasets. Manual methods for minimizing variation are subjective and time-consuming. Automated methods for selectively reducing different contributions to variation would improve subsequent manual or automated analysis. Semi-automated approaches (relying on histogram peaks or manual gates) have helped, and we now propose two fully-automated, objective registration (fluorescence normalization) methods based on SWIFT cluster templates (data-derived Gaussian model descriptions of the multidimensional data).

'Per-channel' registration compares cluster locations between the target and the sample to be registered, reconciling 'global' differences between samples while maintaining local fluorescence differences. This objectively uses information from all clusters and can correct global artifacts introduced by variations in staining or cytometer settings that cause 'batch' differences between assay days.

'Per-cluster' registration iteratively aligns all clusters independently with the corresponding target template clusters, moving cells in overlap regions according to their relative probability of belonging to each cluster. This registers cells more completely, and can remove individual e.g. genetic variation in cluster positions. Per-cluster registration improves the accuracy

of measuring the NUMBER OF CELLS/CLUSTER across many samples, but may remove real biological FLUORESCENCE INTENSITY differences between samples. Thus the optimal registration method depends on the experimental design. Our two methods can be blended with a specified weight, to remove only batch variations, or additionally remove individual intensity differences if cells/cluster are the most important experimental outcome.

⁵Stanford University School of Medicine, Department of Pediatrics (Infectious Diseases), Stanford, United States, ⁶University of Texas Southwestern Medical Center, Department of Clinical Sciences, Dallas, United States, ⁷Emory University, Atlanta, United States

The adaptive immune system's ability to protect the body requires a coordinated response from different components of the immune system. B and T cells with their highly diverse antigen receptor repertoire play a crucial role in the adaptive immune response.

To investigate the immune response, it is essential to first understand how individuals initially differ in their immune system. However, the influence of individual genetic and epigenetic differences on these repertoires is not typically measured. By leveraging the unique characteristics of B, CD4⁺ T, and CD8⁺ T lymphocyte subsets from monozygotic twins, we quantify the impact of heritable factors on both the V(D)J recombination process and on thymic selection. We show that the resulting biases in both V(D)J usage and N/P addition lengths, which are found in naïve and antigen experienced cells, contribute to significant variation in the CDR3 region. Moreover, we show that the relative usage of V and J gene segments is chromosomally biased, with approximately 1.5 times as many rearrangements originating from a single chromosome. These data refine our understanding of the heritable mechanisms affecting the repertoire. We continued the investigation into individual flu vaccine responses as an investigation of how repertoire selection are modified in the context of an ongoing immune response. Combined with a broad immunophenotyping CyToF panel, we can comprehensively show how individuals differ before and after vaccine challenging as well as uncovered remarkable similarities in specific aspects of the immune responses.

The data generated by these studies will be stored in *ImmPort*.

Large-scale network analysis reveals the architecture of antibody repertoires

Miho, E., Greiff, V., Menzel, U., Reddy, S.T.

ETH Zurich, Biosystems Science and Engineering, Basel, Switzerland

Humoral immunity is achieved by a vast ensemble of distinct antibody clones; however, the comprehensive structure of an individual's immune repertoire has remained elusive. Specifically, it is unknown how antibody repertoire structure evolves throughout B-cell development. Network analysis has been used in the last decade to characterize relations in complex systems: we have leveraged the power of network analysis to express the similarity relation between each clone to all other clones in immune repertoire networks. In order to capture expansively the structure of entire antibody repertoire networks, we established a high-performance computing platform. It enables the construction of antibody repertoire networks up to the scale of naïve murine B-cell populations ($\approx 10^6$ estimated clones). We generated and analyzed ≈ 600 million clonal sequences from various stages of the B-cell lineage, pre-B cells, naïve B-cells and memory plasma cells, of unimmunized and immunized cohorts. Our results indicate that throughout B-cell development, the similarity relation among clones is power-law distributed: antibody repertoires are dominated by relatively few clonal hubs which concentrate large numbers of clonal variants. Interestingly, these hubs incorporate clones of higher frequency suggesting their targeted selection. Our large-scale network study provides unprecedented quantitative insight into the processes of antibody clonal selection, expansion and evolution across B-cell ontogeny.

Categorical analysis of the complex associations of T cell antigen specificity and T cell exhaustion in chronic HBV infection

Cheng, Y.¹, Leong, M.-L.¹, Chen, J.¹, De Sessions, P.², Lloyd Hibberd, M.², Poidinger, M.¹, Bertoletti, A.³, Lim, S.G.⁴, Newell, E.¹

¹Singapore Immunology Network (SIgN), A*STAR, Singapore, Singapore, ²Genome Institute of Singapore, A*STAR, Singapore, Singapore, ³Duke-NUS Graduate Medical School, Singapore, Singapore, ⁴National University Health System, Singapore, Singapore, Singapore

Chronic hepatitis B virus (CHB) infection is associated with T cell dysfunction and persistent yet highly variable viral burden. Here, coupling mass cytometry and combinatorial tetramer strategy, we probed 563 different HLA-A*1101-restricted T-cell specificities spanning the entire HBV genome on CD8⁺ T cells from patients across four clinical stages. Antigen-specific T cells were simultaneously profiled using 26 differentiation and coinhibitory markers (PD-1, TIM-3, LAG-3, CTLA-4, TIGIT, 2B4, CD160, BTLA, and HVEM). Using high-dimensional analysis (t-SNE) and a novel analysis platform (One-SENSE) that we recently developed, our data shows that the exhaustion profiles of antigen-specific T cells are highly complex and associated

with T-cell differentiation and function in CHB infection. The remarkable heterogeneity of CD8⁺ T cells suggested the diverse usages of coinhibitory markers in different memory-effector subsets are influenced by the development of CHB. T-cells specific for numerous novel HBV epitopes also displayed variable profiles of coinhibitory markers during the progression of natural persistent infection. HBV_{core178}-specific CD8⁺ T cells correlated with improved clinical outcome by their upregulated frequency and distinct memory phenotype, with high PD-1 and 2B4. HBV_{pol106}-specific T cells had higher 2B4 and TIGIT, but lower BTLA. In addition, the heterogeneous exhaustion profiles of HBV_{pol106}-specific T cells linked to the progression of disease. These results together indicate that a highly complex exhaustion profile of HBV-specific T cells exists during a natural chronic infection and challenges the current model of hierarchical T cell exhaustion. The frequencies and differentiation profiles of HBV-specific CD8⁺ T cells may be useful for predictive value.

Antigen-driven specialization and differentiation of T cells in chronic infections

Utzschneider, D.T.^{1,2}, Alfei, F.², Pinschewer, D.D.³, Zehn, D.²

¹University of California San Diego, Cellular & Molecular Medicine, La Jolla, United States, ²Centre Hospitalier Universitaire Vaudoise (CHUV), University of Lausanne, Lausanne, Switzerland, ³University of Basel, Division of Experimental Virology, Department of Biomedicine, Basel, Switzerland

Chronic infections induce T cells showing impaired cytokine secretion and up-regulated inhibitory receptor expression such as PD-1. What determines the acquisition of this chronic phenotype and how it impacts T cell function remained vaguely understood. Using newly generated recombinant antigen variant-expressing chronic LCMV strains, we uncovered that T cell differentiation and the acquisition of a chronic "exhausted" phenotype depends critically on the frequency of TCR engagement and less significantly on the strength of TCR stimulation. In fact, we noted that low level antigen exposure promotes the formation of T cells with an acute phenotype in chronic infections. Unexpectedly, we found that T cell populations with an acute or chronic phenotype are maintained equally well in chronic infections and undergo comparable primary and secondary expansion. Thus, our observations contrast the view that T cells with a typical chronic infection phenotype are severely functionally impaired and rapidly transition into a terminal stage of differentiation. Instead, our data unravel that T cells primarily undergo a form of phenotypic and functional differentiation in the early phase of a chronic LCMV infection without inheriting a net survival or expansion deficit and we demonstrate that the acquired chronic phenotype transitions into the memory T cell compartment.

Spatiotemporally distinct interactions with DC subsets facilitates CD4 and CD8 T cell activation to localized viral infection

Hor, J.L.^{1,2}, Whitney, P.G.¹, Zaid, A.^{1,2}, Brooks, A.G.¹, Heath, W.R.^{1,2}, Mueller, S.N.^{1,2}

¹University of Melbourne, Department of Microbiology & Immunology, Melbourne, Australia, ²The ARC Centre of Excellence in Advanced Molecular Imaging, University of Melbourne, Melbourne, Australia

The dynamics of when and where CD4 T cells provide help for CD8 T cell priming, and which dendritic cells (DCs) activate CD4 T cells *in vivo* following localized infection are poorly understood. Using a cutaneous herpes simplex virus infection model combined with intravital 2-photon imaging of the draining lymph node (LN) to concurrently visualize pathogen-specific CD4 and CD8 T cells, we found that early priming of CD4 T cells involved clustering with migratory skin DC. CD8 T cells did not interact with migratory DC and their activation was delayed compared to CD4 T cells, instead requiring later interactions with LN-resident XCR1⁺ DC. CD4 T cells interacted with these late CD8 T cell clusters on resident DC. Together, these data reveal asynchronous T cell activation by distinct DC subsets and highlight the key role of XCR1⁺ DC as the central platform for CTL activation and the delivery of CD4 T cell help.

IL-15 and TGF- β promote the selective retention of virus-specific resident memory T cells in human lymphoid organs

Woon, H.¹, Braun, A.², Li, J.², Smith, C.³, Edwards, J.¹, Sierro, F.¹, Feng, C.¹, Khanna, R.³, Elliot, M.⁴, Tangye, S.⁵, Rickinson, A.⁶, Gebhardt, T.², Britton, W.¹, Palendira, M.⁷

¹Centenary Institute, Camperdown, Australia, ²Peter Doherty Institute for Infection and Immunity at The University of Melbourne, Melbourne, Australia, ³QIMR Berghofer Medical Research Institute, Brisbane, Australia, ⁴Royal Prince Alfred Hospital, Camperdown, Australia, ⁵Garvan Institute of Medical Research, Darlinghurst, Australia, ⁶University of Birmingham, Edgbaston, United Kingdom, ⁷Centenary Institute, Newtown, Australia

Tissue-resident memory T (Trm) cells are required for protection at sites of reinfection in mice. The characteristics of these cells and the mechanisms that control their retention in human tissues are poorly understood. Here we describe two distinct subsets of memory CD8⁺ T cells, identifiable as CD69⁺CD103⁺ and CD69⁺CD103⁻, that are retained within human lymphoid tissues in the absence of recent T cell stimulation. These two subsets are not only distinct in their phenotype and transcriptional profile, but also anatomically separated within the tissue environments, with the majority of CD69⁺CD103⁺ cell population positioned along the epithelial barrier. Our study also reveals for the first time that IL-15 and TGF- β co-operate to extinguish expression of sphingosine-1-phosphate receptor, required for T cell exit from tissues, and its transcriptional activator, Kruppel-like factor 2 (KLF2). Therefore these locally produced cytokines can potentiate the strategic positioning of Trm cells at barrier surfaces. Interestingly, Epstein-Barr virus-

specific (but not cytomegalovirus-specific) CD8⁺ memory T cells preferentially accumulate in the tonsils and acquire a CD69⁺CD103⁺ phenotype, ensuring their retention at the epithelial sites where Epstein-Barr virus is likely to replicate. This strategic positioning of pathogen-specific Trm cells could be critical to prevent reactivation of persisting viral infections in humans.

Migration and transcriptional regulation of T_{FH} cell differentiation

Watson, L.-R.¹, Binek, A.¹, Wang, Z.², Mackay, C.³, Moon, J.⁴, Kedzierska, K.², Good-Jacobson, K.⁵, Belz, G.⁶, Groom, J.¹

¹The Walter and Eliza Hall Institute of Medical Research, Department of Immunology and Molecular Immunology, Parkville, Australia, ²University of Melbourne, Department of Microbiology & Immunology, Melbourne, Australia, ³Pfizer Inc, Inflammation & Immunology, Cambridge, United States, ⁴Massachusetts General Hospital and Harvard Medical School, Center for Immunology and Inflammatory Diseases, Charlestown, United States, ⁵Monash University, Department of Microbiology, Clayton, Australia, ⁶The Walter and Eliza Hall Institute of Medical Research, Department of Molecular Immunology, Parkville, Australia

The differentiation of CD4⁺ T cells into specialised helper subsets, such as T_{H1}, T_{H2}, T_{H17}, T_{FH} and T_{REG}, is essential to orchestrate flexible immune responses. Functional differentiation of CD4⁺ T cells into

T helper subsets is regulated by environmental factors, and instructed by master transcription factors. Recent studies have highlighted the plasticity that occurs between these effector subsets to fine-tune responses. In addition, within these lineages, some further specialisation can occur, such as the context-specific tailoring of T_{REG} cell function. Similarly, we hypothesize that T_{FH} differentiation varies depending on the infectious onslaught, in order to optimize B cell antibody production and isotype switching, and establish protection from vaccine and infection. We have developed a novel influenza model to track antigen-specific CD4⁺ T cell responses by imaging and detection of I-A^b natural repertoire cells. Our data reveal a CXCR3-dependent differentiation pathway for T_{FH} cells following influenza infection. This pathway can be overcome when CD4⁺ T cells are deficient in the transcription factor T-bet. Thus, we have uncovered unique migration and transcriptional requirements for the differentiation of T_{FH} cells, which impact the humoral responses to varying pathogens.

The role of monocyte apoptotic cell disassembly in influenza A virus infection

Atkin-Smith, G., Duan, E., Zanker, D., Chen, W., Poon, I.
La Trobe University, Bundoora, Australia

Everyday billions of cells die through apoptosis and thus it is essential that cell debris is rapidly cleared to avoid pathological events such as cardiovascular and autoimmune disease. The fragmentation of an apoptotic cell into apoptotic

bodies, via a process termed apoptotic cell disassembly, is proposed to facilitate cell clearance and communication through the trafficking of biomolecules (e.g. DNA and RNA). Recently we have characterised a novel membrane protrusion, coined beaded-apoptopodia, which facilitates apoptotic body generation through fragmentation. Importantly, we have characterised pharmaceutical compounds which can manipulate this process. As apoptotic bodies can transport biomolecules we asked whether apoptotic cell disassembly is involved in the pathogenesis of Influenza A virus (IAV). Firstly we demonstrated that IAV can induce THP-1 monocyte apoptosis and promote the generation of beaded-apoptopodia and apoptotic bodies *in vitro*. Additionally IAV induces monocyte apoptosis and apoptotic body generation *in vivo*. Secondly, IAV proteins including hemagglutinin and nucleoprotein were found in beaded-apoptopodia and apoptotic bodies derived from infected THP-1 monocytes. Apoptotic bodies purified from IAV-infected cells induced apoptosis when incubated with uninfected host cells, whereas control apoptotic bodies (UV treatment) did not. This indicates that after initial viral infection, apoptotic bodies may propagate infection. Lastly when blocking apoptotic cell disassembly by pharmaceutical manipulation, viral propagation to uninfected host cells was inhibited. Overall data suggests that monocyte apoptotic cell disassembly may play an important role in the pathogenesis of IAV and unveils novel therapeutic strategies to target viral spread.

Rhinovirus (RV) infections are major triggers of acute exacerbations of asthma and chronic obstructive pulmonary disease (COPD) in both children and adults. The association of rhinovirus infections with exacerbations of respiratory disease is mainly based on the demonstration of the presence of virus at the onset of exacerbation. However, there are currently no serological tests available which would allow detecting specificities of antibody responses against RV epitopes as a result of infection. We, therefore, developed a high resolution antibody assay based on recombinant proteins, fragments and

synthetic peptides derived from VP1 N-terminal fragment of the most diverse RV strains. Using this microarray, we measured RV-specific IgG antibodies in serum samples from 120 preschool children collected during an acute episode of wheeze and at follow-up visit after approximately 12 weeks. We demonstrated that extremely small sample volumes were sufficient to detect RV-specific IgG antibodies to a broad panel of micro-arrayed RV antigens and that it was possible to discriminate between group- and partially strain-specific antibody responses. Furthermore, we found that the number of reactive VP1 N-terminal peptides was age-dependent. The number of peptides recognized by RV-specific IgG antibodies at the acute and the follow-up visit in the youngest group of children, 6-8 months, was significantly lower than in children above 1 year. Our results thus suggest that the microarray will be useful to identify the most relevant and clinically important RV strains involved in exacerbations of respiratory diseases and will provide a rational basis for the design of a RV vaccine.

3468

Bone marrow monocyte priming and pathological CNS infiltration are independently mediated by local IFN- γ production in WNV encephalitis

Niewold, P., Ashhurst, T., van Vreden, C., King, N.
University of Sydney, Sydney, Australia

During murine West Nile virus (WNV) encephalitis, bone marrow (BM)-derived Ly6C^{hi} inflammatory monocyte infiltration of the central nervous system (CNS) causes lethal immunopathology. Recently, NK cell-derived IFN- γ has been shown to prime Ly6C^{hi} monocytes in the BM prior to their emigration during anti-parasitic responses in C57BL/6 mice. To determine if this pathway plays a role in viral infection, we compared the pathogenesis of WNV encephalitis in C57BL/6 and SJL/J mice, since the latter have reduced NK cell numbers and IFN- γ responses. Using 18-colour flow cytometry, we found that CNS infiltration of Ly6C^{hi} monocytes was 2-fold lower in SJL/J than C57BL/6 mice. Depletion of IFN- γ in WNV-infected C57BL/6 mice reduced both efflux of monocytes from the BM and monocyte influx into the brain, significantly improving clinical disease scores. Furthermore, in NK cell-depleted C57BL/6 mice, Ly6C^{hi} monocyte accumulation in the BM was similar to IFN- γ -neutralised mice. However, migration of monocytes into the brain in these mice was not reduced, suggesting that a CNS source of IFN- γ influences brain infiltration. Indeed, T cells were the main IFN- γ -producing subsets in the encephalitic brain; although numbers of CNS-infiltrating T cells and NK cells were not statistically different, there were 13-fold more IFN- γ ⁺ CD4⁺ and CD8⁺ T cells than IFN- γ ⁺ NK cells. Therefore, we propose a 2-step model where monocytes undergo NK-cell-driven IFN- γ -mediated priming prior to BM egress, followed by local T cell-driven IFN- γ -dependent entry into the brain. IFN- γ , critical in viral eradication, thus exacerbates WNV disease by driving CNS infiltration of pathological inflammatory monocytes.

HLA-B polymorphisms and their influences on immunity

Raghavan, M., Geng, J., Yarzabek, B., Silva, G.
University of Michigan Medical School, Ann Arbor, United States

Major histocompatibility complex (MHC) class I polymorphisms are shown to influence outcomes in a number of infectious diseases, cancers and inflammatory diseases. In human immunodeficiency virus (HIV) infections, among all genetic factors known to influence progression to acquired immunodeficiency syndrome (AIDS), the strongest associations link to human MHC class I genes (human leukocyte antigens (HLA)). There are three sets of genes that encode human MHC class I proteins. These are the HLA-A, HLA-B and HLA-C genes, with each locus being highly polymorphic, and the HLA-B locus being the most variable. Each HLA class I protein binds to distinct sets of peptide antigens, which are presented to CD8 T cells. While it is generally assumed that HLA-disease associations link to the peptide binding characteristics of individual HLA class I molecules, it remains largely unknown whether and how differences in assembly characteristics of HLA class I molecules could influence immunological outcomes. Polymorphisms at the HLA-B locus profoundly influence the intracellular assembly characteristics of HLA-B molecules. Based on these findings, we used quantitative flow cytometry to compare HLA-B cell surface expression levels in primary human lymphocytes in a large cohort of healthy donors. Our findings indicate allele and donor dependent variations in HLA-B cell surface expression, the molecular mechanisms of which are being defined. Such differences are expected to contribute to the known influences of HLA-B allelic variations upon disease outcomes.

A mucosal-derived systemic IgM B-cell memory response in non-immunized mice

Le Gallou, S., Fritzen, R., Thai, L.-H., Weller, S., Weill, J.-C., Reynaud, C.-A.
Université Paris Descartes Faculté de Médecine, Institut Necker-Enfants Malades - INSERM U 1151/CNRS UMR 8253, Paris Cedex, France

The AID-Cre-EYFP mouse (Dogan et al., 2009) allows the irreversible labelling of B cells engaged in an immune response upon tamoxifen ingestion. We observed a systemic response in absence of immunization, with EYFP⁺ B cells detectable at different frequencies in Peyer's patches, spleen and bone marrow up to 6 months after a 2-weeks tamoxifen-labelling episode. Plasma cells and memory B cells were present, with 80 % of the EYFP⁺ plasma cells being IgA⁺ and 70-80% of EYFP⁺ memory B cells being IgM⁺. Both subsets had mutated Ig genes, with mutation frequencies 2-3 times higher in IgA⁺ than in IgM⁺ B cells. Adoptive transfers showed that EYFP⁺ B cells have a B2, not a B1, origin. A large reduction in the memory and plasma cell IgA compartment was observed in germ-free animals, while the IgM response was still present, but was almost unmutated. Hybridomas were generated for the spleen IgM memory subset,

and harbored specificities against the commensal flora, as well as against human bacterial isolates. Ig sequencing revealed clonal relationships between Peyer's patch EYFP⁺ memory B cells and spleen IgM and IgA subsets, as well as with bone marrow plasma cells. BrdU labeling pulse-chase experiments and kinetics of germinal center EYFP⁺ B cell maintenance in Peyer's patches suggested that the systemic compartment is constantly renewed from a stable pool of mucosal B cell clones. This population represents a new layer of pre-activated B cells, generated in the gut, persisting through continuous replenishment, and ensuring a systemic survey for bacterial antigens.

IL21 signaling in the B-cell response to antigen

Tarlinton, D.¹, Zotos, D.², Fung, I.², O'Donnell, K.², Light, A.²

¹Monash University, Immunology and Pathology, Prahran, Australia, ²Walter & Eliza Hall Institute of Medical Research, Parkville, Australia

The B-cell response to protein antigens initially generate short-lived, extra-follicular plasma cells; long-lived early memory B-cells that are not affinity matured; and germinal centers (GC). GC produce high affinity memory B-cells and long-lived, bone marrow resident plasma cells. We and others have previously reported that the Tfh-derived cytokine IL21 in the GC sustains B-cell proliferation, allowing affinity maturation to proceed, and promotes high affinity plasma cells in the bone marrow. These activities of IL21 on GC B-cells were direct rather than altering the development or behaviour of Tfh. We found also that IL21 receptor (IL21R) deficiency reduced the frequency of extrafollicular plasma cells and enhanced the appearance of early, pre-GC memory B cells. Collectively these results identified multiple roles for IL21 signaling in the B-cell response, acting either at multiple stages via multiple mechanisms or alternatively affecting a single, pre-GC stage, the consequences of which unfolded in the subsequent different pathways.

To define further the functions of IL21 in the B-cell response, we tracked antigen specific B cells during the very early stages of the response and have determined cell location and in vivo B-cell proliferation. We find that absence of IL21R affects B cell migration into GC through what appears to be a chemokine mediated mechanism. In addition IL21R deficiency leads to significantly reduced proliferation at a discrete stage of GC development. These results refine our understanding of IL21 action on antigen activated B-cells, identifying multiple points of action with their corresponding implications for B-T cell interactions.

618

Dynamic changes in E-protein activity orchestrate germinal center and plasma cell development

Gloury, R., Zotos, D., Nutt, S., Tarlinton, D., Kallies, A.

The Walter and Eliza Hall Institute of Medical Research, Molecular Immunology, Melbourne, Australia

The interplay between transcription factors of the E protein family and their antagonists, the Id proteins, is important for

the regulation of lymphocyte development and differentiation. In the B cell lineage, E2A in particular is essential for early B cell commitment. However, despite being expressed at high levels throughout B cell development, E2A is dispensable for the generation of mature B cells and plasma cells in peripheral lymphoid organs.

Using a number of genetic approaches we have now further examined the role of E and Id proteins in B cells. We have found that Id3 was expressed at high levels in resting B cells and was downregulated in a division dependent manner after B cell activation. This suggested that tight Id3-mediated regulation of E protein activity might be important for B cell activation. Indeed, our studies have shown that the down-regulation of Id3 in B cells is essential for releasing E2A and E2-2, which in a redundant manner are required for antigen-induced B cell differentiation, being essential to both germinal centre formation and plasma cell differentiation. Thus, mice deficient in both E2-2 and E2A lacked any humoral immune response. Applying RNA-seq and ChIP-seq technologies we have identified critical target genes of E protein activity in B cells and uncovered a new layer of the gene regulatory network, which controls B cell responses.

A novel motif in activation induced deaminase (AID) is necessary for targeting its mutagenic activity in B cells but is dispensable for E coli mutagenesis

Methot, S.P.^{1,2}, Litzler, L.C.^{1,3}, Eranki, A.K.¹, Fifield, H.⁴, Patenaude, A.-M.¹, Cote, J.-F.¹, Verdun, R.E.⁵, Larijani, M.⁴, Di Noia, J.M.^{1,2,3}

¹Institut de Recherches Cliniques de Montreal, Mechanisms of Genetic Diversity, Montreal, Canada, ²McGill University, Experimental Medicine, Montreal, Canada, ³University of Montreal, Biochemistry, Montreal, Canada, ⁴Memorial University of Newfoundland, Medicine, St. Johns, Canada, ⁵University of Miami Miller School of Medicine, Gerontology and Geriatric Medicine, Miami, United States

Activation-Induced deaminase (AID) introduces mutations and initiates DNA breaks at the Immunoglobulin genes (*Ig*), thereby initiating antibody somatic hypermutation (SHM) and class switch recombination (CSR) in activated B cells. As a side effect, AID can also damage hundreds of other genomic locations. Most AID is cytoplasmic and must be imported into the nucleus, where it associates with thousands of genomic locations. Many questions remain about the genomic targeting of AID, including whether there are mechanisms regulating its ability to deaminate or not after occupying a given locus.

Our work has identified a structurally defined arginine-rich motif in AID that is necessary for its mutagenic activity in B cells. Substituting any of these residues prevents SHM and CSR in B cells. Strikingly, these mutations do not affect the ability of AID to bind to or deaminate DNA *in vitro*, or to mutate the *E coli* genome. They do not affect AID subcellular trafficking, RNA association, SPT5 binding or nuclear chromatin association; yet, all these mutations abrogate the interaction of AID with the *Igh* locus. Furthermore, these mutants seem to lose the ability to damage the eukaryotic genome altogether, as judged by their lack of cellular toxicity when forced to accumulate inside the nucleus.

Our results identify a novel functional domain in AID that either mediates its specific recruitment to mutation-susceptible loci in B cells, or mediates a "licensing" step of AID mutagenic activity at the chromatin. This finding also has implications for the mutagenic activity of the APOBEC enzymes in vertebrates.

Investigating the role of the Bcl2 family member A1/Bfl1 in lymphocyte homeostasis and function

Tuzlak, S.¹, Sochalska, M.¹, Haschka, M.¹, Strasser, A.², Herold, M.², Villunger, A.¹

¹Medical University Innsbruck, Div. of Developmental Immunology, Innsbruck, Austria, ²WEHI, Molecular Genetics of Cancer Division, Melbourne, Australia

The Bcl2 family controls lymphocyte development and homeostasis by regulating mitochondrial apoptosis in response to a large set of cues, including self- or foreign peptides/antigens, cytokine-deprivation or metabolic stress. Anti-apoptotic Bcl2 proteins such as Bcl2 itself, Bclx or Mcl1 have established roles in lymphocyte development and survival but the importance of A1/Bfl1 in these processes remains ill-defined.

We have used conditional RNAi in vivo to explore the role of A1/Bfl1 in immune cell homeostasis. These studies suggest rate-limiting roles in mast cells as well as B cell homeostasis and activation. We observed that A1/Bfl1 expression is placed under control of the B cell receptor (BCR) and the SYK/BTK kinase module. Tonic, as well as activation-induced BCR-signalling thereby seems to control A1 levels to antagonize Bim-dependent apoptosis.

Future analysis will aim at exploring B cell dependent immunity in RNAi vs. conditional knock-out mice lacking A1 selectively in lymphocytes.

Serine/threonine phosphatase PP4 is required for class switch recombination through recruitment of gammaH2AX

Chen, M.-Y.¹, Chen, Y.-P.¹, Tan, T.-H.^{1,2}, Su, Y.-W.¹

¹National Health Research Institutes, Immunology Research Center, Miaoli County, Taiwan, Republic of China, ²Baylor College of Medicine, Department of Pathology & Immunology, Houston, United States

PP4 is a serine/threonine phosphatase, which regulates a number of crucial cellular physiology. We have previously reported that genetic ablation of PP4 in mature B cells by CD23 promoter-mediated cre-loxp system impairs immunoglobulin (Ig) class switch recombination (CSR). However, the mechanism behind PP4 for CSR is unknown. In those mutant mice, the basal levels of serum Igs of all isotypes including IgM were strongly reduced. To address whether the impaired CSR in PP4-deficient B cells was derived from the reduced IgM production, we generated PP4 conditional knockout mice by deaminase activation-induced deaminase (AID) promoter-mediated cre. As expected, the basal level of serum IgM in AID/cre/PP4^{F/F} mice was comparable to control mice. Despite of that, the basal levels of all switched Ig isotypes were drastically reduced in AID/cre/

PP4^{F/F} mice. After challenged with T cell-independent antigen TNP-Ficoll, AID/cre/PP4^{F/F} mice failed to mount antigen-specific IgG3 and IgG1. The results revealed that with normal mature B cells and serum IgM, CSR remained defect in AID/cre/PP4^{F/F} mice. Upon stimulation by LPS plus IL-4, PP4-deficient B cells exhibited increased ATM phosphorylation on S1987, suggesting severe DNA damage during CSR. Consistently with this, PP4-deficient B cells had increased p53-foci and phospho-p53-foci on S15 upon stimulation by DNA damaging drug etoposide *in vitro*. Although ATM-p53 axis was activated in PP4-deficient B cells, upon stimulation by etoposide the mutant B cells showed reduced gammaH2AX-foci in intensity and duration. We thus propose that PP4 is required for CSR through efficient recruitment of gammaH2AX, which is essential for S-region repair.

Selective regulation of noncoding RNA by mediating AID-interacting molecule GANP

Maeda, K.¹, Singh, S.K.², Shimoda, M.^{1,3}, Akira, S.¹, Sakaguchi, N.⁴

¹IFReC, RIMD, Osaka University, Laboratory of Host Defense, Suita, Japan, ²IFReC, Osaka University, Laboratory of Host Defense, Suita, Japan, ³Kumamoto University, Graduate School of Medical Sciences, Immunology, Kumamoto, Japan, ⁴IFReC, Osaka University, Suita, Japan

GANP is a component of RNA export transcription/export-2 (TREX-2) complex in mammalian cells. GANP interacts to activation-induced cytidine deaminase (AID) and plays important role for affinity maturation of antibodies in B-cells. We explore how GANP controls the interaction of translation machinery with RNA transcripts in B-cells. We found that GANP physically interacts with eIF4E under the phosphorylation-dependent manner in the cytoplasm of B-cells. Phosphorylation of eIF4E increases its affinity for capped mRNA and favors its entry into translation initiation complexes. GANP also interacts with cap structure at the 5'-end of mRNAs and recruits cap-dependent translation initiation complex. Remarkably, GANP-depletion reduced the non-coding RNAs of particular clusters that are known to be essential for B-cell differentiation and activation. GANP is presumably interacted with the metabolism of particular RNA species transcribed from the B-cell genome throughout initial transcription, ribonucleoprotein assembly, RNA export and the later regulation processes. GANP might play a critical role in regulation of selective RNA for maturation of GC B-cells.

Unraveling the function of human IgD in individuals with heterozygous mutations in IGHD

Nechvatalova, J.^{1,2}, Bartol, S.J.W.³, Chovancova, Z.^{1,2}, Vlkova, M.^{1,2}, van Zelm, M.C.^{3,4}

¹St Anne's Faculty Hospital, Clinical Immunology and Allergology, Brno, Czech Republic, ²Masaryk University, Faculty of Medicine, Brno, Czech Republic, ³Erasmus MC, Dept. Immunology, Rotterdam, Netherlands, ⁴Monash University, Dept. Immunology and Pathology, Melbourne, Australia

Surface immunoglobulin D (IgD) is co-expressed with IgM on naive B cells. Still, the role of surface IgD remains enigmatic >50

years after its discovery. We here identified four members of one family who carried heterozygous nonsense mutations in exon 1 of *IGHD*. We judged this a unique setting to study the role of surface IgD in B-cell homeostasis and antibody responses. Blood B-cells were analyzed with multi-color flow cytometry. IgD⁺ and IgD⁻ naive mature B cells were FACS-purified for replication history analysis using KRECs. IgG and IgA transcripts were sequenced to study somatic hypermutations (SHM). IgD allele usage was determined with a restriction enzyme assay. All *IGHD* heterozygous individuals had normal numbers of B cells and serum immunoglobulins, and did not show signs of an immunodeficiency. IgD⁺ and IgD⁻ naive mature B cells were present in equal numbers and showed similar immunophenotypes. Only CD79b expression was lower in the IgD⁻ subset, reflecting the absence of IgD. The replication history of IgD⁻ naive mature B cells was normal. IgA and IgG-switched alleles were equally derived from the wildtype and mutant alleles, and carried similar mutation frequencies between transcripts derived from IgD-wildtype and IgD-mutant alleles. Human IgD⁻ B cells are not out-competed by IgD⁺ B cells *in vivo*, and surface IgD is not required for naive B-cell homeostasis and antibody maturation. Thus, the evolutionary conservation of IgD might be more related to the function of secreted rather than surface IgD.

The role of gene conversion in the diversification of murine IgM plasma cells

Dale, G.¹, Bohannon, C.², Antia, R.², Jacob, J.¹

¹Emory School of Medicine, Emory University, Atlanta, United States, ²Emory University, Atlanta, United States

Humoral immunity is marked by long-lived antibody responses against pathogens. The duration of this response is dependent on long-lived plasma cells that are primarily located in the bone marrow and are of IgG isotype. However, we have identified a population of antigen specific, long-lived IgM plasma cells that reside in the red pulp of the spleen and display an atypical mutation profile. Following immunization of mice with 4-Hydroxy-3-nitrophenyl (NP) conjugated to chicken gamma globulin (CGG) (NPCGG) in alum, we isolated plasma cells (CD138⁺ B220⁻) and sequenced them via 454 pyrosequencing for μ heavy chain. Out of a total of 292 IgHV186.2 (which encode NP-specific antibodies) IgM sequences, we observe at least 58 that exhibited shared tracts of mutations (≥ 3 mutations per tract). We find that these mutations are AID dependent and primarily occur in the framework regions of the V_H gene - unlike IgG plasma cells, where mutations are predominantly located within the complementarity determining regions (CDRs). Upon further analysis, we find strong evidence that these mutations appear to be shared between multiple unique IgM plasma cell clones isolated from different individual animals. Additionally, these tracts match other highly homologous V_H genes in both position and identity. Taken together, we posit that these mutations in IgM plasma cells are not generated through murine somatic hypermutation pathways as described extensively in the literature but are, in fact, generated through templated mutagenesis using highly homologous V_H genes through gene conversion.

Analysis of the IgE repertoire in healthy, non-allergic individuals by massive parallel sequencing

Koning, M., Trollmann, I., Griffioen, M., Veelken, H.

Leiden University Medical Center, Department of Hematology, Leiden, Netherlands

The largest reported IgE repertoire comprises merely thirty immunoglobulin sequences. We investigated the healthy IgE repertoire in comparison to IgM and IgG.

Peripheral blood CD19⁺ cells from six healthy donors were divided into aliquots of 2×10^6 cells. For each donor, mRNA was amplified by ARTISAN PCR (bias-free isotype-specific 5'RACE protocol) from 5 aliquots per IgE, IgG, and IgM isotype in parallel. PacBio sequencing of the resulting 15 amplicon libraries per donor yielded a median of 284 (range: 100-743) full-length sequences/aliquot and 27500 sequences in total.

A median of 261 (range: 175-358) unique IgE sequences were obtained per donor. 9.1-61.8% of individual IgE sequences were represented in >2 aliquots of the same donor. Only 1.4-7.8% IgM and 5.7-16.3% IgG sequences, respectively, were identified in multiple aliquots. Whereas 29VDJ sequences were found as both IgM and IgG isotype, all IgE sequences were restricted to their isotype. The median number of somatic mutations per sequence differed significantly between IgE (median 5.6%), IgM (0.3%), and IgG (8.3%). Intraclonal sequence diversity in IgE clones was predominantly due to silent FR mutations. IGHV3-11, IGHV3-9, and the IGHV3 family were significantly overrepresented in IgE compared to IgM/IgG. IGHV3-30, IGHV3-33, IGHV4-59, and IGHV2, 4, 5, and 6 families were underrepresented.

The peripheral IgE repertoire is less diverse than IgM/IgG and displays a strong IGHV bias and an intermediate mutation load without ongoing affinity maturation. IgE and IgG/IgM repertoires apparently do not overlap. These data provide a reference to investigate the IgE repertoire in allergy, parasitology, or desensitization.

NK cell receptor inhibition determines NK cell cytolytic potential through accumulated granular load

Goodridge, J.¹, Clancy, T.¹, Jacobs, B.¹, Pfeifferle, A.², Brech, A.³, Skarpen, E.³, Stenmark, H.³, Malmberg, K.J.¹

¹Institute for Cancer Research, Norwegian Radium Hospital, Department of Immunology, Oslo, Norway, ²Karolinska Institute, CIM, Stockholm, Sweden, ³Institute for Cancer Research, Molecular Cell Biology, Oslo, Norway

Discrimination of self from non-self through the continuous selection of effector specificity is the backbone of multicellular immunity. For natural killer (NK) cells this specificity is achieved by unique combinations of variable germ-line receptors that recognize self-MHC antigens. The expression of NK cell receptors and their inhibitory interaction with self-ligands is a key determinant for the development of pre-primed effector responses, a process termed NK cell education. This calibration of effector potential to self-MHC allows for rapid sensing of

discontinuity in the level of MHC expression during infection, cellular stress or tumor transformation, whilst operating within a framework of overall tolerance to normal tissues. While NK cell education is firmly established across species, the underlying mechanism connecting inhibitory signaling to the development of intrinsic functional potential has yet to be resolved. We describe here the first stable imprint of NK cell education, the granular accumulation of granzyme B that occurs in primary NK cells under specific inhibitory self-interaction. This accumulation underlies the development of natural killer cell effector potential, traced first in the regulatory shift from inducible to constitutive effector transcription that occurs during NK cell differentiation, then shaped by surface signaling through killer cell immunoglobulin-like receptors as maturing NK cells interact continuously with the MHC environment. The development of a granular effector phenotype that is influenced directly by inhibitory interactions provides insight into the possible role cytolytic granules play in potentiating effector signals, as a function of granular intensity and as a means to cultivate NK cell specificity.

Targeting regulators of natural killer cell homeostasis in cancer immunotherapy

Delconte, R.B.¹, Kolesnik, T.B.¹, Rautela, J.¹, Smyth, M.J.², Nicholson, S.E.¹, Huntington, N.D.¹

¹The Walter and Eliza Hall Institute of Medical, Parkville, Australia,

²Queensland Institute of Medical Research, Brisbane, Australia

Natural Killer (NK) cells are cytotoxic cells found throughout the body and are integral in the identification and destruction of malignant cells. This activity is governed by the cytokine interleukin (IL)-15 and the presence of foreign and self-ligands. We have identified CIS (Cytokine-inducible SH2-containing protein; *Cish* gene) as the critical negative regulator of IL-15 signalling in NK cells. *Cish* was rapidly induced in response to IL-15 and deletion of *Cish* rendered NK cells hypersensitive to IL-15, as evidenced by superior proliferation, survival, IFN- γ production and cytotoxicity towards tumours. This was associated with enhanced JAK/STAT signalling in *Cish*-deleted NK cells. *Cish*^{-/-} mice were resistant to melanoma, prostate and breast cancer metastasis *in vivo*, and this was intrinsic to NK cell activity. This study has uncovered a potent checkpoint in NK cell-mediated tumour immunity and holds promise for novel immunotherapies directed at blocking CIS function.

3563

Novel function of NK cell to regulate cancer-associated inflammation

Hayakawa, Y.

Institute of Natural Medicine, University of Toyama, Division of Pathogenic Biochemistry, Toyama, Japan

Although many studies show the importance of NK cells as a direct anti-tumor effector cell to control tumor growth, the immuno-regulatory function of NK cells to control cancer-associated inflammation, which facilitate tumor progression,

remains unknown. By using *in vivo* bioluminescent imaging, we monitored the exact behavior of cancer cells controlled by NK cells. Consistent with previous observations, depletion of NK cells resulted in facilitating *in vivo* cancer cell proliferation and IFN- γ was a dominant effector molecule to control *in vivo* cancer cell proliferation. Importantly, depletion of NK cells did not affect cancer cell proliferation in mice lacking IL-17, which has been known as an important cytokine for triggering neutrophilic inflammation. Furthermore, depletion of neutrophils diminished such facilitation of *in vivo* cancer cell proliferation in NK cell-depleted mice. These findings imply a novel function of NK cell as a regulatory cell to suppress tumor-promoting neutrophilic inflammation. We would like to further discuss our current effort on investigating the mechanism by which NK cell regulates tumor-promoting neutrophilic inflammation.

Extent of inflammatory stimuli influences the response of functionally distinct natural killer cell subsets

Aguilar, E.G.¹, Zamora, A.E.¹, Sungur, C.M.¹, Murphy, W.J.^{1,2}

¹University of California, Davis, Dermatology, Sacramento,

United States, ²University of California, Davis, Internal Medicine, Sacramento, United States

Natural Killer cells are lymphocytes of the innate immune system that play roles in both viral infection and cancer. NK cells can be divided into distinct subsets based on expression of inhibitory receptors capable of binding to MHC class I molecules. Those that are capable of binding to self-MHC are termed licensed NK cells, and are the classic cytotoxic effector cell. Those that cannot bind to self-MHC are termed unlicensed, and are thought to be hyporesponsive in terms of cytotoxicity. The functional consequences of licensing outside of cytotoxicity remain unclear, with some reporting distinct effector roles for each subset during viral infection. Here, we show differences in the NK subset response to MCMV infection, dependent on the dose of virus used to challenge mice. With a lower dose of virus, differences in the localization of NK subsets after infection were noted, as well as differences in the extent of the virus-specific T cell responses and viral titer in mice depleted of specific NK subsets. When a higher dose of virus was used, these differential effects were abrogated and associated with an overall expansion of both licensed and unlicensed virus-specific Ly49H⁺ NK cells. Collectively, these results suggest that the inherent functional differences between the licensed and unlicensed NK cell subsets may be overcome depending on the extent of the inflammatory stimuli.

4610

Human NK cell maturation requires CD56-mediated motility and formation of the developmental synapse

Mace, E.¹, Gunesch, J.¹, Dixon, A.², Orange, J.¹

¹Baylor College of Medicine, Houston, United States, ²Rice

University, Houston, United States

Natural killer cells are critical for the control of viral infection and malignancy and hold tremendous promise in the field of

immunotherapy. Despite their importance, human NK cell development is poorly understood. It is thought that NK cells are derived from CD34⁺ precursors that ultimately generate the two subsets of NK cells found within peripheral blood, CD56^{bright} and CD56^{dim}. Each has unique phenotypic and functional properties, although the role of CD56 on human NK cells has not been described. Both subsets can be recapitulated in vitro from precursors using stromal cells and cytokines. While it is known that stromal cell contact is required, the nature of these interactions is not known.

To dissect the contacts that drive human NK cell maturation, we performed high resolution live cell confocal microscopy of developing NK cells with stromal cells. We found that NK cells undergo substantive motility on stroma, and that this motility is driven by CD56 itself. Further, we identify a novel immunological synapse, which we term the developmental synapse, formed between developing NK cells and stroma. **Formation of the developmental synapse leads to polarization and downstream signaling, and blocking its formation leads to aberrant NK cell development.** Stromal cell contact also regulates expression of L-selectin, which cooperates in NK cell motility. Together, our data shows for the first time a functional role of CD56 in human NK cell homeostasis. It also introduces the developmental synapse, a novel bona fide immunological synapse that drives human NK cell development.

3320

Natural killer (NK) cells and $\gamma\delta$ T cells differentially modulate Th17-driven disease in ankylosing spondylitis

Wythe, S., Griseri, T., Freidin, A., Demetriou, P., Samson, S., Mccann, F., Horwood, N.

University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom

Ankylosing spondylitis (AS) is characterised by chronic joint inflammation, inflammatory bowel disease, and inappropriate new bone formation at the entheses. However, the immunological factors linking gastrointestinal inflammation with joint pathology are not well delineated. Natural Killer (NK) cells are recruited to these inflammation sites. As such we hypothesized that NK cells form a bridge linking gastrointestinal inflammation and joint pathology. To test this hypothesis we used the recently characterised BALB/c ZAP-70W163C-mutant (SKG) mouse model of AS, in which disease is initiated by a single intraperitoneal (i.p.) injection of beta-1,3-glucan (curdlan). Mice were depleted of NK cells (anti-asialo GM1; 2x/wk; i.p) and arthritis, enthesitis and weight scored weekly. Inflammation was observed in both the ileum and the joint following challenge, and NK cell numbers were increased in both locations. NK-depletion exacerbated weight loss and ileitis score, correlating with increased numbers of IL-22-producing $\gamma\delta$ T cells, Th17 cells, and neutrophils. In the joint, arthritis, enthesitis and new bone formation were all ablated and correlated with a significant reduction in gdT cells and neutrophils. In contrast, $\gamma\delta$ T cell depletion (clone GL3; 2x/wk; i.p) increased disease in both ileum and joint. These data identify a protective role for NK cells and $\gamma\delta$ T cells in ileitis and suggest that NK-gdT cell cross-regulation may be an important factor in determining

morbidity. This study highlights novel cellular targets for the treatment of this complex multifactorial human disease.

Human lung NK cells are predominantly constituted by highly differentiated hypofunctional CD69⁺CD56^{dim} cells

Marquardt, N.¹, Kekäläinen, E.¹, Wilson, J.N.¹, Ivarsson, M.A.¹, Mjösberg, J.¹, Säfholm, J.², Manson, M.L.², Adner, M.², Al-Ameri, M.³, Bergman, P.³, Orre, A.-C.³, Dahlén, B.², Dahlén, S.-E.², Ljunggren, H.-G.¹, Michaëlsson, J.¹

¹Karolinska Institutet, Department of Medicine, Stockholm, Sweden, ²Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden, ³Karolinska University Hospital, Department of Molecular Medicine and Surgery, Stockholm, Sweden

Background: In contrast to the extensive knowledge about human NK cells in peripheral blood, relatively little is known about NK cells in human lung. Knowledge about the composition, differentiation, and function of human lung NK cells is critical to better understand their role in diseases affecting the lung, including asthma, COPD and cancer.

Objective: We sought to analyze and compare the phenotypic and functional characteristics of human NK cells in lung and peripheral blood at the single cell level.

Methods: NK cells in human lung tissue and matched peripheral blood from a total of 132 subjects were analyzed by 16-color flow cytometry.

Results: CD56^{dim}CD16⁺ NK cells made up the vast majority of NK cells in human lung, had a more differentiated phenotype, and more frequently expressed educating KIR compared to NK cells in peripheral blood. Despite this human lung NK cells were hyporesponsive, even after priming with IFN- α . Most NK cells in lung lacked expression of CD69, a marker of tissue residency, whereas the majority of T cells and CD127⁺ innate lymphoid cells in lung expressed CD69. The small detectable population of tissue-resident CD69⁺ NK cells in the lung consisted of immature CD56^{bright}CD16⁻ NK cells and less differentiated CD56^{dim}CD16⁺ NK cells.

Conclusion: We here identify and characterize the major NK cell populations in the human lung. Our data introduce the concept that the majority of NK cells in the lung dynamically move between the blood and lung, rather than residing in the lung as *bona fide* tissue-resident CD69⁺ NK cells.

1915

Harnessing NK cells to target chronic lymphocytic leukemia: design and efficacy of novel trispecific immunoligands

Vyas, M., Pogge von Strandmann, E., Innate Immunity Group University Clinic Cologne, University of Cologne, Cologne, Germany

Chronic lymphocytic leukemia (CLL) is the most prominent B cell malignancy among adults in the Western world and characterized by a clonal expansion of B cells. There is emerging evidence that natural killer (NK) cells play a pivotal role in the immunosurveillance of CLL. Currently available mAbs are partially efficient in CLL and new agents that are more specific and effective are needed.

Our approach is to design bi- and tri-specific recombinant proteins (immunoligands) which simultaneously bind to tumor cells and NK cells resulting in NK cell-mediated killing of the former while bypassing their immune-escape mechanisms. One such trispecific immunoligand (ULBP2-aCD19-aCD19) aims to target CD19 antigen on CLL cells while a second arm activates NK cells through ULBP2, a ligand for the activating receptor NKG2D. *In vitro* data with ULBP2-aCD19-aCD19 revealed an enhanced NK cell-dependent lysis of CLL cell line and primary CLL cells in allogenic and autologous settings. This effect could be successfully replicated in an immunodeficient mouse model (NSG) as a part of *in vivo* analysis.

On the other hand, novel trispecific immunoligands are being analysed for their ability to enhance the efficacy of NK cell activation. This design includes a single chain (scFv) recognizing CD19 and two arms engaging different NK cell receptors CD16 (via anti-CD16 scFv) and NKG2D (via ULBP2). Based on the evidence that activating receptors on NK cells can synergize to enhance NK cell effector functions, we hypothesize that such trispecific immunoligands will be more potent immunotherapeutic agents.

2638

Selective modulation of Natural Killer (NK) cell phenotypes through chromatin modifying mechanisms

Cribbs, A.^{1,2,3}, Feldmann, M.², Soderstrom, K.³, Oppermann, U.³

¹University of Oxford, DPAG, Oxford, United Kingdom, ²Kennedy Institute of Rheumatology, Oxford, United Kingdom, ³Botnar Research Centre, Oxford, United Kingdom

Background: Natural killer (NK) cells are sentinels of the innate immune system by monitoring cell surfaces for the expression of MHC class I molecules and stress markers. For example, NK cells are critical for immune defence against malignant or virus infected target cells by engaging activating receptors, such as NKp30, leading to a cytolytic response.

Aims: Our research aims are to identify epigenetic mechanisms controlling immune cell functions. To understand NK cell function we use chemical and knockdown tools to study “readers, writers and erasers of a histone code” that regulate gene transcription.

Results: A focused epigenetic compound screen, comprising 60+ potent and selective epigenetic inhibitors, identified Jumonji-type histone demethylases and the BET bromodomains to play a fundamental role in regulating NK cell effector function. We show that JMJD3/UTX and BRD2/4 regulate a number of inflammatory cytokines, most notably pro-inflammatory IFN- γ . Inhibition of BRD2/4, but not JMJD3/UTX, resulted in inhibited NK cell-mediated cytotoxicity in a model system using K562 target cells. Transcriptome analysis revealed that this was accompanied by a robust down-regulation of key genes, in particular NKp30, further highlighted by antibody blocking experiments, revealing a critical role for NKp30 in mediating target killing.

Conclusion: Our results suggest that BET inhibitors exert deleterious effects on NK cell function by downregulating NKp30, which may weaken immune surveillance. Overall, our results show that both Jumonji histone demethylases and BET

bromodomains are important in regulating NK cell function, with BET bromodomains being key regulators of NK cell mediated cytotoxic killing of tumour cells.

Autoimmunity 2

Regulation of immune response genes by endogenous retroviruses

Loetsch, C.^{1,2}, Warren, J.¹, Parsons, J.¹, Buske, F.¹, Dinger, M.¹, King, C.^{1,2}

¹Garvan Institute of Medical Research, Darlinghurst, Australia, ²St. Vincent's Clinical School, University of New South Wales, Sydney, Australia

Type 1 diabetes (T1D) is an autoimmune disease caused by a combination of genetic and environmental factors. Results from genome-wide association studies and sero-epidemiological studies have linked infections with human enteroviruses, such as coxsackievirus B4 (CVB4), with an increased risk of T1D. Despite their relative abundance within mammalian genomes (8-10%), the role of endogenous retroviruses (ERVs) in the development of virus-induced chronic inflammation and autoimmunity remains unknown. We hypothesize that endogenous retroviruses can actively shape immune responses to exogenous virus infections and may thereby contribute to inappropriate responses against the host tissue.

Taking a genome-wide approach, we analysed the response of pancreatic target tissue to inflammation resulting from both pancreatrophic virus infection (Coxsackievirus B4) and spontaneous autoimmunity (NOD mice). Tissue specific upregulation of ERV expression was observed in the pancreatic beta cells of CVB4-infected mice and prolonged ERV up-regulation was exclusively observed in diabetes-prone mice. Viral response gene pathways were similarly overrepresented in CVB4 infected and pre-diabetic uninfected NOD mice. Beyond this, viral infection and spontaneous autoimmune inflammation induced the expression of endogenous retroviruses (particularly *ERV1* elements) and retroviral sensors (e.g. *Aim2* and *Irf16*). Feature analysis revealed that genomic positions of endogenous retroviruses positively correlated with promoter regions of CVB4-induced genes, while ERV expression within down-regulated genes was associated with enhancers, TF-binding sites and open chromatin regions.

Taken together, our findings suggest that ERVs can contribute to host-specific immune responses through both immune recognition and transcriptional regulation, and support their involvement in the development of chronic inflammation and autoimmune disease.

A single epitope is recognized by anti-IFN γ autoantibodies in patients with mycobacterial disease: clinical implications

Lin, C.-H.¹, Chi, C.-Y.², Ding, J.-Y.¹, Shih, H.-P.¹, Lo, C.-C.¹, Ku, C.-L.¹

¹Chang Gung University, Taoyuan, Taiwan, Republic of China,

²China Medical University Hospital, Taichung, Taiwan, Republic of China

Autoantibodies (AutoAbs) against interferon-gamma (IFN γ)

underlying mycobacterial diseases are an emerging medical issue in Southeast Asia. The origin of these AutoAbs is unclear. However, a vast majority of patients share the human leukocyte antigen (HLA) class II DRB1*15:02/16:02-DQB1*05:01/05:02 haplotype, suggesting a common T-cell- and B-cell-dependent mechanism underlying the production of IFN γ -specific AutoAbs. Herein, we report that these AutoAbs recognize a major epitope (P₁₂₁₋₁₃₁) in the C-terminus of IFN γ , a region critical for IFN γ receptor (IFN γ R) activation. AutoAbs to this epitope demonstrate neutralizing activity against IFN γ , preventing signaling via its receptor. Interestingly, the primary structure of this epitope is 100% homologous to a stretch of environmental fungus *Aspergillus* protein Noc2. We show that AutoAbs from patients can react with Noc2. In *in vivo* studies, rats immunized with *Aspergillus* Noc2 peptide developed antibodies against human IFN γ , and rats immunized with human IFN γ peptide developed antibodies against *Aspergillus* Noc2. Moreover, we generated epitope-erased IFN γ (EE-IFN γ), which has a modified major neutralizing epitope region that reduces 38% of its binding affinity with anti-IFN γ AutoAbs but not with the IFN γ receptor. EE-IFN γ can activate the IFN γ R downstream signaling pathway in the presence of anti-IFN γ AutoAbs *ex vivo*. In conclusion, we identified a shared, critical B-cell epitope of anti-IFN γ AutoAbs in patients and propose a molecular mimicry model in which the production of anti-IFN γ AutoAbs is triggered by the *Aspergillus* Noc2 protein. Moreover, EE-IFN γ may exhibit therapeutic potential for patients with anti-IFN γ AutoAbs.

2639

Isolation and characterization of hypocretin-reactive CD4⁺ T cells in narcoleptic patients

Latorre, D.¹, Armentani, E.¹, Kallweit, U.², Manconi, M.³, Khatami, R.⁴, Bassetti, C.L.², Sallusto, F.¹

¹Center of Medical Immunology, Institute for Research in Biomedicine, Università della Svizzera Italiana, Bellinzona, Switzerland, ²University Hospital, Neurology Department, Bern, Switzerland, ³Ospedale Regionale di Lugano (EOC), Lugano, Switzerland, ⁴Center for Sleep Research and Sleep Medicine, Clinic Barmelweid, Barmelweid, Switzerland

Narcolepsy-cataplexy is a rare sleep-wake disorder that manifests in genetically predisposed individuals and is caused by the selective loss of neuronal cells of the posterior hypothalamus that produce the neuropeptide hypocretin. Genome-wide association studies showed a strong association with HLA-DQB1*06:02 and other genes involved in immune modulation, supporting the notion that narcolepsy is a T cell-mediated autoimmune disease. However, attempts to identify hypocretin-specific T cells in narcoleptic patients have been so far unsuccessful. In this study we combined antigenic stimulation, T cell cloning, and TCR deep sequencing to characterize the T cell response in narcoleptic-cataplectic HLA-DQ0602-positive patients. T cells were isolated from blood and, when available, CSF, and either directly stimulated with overlapping peptides covering the entire hypocretin precursor protein (prepro-hypocretin) or expanded polyclonally to generate T cell libraries that were subsequently interrogated for reactivity against

prepro-hypocretin peptides as well as putative cross-reactive antigens. Hypocretin-reactive CD4⁺ T cell clones were identified in all patients analyzed so far, but not in HLA-DQ0602-positive control donors. The clones use different TCR α/β and recognize several regions of the prepro-hypocretin protein. Next-generation TCR sequencing was also performed on total T cells from blood and CSF in order to gather information on narcoleptic patients' TCR repertoire, to search for shared clonotypes, and to define expansion and localization *in vivo* of hypocretin-reactive T cell clones. Collectively, our data demonstrate for the first time the existence of expanded hypocretin-reactive CD4⁺ T cells in narcoleptic patients.

Stimulation of the melanocortin-1 receptor leads to direct neuroprotection via orphan nuclear 4 receptor in inflammatory neurodegeneration

Sucker, N.¹, Herrmann, A.M.², Faber, C.³, Wiendl, H.², Luger, T.A.¹, Meuth, S.G.², Loser, K.¹

¹University of Münster, Department of Dermatology, Münster, Germany, ²University of Münster, Department of Neurology, Münster, Germany, ³University of Münster, Institute for Clinical Radiology, Münster, Germany

In inflammation-associated progressive neurodegenerative disorders, e.g. multiple sclerosis (MS), inflammatory infiltrates, including Th1 and Th17 cells, cause demyelination and axonal/neuronal damage. Regulatory T cells (Treg) control the activation and infiltration of autoreactive T cells into the central nervous system (CNS). However, in experimental autoimmune encephalomyelitis (EAE) and MS, Treg function is severely impaired. Here we demonstrated that Nle4-D-Phe7- α -melanocyte-stimulating hormone (NDP-MSH), by binding to the melanocortin-1 receptor (MC-1R), induced functional Treg, which efficiently inhibited EAE progression. Strikingly, NDP-MSH also prevented immune cell infiltration into the CNS by restoring the integrity of the blood-brain barrier and exerted strong, long-lasting direct neuroprotective effects in an active (MOG-immunization) and spontaneous EAE model (Devic mice). Moreover, NDP-MSH prevented excitotoxic neuronal cell death in isolated mouse as well as human neuronal cells and re-established action potential firing in embryonic hippocampal neurons. Gene expression studies performed in brain and spinal cord tissue from MOG-immunized and NDP-MSH-treated mice revealed that neuroprotection by NDP-MSH was mediated via signaling through MC-1R, phosphorylation of the cAMP response element-binding protein (CREB) and subsequent activation of the orphan nuclear 4 receptor NR4A1 in mouse and human neurons. NDP-MSH has recently received European Medicines Agency (EMA) approval for the treatment of erythropoietic porphyria and thus, our novel data might support its use in treating neuroinflammatory and neurodegenerative diseases, e.g. relapsing-remitting MS.

2544**Macrophage derived ROS regulate arthritis and psoriasis-like dermatitis in ZAP deficient SKG mice***Guerard, S., Holmdahl, R., Wing, K.**Karolinska Institutet, MBB, Stockholm, Sweden*

A key issue in immunology is to reveal the interplay of factors that lead to multi-factorial diseases such as rheumatoid arthritis (RA) and psoriasis. ZAP70 deficient SKG mice develop a T cell-dependent arthritis that mimics RA when injected with mannan, a polysaccharide from yeast. However, injection of mannan also induces a T cell independent psoriasis like disease, even in wild type mice, which is dramatically enhanced by lack of reactive oxygen species (ROS). To investigate the role of ROS in T cell-driven autoimmunity, we introduced the *Ncf1^{m1j}* mutation in the SKG mouse model to prevent ROS burst by phagocytes. SKG mice were susceptible to both IL-17 mediated T cell driven arthritis and acute psoriasis-like dermatitis. *In vivo* imaging showed higher ROS concentrations in joints of arthritic SKG mice compared to naïve and wild type mice, which demonstrate an association between ROS and joint inflammation. However SKG.*Ncf1^{m1j/m1j}* mice, which lack ROS, developed more severe arthritis and psoriasis-like dermatitis that could not be attributed to either T cell or B cell responses. However, autoimmunity drastically reverted to baseline level when ROS production was introduced in macrophages under the human CD68 promoter. This clearly demonstrates the critical role of macrophage-derived ROS in regulating aberrant inflammation in tissue. Thus, despite the T cell dependency of arthritis in the SKG model, the lack of ROS enhanced autoimmunity through T cell independent mechanisms.

3191**The role of anti-inflammatory cytokine interleukin-27 in atherosclerosis***Peshkova, I., Fatkhullina, A., Koltsova, E.**Fox Chase Cancer Center, Philadelphia, United States*

Atherosclerosis is a lipid-driven chronic inflammatory disease. Cytokines are important mediators of inflammation and atherosclerosis. While pro-inflammatory cytokines were extensively investigated, little is known about the role of anti-inflammatory cytokines in regulation of vascular inflammation. We tested whether immunoregulatory IL-27R signaling controls inflammation in mouse models of atherosclerosis. We found that atherosclerosis-prone mice with hematopoietic deficiency of IL-27R (*Ldlr^{-/-}* mice reconstituted with bone marrow from *Il27ra^{-/-}*) or global deficiency (*Il27ra^{-/-} x ApoE^{-/-}*) developed significantly larger atherosclerotic lesions compared to controls. Aortas of *Il27ra^{-/-}* mice contained more CD45⁺ leukocytes and CD4⁺ T cells, which produced pro-atherogenic cytokines IL-17A and TNF- α . These cytokines normally suppressed by IL-27, regulated the expression of CCL2 and other chemokines, which in turn led to accumulation of myeloid CD11b⁺ and CD11c⁺ cells in atherosclerotic aortas. Two-photon live imaging revealed enhanced interactions between antigen presenting cells and CD4 T cells in the aortas of *Il27ra^{-/-}* mice accompanied by enhanced T cell proliferation. Moreover, macrophages in *Il27ra^{-/-}* aortas also demonstrated enhanced ability to produce

pro-inflammatory cytokines, including IL-1. The blockade of IL-1R signaling, however, strongly suppressed atherosclerosis in *Il27ra^{-/-}* but not control mice, suggesting regulatory role of IL-27 in IL-1 production in atherosclerosis.

Overall, our data demonstrate that IL-27R signaling in atherosclerosis is required to control function of antigen presenting cells modulating subsequent T cell activation in the aortas. Moreover, it controls macrophage activation and pro-inflammatory cytokine production. These mechanisms altogether curb pathogenic T cell lineage differentiation and, thus, atherosclerosis, suggesting potent anti-atherogenic role of IL-27.

4167**T cell tolerance in the pancreatic islets is mediated by MerTK during type 1 diabetes***Lindsay, R.^{1,2}, Tracy, D.¹, Friedman, R.^{1,2}**¹National Jewish Health, Biomedical Research, Denver, United States, ²University of Colorado Denver, Immunology and Microbiology, Denver, United States*

Type 1 diabetes (T1D) is a T cell mediated autoimmune disease that results from destruction of pancreatic islet β -cells. Curiously, for years following disease onset β -cell containing islets with T cell infiltration can still be found, suggesting a tolerance checkpoint following islet infiltration. While T cells are required for T1D progression, CD11c⁺ cells also infiltrate the islets. We depleted CD11c⁺ cells to determine their role in maintaining T cell tolerance in the islets. CD11c depletion resulted in increased CD8 T cell motility arrest and effector function. MerTK⁺ antigen presenting cells are associated with T cell tolerance induction following apoptotic cell uptake. We identified MerTK expression on a subset of islet-infiltrating CD11c⁺ cells. To test if MerTK mediates tolerance in the islets, we treated asymptomatic non-obese diabetic (NOD) with pre-existing islet infiltration and non-autoimmune C57BL/6 mice with UNC2025, a MerTK/Flt3 inhibitor. Blood glucose remained normal in C57BL/6 mice. However, in 50% of NOD mice, MerTK/Flt3 inhibition resulted in extremely rapid diabetes onset. The rapid disease onset occurred prior to Flt3-dependent population shifts in the islets, suggesting a MerTK rather than Flt3 mediated effect. Within 24 hours of MerTK inhibition, islet-antigen specific CD4 and CD8 T cells arrested motility in the islets, and CD8 T cell activation increased in the islets. Thus, inhibition of MerTK signaling resulted in a break in T cell tolerance and rapid islet destruction. These results suggest that CD11c⁺ cells are involved in a MerTK-dependent tolerance checkpoint during T1D, which maintains T cell tolerance in the islets.

1305**CD4⁺ T cells from the pancreatic islets of an organ donor who had type 1 diabetes recognize epitopes formed by transpeptidation***Elso, C.¹, So, M.¹, Tresoldi, E.¹, Kumar, N.¹, DeLong, T.², Haskins, K.², Mannerling, S.¹**¹St. Vincent's Institute of Medical Research, Melbourne, Australia,**²Barbara Davis Center for Childhood Diabetes, University of Colorado, Denver, United States*

Type 1 diabetes (T1D) is an autoimmune disease caused by the T-cell mediated destruction of the insulin-producing beta cells. Current evidence suggests that HLA-DQ8 and/or HLA-DQ2 restricted CD4⁺ T-cell responses against (pro)insulin, play an important role in the pathogenesis of T1D. However, the antigens/epitopes recognized by pathogenic CD4⁺ T cells have not been identified. The possibility that autoimmune responses target epitopes formed by posttranslational modification of self-proteins has gained support in several autoimmune diseases, but it remains unclear if a similar mechanism operates in type 1 diabetes. Recently CD4⁺ T cells that cause autoimmune diabetes in the NOD mouse model were shown to recognize a novel form of posttranslational modification - epitopes formed by the fusion of two beta-cell proteins. To investigate if these epitopes, termed hybrid insulin peptides (HIPs), are recognized by human CD4⁺ T cells in T1D we tested CD4⁺ T-cell clones isolated from the residual pancreatic islets of an organ donor who suffered from T1D. Two clones responded to an epitope formed by the fusion of proinsulin with IAPP2, another protein found in the granules of beta cells. The response to this epitope is restricted by HLA-DQ8. Preliminary data suggests that CD4⁺ T-cell responses to this epitope can be detected in the peripheral blood of HLA-DQ8⁺ individuals with T1D, but not those without T1D. These observations support the hypothesis that autoimmune human CD4⁺ T-cell responses in T1D target epitopes formed by protein-protein fusion and may explain how these putatively pathogenic T cells avoid central tolerance.

Granzyme A-deficiency breaks immune tolerance and promotes organ-specific autoimmune disease through a type I interferon-dependent pathway

Mollah, Z.¹, Quah, H.S.¹, Graham, K.¹, Jhala, G.¹, Krishnamurthy, B.¹, Trapani, J.², Bird, P.³, Brodnicki, T.¹, Kay, T.¹, Thomas, H.¹

¹St Vincent's Institute, Immunology and Diabetes, Fitzroy, Australia,

²Peter MacCallum Cancer Centre, East Melbourne, Australia,

³Monash Biomedicine Discovery Institute, Clayton, Australia

Granzyme A is a protease implicated in the degradation of intracellular DNA. Nucleotide complexes are known triggers of innate immunity and systemic autoimmunity, but a role in organ-specific autoimmune disease has not been demonstrated. To investigate whether such a mechanism could be an endogenous trigger for autoimmunity, we examined the impact of granzyme A deficiency in the NOD mouse model of autoimmune diabetes. NOD.Gzma^{-/-} mice developed diabetes earlier than wild-type NOD mice. In addition, granzyme A deficiency was able to break tolerance in NOD.PI mice that are tolerant to proinsulin and never develop diabetes, resulting in insulin autoantibody production and diabetes. Single-stranded DNA was observed more frequently in the cytoplasm of immune cells in NOD.Gzma^{-/-} mice compared with NOD mice, suggesting that granzyme A is required for efficient degradation of aberrant DNA. Consistent with increased nucleic acid sensing, islets from NOD.Gzma^{-/-} mice had increased expression of IFN-response genes. Diabetes returned to the expected rate in NOD.Gzma^{-/-} mice that also lacked type I IFN receptor expression. Our data suggest a new mechanism for the etiology of autoimmune diabetes, where

accumulation of aberrant cytoplasmic DNA in innate immune cells results in excessive IFN production by these cells within islets. This is the first indication of an *in vivo* role for granzyme A in maintaining immune tolerance.

Neutrophils mediate potent and rapid anti-HIV antibody-dependent functions

Worley, M.¹, Kelleher, A.D.^{2,3}, Kent, S.J.^{1,4}, Chung, A.W.¹

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ²University of New South Wales / Kirby Institute, Sydney, Australia, ³St. Vincent's Centre for Applied Medical Research, Immunovirology Laboratory, Sydney, Australia, ⁴Monash University, Melbourne Sexual Health Centre and Department of Infectious Diseases, Melbourne, Australia

Background: Functional antibodies have been shown to mediate innate immune effector responses such as antibody dependent cellular cytotoxicity (ADCC) and their importance in HIV protection was highlighted by the RV144 HIV vaccine trial. However, the majority of studies have focused on antibody activation of NK cells and monocytes, while neutrophils remain understudied. Neutrophils are of particular importance as they are abundantly present in the mucosal sites of HIV transmission, constitute 40-70% of white blood cells and can respond rapidly to stimuli. We investigated the repertoire of antibody dependent functions in HIV infected patients and examined any differences between long-term slow progressors (LTSP) and progressors.

Methods: Fresh human blood neutrophils, NK and monocytes were evaluated for gp120 envelope-specific ADCC using HIV-specific antibodies. In addition, antibody-dependent phagocytosis (ADP) and ADCC activity was evaluated using plasma IgG from 19 LTSP and 14 HIV progressors.

Results: Neutrophils readily mediated HIV-specific ADCC and ADP and significant correlations were observed for LTSP $R_5=0.626$ ($p=0.004$) and progressors $R_5=0.653$ ($p=0.014$). Neutrophils mediated ADCC rapidly having 2 fold greater responses than NK cells and similar responses to monocytes. Similar levels of ADP and ADCC were observed in neutrophils between the LTSP and progressors patient groups.

Conclusion: HIV-specific IgG can activate neutrophils to mediate ADP and ADCC against HIV-1 envelope protein. As both of these functions are highly correlated, the same Fc receptors/antibodies may be utilised to mediate these responses. The rapid action and high magnitude of ADCC by neutrophils highlights their potential importance early in HIV infections.

"HIV-1 controllers"- what's their secret?

Madhavi, V.¹, Wines, B.², Emery, S.³, Amin, J.³, Kelleher, A.³, Hogarth, M.², Stratov, I.^{1,4}, Kent, S.^{1,4,5}

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia, ²Burnet Institute, Centre for Biomedical Research, Melbourne,

Australia, ³Kirby Institute for Infection and Immunity in Society, University of New South Wales, Sydney, Australia, ⁴Melbourne Sexual Health Clinic, Carlton, Melbourne, Australia, ⁵Alfred Hospital, Infectious Diseases Unit, Prahran, Melbourne, Australia

Objectives: HIV-1 elite controllers (ECs) offer a unique opportunity to explore protective immune effector mechanisms. HIV-1-specific antibody-dependent cellular cytotoxicity (ADCC) has been shown to play an important role in protection from HIV-1 infection in various studies including the RV144 vaccine trial. However, evidence for HIV-1 Env and non-Env antigen-specific ADCC role in protection from disease progression among HIV-1-infected individuals including ECs is limited.

Methods: We recruited 22 HIV-1 ECs (< 20 copies RNA/ml) and 44 HIV-1 progressors (>10,000 copies RNA/ml) in order to compare possible immune correlates of HIV-1 control among ECs. We measured HIV-1 Env-specific Fc-mediated antibody effector functions using a novel ELISA-based Fc-receptor-binding assay and rapid fluorometric ADCC-mediated killing assay (RFADCC). We also measured HIV-1 Vpu-specific ADCC responses using Fc-receptor-binding assays.

Results: We found high levels of HIV-1 gp140-specific FcγRIIIa-binding antibodies in ECs compared to progressors ($p=0.001$). ADCC-mediated killing of HIV-1 gp140-coated targets was higher in ECs than progressors. FcγRIIIa binding of antibodies to Vpu was found to be higher in ECs compared to progressors ($p=0.002$). We have mapped Vpu-specific FcγRIIIa-binding antibodies to a 13-mer linear peptide (Vpu19) and found that ECs have higher FcγRIIIa-binding antibodies against Vpu19 compared to progressors ($p=0.004$).

Conclusions: Our data suggests role for HIV-1 Env- and Vpu-specific ADCC in elite immune control of HIV-1. Furthermore, Vpu19 is a common ADCC epitope in ECs. Attempts to isolate monoclonal ADCC antibodies are currently underway. Our findings have implications for understanding a role of ADCC in HIV-1 control and use of ADCC monoclonal antibodies as immunotherapeutics.

Gut microbiome and immune activation in mucosal SHIV transmission

Sui, Y., Dzutsev, A., Venzon, D., Frey, B., Trinchieri, G., Berzofsky, J. National Cancer Institute, National Institute of Health, Bethesda, United States

It is unknown whether the gut microbiome affects HIV transmission. In our recent SHIV vaccine study, in which 42% vaccine efficacy ($p = 0.025$) was achieved, we found that the naïve rhesus macaques from two different sources had significantly different rates of infection against repeated low-dose intrarectal challenge with SHIVSF162P4 virus. Exploring causes, we found that the more susceptible group of 7 macaques (N7) in the original shipment (as well as the 21 vaccinated animals in pre-immunization rectal biopsies) had significantly more activated CD4⁺CCR5⁺Ki67⁺ T cells in the rectal mucosa than the more resistant group of 11 macaques from a different source. The prevalence of pre-challenge activated rectal CD4 T cells in the naïve macaques correlated inversely

with the number of challenges required to infect. The groups also differed significantly by principal component analysis of activation markers, with only N7 matching the vaccinated group. Because the two naïve groups came from different sources, we hypothesized that their microbiomes may differ and might explain the activation difference. Indeed, after sequencing 16s rRNA, at the phylum level and genus level, we found differences between the two naïve groups that correlated with immune activation status. For example, significantly lower ratios of *Bacteroides* to *Prevotella*, and significantly lower levels of *Firmicutes* were found in the susceptible cohort. These parameters also inversely correlated with high levels of immune activation in the rectal mucosa. Thus, host-microbiome interactions might influence the HIV/SIV mucosal transmission through effects on mucosal T-cell activation.

Ablating cellular inhibitors of Apoptosis (cIAPs) specifically sensitizes HIV-infected CD4⁺ T cells to death, reducing viraemia and immune attrition in humanized mice

Allison, C.¹, Preston, S.¹, Mota, T.², Stutz, M.¹, Cheong, K.², Lewin, S.², Pellegrini, M.¹

¹Walter and Eliza Hall Institute of Medical Research (WEHI), Infection and Immunity, Melbourne, Australia, ²Peter Doherty Institute for Infection and Immunity, Melbourne, Australia

Background: Inhibitor of Apoptosis (IAP) molecules are pro-survival proteins, which confer resistance to inflammatory death-inducing molecules, such as TNF and TRAIL. IAP down-regulation thereby enhances cellular susceptibility to apoptosis upon exposure to such stimuli. Modulating IAP expression during chronic infection is a novel strategy to eliminate infected cells.

Methods: We treated HIV-infected primary human CD4⁺ T cells *in vitro* with a IAP antagonist, *birinapant*, which selectively induces the degradation of cellular IAPs, cIAP1 and cIAP2. These experiments were complemented with *in vivo* birinapant treatment of HIV-infected humanised (CD34⁺ human hematopoietic-reconstituted NOD.SCID.IL2gnull) mice. Plasma and cellular viral titres were assessed by qPCR.

Results: Birinapant induced the rapid and preferential killing of infected over uninfected CD4⁺ T cells, and a concomitant reduction in infectious virus. This heightened sensitivity is most likely due to amplified TNF signaling, as we observed enhanced TNF receptor expression on HIV-infected CD4⁺ T cells. We found that treating humanised mice with as few as two doses of birinapant one week after HIV infection induces sustained reductions in viral load. We hypothesise that this is achieved by the rapid apoptosis of infected cells early after treatment, thereby limiting viral spread and disease progression.

Conclusion: This is the first time that modulating IAP expression has been shown to be effective for the selective killing of HIV-infected cells. Our humanized mice data affirms the utility of this approach *in vivo*, warranting further investigation into the ability of cIAP inhibition to sensitize all HIV-infected cells, particularly the latent reservoir, to apoptosis.

Overexpression of total-STAT1 during lymphopenia-induced proliferation leads to diminished CD4 T cell survival: implications in HIV infection

Le Saout, C.¹, Luckey, M.², Villarino, A.³, Smith, M.¹, Myers, T.⁴, Hasley, R.¹, Park, J.-H.², JJ, O.³, Lane, H.C.¹, Catalfamo, M.¹

¹NIH, NIAID, CMRS/Laboratory of Immunoregulation, Bethesda, United States, ²NIH, NIAMS, Bethesda, United States, ³NIH, NCI, CCR, Experimental Immunology Branch, Bethesda, United States, ⁴NIH, NIAID, Genomic Technologies Section/Research Technologies Branch, Bethesda, United States

During HIV infection the CD4 T cell pool is in constant homeostatic pressure because of its depletion. This effect is evident by the association between the rate of proliferating CD4 T cells and CD4 counts, which is also observed in healthy volunteers. In contrast, such associations are not observed in the CD8 T cell pool of patients or healthy controls suggesting that CD4 and CD8 T cell pools are differentially regulated and/or intrinsic characteristics contribute to the homeostatic regulation of these pools. In a model of adoptive T cell transfer into RAG^{-/-} mice, T cells undergoing IL-7 dependent lymphopenia-induced proliferation (LIP), upregulate total STAT1 (t-STAT1) expression leading to an IL-7-dependent STAT1 signaling in addition to STAT5. In patients with HIV infection t-STAT1 expression levels in CD4 T cells correlate with the degree of lymphopenia and showed phosphorylation of STAT1 in addition to STAT5. The IL-7-dependent STAT1 signaling is not very well described. To address the potential involvement of this pathway in human disease, we generated a STAT1 transgenic (STAT1-Tg) mouse to understand the contribution of IL-7-dependent STAT1 activation on T cell homeostasis in the setting of lymphopenia. RNAseq data of *in vitro* IL-7 stimulated CD4 cells showed IFN- γ associated genes. *In vivo*, CD4 T cells from STAT1-Tg mice upregulate the levels of t-STAT1 when undergoing LIP. In these conditions, CD4 T cells showed diminished survival and accumulation in the lymphoid organs. This mechanism maybe involved in regulating the expansion of the CD4 T cell pool under lymphopenic conditions.

Prime-boost immunisation strategies with recombinant HIV vaccines induces vaginal mucosa HIV-specific CD8 T-cells

Tan, H.-X.¹, Alcantara, S.¹, Amarasena, T.¹, Ranasinghe, C.², Kent, S.¹, De Rose, R.¹

¹The University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ²John Curtin School of Medical Research, Australian National University, Division of Immunology and Genetics, Canberra, Australia

Cervico-vaginal HIV-1 infection remains localised for several days, providing a short window for immune clearance before systemic dissemination. We explore vaccine regimens using recombinant vectors expressing HIV-1 proteins to induce HIV-specific CTLs in the vaginal mucosa.

Utilising recombinant influenza viruses encoding whole HIV-1 p24 protein (Flu-p24), we performed heterosubtypic (H1N1-H3N2) intranasal prime and intravaginal boost vaccinations

in BALB/c mice. HIV-specific CTLs were induced in the vaginal mucosa at 6% of total vaginal CD8⁺T-cells. At 14-days post-boost, HIV-specific CTLs were present at 1 in every 1000 nucleated cell of the vaginal mucosa, as quantified by immuno-fluorescence microscopy. HIV-specific CTLs were present at 30-days post-boost, albeit with a 2-fold reduction vs. 14-days post-boost. Spatial analysis revealed that 70% of CD8⁺ T-cells induced were localised in the epithelial lining of the vaginal mucosa. 40% of CD8⁺ T-cells maintained CD103⁺ expression at 14- and 30-days post-boost. The concurrent expression of CD103⁺ and epithelial localisation indicate that a proportion of these cells are vaginal-resident CTLs.

We investigated an alternative heterologous prime-boost intranasal vaccination, combined with an intravaginal treatment to enhance vaginal CTL recruitment. Mice were primed with a Gag-expressing fowlpox virus, followed a Flu-p24 booster. To enhance recruitment or “pull” CTLs into the vaginal mucosa, an inflammatory stimulus (nonoxynol-9) was concurrently administered intravaginally during boosting. Nonoxynol-9 induced a 1.5-fold increase in HIV-specific CTLs vs. a mock intravaginal treatment

($p < 0.05$).

These mucosal prime-boost strategies establish frontline vaginal-resident CTLs and may induce heightened local surveillance for protection against vaginal HIV-1 exposure.

CX3CR1+ CD8 T cells promote monocyte activation and cardiovascular risk

Freeman, M.¹, Panigrahi, S.¹, Mudd, J.^{1,2}, Sieg, S.¹, Funderburg, N.³, Lederman, M.¹, Zidar, D.⁴

¹Case Western Reserve University, Cleveland, United States, ²National Institute of Allergy and Infectious Diseases, Bethesda, United States, ³Ohio State University, Columbus, United States, ⁴University Hospitals, Cleveland, United States

HIV-infected individuals sustain elevated inflammation that is linked to increased risk of cardiovascular disease despite virus suppression with antiretroviral therapy (ART). This inflammatory state is accompanied by expansion of circulating memory CD8 T cells. Also seen is increased platelet activation and sustained increases in proportions of inflammatory and procoagulant monocytes that is similar to the changes seen in uninfected persons with acute coronary syndromes. Recently we and others identified co-localization of macrophages and CD8⁺ T cells in the aortic endothelium of SIV-infected macaques. Because inflammatory cytokines such as IFN γ can exert a “priming” influence on monocytes, leading to exaggerated production of cytokines such as TNF in response to LPS stimulation, we hypothesized that TCR-stimulated CD8 T cells could exert a pro-atherosclerotic effect via paracrine actions on monocytes. Here we identify a population of circulating memory CD8 T cells that express CX3CR1 (fractalkine receptor) that is enriched in ART-treated HIV-infected subjects. CX3CR1⁺ CD8 T cells are the major IFN γ -producing CD8 T cell population and have elevated expression of the platelet-binding receptor PSGL-1 and the thrombin-activated receptor PAR-1, suggesting that these endothelial homing CD8 T cells could interact with coagulation

elements. Additionally, TCR-stimulated CD8 T cells enhance monocyte activation and cell surface tissue factor expression that is dependent on the inflammatory cytokine TNF *in vitro*. Thus, we have identified a link among activated CD8 T cells, platelets, and monocytes that could provide a mechanistic pathway for elevated cardiovascular risk in ART-treated HIV infection.

Immunological efficacy of therapeutic vaccination in chronically HIV-1 infected patients is impacted by the process and the route of vaccine administration

Brezar, V.^{1,2,3}, Hani, L.^{1,2,3}, Surenaud, M.^{1,2,3}, Lacabartz, C.^{1,2,3}, Lelièvre, J.D.^{1,2,3,4}, Lévy, Y.^{1,2,3,4}, Seddiki, N.^{1,2,3}

¹INSERM U 955 Eq 16, Créteil, France, ²Université Paris-Est Créteil, Faculté de Médecine, Créteil, France, ³Vaccine Research Institute (VRI), Créteil, France, ⁴AP-HP, Hôpital H. Mondor - A. Chenevier, Service d'Immunologie Clinique et Maladies Infectieuses, Créteil, France

The role of regulatory T cells (Tregs) in vaccination has been poorly investigated. We have recently reported that vaccination with ex vivo-generated dendritic-cells (DC) loaded with HIV-lipopeptides (LIPO-5-DC vaccine) given subcutaneously to HIV-infected patients was well tolerated and highly immunogenic (Y. Levy et al, EJI 2014).

We show here that vaccinees (n=14) who displayed lower levels of HIV-specific CD4⁺CD134⁺CD25⁺CD39⁺FoxP3⁺ Tregs responded better to the LIPO-5-DC vaccine. After vaccination, the frequency of HIV-specific Tregs decreased (from 69.3 at week -4 to 31.7% at week 16) and inversely correlated with HIV-specific IFN- γ -producing cells (r=-0.64, p=0.002).

We evaluated LIPO-5-specific Tregs responses in another therapeutic immunization study (ANRS093) that combined two different vaccines (recombinant ALVAC-HIV (vCP1433) and Lipo-6T (HIV-1 lipopeptides)). In contrast to the former, this vaccine was not loaded on DC but was administered to patients intramuscularly (n=18). Our data revealed that the frequency of LIPO-5-specific Tregs CD4⁺CD134⁺CD25⁺CD39⁺FoxP3⁺ was similar to baseline (34.22 at week 0 and 40.4% at week 16) and there was no skewing from regulatory to effector phenotype as we observed in the LIPO-5-DC vaccination. Importantly, we also observed that HIV-specific CD4⁺CD134⁺CD25⁺CD39⁺FoxP3⁺ correlated positively with viral load after treatment interruption (ATI).

Taken together our data suggest that the process and the route of therapeutic immunization with HIV-lipopeptides in chronically infected patients impacts on the quality of the responses by shifting the balance between regulatory and effector responses thus leading to efficiency of viral control.

Bad romance: defining the molecular link between *Neisseria gonorrhoeae* and HIV

Xu, S.X.¹, Leontyev, D.², Kaul, R.², Gray-Owen, S.D.¹

¹University of Toronto, Molecular Genetics, Toronto, Canada,

²University of Toronto, Department of Medicine, Toronto, Canada

Human immunodeficiency virus (HIV) is a sexually transmitted infection affecting millions of people worldwide. With no existing cure and development of resistance against current antiviral drugs, there is a pressing need to reduce transmission of the virus and limit disease progression to acquired immune deficiency syndrome (AIDS). Clinical observations show that gonorrhea infection increases HIV shedding and transmission, and enhances an individual's susceptibility to HIV infection upon exposure. While *in vitro* studies of interactions between HIV and *Neisseria gonorrhoeae* (Ngo) have elucidated processes with the potential to drive transmission, these have not been considered *in vivo* because HIV and Ngo are both human-restricted pathogens. Here, we describe the development and initial findings from the first animal model of HIV and Ngo co-infection, using immunodeficient NSG mice reconstituted with a human immune system via hematopoietic stem cell transplantation. While it had not previously been appreciated, we observe that systemic HIV infection results in local shedding of virus in the female genital tract of humanized mice, reflecting the phenomenon seen in humans. While plasma levels of virus were not notably impacted by vaginal Ngo infection, the co-infected mice showed elevated shedding of HIV into the genital tract. Ongoing work aims to reveal the relative contribution of Ngo-derived factors and infection-induced inflammatory responses to this localized increase in HIV within the co-infected mucosa. Moreover, this model lays the foundation for future work aiming to intervene in the pathogenic synergy between these two devastating pathogens.

T cell exhaustion is reinforced by progressive de novo DNA methylation programming

Youngblood, B.¹, Ghoniem, H.¹, Abdelsamed, H.¹, Carter, R.¹, Hale, S.², Ahn, E.², Im, S.², Ahmed, R.²

¹St Jude Children's Research Hospital, Immunology MS 351, Memphis, United States, ²Emory University School of Medicine, Atlanta, United States

Antigen-specific CD8 T cells play a critical role in controlling chronic infections and cancer, but progressively lose their effector functions during prolonged antigen exposure. Repression of CD8 T cell effector functions, commonly referred to as T cell exhaustion, limits the ability of the immune system to purge the chronic pathogen from the host. It has recently become recognized that CD8 T cell exhaustion programs can be reinforced and heritably maintained. Therefore in order to develop and/or improve current therapeutic approaches that utilize host antigen-specific T cells to treat chronic infections or cancer a major challenge for the field is to identify mechanisms that stabilize T cell exhaustion. We have recently found that epigenetic modifications acquired in pathogen-specific CD8 T cells during prolonged antigen exposure reinforce T cell exhaustion. Using the LCMV model system of chronic viral infection we investigated the role of Dnmt3a mediated de novo DNA methylation in regulating CD8 T cell exhaustion. Strikingly, conditional deletion of Dnmt3a in activated CD8 T

cells blocked the cells from becoming exhausted. Longitudinal analysis of whole-genome methylation programming of WT and Dnmt3a cKO CD8 T cells from chronically infected animals reveals progressive acquisition of Dnmt3a-dependent DNA methylation programs in genes, including interferon gamma, that are coupled to the progressive decline of effector functions. These results have significant implications for therapeutic strategies that utilize reactivation of host pathogen-specific CD8 T cells to control chronic viral infections or cancer and provide a nucleotide-resolution map of epigenetic programs progressively acquired during T cell exhaustion.

IL-15 complexes induce migration of resting memory CD8 T cells into mucosal tissues

Marzo, A., Sowell, R., Rogozinska, M.

Rush University Medical Center, Chicago, United States

CD8 T cells are key players in our immune system's defense against infectious diseases and tumors. However, we do not fully understand how CD8 T cells enter and take up residence in mucosal tissues, to protect against mucosa-acquired infections. We sought to identify potential targets to therapeutically enhance CD8 T cell responses within these sites of frequent pathogen exposure. Our study reveals a novel mechanism by which IL-15, a cytokine responsible for the maintenance of memory CD8 T cells, also elicits migration of resting memory CD8 T cells to mucosal tissues. Interleukin-15 (IL-15) is an essential cytokine known to promote T cell survival and activate the effector function of memory phenotype CD8 T cells. Blocking IL-15 signals also significantly impacts tissue specific effector and memory CD8 T cell formation. Here we demonstrate that IL-15 influences the generation of memory CD8 T cells by first promoting their accumulation into mucosal tissues and secondly by sustaining expression of Bcl-6 and T-bet. We show that the mechanism for this recruitment is largely dependent on mTOR and its subsequent inactivation of FoxO1. Last, we show that IL-15 complexes delivered locally to mucosal tissues without re-infection is an effective strategy to enhance establishment of Tissue Resident Memory (T_{REM}) CD8 T cells within mucosal tissues. This study provides mechanistic insight into how IL-15 controls the generation of memory CD8 T cells and influences their trafficking and ability to take up residence within peripheral tissues.

Distinct mechanisms govern resident memory T cell differentiation and survival in different tissues

Wynne-Jones, E., Freestone, D., Davies, B., Newman, D.M., Carbone, F.R., Mackay, L.K.

The University of Melbourne, Microbiology and Immunology, Parkville, Australia

Tissue-resident memory T (Trm) cells are a recently defined population of memory T cells that persist in peripheral tissues after infection, and contribute to effective local immunity. Trm cells have been identified in a number of peripheral tissues

including epithelial and solid organs. Transcription factors governing the development and maintenance of these cells are just beginning to be uncovered. Our data demonstrate that the transcriptional regulation of Trm cells is distinct to memory T cell subsets in the circulation, in that an essential process during Trm formation in the skin and lung is the down-regulation of the T-box transcription factors Eomes and T-bet. Further, we found that some residual T-bet expression was required for Trm cell survival in these organs. Intriguingly, we found that the dependence of Trm cells on transcription factors varied according to anatomic location. In CD103⁺ CD69⁺ Trm cells, expression of the transcription factor T-bet was absolutely required in some organs, whereas in other organs it was dispensable. Lack of T-bet also resulted in altered cytokine production, with Trm cells making a switch to produce IL-17. Additionally, we found that Trm cells in different tissues have distinct cytokine requirements for their survival. These data demonstrate adaptation of Trm cells to specific tissue microenvironments, and highlight the importance of studying these cells in a variety of tissues. In future, such insights will inform approaches used to target Trm cells in various clinical settings.

Intravascular surveillance by terminally differentiated effector and memory CD8⁺ T cells

Barreiro, O., Loughhead, S., Gerlach, C., Wanders, L., Zhang, Z., von Andrian, U.H.

Harvard Medical School, Department of Microbiology and Immunobiology, Boston, United States

Following infection, pathogen-specific T cells proliferate and divide in a heterogeneous manner, giving rise to effector and memory T cells with distinct migratory patterns. This migratory division of labor ensures that the host is efficiently scanned for ongoing or recurring infections. Recent evidence suggests that the presumed migratory behavior of the classical effector memory T cell (Tem) subset needs revision, as Tem appear to be unexpectedly absent from the extravascular compartment in non-lymphoid tissues. Here, we report that terminally differentiated effector and memory T cells adhere to and patrol dermal endothelium, while less differentiated T cells do not. This behavior is preferentially observed in arterioles and migration tends to be retrograde to blood flow. Furthermore, patrolling T cells survey endothelium for antigen (Ag) as injection of cognate Ag results in their immediate arrest. Together, this suggests that terminally differentiated effector and memory T cells engage in a migratory behavior that supports protective scanning of specific vascular beds.

The role of IL-36 in the immune response to influenza infection

Wein, A.¹, Dunbar, P.¹, McMaster, S.¹, Hayward, S.¹, Denning, T.², Kohlmeier, J.¹

¹Emory University School of Medicine, Atlanta, United States,

²Georgia State University, Institute for Biomedical Sciences, Atlanta, United States

The IL-36 family of cytokines is a recently discovered and little-understood relative of IL-1. IL-36 activation plays an important role in the development of psoriasis, tumor rejection, and asthma; however, its role in respiratory viral infection has not been studied. We have found that IL-36 family cytokines are upregulated during influenza infection in mice and the main source of IL-36g is neutrophils. Mice lacking IL-36g or IL-36R have increased viral titers following influenza infection and mice deficient in IL-36g show delayed viral clearance. In addition, mice without IL-36g or IL-36R have increased pathology during influenza infection compared to WT mice. During the early response to influenza, there is a defect in innate immune cell recruitment to the lungs, particularly neutrophils. Following clearance of infection, virus-specific CD8+ T cell memory generation and recall is impaired. These results point to important and diverse roles for IL-36 cytokines in the immune response to influenza as well as the generation of long-lived cellular immunity to respiratory virus infections.

832

Stage-specific role for FoxO1 in the maintenance of T-cell memory

Suresh, M., Tejera, M.M., Neldner, B.

University of Wisconsin-Madison, Pathobiological Sciences, Madison, United States

During CD8 T-cell responses to acute viral infections, naïve CD8 T cells are activated to expand and differentiate into effector cells and a subset of effector cells further differentiate into a self-renewing population of memory CD8 T cells. Specific transcription programs guide the successive progression of responding CD8 T cells through various differentiation states (naïve → effector → memory) during a T-cell response. We and others have identified FoxO1 as a key transcription factor that regulates the differentiation of memory CD8 T cells. However, the temporal requirement for FoxO1 during various phases of the CD8 T-cell response remains unknown. In this study, by inducible ablation of FoxO1 in mixed bone marrow chimeras, we investigated the temporal and cell-intrinsic requirement for FoxO1 in the generation and maintenance of T-cell memory. We find that full expression of key surface molecules including CD44, CD62L and CD127 in memory CD8 T cells required continuous activity of FoxO1. Likewise, FoxO1 plays a vital and non-redundant role in maintaining the polyfunctionality of memory CD8 and CD4 memory T cells and inducing full expression of TCF-1 through out the T-cell response. Additionally, during the contraction phase, FoxO1 represses the expression of effector molecules such as granzyme B and facilitates effector-to-memory transition and functional maturation of memory T cells. Taken together, these findings suggest a non-redundant stage-specific role for FoxO1 in the transcriptional regulation of effector-to-memory transition and maintenance of T-cell memory.

How environment alters immunity: comparing immune systems of children from low- and high-income countries

Wagar, L.E.¹, Bolen, C.R.¹, Sigal, N.², Haque, R.³, Parsonnet, J.⁴, Petri Jr, W.A.⁵, Davis, M.M.^{1,2,6}

¹Stanford University, Department of Microbiology and Immunology, Stanford, United States, ²Stanford University, Institute for Immunity, Transplantation and Infection, Stanford, United States, ³International Center for Diarrhoeal Disease Research, Department of Enteric and Respiratory Infections, Dhaka, Bangladesh, ⁴Stanford University, Department of Medicine, Division of Infectious Diseases and Geographic Medicine, Stanford, United States, ⁵University of Virginia, Department of Microbiology, Immunology and Cancer Biology, Charlottesville, United States, ⁶Howard Hughes Medical Institute, Stanford, United States

The first five years of a child's life are a period of both rapid immune development and increased risk of morbidity and mortality due to infectious etiologies. Lifelong health depends on successful tuning of responses against a wide variety of pathogens and innocuous environmental stimuli encountered during this time. However, relatively little is currently known about the environmental effects on the development of the pediatric immune system. We aimed to understand how a high pathogen burden early in life could alter immune responses and the development of lymphocyte memory. To this end, we performed a high dimensional, 49-parameter mass cytometry (CyTOF) analysis to deeply phenotype unstimulated and ex-vivo stimulated PBMCs from children under five years old from Dhaka, Bangladesh and the San Francisco Bay Area, USA. We find that very early in life (less than one year old), Bangladeshi and American children's lymphocytes are phenotypically and functionally very similar. However, beginning at one year, there is considerable variation in the ability of Bangladeshi children's T, B, and NK cells to respond to restimulation, with many children producing poor pro-inflammatory cytokine responses. We also find that T cell differentiation and cytokine responses within the Bangladeshi cohort correlate with very early CMV infection and recurrent diarrheal illness early in life. These data suggest that early environmental exposure can have a substantial impact on pediatric immune development, and that this factor should be considered when implementing immunization and health strategies in low-income countries.

Local boosting with 4-1BBL induces long-lived lung parenchymal and circulating memory populations that protect against influenza infection

Zhou, A.C., Wagar, L.E., Wortzman, M.E., Watts, T.H.

University of Toronto, Immunology, Toronto, Canada

CD8 T cell immunity against conserved internal viral proteins can confer heterotypic protection against influenza infection when antibody responses are lost due to viral mutations. However, even the induction of flu-specific T cell memory by live infection is transient, particularly in the lung, and immune senescence has been observed with age. To induce long-lived protective cellular immunity, we stimulated the TNFR-family

member 4-1BB in the airways to boost secondary CD8 T cell responses in a prime-boost immunization regimen. Mice were infected with influenza A/HK-X31 and boosted intranasally one-month later with replication-deficient adenovirus encoding influenza nucleoprotein (NP) alone (Ad-NP) or NP with 4-1BBL (Ad-NP-4-1BBL). Local boosting with Ad-NP-4-1BBL induced remarkably long-lived polyfunctional NP-specific CD8 T cell memory populations both within the lung parenchyma and the systemic circulation. Mixed bone marrow chimeras showed this effect to be CD8 T cell intrinsic through the 4-1BB-4-1BBL pathway. Ad-NP-4-1BBL protected mice from lethal heterotypic flu challenge for 9-11 months post-boost at a dose where Ad-NP had minimal efficacy. This may be due to local lung-parenchymal CD103⁺CD69⁺ and CD103⁺CD69⁺ memory populations that persisted for months after Ad-NP-4-1BBL-boost, but not after Ad-NP where parenchymal memory cells were undetectable after 60 days. In addition, Ad-NP-4-1BBL induced a long-lived effector-like circulating CD62L-TCF-1^{lo}T-bet^{hi}Eomes^{lo} memory population that exhibited high IL-7R expression, which might contribute to the longevity of the response. Further investigation of these long-lived tissue and circulating effector memory populations can inform vaccine design and identify early biomarkers of an effective boost.

Long-lived resident CD4⁺ Th2 memory cells cause allergen-induced exacerbations of allergic asthma

Kazemi, S., Bošnjak, B., Altenburger, L.M., Mokrović, G., Epstein, M.M. Medical University of Vienna, Department of Dermatology, DIAID, Experimental Allergy Lab., Vienna, Austria

Allergic asthma is a chronic disease characterized by lung inflammation and allergen-induced exacerbations. Using a mouse model that mimics the relapsing-remitting nature of allergic asthma, we discovered that long-term Th2 memory CD4⁺ T cells reside in the lungs of mice recovered from the initiation of disease. They are found in long-lived lung inflammatory infiltrates for the entire lifetime of the mouse and immediately respond to secondary allergen challenge causing the features of allergic asthma. To further characterize recovered mice, we administered anti-CD4 (GK1.5) antibodies to *in vivo* deplete CD4⁺ T cells with the aim of abrogating allergen-induced disease relapse. After depletion and following administration of a fluorescence-labeled anti-CD4 (RM4-4), we found a population of 'protected' cells located within lung inflammatory infiltrates that resisted depletion and were allergen-specific Th2 memory cells. Furthermore, the protected cells resisted FTY720 treatment, expanded within lung infiltrates upon allergen rechallenge and were responsible for relapses of allergic asthma up to 636 days following disease initiation. Taken together, our data reveal a crucial pathogenic population of long-lived resident Th2 memory cells that cause allergen-induced asthma relapses, explain why most patients with severe allergic asthma do not respond to anti-CD4 treatment, and provide an important target for therapeutic intervention.

Unraveling the dynamics of fate in emergency haematopoiesis using cellular barcoding

Lin, D., Gao, J., Hodgkin, P., Naik, S. WEHI, Melbourne, Australia

Recent single cell tracking studies demonstrate a great deal of fate heterogeneity within the haematopoietic stem and progenitor cell population under steady-state conditions. However, the regulatory mechanisms of single cell fate during emergency conditions such as infection or cytokine exposure (where specific cell types increase in number) are largely unknown. This can theoretically occur either through greater clonal expansion of pre-existing progenitors, and/or emergency recruitment of progenitors. The latter might occur at the expense of other lineages through 'lineage diversion' or via recruitment of otherwise dormant progenitors.

To understand which of these scenarios accounts for fate's highlight the intricacies of how individual progenitors modify their behavior during demand-adapted haematopoiesis.

3253

Increased Src kinase activity leads to chronic obstructive pulmonary disease (COPD) and lung cancer

Lau, M.¹, Tsantikos, E.¹, Maxwell, M.¹, Duan, E.², Ernst, M.³, Hibbs, M.⁴ ¹Monash University, Immunology, Melbourne, Australia, ²La Trobe University, Melbourne, Australia, ³Olivia Newton-John Cancer Research Institute, Melbourne, Australia, ⁴Monash University, Melbourne, Australia

Members of the Src family of kinases especially Hck, Lyn and Fgr, which are highly expressed in myeloid cells, are known for their roles in innate immunity. Increased Lyn and Hck activity elevates the magnitude of a classical innate immune response elicited by LPS. However, inappropriate activity by Src kinases can result in other severe consequences. Specifically in the lung, the increase of Hck activity in Hck^{F/F} mice results in spontaneous lung inflammation and multiple phenotypes resembling COPD. Increased Lyn activity in Lyn^{up/up} mice not only causes COPD traits but also increases lung cancer susceptibility. Lung inflammation in Lyn^{up/up} mice was found to be driven by the lung epithelium. Although not considered an immune cell, epithelial cells are especially important in lung immunity against infection and injury. Further characterisation showed early sign of epithelial to mesenchymal cell transition and upregulation of EGF-receptor expression in the lung, providing a mechanism for cancer progression. The pathways that predispose COPD patients to lung cancer is still a mystery and our study has uncovered a possible underlying mechanism. By contrast, lung inflammation and COPD traits in Hck^{F/F} mice were immune cells driven. However, depleting neutrophils alone resolved airspace enlargement but not mucus cell metaplasia. This suggests that different traits of COPD are contributed by different processes of the multi-faceted lung inflammation in Hck^{F/F} mice. As the roles of Src kinases in COPD development is only recently appreciated, our unique mouse models has allow

better understanding of this emerging new signaling networks that drives COPD.

Interleukin-3 amplifies acute inflammation and is a potential therapeutic target in sepsis

Weber, G.F.^{1,2}, Chousterman, B.G.², He, S.², Fenn, A.M.², Nairz, M.², Anzai, A.², Brenner, T.³, Uhle, F.³, Iwamoto, Y.², Robbins, C.S.², Noiret, L.², Maier, S.L.⁴, Zönnchen, T.⁴, Rahbari, N.N.⁴, Schölch, S.⁴, Klotasche-Von Ameln, A.⁵, Chavakis, T.⁵, Weitz, J.⁴, Hofer, S.³, Weigand, M.A.³, Nahrendorf, M.², Weissleder, R.², Swirski, F.K.²

¹Universitätsklinikum Erlangen, FAU Erlangen-Nürnberg, Department of Surgery, Erlangen, Germany, ²Massachusetts General Hospital/Harvard Medical School, Center for Systems Biology, Boston, United States, ³Universitätsklinikum Heidelberg, Ruprecht-Karls-Universität Heidelberg, Department of Anaesthesiology, Heidelberg, Germany, ⁴Universitätsklinikum Dresden, Technische Universität Dresden, Department of Surgery, Dresden, Germany, ⁵Universitätsklinikum Dresden, Technische Universität Dresden, Department of Clinical Pathochemistry, Dresden, Germany

Purpose: Sepsis is a frequently fatal condition characterized by an uncontrolled host reaction to microbial infection claiming millions of lives world wide every year. In the initial, inflammatory phase, the immune system overproduces cytokine-secreting leukocytes that can cause organ damage and death. Recent clinical trials targeting inflammatory mediators have failed, reflecting an urgent need for a better fundamental understanding of sepsis' pathophysiology.

Methods: In a translational approach we subjected IL-3^{-/-} and wild type (wt) mice to Cecal Ligation and Puncture (CLP), a mouse model of experimental sepsis. After extensive *in vivo* and *ex vivo* phenotyping we enumerated the emergency myelopoiesis using *in vivo* adoptive transfer and *in vitro* experiments. We identified the source of interleukin (IL)-3 using flow cytometric, RT-PCR and immunofluorescence analysis. Finally, we determined the importance of Interleukin-3 in human sepsis in an independent retrospective and prospective clinical trial.

Results: Here we show that IL-3 is an essential inducer of inflammation in sepsis. We show that innate response activator (IRA) B cell produced IL-3 amplifies myelopoiesis of Ly-6C^{high} monocytes and neutrophils, and potentiates the cytokine storm in sepsis. Compared to IL-3^{-/-} mice, wt animals develop multi-organ damage and succumb to infection more rapidly and in larger numbers. In patients with sepsis, high plasma IL-3 levels associate with high mortality even after adjusting for prognostic indicators.

Conclusions: Altogether, this study enriches our understanding of immune activation, and identifies IL-3 as an orchestrator of emergency hematopoiesis and potential therapeutic target for the treatment of sepsis.

SMG1 is a regulator of toll-like receptor responses

James, A.¹, Luff, J.², Ho, U.³, Quek, H.², Lavin, M.², Roberts, T.^{1,4}

¹Western Sydney University, Ingham Institute for Applied Medical Research, Sydney, Australia, ²The University of Queensland, Centre for Clinical Research, Brisbane, Australia, ³QIMR Berghofer Medical Research Institute, Brisbane, Australia, ⁴Western Sydney University, Molecular Medicine Research Group, Sydney, Australia

Cells can stimulate innate immune responses by recognising the presence of conserved components of bacteria or viruses such as lipopolysaccharide, double-stranded RNA or unmethylated DNA. A key family involved in recognition of these molecules is the toll-like receptors (TLR). Activation of TLRs leads to a pro-inflammatory response characterised by activation of cell signalling cascades and cytokine production. Here we have identified the protein kinase Suppressor of Morphogenesis in Genitalia 1 (SMG1) as a regulator of TLR responses. SMG1 is a member of the PI3-Kinase like kinase family and has known roles in post-transcriptional regulation of gene expression and in DNA damage response. SMG1 has also been identified as a tumour suppressor potentially due to regulation of inflammatory pathways. SMG1 regulates both cellular signalling in response to TLR activation and also RNA metabolism. Loss of SMG1 has no effect on MAP kinases activation but enhanced NF- κ B dependent gene expression. Down-regulation of SMG1 also prevented regulation by nonsense mediated decay during an inflammatory response. Further SMG1 loss also affected feedback signalling via Type I interferon receptors and the subsequent expression of interferon stimulated genes.

2000

GM-CSF-induced expansion of phagocytes is sufficient to trigger demyelination and neurological deficits

Spath, S.¹, Komuczki, J.¹, Hermann, M.², Pelczar, P.^{2,3}, Schreiner, B.¹, Becher, B.¹

¹University of Zurich, Institute of Experimental Immunology, Zurich, Switzerland, ²University of Zurich, Institute of Laboratory Animal Science, Zurich, Switzerland, ³University of Basel, Center for Transgenic Models, Basel, Switzerland

Elevated frequencies of GM-CSF-producing helper T (Th) cells are consistently found in multiple sclerosis (MS) patients and GM-CSF expression is a non-redundant feature of pathogenic Th cells in preclinical models of MS. GM-CSF activates an inflammatory signature in monocytes, and their progeny are the most abundant cellular infiltrate in acute MS lesions. To model deregulated GM-CSF levels, we generated a transgenic mouse line allowing the induction of GM-CSF expression in mature, peripheral Th cells. This antigen-independent GM-CSF release induced severe neurological deficits with almost 100% penetrance, accompanied by the infiltration of inflammatory monocyte-derived phagocytes into the brain stem and spinal cord. These tissue-invading phagocytes contacted neuronal cell bodies and nerve fibers, produced reactive oxygen species (ROS) and caused demyelination. We propose that the CNS is particularly vulnerable to the infiltration of inflammatory phagocytes driven by deregulated GM-CSF production.

3066 HGK/MAP4K4 deficiency induces TRAF2 stabilization and Th17 differentiation leading to T-cell-mediated type 2 diabetes

Chuang, H.-C., Tan, T.-H.

National Health Research Institutes, Zhunan, Taiwan, Republic of China

Proinflammatory cytokines play important roles in insulin resistance. Here we report that T-cell-specific conditional HGK (MAP4K4) knockout (T-HGK cKO) mice developed systemic inflammation and insulin resistance, which was ameliorated by either IL-6 or IL-17 neutralization. HGK directly phosphorylated TRAF2 at Ser-35, leading to lysosomal degradation of TRAF2 and subsequent inhibition of IL-6 production. HGK kinase activity was decreased and TRAF2 protein levels were increased under TCR signaling, suggesting that HGK maintains a resting state of T cells. Thus, HGK knockout T cells constitutively displayed overexpression of TRAF2 and overproduction of IL-6.

IL-6-overproducing HGK knockout T cells were attracted to adipose tissue by the CCL20-CCR6 axis; the accumulation of HGK knockout T cells in adipose tissue was blocked by CCR6 knockout. In adipose tissue, IL-6 secreted from HGK knockout T cells enhanced the levels of the adipokine leptin. The data derived from T-cell-specific leptin receptor/HGK double knockout mice or IL-6 KO/HGK cKO mice demonstrated that IL-6-overproducing HGK knockout T cells further differentiated into Th17 cells by a synergistic effect of leptin and IL-6. Adoptive transfer experiments further showed that these IL-6/IL-17 double-positive T cells were pathogenic cells for insulin resistance. Clinical samples from type 2 diabetes (T2D) patients were used to study the clinical relevance. Notably, HGK levels fell and IL-6 levels increased in T cells from T2D patients. The clinical significance of HGK-deficient T cells will be presented in the meeting. Taken together, HGK plays important roles in the generation of adipose-tissue Th17 cells and the pathogenesis of T-cell-mediated T2D.

3686 Matrix Metalloproteinase-7 increases IL-8 release from primary lung fibroblasts derived from patients with/without chronic lung transplant rejection

Jaffar, J.^{1,2}, Symons, K.¹, Phan, T.^{1,2}, O'Hehir, R.^{1,2}, Glaspole, I.¹, Westall, G.^{1,2}

¹Monash University, Alfred Hospital, Allergy, Immunology and Respiratory Medicine, Melbourne, Australia, ²Monash University, Immunology and Pathology, Melbourne, Australia

Fibroblasts are the main producers of extracellular matrix (ECM) in the body and when dysregulated, turn normal wound healing into fibrosis, as seen in chronic graft rejection. In lung transplant patients with chronic graft rejection, pro-inflammatory interleukin (IL)-8 cytokine levels are elevated in bronchoalveolar lavage (BAL) and coincide with fibrosis. Matrix Metalloproteinase (MMP)-7 is an ECM degrading enzyme which has been shown to be elevated in fibrotic lung disease. However, its effect on lung fibroblasts is unknown. Primary lung fibroblasts from patients with and without

chronic rejection were stimulated with MMP7 with/without the pro-fibrotic cytokine transforming growth factor (TGF)- β 1. Expression of MMP7/IL-8 in blood, BAL, lung tissue, and fibroblasts was measured in healthy lungs and from patients undergoing transplantation for graft rejection. Transplant patients were followed post operation and repeat blood and BAL collection was performed at 3, 6, 12 months.

MMP7 increased IL-8 release into culture supernatant by lung fibroblasts at 72 hours post stimulation. MMP7 augmented TGF β 1-induced activation of fibroblasts as measured by α -smooth muscle actin production. MMP7 was detected in lung tissue and mainly colocalized with epithelial cells.

IL-8 is a major chemotactic factor for neutrophils, which hone to sites of wound healing in the lung. MMP7 is upregulated quickly after injury by epithelial cells. Patients with idiopathic pulmonary fibrosis, a lethally progressive disease, have elevated IL-8 and MMP7 levels. This is the first study to show that MMP7 may play a role in chronic lung rejection driven by increased IL-8 production by lung fibroblasts.

1014 Altered response of macrophages to an inflammatory stimulus in an allergic environment

Herbert, C., Chia, N., Garthwaite, L., Kumar, R.K.

UNSW Australia, Inflammation and Infection Research, School of Medical Sciences, Sydney, Australia

Exacerbations of asthma are associated with the production of interleukin-33 (IL-33) by airway epithelial cells, which activates many immune cells, including macrophages. The presence in an asthmatic airway of T_H2 cytokines, which are strongly associated with allergy, may contribute to the exaggerated airway inflammation. We hypothesised that the production of pro-inflammatory cytokines by IL-33-stimulated macrophages would be enhanced in an allergic cytokine environment, and that drugs which promote the resolution of inflammation, including resolvin E1 (RvE1), would suppress this enhanced response. Further, we hypothesised that these enhanced responses would be associated with altered expression of regulatory microRNAs (miRNAs). RAW264.7 cells were cultured with T_H2 cytokines (IL-4/IL-13) for 48 hrs, then stimulated with IL-33 for 4 hrs. In other experiments, cells were treated with RvE1 concurrently with IL-33. Pro-inflammatory mediators were assessed using quantitative real-time PCR (RT-PCR). Expression of miRNAs was explored using microarray analysis, RT-PCR and miRNA-mRNA prediction databases. In cells pre-treated with IL-4 and IL-13, expression of mRNA for *Ccl3*, *Ccl5*, *Ccl17*, *Ccl24* and *Il1b* was significantly elevated following IL-33 stimulation. RvE1 suppressed the enhanced production of *Ccl3*, *Ccl5*, *Ccl24* and *Il1b*. There was up-regulation of miR-155-5p and down-regulation of miR-106b-3p in response to T_H2 cytokines and IL-33 stimulation; these miRNAs are predicted to regulate aspects of allergic inflammation. We conclude that macrophages may contribute to the exaggerated airway inflammation in exacerbations of allergic asthma, and that RvE1 has potential as a therapeutic agent that targets macrophages. The mechanisms which regulate inflammatory cytokine production in asthma warrant further investigation.

An alternatively spliced IL-15 isoform modulates cell signaling and promotes skin lesions in herpes simplex virus-1 zosteriform mouse model

Ku, C.-C., Chang, Y.-H., Lin, Y.-J., Chien, Y.

National Taiwan University, Taipei, Taiwan, Republic of China

Interleukine15 (IL-15) is the member of IL-2 family cytokines, signaling through the common γ chain (γ_c) and the shared IL-2 receptor β (IL-2/IL-15R β) to activate Jak3/Stat5, Ras/MAPK and PI3K/Akt pathways. While IL-15 is best known to support memory CD8⁺ T cells and NK cells, our previous study demonstrated novel functions of an alternatively spliced IL-15 isoform that has a partial deletion in exon 7 of the IL-15 gene (IL-15 Δ E7). IL-15 Δ E7 failed to activate phosphorylation of STAT5, reduced the level of IKK β phosphorylation and delayed the activation of JNK in *in vitro* experiments. These results show that IL-15 Δ E7 induces less optimal activation in treated cells. Ectopic expression of IL-15 Δ E7 in C57/BL6 wild type (WT) mouse skin profoundly blocked neutrophil infiltration to inflamed skin induced by abrasion, sodium dodecyl sulfate or imiquimod treatment, suggesting a regulatory role of IL-15 Δ E7 in mediating proinflammatory response. Furthermore, infection of IL-15 Δ E7 ectopically expressed mouse skin with HSV-1 resulted in a prolonged and earlier re-emerged zosteriform rash compared with mock expressed WT mice. While HSV-1 significantly induced expression of genes that encode for neutrophils recruiting (*Cxcl1*, *Cxcl2*, *Cxcl3* and *Cxcl5*), macrophages recruiting (*Ccl2*) chemokines, proinflammatory cytokines (*Il6*, *Il1b*) and HSV-1 induced T cell activation factor (*Tnfsf14*), they were all suppressed in HSV-1 infected IL-15 Δ E7-expressed skin. These results suggest that IL-15 Δ E7 modulates immune cell chemotaxis and anti-HSV-1 immunity in skin and affects reactivation of HSV-1 from the innervating neurons. The naturally occurring IL-15 Δ E7 serves as a potential therapeutic agent for treating recurrent cutaneous HSV-1 infection and inflammatory diseases.

490

A new Toll-like receptor adaptor protein that provides specificity to inflammatory cytokine production from macrophages

Luo, L.¹, Bokil, N.¹, Lansdaal, N.¹, Wall, A.¹, Marceline, F.¹, Guo, Z.¹, Alexandrov, K.¹, Ross, I.¹, Hibbs, M.², Stow, J.¹, Sweet, M.¹

¹Institute for Molecular Bioscience, The University of Queensland, Brisbane, Australia, ²Monash University, Department of Immunology, Melbourne, Australia

Toll-like receptors (TLRs) relay downstream pro-inflammatory signalling responses through well-characterized adaptor proteins that contain Toll/Interleukin-1 receptor (TIR) domains. However, many cell types express TLRs and TIR-containing adaptor proteins, and the molecular mechanisms that enable heightened and selective TLR-inducible inflammatory responses in innate immune cells are not well understood. Herein, we describe a novel member of the transmembrane adaptor protein (TRAP) family, which is exclusively expressed by macrophages, dendritic cells and B cells. Using recombinant proteins, we show

that this non-TIR adaptor protein directly interacts with the TLR4 TIR domain. In macrophages, the interaction between this cell-surface adaptor and TLR4 is agonist (lipopolysaccharide, LPS)-induced. Using both gain- and loss-of-function approaches in primary macrophages, we demonstrate that the adaptor is essential for LPS-inducible IL-6 and IL-12 production, whereas this pathway does not regulate the production of other TLR-inducible inflammatory or regulatory cytokines. Moreover, the adaptor does not control TNF-inducible IL-6 and IL-12 production, thus demonstrating its selective role in TLR signalling. Mutations in the adaptor that abolish the interaction with TLR4 also abrogate LPS-inducible cytokine production. Mechanistically, the adaptor recruits the Lyn tyrosine kinase to enable agonist-induced TLR4 tyrosine phosphorylation, and subsequent pro-inflammatory signalling responses. We thus define a new pathway that provides exquisite specificity to inflammatory cytokine outputs downstream of TLRs in innate immune cells. Given its specific cytokine targets (IL-6 and IL-12), this pathway is likely to be critical in shaping adaptive immune responses.

Loss of DNAM-1 ligand expression by acute myeloid leukemia cells renders them resistant to NK cell killing

Kearney, C., Ramsbottom, K., Voskoboinik, I., Darcy, P., Oliaro, J.
The Peter MacCallum Cancer Centre, Melbourne, Australia

Acute myeloid leukemia (AML) is associated with poor natural killer (NK) cell function through aberrant expression of NK cell activating receptors and their ligands on tumor cells. These alterations are thought to promote formation of inhibitory NK-target cell synapses, in which killer cell degranulation is attenuated. Allogeneic stem cell transplantation can be effective in treating AML, through restoration of NK cell lytic activity. Similarly, agents that augment NK cell activating signals within the immunological synapse may provide some therapeutic benefit. However, the receptor-ligand interactions that critically dictate NK cell function in AML remain undefined. Here we demonstrate that CD112/CD155 expression is required for DNAM-1-dependent killing of AML cells. Indeed, the low, or absent, expression of CD112/CD155 on multiple AML cell lines resulted in failure to stimulate optimal NK cell function. Importantly, isolated clones with low CD112/155 expression were resistant to NK cell killing while those expressing abundant levels of CD112/155 were highly susceptible. Attenuated NK cell killing in the absence of CD112/CD155 originated from decreased NK-target cell conjugation. Furthermore, we reveal by time-lapse microscopy, a significant increase in NK cell 'failed killing' in the absence of DNAM-1 ligands. Consequently, NK cells preferentially lysed ligand-expressing cells within heterogeneous populations, driving clonal selection of CD112/CD155 negative blasts upon NK cell attack. Taken together, we identify reduced CD155 expression as a major NK cell escape mechanism in AML and an opportunity for targeted immunotherapy.

Killer cell immunoglobulin-like receptor 3DL1 polymorphism defines distinct hierarchies of human leukocyte antigen recognition

Saunders, P.¹, Pymm, P.², Rossjohn, J.^{2,3}, Brooks, A.¹, Vivian, J.^{2,3}

¹Melbourne University, Melbourne, Australia, ²Monash University, Biochemistry, Clayton, Australia, ³ARC Centre of Excellence in Advanced Molecular Imaging, Monash University, Clayton, Australia

The interaction between killer cell Immunoglobulin-like Receptor 3DL1 (KIR3DL1) and HLA-class I molecules has been linked to NK cell control of viral infections and malignancy. However due to the vast polymorphism of the genes encoding both its HLA-I ligands and the receptor itself, a mechanistic

understanding of how these receptor/ligand interactions impact disease outcomes remains unclear. KIR3DL1 tetramers representative of the two main inhibitory KIR3DL1 lineages (-*005 and -*015) together with an interlineage recombinant (*001) were screened for reactivity against a comprehensive panel of HLA-I molecules. This revealed distinct hierarchies of preferred HLA-I ligands for each KIR3DL1 allotype, with KIR3DL1*005 recognising a wider array of HLA-I ligands than either the KIR3DL1*015 or -*001. These differences in binding were also reflected in functional assays utilising NK cell clones expressing specific KIR3DL1 allotypes. Intriguingly, while the polymorphic differences between KIR3DL1*001, *005 and *015 were remote from the KIR3DL1-HLA-I interface, the structures of the three KIR3DL1-HLA-I complexes showed that the broader specificity of KIR3DL1*005 correlated with an altered juxtapositioning of the D1-D2 domains and increased mobility within the ligand binding site, conferring a greater tolerance for disparate ligands. Collectively, we provide a molecular basis underpinning the impact of KIR3DL1 polymorphism on HLA-I recognition.

Plundering the non-classical MHC to find buried treasure

Andrews, D.¹, Nguyen, A.¹, Goodall, K.¹, Berry, R.^{2,3}, Brooks, A.⁴, Rossjohn, J.^{2,3,5}, Sullivan, L.⁴

¹Monash University, Central Clinical School, Immunology and Pathology, Melbourne, Australia, ²Monash University, Infection and Immunity Program and Department of Biochemistry and Molecular Biology, Biomedicine Discovery Institute, Clayton, Australia, ³Monash University, ARC Centre of Excellence in Advanced Molecular Imaging, Clayton, Australia, ⁴University of Melbourne, Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia, ⁵Cardiff University School of Medicine, Institute of Infection and Immunity, Cardiff, United Kingdom

Recognition is central to the development and activation of immune cells and the Major Histocompatibility Complex (MHC) acts as a gatekeeper for these processes. Given the central role of the MHC, understanding the mechanisms by which it interacts with immune cells is key to our knowledge of immunity. One population of cells heavily dependent upon the MHC is Natural Killer (NK) cells. As a member of the frontline immune response, these cells can respond rapidly to pathogens by killing infected targets, with early experiments leading to the assumption that this was their only role in immunity. However, we now understand that the signals controlling NK cell activation are highly complex and that their role in immunity exceeds killing. The mouse non-classical MHC encodes genes that exhibit site-specific expression or unique presentation capabilities and we are exploring these molecules as a means to identify new pathways of NK cell regulation. Among these molecules our studies of H2-Q10 have identified 2 new immune processes including site-specific regulation of NK cell development and interaction with the CD8αα homodimer. Given the emerging role of NK cells in clinically relevant situations such as transplant rejection and viral infection, understanding how NK cells function is of paramount importance to allow us to harness them more effectively in the future.

11 Intratumoral natural killer (NK) cells possess inhibitory phenotype and suppress Th1 effector function

Paul, S., Lal, G.

National Centre for Cell Science, Infection and Immunity, Pune, India

Spontaneous cytolytic function of peripheral NK cells control tumor growth and metastasis. NK cells were used as adoptive cellular therapy to control tumor growth, but clinical trials did not show very encouraging results. The cellular and molecular mechanism that controls the function of intratumoral NK cells is not well defined.

B16F10 melanoma cells (1×10^6 cells/mouse) were subcutaneously injected into C57BL/6 mice. At day 5, CD11b⁺CD27⁺CD3⁺NK1.1⁺ NK cells were selectively recruited into the tumor microenvironment, and these NK cells showed increased CD62L expression and reduced proliferation. Intratumoral NK cells showed significantly reduced expression of activating receptors (NKG2D, Ly49D and Ly49H), cytokine receptors (IL-21R, IL-6R α , IFN- γ R, CD122 and CD25), perforin, IFN- γ and GM-CSF; significantly increased IL-10 and inhibitory receptors (NKG2A and Ly49A), and reduced cytolytic function compared to splenic population. Depletion of NK cells with intravenous injection of anti-NK1.1 mAb reduced the frequency of effector Th1 and Th17 cells in spleen, lymph nodes and tumor. Purified NK cells co-cultured with naive CD4 T cells increased the differentiation into Th1 lineage, and this was dependent on NK cell produced IFN- γ . Since, intratumoral NK cells showed reduced activating receptor, we treated NK cell and CD4 T cell co-culture with anti-NKG2D, anti-Ly49D or anti-Ly49H antibody, and observed enhanced differentiation of Th1 cells.

Inflamed tumor microenvironment selectively recruits a specific subset of NK cells, and regulates the differentiation of effector Th1 cells. Understanding cellular and molecular mechanism of intratumoral NK cell function will help design better anti-tumor therapeutic strategies.

949 Idelalisib promotes anti CD20-mediated ADCC by inhibiting immunosuppressive ROS production in monocytes

Akhiani, A.A.¹, Hallner, A.¹, Werlenius, O.², Aurelius, J.¹, Martner, A.¹, Hellstrand, K.¹, Thorén, F.B.¹

¹University of Gothenburg, Sahlgrenska Cancer Center, Gothenburg, Sweden, ²University of Gothenburg, Sahlgrenska Cancer Center, Department of Medicine, Gothenburg, Sweden

Leukemic cells from patients with chronic lymphocytic leukemia (CLL) display increased phosphatidylinositol 3-kinase (PI3K) activity. The PI3K- δ selective inhibitor idelalisib, alone or in conjunction with anti-CD20 antibodies, was recently approved in the treatment of CLL. Idelalisib is assumed to act by promoting apoptosis in CLL cells, but alternative or supplementary mechanisms are conceivable. Natural killer (NK) cells are pivotal effector cells in the ADCC reaction against anti-CD20-coated target cells, including CLL cells. NK cells are highly susceptible to inhibition exerted by reactive oxygen species (ROS), which are produced by monocytes and other myeloid cells. For the present study, we aimed to determine the impact of PI3K inhibition on

ROS production in human peripheral blood monocytes. It was observed that therapeutic antibodies against CD20 (rituximab and ofatumumab) induced substantial ROS production from monocytes, which in turn triggered extensive cell death in co-cultured NK cells. Idelalisib, at low concentration (0.1 μ M), efficiently reduced the anti-CD20-induced ROS production and prevented NK cell apoptosis (13 ± 2.7 vs $83 \pm 2.5\%$, Mean \pm SEM, MO:NK1:2 ratio). Similar NK cell-protective effects were observed using the pan-PI3K inhibitor Ly294002, inhibitors of ROS formation and reagents neutralizing extracellular ROS. In addition, NK cells were co-cultured overnight with monocytes and assayed for anti-CD20-mediated ADCC against B-lymphoblastoid cells. In these experiments, monocytes strongly inhibited ADCC by producing ROS. Idelalisib efficiently restored anti-CD20-mediated ADCC and NK cell degranulation against lymphoblastoid cells. Our results suggest that idelalisib, by reducing formation of immunosuppressive ROS, improves the NK cell capacity to exert ADCC, which may contribute to its anti-leukemic properties.

Preparation of TERT-modified human NK cells

Streltsova, M.A., Erokhina, S.A., Kanevskiy, L.M., Kovalenko, E.I. Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation

Genetic modification of NK cells with TERT may significantly increase the efficiency of generation of these cells for the anti-cancer treatment. Preliminary choice of NK cells with desired functional properties may provide basis for development of personalized adoptive immunotherapy. The goal of this work is the transduction of telomerase gene into NK cells for optimization of their propagation for immunotherapeutic purposes. Retroviral vector system with TERT was selected. Transfection was performed using calcium phosphate-based method. For transduction procedure we used 24-well plates pretreated with RetroNectin solution. TRAP assay was used for qualitative detection of telomerase activity in the cells. Transduction of tumor cell lines HEK293T and Jurkat were performed to validate the models. Cell fractions expressing reporter protein were 20-30% and 12-25% for HEK293T and Jurkat cells, respectively. Transduced cells showed a higher level of telomerase activity than non-transduced ones. NK cells were isolated from peripheral mononuclear cells of healthy volunteers by magnetic separation. For NK cell transduction we used inhibitor of 3-phosphoinositide-dependent kinase-1 BX795. We had not been able to transduce native NK cells. However, NK cells stimulated with IL-2 and K562 cells bearing membrane-bound IL-21 were successfully transduced (30-50% of whole cell population). Effective genetic modification of NK cells with TERT will make easier an accumulation of NK cells for potential immunotherapy.

Influenza vaccine induces anti-nuclear and anti-double strand DNA IgG antibodies and their relates to levels of microbial translocation in antiretroviral-treated aviremic HIV-infected patients

Luo, Z.¹, Martin, L.¹, Kilby, J.M.¹, Liu, H.², Jin, P.², Stroncek, D.², Jiang, W.¹

¹Medical University of South Carolina, Chareleston, United States,

²National Institutes of Health, Bethesda, United States

The mechanism of autoantibody (autoAb) induction in HIV disease is unknown. In this study, blood samples from healthy controls (n = 16) and ART-treated aviremic HIV+ patients (n = 26) receiving 2013-2014 influenza vaccinations were analyzed pre-vaccination (D0), on day 7 (D7) and 14 (D14) post-vaccination. Microbial translocation was tested for LPS and total bacterial 16S rDNA by limulus amebocyte assay and qPCR respectively. ANA (OD) and anti-dsDNA (IU/ml) IgG were evaluated by ELISA. Microarray was analyzed in purified B cells on D0. Data are presented as median (IQR). Results. At baseline, there was increased plasma LPS [pg/mL, 18.0 (13.3-22.0) vs 13.4 (9.82-15.2), P=0.006] in patients. Bacterial 16S rDNA tended to be higher in patients compared with controls [copies/μL, 18.5 (9.4-25.2) vs 5.3 (0-34.7), P = 0.18]. B cells of patients exhibited increased TLR2 and 4 expression and NF-κB pathway activation by microarray. Plasma ANA on D0 and D14 were 0.31 (0.25-0.41) and 0.58 (0.31-1.29) vs 0.32 (0.23-0.40) and 0.31 (0.24-0.38); and anti-dsDNA IgG levels on D0 and D14 were 15.2 (8.06-23.7) and 20.2 (13.0-50.7) vs 15.3 (12.3-37.1) and 15.5 (13.0-36.7), in patients and controls respectively. Only patients showed significant increases of ANA and anti-dsDNA IgG post-vaccination (P < 0.001). Direct correlations between plasma LPS and ANA (r=0.48, P=0.01) and between plasma 16S rDNA and anti-dsDNA IgGs (r=0.44, P=0.04) were found only in patients. Conclusion. B cell function is not fully recovered by ART, as reflected by producing autoAbs in response to vaccinations and its correlates with levels of microbial translocation.

The role of chemokines in the natural resistance of baboons to SIV infection

Obregon-Perko, V.^{1,2}, Parodi, L.M.², Hodara, V.L.^{2,3}, Giavedoni, L.D.^{2,3}

¹University of Texas Health Science Center at San Antonio, Microbiology & Immunology, San Antonio, United States, ²Texas Biomedical Research Institute, Virology & Immunology, San Antonio, United States, ³Southwest National Primate Research Center, Texas Biomedical Research Institute, San Antonio, United States

Simian immunodeficiency viruses (SIV) naturally infect over 40 species of African non-human primates (NHP) where they usually cause a chronic non-pathogenic infection. Asian macaques, however, progress to simian AIDS when experimentally infected. Baboons, an abundant African NHP, are not naturally infected with SIV. Previous work has demonstrated that baboons are resistant to chronic SIV infection *in vivo*, but mechanisms underlying resistance remain unknown. Identifying molecules

involved in baboon natural resistance to SIV could impact the development of next-generation HIV therapies and preventions. Peripheral blood mononuclear cells (PBMC) and CD4 cells were isolated from baboon and rhesus macaque whole blood. Cells were stimulated for 48 hr and infected with SIVmac251. Flow analysis revealed that before infection, baboon and rhesus PBMC had similar levels of CD4 T cells, CD4 CCR5 T cells, surface CD4, and surface CCR5. Baboon PBMC were susceptible to SIV infection, but replication kinetics were delayed and viral loads were lower compared to rhesus PBMC. SIV infection in baboons was not altered by natural STLV co-infection, but susceptibility to infection increased with age of the cell donor. Infection of isolated baboon CD4 cells progressed faster than in baboon PBMC. Compared to rhesus, baboon PBMC produced higher levels of MIP-1α, MIP-1β, and RANTES before and during infection; RANTES levels were markedly lower in CD4 cultures. Inhibition of these chemokines in baboon PBMC resulted in higher SIV loads. These chemokines suppress HIV/SIV infection by competing for binding to CCR5 and thus may contribute to SIV resistance in baboons.

Immune response to *Mycobacterium tuberculosis* in patients with human immunodeficiency virus vertical infection

Alves, P.C.M.¹, Castelhana, M.V.¹, Macedo, V.S.¹, Arrym, M.P.¹, Mazzola, T.N.¹, Guimaraes, F.², Silva, M.T.N.³

¹University of Campinas/Faculty of Medical Sciences, Center for Investigation in Pediatrics, Campinas, Brazil, ²University of Campinas/Women's Hospital 'Prof Dr José Aristodemo Pinotti' -CAISM, Campinas, Brazil, ³University of Campinas/Faculty of Medical Sciences, Department of Pediatrics and Center for Investigation in Pediatrics, Campinas, Brazil

Background: HIV replication control by combined antiretroviral therapy (cART) reduces by 80% the chance of *Mycobacterium tuberculosis* (MTB) coinfection, but the incidence of cases in HIV patients is still higher than in healthy people. In this scenario, the aim of this study was to enlighten the cellular immune responses against mycobacterial antigens in HIV- infected patients.

Methods: Six vertically HIV-infected patients under cART and without plasma HIV-1 replication, recruited at the University of Campinas Clinical Hospital (UNICAMP, Brazil), and nine healthy controls participated in this study. *Mycobacterium bovis* (BCG) and MTB lysates and MTB recombinant ESAT-6 antigen were used to stimulate peripheral blood mononuclear cell cultures. Lymphoproliferation (measured by Percent Divided - PD, Proliferation Index - PI, and Division Index - DI) and IL-5, IL-17 and IFN-γ frequency among T cell subsets were assessed by flow cytometry.

Results: In MTB lysate-stimulated cultures, controls showed higher PD of CD3+ (p=0.006), TCR-γδ+ (p=0.034) and T CD4+CD45RO+ cells (p=0.035), PI of CD3+ cells (p=0.034), and DI of CD3+ (p=0.001), TCR-γδ+ (p=0.034), T CD4+CD45RO+ (p=0.025) and T CD8+CD45RO+ cells (p=0.05) than the patient group. In BCG lysate-stimulated cultures, there were higher PD values of CD3+ (p=0.029), TCR-γδ+ (p=0.045), T

CD4+CD45RO+ ($p=0.034$) and T CD8+CD45RO+ cells ($p=0.027$), DI of T CD8+CD45RO+ ($p=0.025$) and TCR- $\gamma\delta$ + cells ($p=0.05$), and frequency of IFN- γ +TCR- $\gamma\delta$ + cells ($p=0.05$) from controls in comparison with the patient group.

Conclusions: Even with HIV-1 control, HIV-infected patients still revealed lower T cell responses to mycobacterial antigens, which could set them at risk of HIV/TB co-infection.

HIV-1 Nef down-regulated CD1a lipid antigen presentation in immature dendritic cells through hemopoietic cell kinase (Hck) and p21-activated kinase 2 (PAK2)

Shinya, E., Shimizu, M., Owaki, A., Okura, S., Takahashi, H. Nippon Medical School, Microbiology and Immunology, Tokyo, Japan

Dendritic cells (DCs) might be a key factor in *in vivo* pathogenesis of HIV-1 infection, so that they could provide a promising strategy to control and eventually overcome the fatal infection. DCs specifically express CD1s, the non-MHC lipid antigen (Ag)-presenting molecules. Simultaneously, HIV-1 Nef down-regulates CD1 expression besides MHC in immature DCs. Moreover, CD1d-restricted CD4⁺ NKT cells are infected by HIV-1, reducing the number of these cells in HIV-1-infected individuals. To understand the exact role of DCs and CD1-mediated immune response during HIV-1 infection, Nef down-regulation of CD1a-restricted lipid/glycolipid Ag presentation in iDCs was analyzed. We demonstrated the involvement of Nef in association with hemopoietic cell kinase (Hck) and p21-activated kinase 2 (PAK2), and found that Hck, which is expressed strongly in iDCs, augmented this mutual interaction. Hck might be another therapeutic target to preserve the function of DCs in the course of HIV-1 infection, which are potential reservoirs of HIV-1 even after antiretroviral therapy.

Complement-opsonized HIV-1 overcomes restriction in dendritic cells

Posch, W.¹, Steger, M.¹, Moris, A.², Diaz-Griffero, F.³, Lass-Flörl, C.¹, Keppler, O.⁴, Wilflingseder, D.¹

¹Medical University of Innsbruck, Division of Hygiene and Medical Microbiology, Innsbruck, Austria, ²INSERM U 1135, Center for Immunology and Microbial Infections, Paris, France, ³Albert Einstein College of Medicine, Department of Microbiology and Immunology, New York, United States, ⁴University of Frankfurt, Institute of Medical Virology, Frankfurt, Germany

DCs express intrinsic cellular defense mechanisms to specifically inhibit HIV-1 replication. Thus, DCs are productively infected only at very low levels with HIV-1, and this non-permissiveness of DCs is suggested to go along with viral evasion. We now illustrate that complement-opsonized HIV-1 (HIV-C) efficiently bypasses SAMHD1 restriction and productively infects DCs including BDCA-1 DCs. Efficient DC infection by HIV-C was also observed using single-cycle HIV-C, and correlated with a remarkable elevated SAMHD1 T592 phosphorylation but not SAMHD1 degradation. If SAMHD1 phosphorylation was

blocked using a CDK2-inhibitor HIV-C-induced DC infection was also significantly abrogated. Additionally, we found a higher maturation and co-stimulatory potential, aberrant type I interferon expression and signaling as well as a stronger induction of cellular immune responses in HIV-C-treated DCs. Collectively, our data highlight a novel protective mechanism mediated by complement opsonization of HIV to effectively promote DC immune functions, which might be in the future exploited to tackle HIV infection.

Sequential dysfunction and progressive depletion of *Candida albicans*-specific CD4 T cell response in HIV-1 infection

Hu, H.¹, Liu, F.¹, Fan, X.¹, Ferguson, M.², Hou, W.³, Sun, J.¹, Soong, L.¹
¹University of Texas Medical Branch, Microbiology and Immunology, Galveston, United States, ²University of Texas Medical Branch, Division of Infectious Disease, Galveston, United States, ³Wuhan University School of Medicine, Wuhan, China

Loss of immune control over opportunistic infections can occur at different stages of HIV-1 (HIV) disease, among which mucosal candidiasis caused by the fungal pathogen *Candida albicans* (*C. albicans*) is one of the early and common manifestations in HIV-infected subjects. The underlying immunological basis is not well defined. We have previously shown that compared to cytomegalovirus (CMV)-specific CD4 cells, *C. albicans*-specific human CD4 T cells are highly permissive to HIV *in vitro*. Here, based on an antiretroviral treatment (ART) naïve, HIV infection cohort (RV21), we investigated longitudinally the impact of HIV on *C. albicans*- and CMV-specific CD4 immunity *in vivo*. We found a sequential dysfunction and preferential depletion for *C. albicans*-specific CD4 response during progressive HIV infection. Compared to Th1 (IFN- γ , MIP-1 β) functional subsets, the Th17 functional subsets (IL-17, IL-22) of *C. albicans*-specific CD4 T cells were more permissive to HIV *in vitro* and impaired earlier in HIV-infected subjects. Infection history analysis showed that *C. albicans*-specific CD4 T cells were more susceptible to HIV *in vivo*, harboring modestly but significantly higher levels of HIV DNA, than CMV-specific CD4 T cells. Longitudinal analysis of HIV-infected individuals with ongoing CD4 depletion demonstrated that *C. albicans*-specific CD4 response was preferentially and progressively depleted. Taken together, these data suggest a potential mechanism for earlier loss of immune control over mucosal candidiasis in HIV-infected patients and may provide new insights into pathogen-specific immune failure in AIDS pathogenesis.

Influence of host genetic factors on HIV in North Indian population

Mehra, N. All India Institute of Medical Sciences, National Chair, New Delhi, India

Genomic analyses of viremic controllers, elite controllers, exposed uninfected individuals, rapid and slow progressors have revealed correlates of HIV/AIDS vulnerability in a population

specific manner. We aimed to dissect the largely unknown genetic propensity to HIV infection in the North Indian population. Here we present our data about the influence of genes that regulate HIV cell entry (chemokine coreceptors like CCR5, CCR2 and their ligands like CCL3L1), as well as others that influence viral replication and dynamics, including tripartite interaction motif 5 a (TRIM5 α), apolipoprotein B mRNA-editing enzyme, catalytic polypeptide-like 3G (APOBEC), T cell/ transmembrane, immunoglobulin and mucin (TIM) family proteins as well as pro and anti inflammatory cytokines. Our major findings are i) Protective CCR5 delta 32 mutation is rare (< 1%), and CCR5 promoter variants were found associated with susceptibility and development of AIDS, ii) No association of CCR2 64I, CCL3L1 copy numbers and APOBEC3B deletion (29.5 kb) with HIV susceptibility and/or resistance, iii) Among the observed seven TIM-1 exon-4 haplotypes, significantly higher CD4 counts were observed in D3-A +ve HIV patients, iv) TRIM5 α -exon 2 variant 43Tyr-allele and haplotypes carrying this allele were associated with resistance to HIV infection and v) Significantly higher allelic frequencies of IL-1 α -889 T and IL-4 -1098 T were observed in HIV patients, while IL-1 α -889 CC, IL-4 -1098 GG and IL-6 nt565 AA genotypes were observed significantly lower as compared healthy uninfected controls. The study represents distribution of immunogenetic variants and their influence on HIV/AIDS outcome in North Indian population.

Broad $\alpha\beta$ TCR cross-strain recognition of influenza A viruses

Quiñones-Parra, S.M.¹, Uldrich, A.P.¹, Boon, A.², Rimmelzwaan, G.³, Godfrey, D.I.¹, Rossjohn, J.⁴, Gras, S.⁴, Kedzierska, K.¹

¹University of Melbourne, Dept of Microbiology and Immunology, at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Washington University, School of Medicine, St. Louis, United States, ³Erasmus Medical Centre, Dept of Viroscience, Rotterdam, Netherlands, ⁴Monash University, Dept of Biochemistry and Molecular Biology, School of Biomedical Sciences, Melbourne, Australia

Respiratory infections caused by influenza viruses are a global health concern and persistent pandemic threat. Current antibody-based influenza vaccines are greatly undermined by the antigenic adaptation of influenza viruses. In contrast, protective CD8⁺ cytotoxic T lymphocytes (CTL) recognize more conserved antigenic determinants and thus, provide potential for broadly-protective vaccines. However, although to a less extent compared to antibody epitopes, CTL immunity can also be abrogated by selection of viral escape variants. Thus, $\alpha\beta$ TCR recognition of multiple pHLA-I influenza variants may circumvent immune escape and consequently broaden protective CTL immunity against antigenically distinct and newly-emerged influenza viruses. However, the molecular bases of $\alpha\beta$ TCR cross-strain recognition remain poorly defined. Here, we describe $\alpha\beta$ TCR signatures displaying a spectrum of cross-reactivity towards the hypervariable HLA-B*3501-NP₄₁₈ influenza epitope. Probing against twelve NP₄₁₈ peptide variants occurring in nature, we revealed a remarkable extent

of functional cross-reactivity, with each $\alpha\beta$ TCR recognizing between 5 and 9 peptides presented by HLA-B*3501. Functional avidity analysis showed that fine specificity is determined by the $\alpha\beta$ TCR clonotype and that the cross-reactive capacity comes at the expense of compromising pHLA-I functional avidity. Furthermore, alanine scan experiments showed that a solvent exposed Asp at p5 and an Iso at p7 in the peptide, act as a major pivots for $\alpha\beta$ TCR recognition. Our study illustrates an unrecognized breadth in viral pHLA-I recognition by single $\alpha\beta$ TCRs with the potential to provide broad CTL immunity against multiple IAVs and presents insights into the molecular basis of $\alpha\beta$ TCR cross-recognition of influenza viruses.

To the bat MHC! Antigen processing and presentation during viral infection

Woon, A.¹, Wynne, J.², Dudek, N.¹, Ng, J.³, Baker, M.², Wang, L.³, Purcell, A.¹

¹Monash Biomedicine Discovery Institute, Infection and Immunity Program, Biochemistry & Molecular Biology, Clayton, Australia, ²CSIRO AAHL, Health and Biosecurity, Geelong, Australia, ³Duke-NUS Graduate Medical School, Program in Emerging Infectious Diseases, Singapore, Singapore

Bats are a major reservoir of emerging infectious diseases and harbour deadly viruses such as Ebola, SARS, MERS and Hendra virus without clinical signs of disease. Vaccines are not available against many of these viruses and a better understanding of the bat immune system could aid vaccine development.

We hypothesise that the bat adaptive immune system contributes to the ability of bats to co-exist asymptotically with viruses. One of the key adaptive immune responses is the presentation of antigens by major histocompatibility complex (MHC) class I molecules to CD8⁺ T cells. We sought to further understand antigen processing and presentation in bats by characterising the first bat MHC class I molecules using a proteomic approach.

Using LC-MS/MS, we determined that bat MHC class I molecules, like their human and mouse homologues, associate with a peptide-loading complex. Furthermore, we also characterised the first peptide repertoires of bat MHC class I molecules. These peptides ranged from 8-15 amino acid residues and motif analysis of the endogenous peptides revealed strong amino acid biases at various anchor positions. Lastly, we were able to identify Hendra virus-derived peptides from infected bat cells which also display this binding motif, suggesting these motifs may be exploited to predict epitopes for vaccine development and immunological studies.

This study is the first characterisation of bat MHC class I molecules and their respective peptide repertoires. Our results provide fundamental insights into the antigen processing and presentation pathways of bats, which ultimately can be used to understand viral control.

Innate mediators of amphibian immunity provide protection against human influenza viruses

Holthausen, D.¹, George, S.², Jacob, J.¹

¹Emory University, Atlanta, United States, ²Rajiv Gandhi Centre for Biotechnology, Thiruvananthapuram, India

Frogs and toads are incredible reservoirs of innate immune peptides. Amphibians secrete host defense peptides from their skin as a response to stress. This ancient form of innate immunity acts to protect the amphibians against microbial pathogens. The quantity and scope of secreted peptides dwarfs mammalian analogues, accounting for a considerable portion of all known host defense peptides. The non-invasive and harmless methods for frog peptide collection, along with the abundance and breadth of these peptides, makes them excellent choices for novel peptide drug therapies. Studies have shown that these peptides can effectively neutralize enveloped viruses, gram-negative and gram-positive bacteria, mycobacteria, fungi, and even cancerous or transformed cells. Because of the nature of antimicrobial peptides, often targeting the most critical and conserved aspects of a micro-organism, they may prove a vital alternative to conventional drugs plagued by pathogen resistance. Given the untapped potential of these peptides for anti-viral therapies, we assessed the antiviral activity of novel host defense peptides from the skin of the Indian fungoid frog, *Hylarana malabarica*. During our analyses, we isolated several peptides from *H. malabarica* that show anti-viral activity against human influenza viruses. Our studies indicate that these peptides from *H. malabarica* demonstrate anti-influenza activity *in vitro*, and also show potential as an *in vivo* anti-viral therapy.

1851

Effects of human papilloma virus oncoprotein E7 on antigen presentation and potential involvement of keratinocyte exosomes

Budhwani, M.¹, Jemon, K.², Ly, K.¹, Hibma, M.¹

¹University of Otago, Department of Pathology, Dunedin, New Zealand, ²University Teknologi Malaysia, Faculty of Biosciences and Medical Engineering, Johor, Malaysia

High-risk human papillomavirus (HPV) infection may lead to the development of several human cancers that cause significant mortality worldwide. HPV type 16 (HPV16) is the most common cancer-causing genotype. The HPV16 E7 oncoprotein is expressed in epidermal keratinocytes and has been implicated in evasion of host immunity. The aim of this study is to determine the regulatory effects of E7 on antigen presentation.

To test these effects, E7 or E7 cloned in reverse (E7rev), and ovalbumin (Ova) genes were delivered to mouse skin cells *in vivo*, and their expression controlled by the keratin 14 promoter, and the responses to Ova were measured. We found that co-expression of E7 in the Ova expressing cells strongly suppressed the CD8⁺ T-cell proliferative response towards Ova. We also found that E7 reduced ova uptake by skin Langerhans cells (LCs) and co-stimulatory marker expression of lymph node dendritic cells. Surprisingly, we did not observe any effect on the reduced T-cell proliferation to Ova following depletion of LCs and

langerin positive skin dermal DCs, suggesting that these cells are not involved in activation the the CD8 T cell response to Ova. Instead we found that exosome-like particles produced from E7-expressing mouse keratinocytes significantly reduced co-stimulatory marker expression on DCs, and proliferation of ova specific T-cells *in vitro*.

In conclusion, we provide evidence for E7 regulation of CD8T cell responses, and of E7-exosome mediated antigen presentation via dendritic cells. These regulatory effects may contribute to HPV evasion of the host immune response.

1984

Natural H3N2 influenza A infection in humans expands memory B cells specific for the hemagglutinin stalk domain

Tesini, B.¹, Halliley, J.¹, Ellebedy, A.², Kanagaiah, P.¹, Anderson, C.¹, Dediego, M.¹, Chaves, F.¹, Wang, J.¹, Krammer, F.³, Yang, H.¹, Zand, M.¹, Ahmed, R.², Treanor, J.¹, Topham, D.¹, Sangster, M.¹

¹University of Rochester, Rochester, United States, ²Emory University, Atlanta, United States, ³Icahn School of Medicine at Mt. Sinai, New York, United States

The B cell response to influenza infection and vaccination is profoundly influenced by the composition of an individual's memory B cell (MBC) pool. However, changes to the MBC pool induced by exposure to influenza in different forms are not well characterized. Here, we analyzed virus-specific B cell responses in 8 subjects infected with H3N2 influenza A virus (confirmed by PCR) during the 2012-13 season. Peripheral blood mononuclear cells and plasma were collected at the time of presentation with an influenza-like illness and on days 3, 10, and 28 thereafter. Hemagglutination inhibiting antibody titers against the prevalent H3N2 strain A/Victoria/361/2011 increased 2-4-fold in all subjects by day 28. Circulating IgG plasmablasts (PBs) specific for the Vic/11 H3 and the viral nucleoprotein commonly peaked on day 3. Approximately 25% of H3-specific IgG PBs bound the conserved stalk domain. IgA PBs included the same specificities, but numbers were low and variable. A wave of recently proliferated, non-antibody secreting B cells peaked on day 10. These included virus-specific cells and likely represented newly formed MBC precursors. In most subjects, H3 (head and stalk domain)- and nucleoprotein-specific IgG MBC frequencies progressively increased from days 3 to 28. Increases in virus-specific IgA MBC frequencies were smaller and variable. Overall, we demonstrate that the specificities of MBC populations expanded by natural H3N2 infection reflect the early virus-specific PB response. Importantly, this includes IgG and IgA MBCs specific for the HA stalk domain, a target of broadly neutralizing antibodies that are poorly induced by inactivated H3N2 vaccination.

2364**Suppression of dendritic cell necroptosis by pandemic influenza virus***Hartmann, B., Albrecht, R., Marjanovic, N., Sealfon, S.**Icahn School of Medicine at Mt. Sinai, New York, United States*

The public health risk of a new pandemic influenza virus (IAV) approaching the scope and mortality of the devastating 1918 strain makes it important to identify virus-host mechanisms unique to pandemic strains. Human dendritic cell infection by two different H1N1 seasonal IAV strains (1991 and 1999) induces widespread RNA degradation and programmed cell death beginning at 4 h after infection. Characteristic of necroptosis, the cell death showed nuclear condensation and fragmentation that was caspase independent and RIP3 kinase dependent. Notably, infection with the pandemic 1918 and 2009 H1N1 IAV strains did not induce dendritic cell RNA degradation and necroptosis. Furthermore, necroptosis induced in dendritic cells by polyI:C exposure was suppressed by concomitant infection with the pandemic 2009 IAV. These results indicate that infection with the pandemic viruses not only fails to induce the dendritic cell necroptosis seen with the seasonal IAV strains, but that it actively suppresses necroptosis. Virus chimera studies implicate the HA virus segment as mediating the necroptosis inhibition by the pandemic IAV strains. Necroptosis leads to the release of intracellular components which serve as danger associated molecular patterns (DAMP), making this a highly immunogenic cell death mechanism. Consistent with this view, we find that the suppression of virus-induced necroptosis by the pandemic IAV reduces T cell activation. These studies show that pandemic viruses are unique in suppressing a key immunological danger signal. The suppression of the generation of DAMPs from infected immune cells may contribute to the pathogenicity of pandemic H1N1 IAV viruses.

4464**Targeting the NLRP3 inflammasome is a viable option for the treatment of pathogenic influenza virus infection***Tate, M.¹, Ong, J.¹, Dowling, J.¹, Robertson, A.², Cooper, M.², Mansell, A.¹**¹Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Melbourne, Australia, ²The University of Queensland, Institute for Molecular Bioscience, Brisbane, Australia*

Fatal influenza A virus (IAV) infections in humans, such as those resulting from spill over of virus from birds, are associated with excessive production of pro-inflammatory cytokines and chemokines. The emergence of novel avian H7N9 IAV in humans with over 700 confirmed cases (38% mortality) and associated hypercytokinemia, highlights the need to identify the molecular mechanisms that drive these excessive immune responses.

We investigated the role of the NLRP3 inflammasome in modulating disease during IAV infection of mice. Using the NLRP3 inhibitor MCC950, we reveal for the first time that NLRP3 plays a biphasic role in modulating IAV disease. Early intranasal MCC950 treatment rendered mice more susceptible to PR8 (H1N1) and HKx31 (H3N2) infection; however, late inhibition of NLRP3 reduced local and systemic inflammation and protected against severe disease. Importantly, MCC950 did not alter

viral loads in the respiratory tract of mice. Late treatment with MCC950 was associated with significantly reduced levels of a number of pro-inflammatory cytokines including IL-1 β in the airways and sera. In addition, we have identified which cell populations in the lung MCC950 can penetrate.

Our study is the first to define the role of the NLRP3 inflammasome during pathogenic IAV challenge as both protective and detrimental. In particular, our data indicates NLRP3 plays a role in amplifying the production of local and systemic pro-inflammatory cytokines during severe IAV infections. These data provide the first evidence that temporally therapeutically targeting the NLRP3 inflammasome may be a clinical option for reducing inflammation associated with severe IAV infections.

Allergy 1

1524**Local remodeling, mast cell activation and sphingosine-1-phosphate elevation precede atopic dermatitis***Wedman, P., Aladhami, A., Chumanevich, A., Fuseler, J., Oskeritzian, C.**University of South Carolina School of Medicine, Pathology, Microbiology and Immunology, Columbia, United States*

Atopic dermatitis (AD) is an inflammatory skin disease whose pathogenic mechanisms remain unclear. Chronic lesions have been extensively characterized however few studies have investigated the initial phases of AD, including early skin alterations prior to any visible lesion. We recently reported a novel method of computer-assisted image analysis for *in situ* measurement of mouse skin mast cells (MC) activation. We applied similar morphometric approaches to quantify local MC activation status and skin remodeling after a single epicutaneous exposure to antigen/ovalbumin (OVA), compared to saline controls in a human AD-like preclinical model. Remarkably, epidermal and dermal thickening was substantiated after a single OVA application, also resulting in early cellular infiltration in the vascularized hypodermis layer of the skin. Furthermore, skin remodeling correlated with augmented local chemokine production, MC activation, and increased levels of a potent sphingolipid metabolite sphingosine-1-phosphate (S1P) that we have shown could activate MC-derived chemokine production. Importantly, cell infiltration was severely mitigated in mice genetically ablated for sphingosine kinase 1, predominant enzyme isoform producing S1P, and in MC-deficient *Kit^{W-sh/W-sh}* mice. We conclude that MC and S1P could initiate the development of AD by driving early inflammatory infiltration and skin remodeling through their contribution to local chemokine production, offering perhaps new prophylactic approaches for this disease whose treatment management still remains a clinical challenge.

Perinatal exposure to GOS/inulin prebiotics prevent food allergy by promoting tolerance and protecting intestineBouchaud, G.¹, Castan, L.^{1,2}, Chesné, J.², Braza, F.², Aubert, P.^{3,4}, Neunlist, M.^{3,4}, Magnan, A.^{2,4,5}, Bodinier, M.¹¹INRA, UR 1268 BIA, Nantes, France, ²INSERM, UMR 1087, Institut du Thorax, Nantes, France, ³INSERM, UMR 913, Institut des Maladies de l'Appareil Digestif (IMAD), Faculté de Médecine, Nantes, France, ⁴DHU 2020 Médecine Personnalisée des Maladies Chroniques, Nantes, France, ⁵CHU de Nantes, Service de Pneumologie, Nantes, France

Aims: Food allergies (FA) are increasing and prevention strategies are nonexistent. They are linked to imbalance of microbiota and immune system. Fibers as prebiotics have been proposed to restore this balance and seem to be one alternative to prevent or reduce allergies, particularly during infancy. In this context, we evaluated early nutritional intervention with prebiotics, via the mother during pregnancy and lactation (perinatal), to prevent food allergic risk in mice.

Method: Pregnant and lactating mice were exposed or not to GOS/Inulin prebiotics. Then, pups were intraperitoneally sensitized and then orally exposed to wheat allergen to mimic FA. Phenotypic and blood markers of allergy, immune cells and microbiota were analyzed.

Results: In mice exposed to GOS/Inulin prebiotics via their mothers, we observed a decrease of FA symptoms associated with a fall of allergic markers (IgE), a rise of tolerance markers (IgA) and a protection from the alteration of intestinal permeability and epithelium. Immunity was also modified by prebiotics as shown by the decrease of IL-4 and IL-5 productions and the increase of IFN- γ and TGF- β secretions associated with a rise of T regulatory cells in gut lymphoid organs. Prebiotics also induced a strong modification of mother mice intestinal microbiota especially for *Lactobacillus* that was the only one being transferred to pups.

Conclusion: Prebiotics supplemented diet during perinatal period protects pups against FA by decreasing levels of allergic markers, clinical symptoms and intestinal permeability. Moreover, prebiotics also modulate immune reaction during allergy toward tolerance and modify intestinal microbiota.

Stromal interaction molecule-1/2 plays essential role in basophil activation and development of IgE-mediated chronic allergic inflammationYoshikawa, S.¹, Oh-hora, M.², Adachi, T.³, Yamanishi, Y.¹, Karasuyama, H.¹¹Tokyo Medical and Dental University, Immune Regulation, Tokyo, Japan, ²Kyushu University, Division of Molecular Immunology, Fukuoka, Japan, ³Tokyo Medical and Dental University, Department of Immunology, Tokyo, Japan

Cross-linking of the high-affinity IgE receptors (Fc ϵ RI) in mast cells increases intracellular Ca²⁺ concentration through store operated Ca²⁺ entry (SOCE), leading to mast cell degranulation. Recent report suggested that stromal interaction molecule 1 (STIM1), which is a sensor of ER Ca²⁺ stores that couples

depletion of Ca²⁺ from ER stores with SOCE influx, is essential for mast cell degranulation. However, the function of STIM1 in basophil is unknown. To address this issue, we here established transgenic mice expressing a tamoxifen-inducible improved-Cre recombinase under the control of the basophil-specific promoter (*Mcpt8*^{CreERT2}), and crossbred them with mice carrying loxP-flanked *Stim1* and *Stim2*. The tamoxifen-induced STIM1/2 depletion in basophils resulted in impaired generation of SOCE influx *in vitro* in response to the stimulation with IgE plus antigens. Moreover, STIM1/2-deficient basophils also displayed impaired degranulation and production of IL-4 and IL-6 *in vitro* in response to the IgE/antigen stimulation, suggesting that STIM1/2 is essential for the Fc ϵ RI-mediated basophil activation. Importantly, mice with targeted deletion of STIM1/2 in basophils failed to develop IgE-mediated chronic allergic inflammation (IgE-CAI), a prototype of basophil-mediated allergic response. Although the number of basophils in peripheral blood was comparable in those and wild-type mice, the basophil recruitment to the skin lesions was severely impaired in the former. Taken together, STIM1/2 appears to play an essential role in the recruitment and activation of basophils.

Bronchoepithelial cell-derived prostaglandin D₂ inhibits eosinophilic lung inflammationMaehara, T.¹, Nakamura, T.¹, Aritake, K.², Urade, Y.², Murata, T.¹¹University of Tokyo, Graduate School of Agriculture and Life Science, Department of Animal Radiology, Tokyo, Japan,²University of Tsukuba, International Institute for Intergrative Sleep Medicine, Ibaraki, Japan

Objective: Eosinophilic lung inflammation is a hallmark of asthma. Although the concentration of prostaglandin D₂ (PGD₂) is elevated in the allergic lung tissue, its contribution in disease progression remains unclear. We attempted to clarify the role of PGD₂ in ovalbumin (OVA)-induced allergic lung inflammation using hematopoietic PGD synthase (H-PGDS) deficient mice.

Results: Repeated inhalation of OVA induced eosinophil infiltration which was accompanied by the increase in mRNA expressions of eosinophilic chemoattractant including TNF- α , IL-5, RANTES and Eotaxin-1 in WT mouse lung. Gene deficiency of H-PGDS enhanced both the OVA-induced eosinophilic infiltration and mRNA expressions of these cytokines/chemokines. Continuous administration of a PGD₂ receptor agonist attenuated the OVA-induced allergic lung inflammation in WT mice. Immunostaining showed that bronchoepithelial cells strongly expressed H-PGDS and TNF- α in the allergic WT mouse lung. In cultured bronchus tissue of WT mice, a treatment of TNF- α increased the mRNA expression of RANTES and Eotaxin-1. H-PGDS deficiency promoted the TNF- α induced mRNA expressions of these chemokines, which were inhibited by PGD₂ receptor agonism.

Conclusion: Bronchoepithelial cell-derived PGD₂ acts as a negative regulator by inhibiting the expression of chemoattractants in eosinophilic lung inflammation.

The increasing production and consumption of molluscs is associated with a rise in prevalence of mollusc allergy worldwide, currently ranging from 0.15% to 1.3% of the general population. However, the elucidation of mollusc allergens still lags behind other seafood groups such as fish and crustacean. Genomic data have been utilized previously for improved identification of non-food allergens by performing similarity searching using the BLAST program. Based on the published genome of the Pacific oyster (*Crassostrea gigas*) we aimed to identify novel allergens using a similar genomic approach.

Eleven novel putative and potentially cross-reactive Pacific oyster allergens were discovered using *in silico* analyses. The allergenicity of these proteins was characterized by a combination of immunoassays and transcriptome-derived proteomic analyses. Immunoblotting of Pacific oyster extract showed that many proteins gave a positive reaction with IgE antibodies from patients with confirmed mollusc allergy. The identity of these IgE-reactive proteins was determined by mass spectrometry. Some of the putative and potentially cross-reactive allergens are confirmed to be novel allergens.

Using an integrated genomic approach, this study was able to characterise food allergens from the Pacific oyster not described elsewhere. These newly identified allergens and knowledge of their gene structure will facilitate development of improved diagnosis and specific immunotherapy for oyster allergy.

Treg

Trust, Birmingham, United Kingdom, ⁴Institute of Hepatology, London, United Kingdom

Regulatory T cells (T_{reg}) suppress T effector cell proliferation and maintain immune homeostasis. Autoimmune liver diseases (AILD) persist despite high frequencies of T_{reg} in the liver suggesting that the local hepatic microenvironment might affect T_{reg} stability, survival or function. We hypothesized that interactions between T_{reg} and endothelial cells during recruitment and then with epithelial cells within the liver affect T_{reg} stability, survival and function. We explored the function of T_{reg} after migration through human hepatic sinusoidal endothelium (post-endothelial migrated (PEMT_{reg})) and the effect of subsequent interactions with cholangiocytes and local proinflammatory cytokines on the survival and stability of T_{reg}. We demonstrate by ELISA that the intrahepatic microenvironment is enriched with proinflammatory cytokines but is deficient in IL-2, and confirm that activated CD4 and CD8 T cells are the main source of IL-2 in the inflamed liver. Migration through endothelium into the inflamed liver microenvironment did not affect T_{reg} stability, however functional capacity was reduced. Furthermore, the addition of exogenous IL-2 enhanced PEMT_{reg} phosphoSTAT5 signaling compared with PEMCD8. Liver infiltrating T_{reg} reside close to FAS Ligand expressing bile ducts. T_{reg} from diseased livers expressed high levels of CD95 and co-culture with cholangiocytes or their supernatants induced preferential apoptosis of T_{reg} compared to CD8 effector cells and this apoptosis was inhibited by IL-2 or blockade of CD95. These results provide a mechanism to explain T_{reg} dysfunction in inflamed tissues and suggest that IL-2 supplementation, particularly if used in conjunction with T_{reg} therapy, could restore immune homeostasis in inflammatory and AILD.

1081

CD28 expression by donor CD4⁺ Foxp3⁺ regulatory T cells is required for long-term, but not short-term suppression of acute graft versus host disease in mice

Uri, A., *Werner, S.*, *Hünig, T.*, *Kerkau, T.*, *Beyersdorf, N.*

University of Würzburg, Institute for Virology and Immunobiology, Würzburg, Germany

Acute graft versus host disease (aGvHD) is a major cause of transplant-related death after hematopoietic stem cell (HSC) transplantation and is induced by mature T cells in the graft. In this study, we investigated the role of CD28 co-stimulation in CD4⁺ conventional (CD4⁺CD25⁻, Tconv) and regulatory (CD4⁺CD25⁺, Treg) T cell expansion and function during aGvHD. We used tamoxifen-inducible Cre CD28^{fllox/-} mice (iCD28KO mice) to delete CD28 on either donor CD4⁺ Tconv or Treg in the C57BL/6 into BALB/c HSC transplantation model. Treatment of the recipient mice with tamoxifen from day 0 to day +3 after transplantation, efficiently deleted CD28 on the donor T cells. When we transferred CD4⁺ Tconv only, CD28 deletion on these cells only transiently reduced inflammation but did not prolong survival of the recipient mice, as compared to mice that received CD28-sufficient CD4⁺ Tconv. To test the impact of CD28 deletion on donor Treg in aGvHD, we co-transplanted wild type CD4⁺ Tconv with either CD28 sufficient or iCD28KO Treg.

Both, CD28-sufficient and -deficient Treg protected recipient mice from aGvHD-induced lethality until three weeks after transplantation. However, remission of aGvHD symptoms and long-term survival was highly dependent on CD28 expression by Treg. Together this suggests that in humans therapeutic blockade of CD28, which has been shown to protect mice from aGvHD, should also be limited to the early phase of the disease. This work was supported by a grant from the "Deutsche José Carreras Leukämie-Stiftung".

CD4+ T cell homing in cystic fibrosis peripheral blood

Mulcahy, E.¹, Asad, S.², McGuire, H.², Roddam, L.¹, Beggs, S.³, Cooley, M.¹, Fazekas de St Groth, B.²

¹University of Tasmania, School of Medicine, Hobart, Australia,

²Centenary Institute, Newtown, Australia, ³Royal Hobart Hospital, Hobart, Australia

Cystic fibrosis (CF) is the most common life-limiting single-gene disease, which results from mutations of *CFTR*. *CFTR* is expressed on immune cells including APCs, monocytes and lymphocytes and lack of expression on lymphocytes has been reported to result in abnormal immune responses. A nonresolving hyperinflammatory Th2/Th17-skewed immune response is also characteristic of CF. We therefore hypothesised that altered homing of T cells may play a role in the pathogenesis of CF lung disease.

PBMC isolated from people with CF and healthy age-matched controls were stained for CD4, CD25, CD127 and CD45RO for identification of naive and memory tregs, and for the Th1, Th2 and Th17 homing markers CXCR3, CCR4 and CCR6 for multicolour flow cytometric analysis.

CXCR3+, CCR4+ and CCR6+ memory Treg cell percentages were all decreased in CF blood compared with controls while CCR6+, but not CXCR3+ or CCR4+ memory effector CD4 cells were decreased. No difference was seen between CF and control in any naive CD4 or Treg cell populations. We hypothesise that decreased levels of memory cells in blood is due to their homing to the major site of infection, the lungs, resulting in an imbalance of regulatory and effector subsets homing to the lungs. The ongoing inflammation in CF also suggests that those CXCR3+, CCR4+ and CCR6+ Tregs homing to lungs may not function efficiently to reduce the damaging responses. These alterations in CCR6+ CD4 and Treg subsets support that CF is dominated by Th17 responses that could be targeted to reduce lung inflammation and damage.

Interleukin (IL)-2 dependent T follicular regulatory (Tfr) cells control IL-21 producing T follicular helper cells and B cells during the germinal center (GC) reaction, but how regulation is contained within the GC niche to facilitate antibody production has remained unknown. Here, we report a marked increase of both total regulatory T cells (Tregs) and Tfr cells in peripheral blood of human patients with a loss of function mutation in the IL-21 receptor. In mice, IL-21 similarly inhibited the expansion of Tregs and Tfr cells following T dependent immunization. The negative influence of IL-21 on Tfr cells was cell intrinsic and associated with decreased expression of the high affinity IL-2 receptor (CD25). Bcl6, expressed in abundance in Tfr cells, inhibited CD25 expression and IL-21 mediated inhibition of CD25 was Bcl6-dependent. Parallel immunization of *Il6*^{-/-} mice demonstrated that IL-6, whilst equally able to induce Bcl6, was not effective at inhibiting Tfr cell expansion. Genome wide analyses of differentially expressed genes in CD4+ T cells in response to IL-21 uncovered a cache of genes that negatively regulate FoxP3 expression. These findings identify a mechanism whereby IL-21 reinforces humoral immunity; inhibiting the expansion of Tfr cells by limiting responsiveness to IL-2 and stabilizing FoxP3.

Bach2 is required for sustained CD4 T cell responses

Sidwell, T.¹, Vasanthakumar, A.^{1,2}, Thelemann, C.^{1,2}, Kallies, A.^{1,2}

¹Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ²University of Melbourne, Department of Medical Biology, Melbourne, Australia

To characterise the function of Bach2 in CD4 T cells *in vivo*, we utilised the SMARTA T cell receptor, specific for a lymphocytic choriomeningitis (LCMV) MHCII epitope. Congenically marked wild type (WT) and Bach2-deficient CD4+ SMARTA T cells were co-transferred into the same recipient mice and their responses to infection compared. Bach2-deficient antigen-specific responders initially resembled control cells in activation status, capacity for effector differentiation and division. However, following the peak of the response there was more than ten-fold loss of *Bach2*^{-/-} responder cells compared to controls, a defect that persisted into the memory phase. Further characterisation at and around the time of loss indicated that *Bach2*^{-/-} responder cells and WT controls were similar in cell cycling, metabolic fitness and effector differentiation.

To study this defect in a more controlled manner, we cultured WT and Bach2-deficient CD4 T cells *in vitro*. Bach2-deficient T cells initially upregulated markers of activation similar to WT controls, but progressed more slowly through division. Furthermore, Bach2-deficient cells expressed dramatically increased amounts of effector molecules, including IFN γ , IL-

17 and IL-10, paralleled by derepression of transcription factor Blimp1. In addition we observed a severe impairment of the *Bach2*^{-/-} CD4 T cells in Foxp3 upregulation. A loss of these cells *in vitro* at a similar time post stimulation to *in vivo* cells indicates an underlying requirement for *Bach2* for the survival of CD4 T cells in allowing their continued response to antigen and their subsequent memory generation. Study on the molecular basis of this requirement is ongoing.

Low dose Proleukin promotes enhanced regulatory phenotype with selective induction of phosphoSTAT5 and prosurvival Bcl-2 in blood and liver Treg in autoimmune liver disease

*Jeffery, H.*¹, *Jeffery, L.E.*², *Adams, D.H.*^{1,3}, *Oo, Y.H.*^{1,3}

¹University of Birmingham, Centre for Liver Research & NIHR Biomedical Research Unit, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom, ²University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom, ³University Hospital of Birmingham NHS Foundation Trust, Birmingham, United Kingdom

CD4⁺CD25^{high}CD127^{low}FOXP3⁺ regulatory T cells (Treg) play a central role in maintaining peripheral self-immune tolerance. Functional impairment in Treg and/or imbalances in Treg-to-Teffector cell ratios contribute to the pathogenesis of autoimmune diseases. Treg depend on IL-2 for their survival and function via high expression of CD25 (IL-2R α). Studies in graft-versus-host disease, HCV-induced vasculitis and type-1 diabetes have indicated that low dose IL-2 therapy might help to control autoimmune diseases. The potential to use low dose IL-2 in adults with autoimmune liver diseases (AILD) (Type-1 Autoimmune Hepatitis and Primary Biliary Cholangitis) is unknown and was investigated in this study. Peripheral blood and liver-infiltrating lymphocytes from patients with AILD were treated with doses of clinical grade IL-2 (Proleukin) in the range 0-1000IU/ml and phosphorylation of STAT5, and expression of markers of function and survival analysed. A very low dose of Proleukin, < 5IU/ml, induced STAT5 phosphorylation in Treg but not in other lymphocyte subsets or natural killer cells. This dose of Proleukin stimulated a series of phenotypic changes in blood and liver Treg of patients, including up-regulation of regulatory functional markers CTLA-4, FOXP3 and CD25 and enhanced expression of the anti-apoptotic protein, Bcl-2, without inducing noticeable activation or upregulating survival factors in effector T-cells. The IL-2 level in the human inflamed liver is near undetectable. We report that low dose Proleukin therapy could selectively enhance Treg function and survival to restore tolerance in AILD and consideration of these findings will be important in the ongoing design of GMP Treg therapy for AILD.

The use of Basiliximab as induction therapy in heart-transplanted children deregulates the regulatory T-cell population (Treg), compromising the natural mechanisms of tolerance of transplanted organs

*López-Abente, J.*¹, *Camino, M.*², *Gil, N.*², *Panadero, E.*², *Clemente, M.*³,

*Martínez-Bonet, M.*⁴, *Urschel, S.*⁵, *West, L.*⁶, *Pion, M.*¹, *Correa-Rocha, R.*¹
¹Gregorio Marañón Health Research Institute (IISGM), Laboratory of Immune-Regulation, Madrid, Spain, ²Hospital General Universitario Gregorio Marañón, Pediatric Cardiology Division, Madrid, Spain, ³Gregorio Marañón Health Research Institute (IISGM), Cell Culture Unit, Madrid, Spain, ⁴Gregorio Marañón Health Research Institute (IISGM), Laboratory of Molecular Immunobiology, Madrid, Spain, ⁵University of Alberta / Stollery Children's Hospital, Pediatric Cardiac Transplantation, Edmonton, Canada, ⁶University of Alberta, Alberta Transplant Institute, Edmonton, Canada

Immunosuppressors are used prior and after transplantation to avoid immune rejection of the transplanted organ. However, the lack of specificity of these immunosuppressive drugs produces pleiotropic effects on the whole immune system and potentially on regulatory T cells (Tregs). Tregs suppress inappropriate immune responses, are crucial for the maintenance of immune tolerance, and could be notably relevant to prevent rejection in transplanted children. Between these immunosuppressors, Basiliximab is a monoclonal antibody against the α -chain (CD25) of IL-2 receptor. CD25 allows Tregs to detect the excessive proliferation of effector cells and induce their proliferation and survival. Therefore, although Basiliximab induction immunotherapy could prevent early graft rejection, it could also impede the possible tolerance of the transplanted organ.

We performed an exhaustive analysis of immune subsets including Tregs in heart-transplanted children treated with Basiliximab (n=2) or not treated (n=3). We show that the use of Basiliximab during the first 4 days post-transplant completely blocks CD25 on Tregs for at least three months. We investigated whether this block could "blind" Tregs and alter their functionality and survival by treating *in vitro* PBMC from healthy donors with Basiliximab (n=6). Basiliximab produced a marked Treg deregulation inducing a decrease in Foxp3 expression, a reduction in IL-10 production and a diminution in Treg proliferation under α -CD3/ α -CD28 activation. Therefore, the use of Basiliximab induction in transplanted patients could compromise Treg-mediated tolerance during the first three months post-transplant, which is the period with highest incidence of acute rejection, and could contribute to deregulation of the immune homeostasis.

Gender dimorphism in the immunomodulatory role of beta 2-glycoprotein I in sepsis

El-Assaad, E.^{1,2}, *Kizny Gordon, A.*^{2,3}, *Zhou, S.*^{1,2}, *Qi, M.*^{1,2}, *Beretov, J.*^{1,4}, *Chen, G.*^{1,2}, *Giannakopoulos, B.*^{1,2}, *Krilis, S.*^{1,2}

¹University of New South Wales, St George and Sutherland Clinical School, Faculty of Medicine, Sydney, Australia, ²St George Hospital, Department of Infectious Disease, Immunology and Sexual Health, Sydney, Australia, ³St George Hospital, Department of Anatomical Pathology, South Eastern Area Laboratory Service, Kogarah, Australia, ⁴St George Hospital, Department of Anatomical Pathology, South Eastern Area Laboratory Service, Sydney, Australia

Lipopolysaccharide (LPS) from gram-negative bacteria is a key molecule implicated in the pathogenesis of sepsis. In human sepsis, females have a lower incidence and a less severe presentation than males. However, the mechanisms underlying this gender dimorphism are not clear. In this study, we examined the role of beta 2-glycoprotein 1 (β 2GP-1), an abundant plasma LPS binding protein, in male, female wild type (WT) and β 2GP-1^{-/-} mice challenged with LPS or *E. coli* intravenously.

In WT mice, baseline levels of total β 2GP-1 were higher in male mice and the levels decreased following challenge with LPS or *E. coli*. This is an identical response seen in male human volunteers injected intravenously with LPS. Six hours post LPS or *E. coli* challenge, female and male β 2GP-1^{-/-} mice produced different signatures of pro and anti-inflammatory cytokines. Male β 2GP-1^{-/-} challenged with LPS produced higher levels of the pro-inflammatory cytokines TNF, MCP-1 and IL-12p70 than female β 2GP-1^{-/-} mice. Female mice challenged with *E. coli* produced higher levels of anti-inflammatory cytokine IL-10 whilst male mice produced higher levels of IL-6 and MCP-1. Female WT mice cleared *E. coli* more efficiently from the circulation than male mice. However, in the absence of β 2GP-1 this efficiency is lost and in addition, the sex difference in bacterial clearance is diminished. These findings support a role for β 2GP-1 in modulating the gender-specific susceptibility to bacterial-sepsis, not previously reported, and present potential for targeted treatments.

Langerin⁺ CD8a⁺ dendritic cells play a protective role early after systemic bacterial infection in mice

Prendergast, K.^{1,2}, Petersen, T.¹, Hermans, I.¹, Kirman, J.³

¹Malaghan Institute of Medical Research, Wellington, New Zealand, ²University of Sydney, Sydney, Australia, ³University of Otago, Microbiology and Immunology, Dunedin, New Zealand

Residing in the marginal zone of the murine spleen, langerin⁺ CD8a⁺ dendritic cells (DC) are known to be able to cross-prime CD8⁺ T cells and produce IL-12. Given these qualities, we hypothesised that langerin⁺ CD8a⁺ DC might be critical drivers of adaptive responses to blood-borne bacterial infections. Using intravenous *Mycobacterium bovis* bacille Calmette Guerin (BCG) as a model of blood-borne bacterial infection, we investigated the impact of depleting langerin⁺ CD8a⁺ DC in mice that express the diphtheria toxin receptor under the control of the langerin promoter. We found bacterial numbers in the spleen increased when langerin⁺ CD8a⁺ DC were depleted during the first week of intravenous BCG infection; this was associated with delayed CD8⁺ T cell responses and reduced serum levels of IL-12p40. *In vivo* depletion of CD8⁺ T cells or IL-12 neutralisation did not induce a similar increase in bacterial numbers, suggesting langerin⁺ CD8a⁺ DC were exerting bacterial control by another mechanism. Further experiments revealed depletion of langerin⁺ CD8a⁺ DC led to increased bacterial numbers in the spleen as early as 30 mins after BCG infection. Our data reveal, that in addition to initiating CD8⁺ T cell responses and IL-12 production, langerin⁺ CD8a⁺ DC mediate early control of systemic bacterial infection.

A potential role for bacterial superantigens in tonsillar hypertrophy

Radcliff, F.¹, Clow, F.¹, Mahadevan, M.², Waldvogel-Thurlow, S.³, Proft, T.¹, Douglas, R.³, Fraser, J.¹

¹University of Auckland, Molecular Medicine and Pathology, Auckland, New Zealand, ²Gillies Hospital, Auckland, New Zealand, ³University of Auckland, Department of Surgery, Auckland, New Zealand

The tonsils are lymphoid organs that act as sentinels for the nasopharyngeal region and can be prone to recurrent infection, particularly throughout early childhood. We hypothesise that some cases of tonsillar hypertrophy may be driven by production of bacterial superantigens (SAG), potent activators of selected TCR V β subsets that are primarily produced by *Staphylococcus aureus* and Group A Streptococcus (GAS). To date we have collected tonsil tissue from 81 patients (median age = 4 years) undergoing a tonsillectomy for recurrent tonsillitis (RT) or Obstructive Sleep Apnoea (OSA). *S. aureus* was cultured from the tonsil surface and/or tissue of ~50% (40/81) of patients and GAS from 10% (8/81) of patients. The tonsillar CD4⁺ and CD8⁺ TCRV β repertoire was assessed by flow cytometry and skewing identified in 30% (25/81) of patients, 70% (18/25) of which had RT. *S. aureus* and GAS were cultured from 11/25 and 2/25 of these patients. All bacterial isolates are being profiled for the presence of SAG genes by multiplex PCR and mitogenic activity by proliferation assays to determine whether there is a match between TCR V β skewing patterns and selected SAG in some patients. Fluorescence microscopy is being employed to determine whether bacteria, particularly *S. aureus*, are present in a location where they can interact with T cells and drive inflammation. If a causal association between the presence of *S. aureus* and tonsillar hypertrophy is established, this could lead to a revision of current treatment practices for this illness.

Lung tissue resident T cell immune responses to *Mycobacterium tuberculosis* infection in humans

Ogongo, P.^{1,2}, Leslie, A.¹

¹Kwa-Zulu Natal Research Institute for TB and HIV, Durban, South Africa, ²Institute of Primate Research, Tropical and Infectious Diseases, Nairobi, Kenya

Pathogen specific lymphocytes accumulate in the tissue where they are needed to fight off infection and, importantly, these responses are not necessarily represented in the circulation. Data from animal models of *M. tuberculosis* infection show that even within the lung, immune response differ between different TB granuloma, and these differences correlate with local TB control. However, data on human adaptive immune responses to TB infection come mostly from the study of blood. We hypothesise that adaptive immune responses to *M.tb* infection in the lung are different from immune responses in circulation during infection. We aim to learn the phenotype, function and antigen specificity of TB adaptive immune response that can control *M.tb* at the level of individual lesion and correlate these to responses that are detectable in circulation. Working

with tuberculosis infected human lung samples processed under BSL3 procedures, the immune profiles in the tissue are investigated by an array of immunological techniques including mass cytometry, cell sorting by conventional flow cytometry, as well as histology. Matched blood from same individuals are also processed for PBMC and acquired similarly. Initial results show that CD103 is a better marker of activation of lung resident T cells than CD69. Lung resident T cells are multifunctional producing a mixture of TNF-alpha, IL-2 and IFN-gamma and also produce low levels of IL-17. We observe that CD8+ specifically produce high levels of IFN-gamma. The overall findings of this study will inform better tuberculosis vaccine design strategies to augment tuberculosis control efforts.

ManLAM of mycobacterium tuberculosis negatively regulates anti-TB immunity

Zhang, X.-L., Pan, Q., Yuan, C., Sun, X.-M.

Wuhan University School of Medicine, Immunology, Wuhan, China

Many pathogens-surface glycans have been implicated as an immunosuppressive epitopes and might contribute to chronic or latent infection and immune invasion. Mannose-capped lipoarabinomanan (ManLAM) is a lipoglycan serving as a major cell wall component in Mycobacterium tuberculosis (M.tb). Here, we demonstrated a novel ManLAM mediated immune evasion mechanism by inhibitory effects on the polarizations of M1 macrophages and Th1 cells. Our data suggest that BM2, an aptamer specifically against ManLAM with low and no toxicity, holds a potential application as BCG immunoadjuvant and provides a new strategy for TB vaccine design.

Accumulating evidences suggest that B cells contribute significantly to shaping and modulating the immune response to intracellular microbes. Here we report that IL-10-producing B (B10) cells are increased in peripheral blood mononuclear cells (PBMC) from patients with active pulmonary tuberculosis (TB). We also demonstrate a novel mechanism in which M.tb ManLAM exploits B10 cells to negatively regulate anti-TB immunity.

A forward genetic screen for zebrafish genes involved in pneumococcal infection

Saralahti, A.¹, Harjula, S.-K.¹, Partanen, E.¹, Rantapero, T.¹, Granberg, K.¹, Lohi, O.², Nykter, M.¹, Rounioja, S.³, Parikka, M.¹, Rämetsä, M.^{1,4,5}

¹University of Tampere, BioMediTech, Tampere, Finland, ²University of Tampere, Tampere Center for Child Health Research, Tampere, Finland, ³Fimlab Laboratories, Tampere, Finland, ⁴Tampere University Hospital, Department of Pediatrics, Tampere, Finland, ⁵Oulu University Hospital, Department of Children and Adolescents, Oulu, Finland

Streptococcus pneumoniae (pneumococcus) is a major human pathogen and one of the leading causes of pneumonia, septicemia, and meningitis. The complex interactions occurring between the pneumococcus and the immune system are only partly understood and, therefore, the optimal treatment and

prevention methods are lacking. Previously, we showed that zebrafish (*Danio rerio*) are valuable hosts in the study of the innate immune response against pneumococcus. In the present study, we have employed the zebrafish embryo model for the forward genetic screen to identify novel host genes involved in pneumococcal infection. Using the gene-breaking transposon based mutagenesis method, we generated 150 zebrafish families with unknown mutations and screened these families for the altered susceptibility for systemic pneumococcal infection. With this screen, we were able to reveal 21 mutant families that are hypersusceptible to pneumococcal infection and, recently, we identified the insertion sites in these families by Next Generation Sequencing (NGS). NGS revealed several genes and intergenic regions with a potential, previously unknown, role in pneumococcal infection. Now, the role of these genomic sites is assessed in zebrafish embryos using the CRISPR/Cas9 site-directed mutagenesis and the role of these sites in the defense against pneumococcus is characterized further. Eventually, the screen is likely to expand our understanding of the innate immune response associated with pneumococcal diseases.

Distinct immunological signature for *M.tuberculosis* infected children with and without overt disease

Dreesman, A.¹, Smits, K.¹, Corbière, V.¹, Dirix, V.¹, Debulpaepe, S.¹, Libin, M.¹, De Schutter, I.², Singh, M.³, Locht, C.⁴, Malfroot, A.², Mascart, F.¹

¹Université Libre de Bruxelles, Laboratory of Vaccinology and Mucosal Immunity, Brussels, Belgium, ²Universitair Ziekenhuis Brussel, Department of Pediatric Pulmonology, Brussels, Belgium, ³Lionex Diagnostics and Therapeutics, Braunschweig, Germany, ⁴Inserm U 1019, Institut Pasteur de Lille, Lille, France

Pediatric tuberculosis remains a global health problem associated with high morbidity and mortality. Its clinical spectrum differs from that of adults, as the majority of disease in children results from direct progression of the primary infection. A better understanding of protective immune responses is required to develop improved vaccines, to provide accurate diagnostic tests and to discover innovative therapeutic approaches. We characterized *Mycobacterium tuberculosis*-specific functional T cell subsets induced by two mycobacterial antigens (early-secreted-antigen-6 (ESAT-6), heparin-binding haemagglutinin (HBHA)) by flow cytometry, in 87 children exposed to *M. tuberculosis* in a low TB incidence country. They were classified as active tuberculosis (aTB), infection without overt disease (latent TB infection, LTBI), or uninfected. aTB cases were characterized by higher proportions of TNF- α ^{single+} CD4⁺T cells ($p < 0.05$ and trend in response to ESAT-6 and HBHA, respectively). In contrast, the proportions of IFN- γ ^{single+} CD4⁺ T cells were higher in children with LTBI compared to those with aTB ($p = 0.001$ and $p < 0.05$ for ESAT-6 and HBHA, respectively). The proportion of HBHA-induced IL-17^{single+} CD4⁺T cells was also higher in children with LTBI ($p < 0.05$). In contrast to the existing immunodiagnostic tests that are unable to discriminate between aTB and LTBI, we identify here distinct immunological signatures for children infected with *M. tuberculosis* at different stages of the disease. Our results provide the proof of concept

for the development of new, stage-specific diagnostic tests, that may help to target treatment of childhood tuberculosis to those that need it most.

The role of the CXCL9/CXCR3 axis in mediating T-cell skewing in chronic lymphocytic leukemia

Hanna, B.S., Röbner, P.M., Lichter, P., Seiffert, M.

German Cancer Research Center (DKFZ), Molecular Genetics, Heidelberg, Germany

Chronic lymphocytic leukemia (CLL) is a malignancy of mature CD5⁺ B-cells that is characterized by a dysfunctional immune system. Disease development in CLL patients and mouse models is associated with skewing of T-cells towards antigen-experienced and exhausted phenotypes. However, the mechanisms governing these changes remain largely elusive. Serum analysis of the E μ -TCL1 mouse model of CLL has previously shown upregulation of various T-cell chemoattractants such as CXCL9 and CXCL16. Gene expression profiling and intracellular flow cytometric analysis further confirmed that monocytes are the major source of the increased CXCL9 in leukemic mice. In addition to impacting on CLL development, myeloid cell depletion using liposomal clodronate was associated with downregulation of serum CXCL9 levels. Concomitantly, decreased numbers of antigen-experienced T-cells were detected following myeloid cell depletion, suggesting a role of monocyte-derived CXCL9 in regulating T-cell skewing in CLL. Flow cytometric analysis revealed that higher percentages of T-cells in leukemic mice express the corresponding receptor, CXCR3. In addition, CXCR3 was mainly expressed on memory CD8⁺ T-cells with significantly lower levels on the PD-1^{hi} population. Furthermore, CXCR3⁺ CD8⁺ T-cells showed remarkable differences in the expression of several transcriptional regulators, activation markers and cytokines compared to PD-1^{hi} T-cells. Moreover, CLL development in CXCR3^{-/-} mice induced significantly lower numbers of memory T-cells, yet the numbers of PD-1^{hi} cells remained largely unaffected. Collectively, these data suggest that the CXCL9/CXCR3 axis specifically contributes to memory T-cell accumulation in CLL. The molecular mechanisms that regulate CXCR3 expression on various T-cell populations in CLL are currently under investigation.

The tumor antigen NGcGM3 is a human CD1d ligand capable of mediating B cell and NKT interaction

Gentilini, M.V., Perez, M.E., Fernandez, P., Fainboim, L., Arana, E.

INIGEM (University of Buenos Aires-CONICET), Buenos Aires, Argentina

The ganglioside NGcGM3 is a tumor antigen (Ag). Some people have circulating Ag specific IgGs, capable of complement mediated cytotoxicity against NGcGM3 positive cells, relevant for tumor surveillance. Considering the Ag's chemical nature, we postulated it as a candidate ligand for CD1d. We aimed to assess whether the immune mechanism involved in the generation of

anti-NGcGM3 Abs entailed an interaction between B cells (Bc) and invariant NKT cells (iNKT).

We set up a cell free Ag presentation assay using a recombinant CD1d-IgG1 fusion on NGcGM3-coated plates and tested whether there were differences in the binding of the fusion and an IgG1 isotype control. Differences between them were reproducibly significant ($p < 0.01$), which was also true for differences with uncoated control wells. The results were confirmed through alternative biochemical assays including competitive ELISA with a known CD1d ligand (IC₅₀ 1.2 mmol/L). Using FACS, we demonstrated that human Bc present NGcGM3 in a CD1d context and paraformaldehyde treatment of cells expressing CD1d affects the presentation. Finally, by co-culturing primary human Bc with autologous iNKT and measuring Ki-67 expression, we detected a significant increment in the proliferation of both cell populations when Ag was on the medium, which was abrogated by blocking CD1d.

Our findings identify a novel, endogenous, human CD1d ligand, which is sufficiently competent to stimulate iNKT. We postulate that CD1d-restricted Bc presentation of NGcGM3 drives effective iNKT activation, a mechanism involved in the antitumor response that has not been previously described for humans, which may contribute to understanding anti-NGcGM3 occurrence.

Tregs and exhausted T CD8 cells play an important role in immune evasion mechanisms exploited by cancer. These cells

have been found in tumor and peripheral blood of breast cancer (BrCA) patients. TIM-3 and PD-1 are inhibitory molecules upregulated in exhausted T CD8 cells and in highly suppressive Tregs located in blood and tumor of cancer patients. We compared the expression profile of PD-1 and TIM-3 in Tregs and T CD8⁺ in the peripheral blood of 7 healthy women vs. 14 stage III breast cancer patients; and studied the correlation between Tregs and exhausted T CD8⁺ subpopulations. We obtained 15 ml of peripheral blood; mononuclear cells were separated by ficoll density gradient, stained with monoclonal antibodies and analyzed by flow cytometry. PD-1⁺TIM-3⁺Tregs were increased in BrCA patients vs. controls ($p=0.01$) and correlated positively with PD-1⁺TIM-3⁺ memory and TEMRA T CD8⁺ ($r=0.56$); negatively with PD-1⁺TIM-3⁺ memory T CD8⁺ ($r=-0.56$). TIM-3⁺ (PD-1⁻ and PD-1⁺) Tregs correlated positively with PD-1⁻ TIM-3⁺ ($r=0.64$) and PD-1⁻TIM-3⁺ TEMRA T CD8⁺ ($r=0.56$). PD-1⁻TIM-3⁻ Tregs were decreased in BrCA vs. controls ($p=0.04$). PD-1⁺TIM-3⁻ Tregs were not significantly different, but in BrCA patients they correlated positively with PD-1⁺TIM-3⁻ TEMRA T CD8⁺ ($r=0.78$); negatively with PD-1⁻TIM-3⁻ TEMRA T CD8⁺ ($r=-0.60$), PD-1⁻TIM-3⁺ memory ($r=-0.60$) and TEMRA T CD8⁺ ($r=-0.70$). Our data reveal that PD-1⁺TIM-3⁺ Tregs are elevated in BrCA patients' blood and are associated with the exhausted T CD8⁺ lymphocytes, suggesting that Tregs and exhausted T CD8 populations may be interacting between them, contributing to immune evasion mechanisms in BrCA patients.

1819

Positive feedback loop between B cells/plasma cells and macrophages promote M2 macrophage-elicited hepatoma progression

Kuang, D.-M.

Sun Yat-sen University, School of Life Sciences, Guangzhou, China

Tumor progression has been recognized as the product of an evolving crosstalk between different cell types within tumor and its stroma. However, the crosstalk between humoral immunity and innate immunity within human cancer microenvironments is poorly defined. We show that infiltration of plasma cells orchestrates the differentiation and function of protumorigenic macrophages in human hepatocellular carcinoma (HCC): specialized polarized immunoglobulin G (IgG)-secreting plasma cells in HCCs trigger the differentiation of protumorigenic M2b polarized macrophages. Reciprocally, autocrine interleukin 6-elicited-interferon-inducible protein 10 (IP-10) and membrane-bound intercellular cell adhesion molecule-1/vascular cell adhesion molecule (ICAM-1/VCAM) expressed by macrophages selectively induces long-lived IgG-secreting plasma cells, forming a positive feedback loop, in coculture systems and mice. Plasma cell infiltration determines macrophage-associated clinical outcome of HCC patients. These findings suggest that bidirectional communications between macrophages and B cells in cancer microenvironments support humoral immunity-elicited myeloid cell suppression and disease progression.

2208

Anti-VISTA antibody enhances the anti-tumor immune response in mice with mammary tumors

Jensen, S.M.¹, Afentoulis, M.¹, Wegmann, K.W.¹, Campion, L.², Snyder, L.A.², Fox, B.A.¹

¹Earle A Chiles Research Institute, Portland Providence Medical Center, Portland, United States, ²Janssen Research and Development, LCC, Spring House, United States

The recent success of a number of immune checkpoint inhibitors in clinical cancer trials has spurred on research for other potential checkpoint targets. VISTA, V-domain Ig suppressor of T cell activation, is a novel checkpoint inhibitor that has shown the ability to suppress T cell proliferation and functionality. We examined the antitumor efficacy of an anti-mouse VISTA antibody (13F3) in established orthotopic murine mammary tumors (FAT) in female FVB/NJ mice. Mice bearing palpable tumors were treated with the anti-VISTA antibody every other day for 6 total doses, with the first treatment starting at day 11 post-tumor challenge. Treatment with anti-VISTA resulted in a statistically significant reduction in mean tumor growth. T cells from tumor draining lymph nodes of anti-VISTA treated mice secreted more IFN γ when stimulated with tumor compared to T cells from non-treated mice. Depletion of CD8⁺ cells, but not CD4⁺ cells, prior to treatment abrogated the therapeutic anti-tumor response. Employing multicolor immunohistochemistry we detected T cell infiltration of both CD4⁺ and CD8⁺ T cells into tumors. These studies demonstrate that an anti-VISTA antibody can augment the anti-mammary tumor immune response leading to a reduction in tumor growth.

APOBEC gene family expression and activity in chronic lymphocytic leukemia: APOBEC3F splice variants correlate with patient outcome

Chu, C.C.^{1,2,3}, Vergani, S.¹, Yan, X.-J.¹, Dhayalan, A.¹, Patten, P.E.M.⁴, MacCarthy, T.⁵, Yuan, C.⁵, Barrientos, J.C.^{1,2}, Kolitz, J.E.^{1,2}, Allen, S.L.^{1,2}, Rai, K.R.^{1,2}, Chiorazzi, N.^{1,2,3}

¹Feinstein Institute for Medical Research, Northwell Health, Manhasset, United States, ²Hofstra Northwell School of Medicine, Department of Medicine, Hempstead, United States, ³Hofstra Northwell School of Medicine, Department of Molecular Medicine, Hempstead, United States, ⁴King's College London, Department of Haemato-Oncology, London, United Kingdom, ⁵Stony Brook University, State University of New York, Department of Applied Mathematics and Statistics, Stony Brook, United States

Human chronic lymphocytic leukemia (CLL) is an accumulation of clonal CD5⁺CD19⁺ B-lymphocytes, which may become more aggressive by acquisition of genome-wide somatic gene mutations and cytogenetic aberrations. Large-scale genomic ultra-deep sequencing of CLL cells has detected mutational signatures consistent with activity of the APOBEC (apolipoprotein B mRNA editing enzyme, catalytic polypeptide) family of cytidine deaminases, including activation-induced deaminase (AID) and APOBEC3 genes. This suggests that expression of APOBEC family members may lead to CLL progression. To test this, we correlated APOBEC family member gene expression

in CLL cells by microarray and quantitative real time PCR with patient outcome (time to first treatment and overall survival). Expression differences in AID, APOBEC3B, APOBEC3F and APOBEC3H in CLL cells exhibited correlations with worse patient outcome, whereas APOBEC3G did not. APOBEC3A levels were very low and difficult to measure. Interestingly, expression of a truncated splice variant of APOBEC3F exhibited an inverse correlation with worse patient outcome. We hypothesize that expression of truncated APOBEC3F may interfere with APOBEC3 family member mutational activity. To test mutational activity in CLL, we activated CLL cells by xenograft transfer into NOD-scid IL2Ry^{null} mice and analyzed mutational signatures in the expressed immunoglobulin variable region (IGHV). Induced IGHV mutational signatures consistent with AID, but little APOBEC3 activity, were found. This suggests that mutational activity of APOBEC3 genes in IGHV is inhibited, although their activity outside of IGHV cannot be excluded. Furthermore, these data support the hypothesis that AID mutation activity in CLL could lead to adverse consequences.

Regulation of inflammatory tumor microenvironments by SphK1/S1P signaling

Guo, B.¹, Ogretmen, B.², Li, Z.¹

¹Medical University of South Carolina (MUSC), Department of Microbiology and Immunology, Charleston, United States, ²Medical University of South Carolina (MUSC), Department of Biochemistry and Molecular Biology, Charleston, United States

Tumor growth and progression are influenced by the interaction between tumor cells and inflammatory microenvironments. Sphingolipids, specifically ceramide and sphingosine 1-phosphate (S1P), are bioactive signaling molecules, which regulate cellular survival, proliferation, migration in innate and adoptive immune systems. Emerging evidence indicates that S1P also plays important roles in the development of various tumors, including breast cancer, through its ability to promote tumor cell growth, and invasion. In human cancer patients, increased expression of sphingosine kinase 1 (SphK1), a kinase for S1P synthesis, is correlated with poor prognosis and high incidence of diseases recurrence. While most of studies have focused on the role of sphingolipids in proliferation and survival of cancer cells, how the SphK1/S1P pathway modulates inflammatory microenvironments and tumor immunity is poorly understood. Our preliminary data have demonstrated that the interaction of sphingolipids and inflammasomes modulates tumor microenvironment and promote tumor metastasis. Inflammasomes are newly recognized innate immune sensors critical for active IL-1 β production and inflammatory response. Our results show that S1P induced inflammasome activation and IL-1 β production. We found that mice deficient for SK1 or inflammasome components had much reduced tumor growth and lung metastasis. Interestingly, we also found that IL-1 induced expression of SK1 in macrophages and tumor cells. Together, our results support a novel model whereby sphingolipids and inflammasome/IL-1 pathways are functional linked to induce inflammation and tumor development.

Cytokines, Interferons & Inflammation 1

The potential of inflammatory responses to contribute to the development of transfusion-related acute lung injury (TRALI)

Sultana, A.^{1,2,3}, Meka, D.^{1,3}, Dean, M.M.^{1,3}, Simonova, G.^{1,4}, Christensen, A.-M.^{1,3}, Flower, R.L.^{1,2,3}, Tung, J.-P.^{1,2,3,4}

¹Australian Red Cross Blood Service, Research and Development, Kelvin Grove, Australia, ²University of Queensland, School of Medicine, Brisbane, Australia, ³Queensland University of Technology, Faculty of Health, Brisbane, Australia, ⁴The Prince Charles Hospital, The Critical Care Research Group, Chermside, Australia

Transfusion-related acute lung injury (TRALI) is a significant cause of post-transfusion morbidity and mortality. TRALI develops via a two-insult mechanism: the first insult being the patient's underlying morbidity, and the second insult being transfusion-related. Biological response modifiers (BRMs) that accumulate during blood product storage and anti-leucocyte antibodies are considered causative. Recruitment and activation of neutrophils and monocytes is implicated in TRALI; however, the precise mechanisms remain uncertain.

An in vitro transfusion model was developed in which blood from healthy volunteers, incubated with or without lipopolysaccharide (LPS; first insult), was exposed to either a BRM (soluble CD40 ligand (sCD40L), 5-hydroxyeicosatetraenoic acid (HETE), 12-HETE, 15-HETE or interleukin (IL)-8) or an antibody (antibody targeting human leucocyte antigen (HLA) class II). Cytometric bead array, intracellular staining and flow cytometry were used to investigate overall, neutrophil-specific and monocyte-specific inflammatory responses (i.e. changes in concentration or expression of a panel of chemokines and cytokines).

Without LPS, inflammatory responses were suppressed following exposure to BRMs or anti-HLA-II, suggesting that less ill patients may have an increased risk of infection following transfusion of these factors. In contrast, in an induced inflammatory state (i.e. with LPS), exposure to anti-HLA-II, IL-8, 12-HETE or 15-HETE resulted in pro-inflammatory changes, suggesting that the transfusion of these factors may contribute to TRALI development in severely ill patients.

This study modelled how transfusion-related inflammation may contribute to the development of TRALI. This improved understanding may contribute to the identification of strategies to reduce the risk of TRALI and improve blood transfusion safety.

IL-27 induces T cell stemness and restrains their effector functions in vivo

Liu, Z.¹, Zhu, J.², Liu, J.-Q.¹, Wu, L.¹, Zhu, X.¹, Bai, X.-F.^{1,2}

¹Ohio State University, Columbus, United States, ²Shanghai Jiaotong University School of Medicine, Shanghai, Shanghai, China

Interleukin-27 (IL-27) is a heterodimeric cytokine that is composed of two subunits, i.e. Epstein-Barr virus (EBV)-induced gene 3 (EBI3) and IL-27p28 (also known as IL-30). IL-27 is known

to induce the expression of a range of inhibitory molecules such as IL-10 and PD-L1 in T cells. Our previous *in vitro* study has revealed that IL-27 also induces T cell expression of Sca-1/Ly-6A, a cell surface glycoprotein that controls self-renewal capacity of stem cells. In this study, we have examined if IL-27 induces Sca-1 expression in T cells *in vivo* and its functional relevance. We found that IL-27-deficient mice (deficient for either P28 or EBI3) had profound reduction of Sca-1 expression in naïve and memory T cells. In contrast, *in vivo* delivery of IL-27 using adeno-associated viral vectors (AAV) strongly induced the expression of Sca-1 in naïve and memory T cell populations in a Stat1-dependent manner. In IL-27-deficient mice, ConA-induced liver injury was significantly enhanced, with reduced expression of Sca-1, PD-L1 and IL-10 in liver T cells. In contrast, *in vivo* delivery of IL-27 by AAV induced the expression of Sca-1, PD-L1 and IL-10 in liver T cells and significantly protected mice from ConA-induced liver injury. Thus, IL-27 induces T cell “stemness” but at the same time restrains their immediate effector functions *in vivo*.

A new GM-CSF-dependent pathway in arthritis

Achuthan, A., Lee, M.-C., Saleh, R., Frye, A., Fleetwood, A., Cook, A., Hamilton, J.

University of Melbourne, Dept of Medicine, Parkville, Australia

The socioeconomic burden of inflammatory diseases, such as rheumatoid arthritis, is enormous both in terms of direct and indirect healthcare costs. Clinical trials in rheumatoid arthritis targeting the cytokine, granulocyte macrophage-colony stimulating factor (GM-CSF) are showing promise although its mode of action remains largely unknown. Increased macrophage numbers in the synovial fluid from arthritic knee joints is highly correlated with the severity of the disease. The interferon regulatory factor (IRF) family of transcription factors are important in controlling expression of genes involved in immune functions. Their key role in controlling gene expression in monocytes/macrophages has recently become a major focus of research.

We report here that GM-CSF induced IRF4 expression, while suppressing IRF8 in primary human monocytes. We found that the chemokine CCL17 expression was induced in GM-CSF-treated human monocytes and largely dependent on IRF4 transcription factor. Significantly, a recent study reported that synovial fluid from patients with rheumatoid arthritis had elevated levels of CCL17 as compared to healthy controls. Interestingly, CCL17 gene is clustered together with CCL22 and CX3CL1 on human chromosome 16q13. The transcriptional regulation of these three chemokines by GM-CSF in human monocytes and their role in *in vivo* arthritis models will be presented and discussed.

137

Enhanced expression of BAFF receptor (BR3) on peripheral monocytes contributes production of IgG by B cells through IL-6 signaling in patients with primary Sjögren's syndrome

Yoshimoto, K., Ishioka, E., Nishikawa, A., Suzuki, K., Takeuchi, T.

Keio University School of Medicine, Tokyo, Japan

Background and purpose: We found that the expression level of BAFF receptor (BR3) on pSS monocytes was significantly elevated compared with normal monocytes, and that BAFF robustly increased IL-6 production by pSS monocytes *in vitro*. We also found that the proportion of BR3 positive monocytes (BR3+/CD14+) was positively and significantly correlated with the serum IgG level in pSS patients. These data suggest a possible involvement of monocytes in IgG production. In this study, we investigated a role of BAFF and IL-6 as mediators in the stimulation of B cells by monocytes.

Methods: Peripheral monocytes were co-cultured with B cells in the presence of soluble BAFF (sBAFF) and an anti-human sIL-6R antibody. B cells and monocytes were either directly mixed or separated with a transwell insert in the well. The amounts of IL-6 and IgG in the culture supernatants were measured by ELISA. The expression of BR3 and CD14 on monocytes was analyzed by FACS.

Results: Stimulation of a co-culture of pSS B cells and monocytes with sBAFF drastically enhanced IgG production *in vitro*. It should be noted that separation of these cells by a transwell insert in a well did not suppress the IgG production, suggesting an involvement of humoral factor(s) in the IgG production. Moreover, addition of an anti-human sIL-6R antibody to the co-culture significantly inhibited the IgG production.

Conclusions: Based on these findings, we presume that IL-6 produced by BAFF stimulated monocytes plays a pivotal role in IgG production by pSS B cells.

Methylation transferase EZH2 was involved in the effect of let-7e on TNF- α expression in DENV2-infected THP-1 cells

Zhang, Y., Zhang, Q., Gui, L., Cai, Y., Guo, Q., Huang, J., Junqi

Huang's Lab

The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

In a small proportion of cases, dengue fever (DF), a mosquito-borne tropical disease caused by the dengue virus (DENV), develops into the life-threatening dengue hemorrhagic fever (DHF), or into dengue shock syndrome (DSS). Patients with DHF/DSS present a ‘cytokine storm’, with high levels of circulating cytokines and chemokines, including tumor necrosis factor α (TNF α). Our previous study revealed that the increased level of miRNA let-7e was associated with downregulation of TNF α in DENV-infected PBMCs. In this study we demonstrated that let-7e was able to inhibit TNF α expression and confirmed that not TNF α but methylation transferase enhancer of zeste homolog 2 (EZH2), histone methyltransferase catalyzing histone H3K27me₃, was the direct target of let-7e. We found silence of EZH2 (siEZH2) could inhibit TNF- α expression by downregulation of Arfaptin2 and ARFGAP1, two vesicular transporter that are helpful for

cytokine secretion with the function in ADP-ribosylation factor (Arf)-dependent membrane traffic outside the ER-Golgi. siEZH2 can also inhibit NF kappa B pathway to downregulate TNF- α expression.

ApoE production in monocytes is altered by anti-inflammatory drugs

Beckman, L.¹, Kumagai-Braesch, M.², Lind, K.¹, Braesch-Andersen, S.¹
¹Mabtech AB, Nacka Strand, Sweden, ²Karolinska Institutet, Transplantation Surgery, Stockholm, Sweden

We have previously shown that peripheral blood monocytes produce considerable amounts of apoE when induced by TGF β and that this apoE production is inhibited by inflammatory signals, similarly to tissue macrophages. In apoE deficient mice it has been shown that restoring apoE production in tissue macrophages is crucial for preventing damage to blood vessels. It is well known that patients suffering from atherosclerosis have signs of chronic low grade inflammation in their vessels and it is likely that this will affect apoE production vital for healing. There are a large number of different anti-inflammatory substances on the market and here we want to see if any of these could be useful for restoring apoE production in atherosclerotic tissues. We have used Peripheral Blood Mononuclear Cells (PBMC) and the monocytes present in these preparations to look at the effects of a large number of anti-inflammatory pharmacological substances on apoE production. By addition of TGF β with or without TNF α in the culture, we can alter the basic apoE production of PBMC and then investigate how the production is affected by co-culturing with pharmacological substances at concentrations achieved by recommended doses. We analyzed apoE production by ELISA, ELISpot and Fluorospot. We can show that several anti-inflammatory substances affect the monocyte apoE production. Ibuprofen significantly increases apoE production while Diclofenac, acetyl-salicylic acid and Exendin-4 have no such effects. This indicates that these substances vary in their ability to increase monocyte apoE production and maybe how they modulate the immune system in an anti-atherogenic direction.

Zebrafish as a genetic model for leukemia and other hematopoietic disorders

Basheer, F., Liougue, C., Ward, A.C.
 Deakin University, School of Medicine, Waurn Ponds, Australia

Cytokines play a major role in regulating hematopoiesis and immunity. Perturbed cytokine signalling has been implicated in a variety of myeloproliferative disorders, including leukemia. Unravelling the molecular mechanisms involved in the pathogenesis of these hematological malignancies can provide major insights into their mechanism of action and contribute to the development of novel therapeutics. Indeed cytokine receptors and the associated tyrosine kinases are attractive targets for oncogenic therapy, with dysregulation often leading to constitutive activation that can be successfully inhibited

by pharmacological agents. Zebrafish is well suited to model hematopoiesis and leukemogenesis, providing information into underlying genetic causes, as well as providing a platform for therapeutic testing. This project aims to generate mutants of relevant cytokine signalling components by genome editing to create zebrafish models of hematologic malignancies and other disorders. The first of these targets the *jak3* gene, encoding a key tyrosine kinase downstream of the interleukin 2 receptor family.

Anti-myeloperoxidase pathogenic autoimmunity can be induced by a *Staphylococcus aureus* plasmid derived peptide

Ooi, J.D.¹, Jiang, J.-H.², Eggenhuizen, P.J.¹, Holdsworth, S.R.^{1,3}, Peleg, A.Y.^{2,4}, Kitching, A.R.^{1,3,5}

¹Monash University, Centre for Inflammatory Diseases, Clayton, Australia, ²Monash University, Infection and Immunity Program, Monash Biomedicine Discovery Institute, Department of Microbiology, Clayton, Australia, ³Monash Health, Department of Nephrology, Clayton, Australia, ⁴Monash University, Department of Infectious Diseases, The Alfred Hospital and Central Clinical School, Prahran, Australia, ⁵Monash Health, Department of Paediatric Nephrology, Clayton, Australia

Microscopic polyangiitis is a small-vessel vasculitic autoimmune disease whereby autoreactivity to the neutrophil enzyme myeloperoxidase (MPO) causes rapidly progressive glomerulonephritis. It is unknown how tolerance is lost, but there are reports in patients that *S aureus* infections precede anti-MPO autoimmunity, and in other forms of vasculitis, molecular mimicry has been shown to induce cross-reactive pathogenic autoimmunity.

This study tests the hypothesis that molecular mimicry induces cross-reactive pathogenic anti-MPO autoimmunity. A BLAST search was used to identify 5 candidate microbial peptides with homology to the immunodominant MPO T-cell epitope, MPO₄₀₉₋₄₂₈. Anti-MPO T-cell responses were determined by immunizing C57BL/6 mice with candidate peptides then measuring recall responses *ex vivo* to MPO by ³[H]-T proliferation and IFN- γ and IL-17 ELISPOTs. Anti-MPO antibodies were measured by ELISA, immunofluorescence on ethanol-fixed neutrophils and by enumerating neutrophil glomerular recruitment after passive transfer of antibody. Disease was assessed by immunizing mice with peptide or whole bacteria followed by depositing MPO in the glomerulus using low-dose sheep anti-mouse glomerular basement membrane antibodies, then measuring functional and histological endpoints.

Only 1 peptide induced cross-reactive T-cell responses to MPO. This peptide was derived from a *S aureus* plasmid. Antibodies from mice immunized with this peptide cross-reacted with MPO, bound to neutrophils in a perinuclear fashion, and induced neutrophil glomerular recruitment. Furthermore, mice immunized with either this peptide or a clinical strain of *S aureus* containing the plasmid, developed albuminuria and focal necrotizing glomerulonephritis. This shows that molecular

mimicry by a *S aureus* plasmid derived peptide induces anti-MPO pathogenic autoimmunity.

Short chain fatty acids regulate CD1d-restricted natural killer T cells in limiting autoimmune diabetes

Richards, J.L., McLeod, K.H., Yap, Y.A., Mackay, C.R., Mariño, E. Monash University, Biochemistry, Clayton, Australia

Type 1 Diabetes (T1D) is a T cell-mediated autoimmune disease leading to serious complications, with rising incidence in western countries. Protection in non-obese diabetic (NOD) mice deficient in MyD88, and housed in specific pathogen free facilities, have reduced T1D incidence, while germ-free counterparts experience exacerbated disease, implicating gut microbiota in T1D protection. High fiber diet modify commensal gut microbiota to produce short-chain fatty acids (SCFAs) acetate and butyrate, which have anti-inflammatory effects. Acetate is the main ligand for the receptor GPR43, and deficiency of this receptor in NOD mice results in accelerated disease under SPF housing. Here we showed that NOD.Gpr43^{-/-} mice as well as germ free NOD mice presented a reduced frequency of CD1d-restricted iNKT cells compared to NOD mice. iNKT cells are implicated in the regulation of different autoimmune diseases in mice and humans. We found that feeding NOD mice with high acetate-yielding diets increased splenic iNKT numbers coincident with decreased mature CD1d⁺ marginal zone B cell numbers. Interestingly, IL-17A⁺ iNKT cells from the pancreatic lymph nodes were reduced, whereas IL-4⁺ NKT (NKT2) cell numbers were elevated. Thus, SCFA may target iNKT cell subsets differently based on tissue distribution and T1D progression. This is a critically important since poor quality of diets affecting the gut microbiota towards pathogenic bacteria could contribute to the increased T1D in western countries.

Autoimmune response to amyloidogenic transthyretin in childhood arthritis

Moncrieffe, H.¹, Clement, C.C.², Lele, A.¹, Porcelli, S.A.³, Santambrogio, L.^{2,3}

¹Cincinnati Children's Hospital Medical Center, Center for Autoimmune Genomics & Etiology, Cincinnati, United States,

²Albert Einstein College of Medicine, Department of Pathology, New York, United States, ³Albert Einstein College of Medicine, Pediatric Rheumatology, New York, United States

The most common pediatric rheumatologic condition is juvenile idiopathic arthritis (JIA): an estimated 1 child in every 1000 develops inflammation of the joints before the age of 16. The antigens which trigger JIA are unknown and are hypothesized to be autoantigenic. The aim of this study was to identify putative autoantigenic triggers using a cohort of 50 patients with JIA and 24 age-matched healthy controls. Through detailed proteomic profiling, the transporter protein transthyretin (TTR) was revealed as a candidate antigenic target for B and T cell immune responses in JIA. To assess whether TTR was located in the JIA inflamed site, ELISA was performed and

both TTR protein and anti-TTR autoantibodies were present at a significantly higher amount in JIA patients and compared to controls ($p < 0.001$). Profiling of immune complex-associated antigens in JIA synovial fluid revealed transthyretin was bound to IgG at the site of inflammation. TTR peptides were found in peptidome of JIA patient synovial fluid and synthesized TTR peptides were used to test T cell reactivity. HLA-DR1-restricted peptides induced production of the proinflammatory cytokines IFN γ and TNF α as well as CD4⁺ T cell proliferation in a subset of patients. Together, these data indicate a role of TTR as an autoantigen involved in JIA pathology.

⁴Taipei Medical University Shuang Ho Hospital, Department of Internal Medicine, Taipei, Taiwan, Republic of China, ⁵National Taiwan University College of Medicine, Graduate Institute of Immunology, Taipei, Taiwan, Republic of China, ⁶National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Republic of China

Rheumatoid arthritis (RA) is a complex, heterogeneous systemic autoimmune disease involving a wide array of joint inflammation and bone erosion, eventually leading to disabling with a significant morbidity and mortality. Targeting to key points of the pathogenesis of RA is the current mainstay of new therapeutics development. Tumor necrosis factor (TNF)-related apoptosis-inducing ligand (TRAIL) belongs to TNF superfamily; from recent studies and accumulated evidences, in addition to triggering apoptosis, TRAIL has been implicated its actual biological function in immune-regulation and immune-mediated diseases. However, the role of TRAIL in autoimmune arthritis remains to be elucidated. In this study, we demonstrated that TRAIL significantly inhibited joint inflammation and development of arthritis in collagen-induced arthritis (CIA) rats. The effect of TRAIL-induced suppression of arthritis in CIA was as potent as TNF inhibitor, etanercept. Furthermore, TRAIL profoundly suppressed the joint inflammation, synovium proliferation and restored bone erosion. Interestingly, the inhibition of joint inflammation by TRAIL was not through the effects of inducing apoptosis in T cells or macrophages. By contrast, TRAIL could directly inhibit T cell proliferation and T cell-derived inflammatory cytokines, indicating TRAIL may exert its anti-arthritic effect through T cell inactivation. Our results provided evidence of a novel mechanism of TRAIL in anti-inflammatory arthritis and shed light on the possible therapeutic application in inflammatory arthritis and in developing better strategies for treating RA in the future.

3045**IL-33 modulates IL-10 and Treg responses in a mouse model of drug hapten, immune-mediated hepatitis**

Cottagiri, M.¹, Mallory, B.¹, Chen, G.¹, Thomas, D.¹, Mantila, J.¹, Rose, N.^{2,3}, Njoku, D.⁴

¹Johns Hopkins University, ACCM, Baltimore, United States, ²Johns Hopkins University, Pathology, Baltimore, United States, ³Harvard University, Pathology, Boston, United States, ⁴Johns Hopkins University, ACCM, Pathology, Pediatrics, Baltimore, United States

Hepatitis is a global health problem linked to autoimmunity, fibrosis and cancer. IL-33 modulates hepatitis and fibrosis in animal models; however, in these models IL-33/ST2 signaling is either protective¹ or pathogenic². IL-33 has been detected in sera of hepatitis C patients. We detected significantly elevated IL-33 in sera from patients with immune-mediated hepatitis from anesthetics, as well as in BALB/c mice with drug-hapten hepatitis modeled after this disease, where mice are immunized on days 0 and 7 with cytochrome P450E1 epitopes covalently modified by trifluoroacetyl chloride drug haptens formed during anesthetic metabolism. In our mouse model, we detected innate lymphoid cells expressing the IL-33 receptor ST2 by flow cytometry, as well as IL-4 and IL-6-driven hepatitis by 3 weeks. Intraperitoneal anti-IL-33 diminished hepatitis in BALB/c mice, and IL-33 deficient (-/-) mice produced significantly less IL-4 and IL-6 (ELISA) early in the disease pathogenesis. However, IL-33-/- mice developed significant hepatitis by 3 weeks along with significantly down-regulated hepatic IL-10 (ELISA) and regulatory T cell (Treg)-associated Foxp3 mRNA (NanoString®), suggesting that IL-33 modulates IL-10 and Treg responses to immunizations. A recent study reported that IL-33 promotes Treg function in rodent experimental colitis³. We previously showed that Tregs significantly reduced drug-hapten hepatitis⁴. Our preliminary findings suggest that IL-33 has both proinflammatory and suppressive roles in drug-hapten hepatitis possibly via Treg immunomodulation. Investigating IL-33 immunomodulation in drug-hapten hepatitis could uncover targets that modulate hepatitis from other etiologies.

564**The role of somatic hypermutation and N-glycosylation in the anti-NET immunoreactivity of RA synovial monoclonal antibodies**

Corsiero, E., Carlotti, E., Prediletto, E., Jagemann, L., Pitzalis, C., Bombardieri, M.

William Harvey Research Institute, Centre for Experimental Medicine & Rheumatology, London, United Kingdom

Anti-citrullinated peptide/protein antibodies targeting citrullinated antigens in neutrophils-extracellular-traps (NET) can be manufactured within ectopic-germinal-center-like structure (GC-LS) in the rheumatoid arthritis (RA) synovium. Here, we aimed to characterise: whether RA-synovial anti-NET antibodies had undergone antigen-driven affinity maturation,

somatic hypermutations (SHM) importance within VH/VL chain for NET binding and for Fab-domains N-glycosylation.

82 recombinant monoclonal antibodies (RA-syn-rmAbs) were generated from single CD19+B-cells FACS-sorted from fresh GC-LS+ synovial cell suspensions following IgVH+VL genes cloning. N-glycosylation was predicted with NetNGlyc1.0-Server and glycans presence was detected by total glycoprotein staining on gel. IgV genes reversion into germ-line (GL), generation of hybrid clones (VH/VL or selected CDRs/FRs reverted into GL, n=5) and N-glycosylation mutants (NtoQ, n=7) was performed by overlap-PCR. Anti-NET immunoreactivity was detected using cell-based immunoassays with activated peripheral blood or RA-synovial fluid neutrophils.

The RA-syn-rmAbs anti-NETs immunoreactivity was dependent on affinity maturation within GC-LS and was completely abrogated in the GL counterpart. Similarly, when only the single IgVH/VL gene was reverted into GL, NETs reactivity was lost suggesting that both VH+VL chains are important in this reactivity. The increased molecular weight observed in selected anti-NET antibodies was dependent on the presence of Fab-linked glycans and was lost in the GL counterpart.

Thus, SHM seems necessary for high-affinity NET-binding antibodies development in synovial GC-LS and for N-glycosylation introduction sites in the Fab-domain which could influence the NET-antigens binding. Defining the contribution of individual CDRs/FRs to the affinity of antigen-binding sites may help to engineer new therapeutic Abs and design of CDRs/FRs-specific peptides for tolerogenic strategy.

3291**A small-molecule preclinical candidate targeting ROR γ t shows a benign safety profile and effectively reduces clinical scoring and biomarker levels in mouse disease models**

Nielsen, S.J., Christiansen, S.J., Bengtsson, M., Andersson, J.L., Nørager, N.G., Ryborg, S., Jensen, K., Vestergaard, M., Stasi, L.P., Gouliarov, A.H., Franch, T., Glad, S.
Nuevolution A/S, Copenhagen, Denmark

Excessive production of the cytokine IL17A is the key driver in multiple autoimmune diseases, including Psoriasis, Psoriatic arthritis, and Ankylosing spondylitis as supported by clinical data using IL17A-directed antibodies.

The nuclear hormone receptor ROR γ t is a ligand-activated transcription factor, exclusively expressed in cells of the immune system, acting as a master regulator of IL17A production. Consequently, a small molecule targeting the ligand binding domain (LBD) of ROR γ t preventing the production of pro-inflammatory IL17A may offer a convenient oral therapy for IL17A-triggered inflammatory diseases.

We identified potent small molecule inhibitors from the screening of 830 million DNA-encoded compounds against ROR γ t-LBD. A lead series preventing SRC-1 co-activator recruitment was selected for further medicinal chemistry optimization. The resulting candidate compound has an IC₅₀ of 8nM in cell-based reporter assays and >100-fold selectivity against other NHRs. It is a low nM inhibitor of IL-17 production in PBMC and T-cell polarization assays with no effect on T_H1/2

cytokines. The candidate has attractive DMPK properties, high oral bioavailability and shows strong efficacy in clinical scoring and on biomarkers in several animal models of arthritis and dermatitis. In 7-day exploratory toxicology studies in mice, daily doses up to 600 mg/kg were well tolerated with no adverse effects, and only minimal findings in lymphoid tissues, indicating a safety window of ≥ 20 fold over a maximally efficacious dose. Our studies validate ROR γ t as a therapeutic target and indicate that our candidate warrants further investigation as a once-daily oral medicine in human autoimmune diseases.

Adoptive Cell Therapy

1

CAR T cells are potent serial killers

Davenport, A.¹, Jenkins, M.R.¹, Cross, R.S.¹, Yong, C.S.¹, Trapani, J.A.¹, Kershaw, M.H.¹, Ritchie, D.S.^{1,2}, Darcy, P.K.¹, Neeson, P.J.¹

¹Peter MacCallum Cancer Centre, Cancer Immunology Research, Melbourne, Australia, ²Royal Melbourne Hospital, ACRF Lab, Department of Medicine, Melbourne, Australia

Adoptive therapy with autologous chimeric antigen receptor (CAR) T cells was rapidly translated into the clinic with success in refractory B-ALL and B cell lymphoma, but not other types of cancer. We postulate unknown features of CAR-T cell biology contribute to this low response rate in non-B cell cancers. We investigated whether the antigen receptor (CAR vs endogenous TCR) affected CAR-T cell immune synapse formation and tumour cell killing kinetics. We developed a novel transgenic mouse (designated CAR.OT-I), in which CD8⁺ T cells co-express the OVA₂₅₇-specific T cell receptor (TCR) and a second generation CAR with an scFv specific for human HER2. Day 7 OVA₂₅₇ activated CAR.OT-I T cells were re-stimulated with OVA₂₅₇-pulsed (TCR) or HER2-expressing tumour cells (CAR) and killing kinetics examined using time-lapse and confocal microscopy.

We show for the first time, irrespective of the mode of recognition, individual CAR.OT-I cells kill multiple tumour cells ('serial killing') and they detach more quickly from dying targets. We provide evidence for a different immune synapse structure between CAR and TCR mediated killing by CAR.OT-I T cells. Despite a faster detachment rate, CAR-T cells do not display enhanced cytotoxicity of tumour target cell populations in the long term (48 hrs), as CAR expression becomes downregulated. This study provides visual evidence that CAR T cells can serially kill multiple tumour targets in quick succession and provides important insights into CAR-T/tumour cell molecular interactions, which may have wider implications for solid tumour therapy using CAR T cells.

2

Combined immune and epigenetic therapy for high risk and relapsed leukaemias and lymphomas

Dolnikov, A.¹, Yang, S.², Shen, S.¹, Xu, N.¹, O'Brien, T.¹

¹Sydney Children's Hospital, Cord and Marrow Transplant Laboratory, Randwick, Australia, ²Children's Cancer Institute for Medical Research, Randwick, Australia

T-cells genetically modified with Chimeric Antigen Receptor (CAR) to target malignant cells is a novel approach with proven success in early phase human trials. A patient's own T-cells genetically modified with CAR can be amplified ex-vivo to numbers suitable for adoptive cell therapy and administered to the patient. Engineered T cells traffic to the tumour site

and kill cancer cells. CART cells then up-regulate immune-inhibitory receptors that suppress their immune function. In addition, CART-cell functionality can be compromised by the immunosuppressive tumour microenvironment. We have proposed the use of immune modulatory agents to maximise the effect of CART-cells. Using xenograft mouse model of chemoresistant paediatric B-cell lymphoblastic leukaemia (B-ALL) we have shown that CART-cell therapy can be potentiated by administration of a demethylating agent azacytidine (AZA) given prior to CART-cell infusion. Pre-treatment with AZA increased the numbers of short-lived effector memory (Tem)-cells with the robust anti-tumour activity. AZA-treated leukaemia cells expressed increased levels of CD80 ligand activating co-stimulatory CD28 signalling in Tem cells and commonly down-regulated in paediatric B-ALL. We hypothesise that AZA up-regulates the immune stimulatory ligands expressed by cancer cells thus converting tumour environment from immunosuppressive to immune-stimulating. B-ALLs demonstrate variable levels of multiple immune stimulatory and inhibitory molecules. Significant differences in CART-cell functions were found to be target B-ALL-dependent and correlate with the expression of co-stimulatory and inhibitory molecules on B-ALL cells. Our data justify the use of combined checkpoint inhibitor and epigenetic treatments to further potentiate CART-cell therapy.

3

Haematopoietic stem cells to generate chimeric antigen receptor (CAR)-modified T cells

Shen, S.¹, Xu, N.², Yang, S.³, O'Brien, T.², Dolnikov, A.²

¹Sydney Children's Hospital, Randwick, Australia, ²Sydney Children's Hospital, Cord and Marrow Transplant Laboratory, Randwick, Australia, ³Children's Cancer Institute for Medical Research, Randwick, Australia

Using T cells modified with a chimeric antigen receptor (CAR) recognising tumour antigen is a novel approach to treat cancer with proven success in clinical trials demonstrating a potent anti-cancer effect of CART-cells. However, the proportion of patients demonstrated only transient *in vivo* persistence of CART-cells was demonstrated, resulting in tumour recurrence. We and others have proposed that T cells with younger phenotype - central memory or naïve T cells and even stem memory T cells and T-cell precursors transduced with CARs can provide better *in vivo* expansion and long-term *in vivo* persistence of mature CART-cells. Here we tested a new approach to improve CART-cell persistence through the transduction of CARs into haematopoietic stem cells (HSC). Retroviral vector was used to transduce cord blood derived CD34⁺HSCs with CAR targeting human CD19 expressed in B-cell malignancies and normal B-cells or GD2 expressed in neuroblastoma and sarcomas.. Transduction with CARs achieved 60-70% and CAR-transduced HSCs engrafted immune-deficient mice with some delay compared to mock-HSCs. T-cells generated from CAR-transduced HSCs developed memory subsets confirming the expectation of development of long-lasting phenotypes. Mice transplanted with CAR-HSCs targeting CD19 had decreased CD19⁺B-cell populations confirming functionality of CAR targeting *in vivo*.

Delayed cancer progression following challenge with CD19⁺ leukaemia Raji cells or GD2⁺ neuroblastoma was observed in CAR-HSC-reconstituted mice compared to untreated controls. Anti-cancer effect was more robust and durable in stem cell reconstituted mice compare to mice received mature CART-cells. In summary, our data support the concept of genetic modification of HSCs with CARs.

4

Scalable human T cell isolation, activation and expansion using EasySep™ and ImmunoCult™

Kokaji, A.L.¹, Sun, C.A.¹, Ng, V.¹, Lam, B.S.¹, Clarke, S.J.¹, Woodside, S.M.¹, Eaves, A.C.^{1,2}, Thomas, T.E.¹

¹STEMCELL Technologies Inc., Vancouver, Canada, ²Terry Fox Laboratory, BC Cancer Agency, Vancouver, Canada

Cancer immunotherapy using chimeric antigen receptor T cells has demonstrated unprecedented success in early clinical trials. To enable researchers advancing this exciting field, we have developed novel cell isolation and activation reagents, and specialized culture medium required for the manufacturing of these cellular products. EasySep™ is a fast and easy immunomagnetic cell isolation platform for purifying T cells directly from leukopheresis samples. To induce T cell activation, we developed the soluble ImmunoCult™ Human T Cell Activators that have been optimized for use with our serum- and xeno-free ImmunoCult™-XF T cell expansion medium.

EasySep™ isolated T cells were cultured using soluble ImmunoCult™ activators or a bead-based CD3/CD28 activator in the presence of IL-2 or IL-7 and IL-15. The expression of activation markers including CD25, CD137, and PD-1 was monitored and the phenotype of the expanded T cells was determined with an antibody panel that included CCR7, CD27, CD28, CD45RA, CD95 and CD62L.

To demonstrate the scalability of our reagents, EasySep™ isolated T cells were expanded using ImmunoCult™ and bead-based CD3/CD28 activators in two large-scale systems: G-REX flasks and the GE Xuri cell expansion system. Both bioreactor systems and activators effectively expand T cells over the course of a 10 day culture period and upon restimulation, the T cells can continue to proliferate and produce effector cytokines, thereby confirming their functionality post-expansion. Taken together, our EasySep™ and ImmunoCult™ reagents can be used for the isolation and large-scale expansion of functional human T cells with equivalent performance to bead-based activation reagents.

5

iPSC based adoptive immunotherapy by using genome editing strategy

Minagawa, A.¹, Hotta, A.¹, Uemura, Y.², Nakatsura, T.², Kawana, K.³, Kaneko, S.¹

¹Kyoto University, Center for iPSC Research and Application, Kyoto, Japan, ²National Cancer Center, Kashiwa, Japan, ³University of Tokyo, Gynecology, Tokyo, Japan

We have reported that differentiating iPS cells established from antigen specific monoclonal CD8 T cells (T-iPSCs)

enables us to produce large amount of young CD8 T cells that are comparable to original CD8 T cells in antigen specificity. This technology enables us to establish iPSC based adoptive cancer immunotherapy. However it turned out that loss of antigen specificity occurs during optimized differentiation method into functional CD8 T cells. As a solution for this, we have developed Recombination Activating gene2 (RAG2) knock-out strategy by using CRISPER Cas9 system.

Method and outcome: We established Glypican-3 (liver cancer expressing antigen) specific TCR having T-iPSCs and knocked out RAG2 gene. By differentiating these cells into CD8 T cells and analyzing TCR $\alpha\beta$ sequence we confirmed the positive effect of RAG2 KO for preserving Glypican-3 specificity. We also confirmed the specific killing function of differentiated RAG2 KO CD8 cells against Glypican-3 expressing tumor in vitro and in vivo.

Discussion: We have succeeded in making safer and more practical cells for clinical application by using genome editing strategy. This strategy would enables us to supply safe and effective cells for adoptive cancer immunotherapy in the future.

6

High throughput flow screening assays to profile cell-mediated killing

Chan, Y.Y., Kedarnath, S., Skiba, B.,

IntelliCyt Corporation, Albuquerque, United States

While enhancing T-cell mediated killing of tumor cells is emerging as a successful therapeutic approach for a variety of cancers, improvements to these therapies are actively being sought. Traditional assays for monitoring cell-mediated killing are only capable of homogenous live/dead readouts for an entire sample. As an alternative platform for cell-mediated killing studies, IntelliCyt's iQue Screener can identify multiple cell types in suspension and report multiple cell killing readouts in streamlined no wash assay formats. We demonstrate two example high throughput assays for cell-mediated killing using NK cells and chimeric antigen receptor (CAR) T-cells. Using the NK92 cell line as an effector cell and fluorescently encoded Jurkat cells as target cells, viability and Caspase 3 activation was determined for both Jurkat and NK92 cells in the same sample, and compounds that were generally cytotoxic to both cells could be identified. Specificity of the cell-mediated killing response was demonstrated using known signal transduction inhibitors including sunitinib, U73122, pp2, and wortmannin that would attenuate the NK cell killing activity, at a fixed target to effector cell ratio. In the CAR T-cell assay, efficacy of different CARs at targeting and killing a B-cell line (NALM-6) was profiled using multiplex readouts for cell health and secreted cytokines. Multiple cytokines including inflammatory markers and Granzyme B were quantified using bead-based ELISA on the same analysis platform. These application examples highlight the robustness and flexibility of the iQue Screener for performing multiplexed screening assays with cells and beads.

7

High potency dendritic cells generated via CD137L reverse signaling for dendritic cell-based immunotherapy

Dharmadhikari, B.¹, Harfuddin, Z.², Schwarz, H.^{1,2}

¹National University of Singapore, Physiology and Immunology Programme, Singapore, Singapore, ²National University of Singapore, 2. NUS Graduate School of Integrative Sciences and Engineering, Singapore, Singapore

Dendritic cell (DC)-based immunotherapy has relied on the use of monocyte-derived DCs, generated in vitro in the presence of GM-CSF and IL-4. Despite reported clinical benefits, the overall response remains low, largely due to the inability of DCs to mount a sufficiently strong T cell response. We have previously shown that CD137L reverse signaling induces differentiation of human monocytes to a novel type of dendritic cell (CD137L-DC) which are more potent than GM-CSF + IL-4 derived DCs. Here we report that CD137L-DCs have an inflammatory phenotype and are potential candidates for immunotherapy of Epstein-Barr Virus (EBV)-associated cancer(s). In our current study, CD137L-DCs generated from peripheral human monocytes (isolated by EasySep, STEMCELL Technologies) were used to test T cell responses against the LMP1 and LMP2 proteins of EBV via ELISPOT, followed by a cytotoxicity assay to test the ability of T cells activated CD137L-DCs to lyse HLA-matched, antigen-pulsed target cells. Our data shows that induction of proliferation and activation of EBV-specific T cells was significantly higher by CD137L-DCs than by GM-CSF + IL-4 derived DCs. Also the killing activity of CD137L-DC activated T cells was about 2-fold higher. The T cell exhaustion level was significantly lower upon activation of T cells by CD137L-DCs. Further characterization of CD137L-DCs showed low expression of PD-L1, an inflammatory phenotype with caspase-dependent IL-1 β secretion and a significant enrichment of inflammatory gene signatures. Thus, CD137L-DCs are a novel and highly potent type of in vitro generated DCs that should be of benefit for cancer immunotherapy.

Adoptive anti-tumor T cell immunotherapies have demonstrated promising results, notably for the treatment of chemotherapy-resistant cancers. Specifically, CD8⁺ T lymphocytes, genetically modified to express a chimeric antigen receptor (CAR) against the CD19 antigen, have been used to successfully treat refractory B leukemias/ lymphomas. However, recent studies also highlight

the potential role of other immune subsets in improving anti-tumor immunity. In order to fully explore the potential of different T cell subsets as well as other leukocytes armed with an anti-tumor CAR, we generated a preclinical transgenic mouse model expressing a CAR specific for the Her2 (ERB) tumor antigen in all immune subsets. Using this model, wherein the Her-CAR is expressed under the control of the *vav* pan-hematopoietic promoter, we found that Her2-CAR T cells exhibit Her2-specific immune responses, monitored as a function of cytokine secretion as well as cytotoxicity. Furthermore, we are assessing whether the metabolic features of Her2-CAR immune cells regulate their relative persistence, proliferation, differentiation and anti-tumor potential. To this end, the cellular metabolism of Her2-CAR immune cells has been altered by nutrient availability and Her2-CAR cells segregated on the basis of their glycolytic state, identified by surface Glut1 glucose transporter levels. The capacity to modulate the function of anti-tumor immune cells through a metabolism-based approach opens new avenues for optimizing adoptive immunotherapies.

9

Construction of CD47 specific CAR-NK and its anti-tumor activity *in vitro*

Huang, Q., Ren, H., Yang, H., Wang, Y., Li, Q., Shi, J., Shao, D., Zhang, M. Northwestern Polytechnical University, School of Life Sciences, Xi'an, China

T cells engineered with chimeric antigen receptors (CAR) and transferred into oncology patients is a promising approach to eradicate tumor cells. One major obstacle with CAR-T is the need to collect and utilize autologous cells. In contrast to T cells, natural killer (NK) cells are known to mediate anti-cancer effects without the risk of inducing graft-versus-host disease (GvHD). Therefore NK cells can be used as allogeneic effector cells since they do not require HLA matching.

At present, the CAR lentiviral expression vector designed for immuno-therapy CAR-NK was generated by connecting an extracellular antigen-binding domain of CD47 MAb single-chain variable fragment (scFv) to transmembrane domain of CD28 and intracellular signal transduction domain of CD28 and CD3z. A signal peptide of CD8 was introduced at N-terminal. Lentiviral particles were produced by transfecting 293 T cells with the lentiviral expression vector and the packaging vectors. CAR modified primary human NK cells were prepared by infecting the NK cells with lentiviral particles during the NK cells were expanded by co-culture with the irradiated K562 cell line expressing membrane bound IL-15 and 41BBL. For the anti-tumor activity of the CAR-NK *in vitro*, HepG2 and Caco2 cells were used as target cell. The cytotoxicity of CAR modified human primary NK cells showed 15% and 10% higher cytotoxicity of lysing HepG2 and Caco2 cells than that of unmodified human primary NK cells. This results will provide the basic data for the further study of CD47 specific CAR NK *in vivo*.

10

A rapid and easy system for screening of antigen-specific TCRs

Hamana, H., Kishi, H., Shitaoka, K., Xiuhong, P., Ozawa, T., Muraguchi, A. University of Toyama, Toyama, Japan

T cell receptor (TCR) gene therapy is a promising strategy for the treatment of various cancers. We reported an efficient cloning system for TCR cDNA from single antigen-specific human T cells within 10 days (Nature Med, 2013). However, evaluation of antigen specificity of cloned TCRs by using T cell line and retroviral vector is still troublesome and time-consuming. Therefore, we tried to establish a more convenient strategy. In this study, we constructed a 293T-NFAT-Luc cell line that enables us to detect activation of TCR by luciferase reporter assay. To this end, firstly we transduced NFAT-RE-luciferase reporter gene, cDNAs of mouse-CD8 and human-CD3 complex, -CD8, -SYK, -NFAT-C2 into 293T cells. To confirm the cell function, we expressed a 1G4 TCR that was specific to NY-ESO-1 on the cells and co-cultured them with COS-7 cells expressing NY-ESO-1 peptide, HLA-A02 and human beta-2-microglobulin. As a result, we observed the luciferase production in a peptide-dependent manner. Next, we tried to express TCR by using transcriptionally active PCR (TAP) fragments that have CMV promoter and poly-A additional signal. The 293T-NFAT-Luc cells transfected with TAP fragment of OT-I TCR cDNA produced luciferase when the cells were co-cultured with OVA peptide pulsed EL4 cells. These results suggest that a combination of 293T-NFAT-Luc and TAP fragment is useful for rapid and easy analysis of the specificity of cloned TCR from human as well as mouse. Now, we are trying high-throughput screening of melanoma-associated antigen TRP2-specific TCRs in mice by using our strategy.

11

Adoptive transfer of Tc17 CD8 T cells as an approach to elicit a better immune response to vaccination

Yen, H.-R.^{1,2}

¹China Medical University, School of Chinese Medicine, Taichung, Taiwan, Republic of China, ²China Medical University Hospital, Research Center for Traditional Chinese Medicine and Department of Chinese Medicine, Taichung, Taiwan, Republic of China

In our previous study, we found a novel subset of IL-17 producing CD8 Tc17 cells persisted longer and convert to an IFN- γ producing phenotype in a self-antigen autoimmune model; however, such an IL-17 producing Tc17 cells had less expression of cytolytic molecules and activity. In the present study, we adoptively transferred a relatively small numbers (100,000) of IL-17 secreting TCR-transgenic antigen-specific CD8 T cells one day before vaccination with recombinant vaccinia virus encoded with full-length hemagglutinin. Tc 17 cells activated, expanded better than Tc1 cells 9 days after vaccination (Mean = 7.425×10^6 versus 1.350×10^6 , $p < 0.05$). Interestingly, Tc17 can convert to an IFN- γ producing phenotype after vaccination. Our preliminary data fit the niche that is required to improve vaccination and immunotherapy and we suggest that, to treat infectious disease, CD8 Tc17 could be a promising

effector T cell subset to achieve the goal. Additional mechanisms are being explored.

12

Functional signature of CD19 CAR transduced T cells

Magalhaes, I., Mattsson, J., Uhlin, M.

Karolinska Institutet, Stockholm, Sweden

B cell malignancies consist of a heterogeneous group of leukemias and lymphomas and despite improvements in treatment strategies many patients still succumb to the diseases. Several clinical trials of adoptive cell therapy of chimeric antigen receptor (CAR) modified T cells targeting CD19 have shown dramatic results in both pediatric and adult patients.

CD19 CAR transduced T cells were generated from patients with chronic lymphocytic leukemia (CLL), acute lymphoblastic leukemia (ALL) and healthy donors. CD4⁺ and CD8⁺ CD19 CAR transduced T cells displayed an effector memory (CD45RO⁺CCR7⁻) phenotype. We evaluated the cytokine (IL-2, IFN- γ , TNF- α and IL-17) production and degranulation (CD107a) of CD19 CAR transduced T cells after stimulation with either K562-CD19⁺ cells or autologous B cells. We show that when stimulated with K562-CD19⁺ cells the majority of CD4⁺ and CD8⁺ CD19 CAR transduced T cells showed a polyfunctional (3⁺ functions) profile and cytotoxic capacity (CD107a⁺). Furthermore, CD4⁺ CD19 CAR transduced T cells produced IL-17 specifically against CD19⁺ target cells. Interestingly when stimulated with autologous B cells, as compared to cells stimulated with K562-CD19⁺, CD19 CAR transduced T cells were less polyfunctional with the majority of the cells (CD4⁺ and CD8⁺) exhibiting only one function and particularly CD107a⁺. These results suggest that CD19 CAR transduced T cells stimulated with different CD19⁺ target cells have different functional signatures (cytotoxicity vs cytokine secretion). We are investigating the role of CD19 density on CD19⁺ target cells and the signaling profile in CD19 CAR transduced T cells stimulated by different CD19⁺ target cells.

13

Generation of T cell effectors using LNCap-loaded DC vaccine for adoptive T cell therapy

Vavrova, K., Vrabцова, P., Horvath, R., Bartunkova, J.

2nd Faculty of Medicine, Charles University, Dept. of Immunology, Prague, Czech Republic

Adoptive T cell transfer (ACT) is a cell coculture-based approach whereby anti-tumor-specific lymphocytes derived from a patient are expanded *in vitro* and transferred back into the patient. ACT has been shown to be an effective method used to boost tumor-specific immune responses in several types of malignancies. In our study, we set out to optimize the ACT approach for treatment of prostate cancer with an expansion protocol that involves the generation of DC vaccine-primed autologous T cells. The protocol includes a pre-stimulation step where T cells were primed with autologous DCs loaded with high hydrostatic pressure-treated prostate cancer cell line LNCap. Primed T cells were further *in vitro* expanded with

anti-CD3/CD28 Dynabeads and tested for cytotoxicity using a lactatedehydrogenase assay. Our data indicate that Dynabead expansion leads to the expansion of tumor-specific CD4⁺IFN- γ ⁺ T cells while the frequencies of CD8⁺ IFN- γ ⁺ T cells remain largely unchanged. The majority of both CD4⁺ and CD8⁺IFN- γ ⁺ producing cells were CD62L⁻, CCR7⁻ and CD57⁻ but CD28⁺ and CD27⁺ positive, indicating an early/intermediate effector memory phenotype (T_{EM}) in non-terminal differentiation stage. Expanded T cells showed significantly greater cytotoxicity against LNCap cells compared to control SKOV-3 cells, with the highest efficiency of killing at the ratio of 20:1. Our data show that the ACT approach in combination with a DC-based vaccine provides a viable way to generate prostate cancer reactive T cell effectors which could be tested for clinical treatment of this malignancy.

The study was supported by the Charles University, project GA UK 2120182

14

Identification of tumor-specific T cell receptors of primary tumor-infiltrating lymphocytes (TILs) from B16F10 melanoma-bearing mice at single cell levels

Shitaoka, K., Hamana, H., Kishi, H., Ozawa, T., Muraguchi, A.

University of Toyama, Toyama-shi, Japan

T cell receptor (TCR) gene therapy is a promising cancer therapy and requires tumor-specific TCR gene. In general, tumor-specific antigens are pre-requisite for identifying tumor-specific T cells and cloning their TCR. However, identification of tumor-specific antigen in each patient is not easy and time-consuming. Consequently, the research is skewed to the major HLA haplotypes such as HLA-A24 in Asia and HLA-A2 in Europe and USA. The patients with minor HLA haplotypes do not benefit from those researches. It has been reported that tumor-specific T cells are activated and proliferate in the tumor. In this study, we tried to clone cDNAs of tumor-specific TCR from primary tumor-infiltrating lymphocytes (TIL) without using tumor-specific antigen. To this end, we sorted CD8⁺ or CD8⁺CD137⁺ single TILs from B16F10 melanoma tissues in C57BL/6 mice with FACS and their TCR α and β cDNAs were obtained. TCR repertoire analysis indicated the clonal expansion of CD8⁺ CD137⁺ T Cells in the tumor. We inserted the TCR cDNA into a retroviral vector, transduced the cDNA into splenic T cells, and examined their reactivity against B16F10 melanoma cells. Most of the TCRs obtained from clonally expanded TILs induced cytotoxicity against B16F10 melanoma cells and interferon- γ production. Thus, our protocol enables us to easily obtain tumor-specific TCR from primary TILs without antigenic peptides presented on individual MHC haplotypes.

15

Engineering T cells for cancer therapy by expressing a chimeric antigen receptor (CAR) targeting the tumour endothelial marker ROBO4

Cawkwell, L.¹, Bicknell, R.², Lee, S.¹

¹University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom, ²University of

Birmingham, Institute of Cardiovascular Science, Birmingham, United Kingdom

Adoptive T cell transfer of tumour-specific engineered T cells has become an attractive area of cancer research. However, few groups have attempted to target the tumour vasculature using T cells. Roundabout Homolog 4 (ROBO4) is an endothelial specific gene that is overexpressed in the vasculature of multiple different solid tumours but is absent or expressed at very low level in normal adult tissue. Chimeric antigen receptors (CARs) are fusion proteins linking an extracellular antigen binding domain derived from an antibody, with an intracellular signalling domain. Here we have attempted to target ROBO4 using T cells engineered to express a CAR. Two monoclonal antibodies that both bind human and mouse forms of ROBO4 were engineered into second generation CARs (named R1 and R2) containing a CD28 signalling domain. R1 and R2 CARs successfully retargeted T cells to recombinant human and mouse ROBO4 protein and ROBO4-expressing cell lines in multiple in vitro assays of T cell function, with R1 displaying greater functional activity. When mouse T cells engineered with these CARs were injected into healthy mice, no signs of toxicity were observed. However, both R1 and R2 CAR

T cells were selectively and rapidly removed from the peripheral blood whereas T cells expressing a non-targeting control CAR persisted. We are currently investigating the fate of these ROBO4-specific CARs, with the possibility that they are accumulating in response to ROBO4 expressed in healthy organs.

16

Ex vivo generation of alloantigen-specific T regulatory cells using selective T-cell co-stimulation blockade

Watanabe, M.¹, Kumagai-Braesch, M.¹, Thunberg, S.², Henrikson, J.¹, Sellberg, F.³, Lundgren, T.¹, Yao, M.H.¹, Jorns, C.¹, Berglund, D.³, Berglund, E.¹, Ericzon, B.-G.¹

¹Karolinska Institutet, Transplantation Surgery, Stockholm, Sweden, ²Karolinska Institutet, Laboratory Medicine, Stockholm, Sweden, ³Uppsala University, Immunology, Genetics and Pathology, Uppsala, Sweden

Purpose: Adoptive transfer of alloantigen-specific T regulatory cells (Tregs) generated ex vivo by co-culture with anti-CD80/CD86 mAbs (2D10.4/IT2.2) has been shown to allow early withdrawal of immunosuppressant and graft acceptance after liver transplantation. Belatacept, a clinically approved CTLA4-Ig, may be an alternative agent for the ex vivo generation of alloantigen-specific Tregs. The efficacies of anti-CD80/CD86 mAbs and Belatacept on ex vivo generation of Tregs were evaluated.

Methods: Human peripheral blood mononuclear cells (PBMCs) (50 x 10⁶ cells) were co-cultured with irradiated donor PBMCs (20 x 10⁶ cells) in the presence of 2D10.4/IT2.2, or Belatacept in eight different pairs. At day 7, irradiated donor PBMCs, culture media, and 2D10.4/IT2.2, or Belatacept, were replenished. Phenotypes and immunomodulatory effects of the generated cells were assessed at day 14.

Results: After 14 days of co-culture CD4⁺CD25⁺CD127^{lo}Foxp3⁺ Tregs increased from 4.1±1.0% to 7.1±2.6% and 7.3±2.6% in

2D10.4/IT2.2 and Belatacept groups, respectively. Concurrently, delta-2 FOXP3 mRNA expression increased significantly. Generated cells from both treatment groups effectively impeded proliferative responses of freshly isolated recipient PBMC against donor-antigen in mixed lymphocyte reactions, in a generated cell-number dependent fashion. While, such effect was minor against third-party antigens. IFN-γ production was downregulated and IL-10 production increased in ELISPOT and ELISA assays from 2D10.4/IT2.2 and Belatacept treated groups, as compared to sham treated cells.

Conclusion: Alloantigen-specific Tregs generated with Belatacept showed comparable immune-modulatory effects as compared to those of 2D10.4/IT2.2. Belatacept seems to be a promising agent for ex-vivo generation of alloantigen-specific Tregs.

17

Generating CD4⁺ and CD8⁺ T cells using BMDCs and BMMΦs improves adoptive cell therapy for B16 melanoma

Shields, N., Young, K., Li, K., Young, S.

University of Otago, Department of Pathology, Dunedin, New Zealand

The adoptive transfer of tumour-specific T cells, known as adoptive cell transfer (ACT), is a promising novel approach for the treatment of cancer. Antigen presenting cells (APCs) can serve as a tool for the *ex vivo* expansion of tumour-specific T cells for use in ACT, with the functional state of these cells during antigen presentation playing a pivotal role in shaping resultant T cell responses. Due to their status as the most potent APC, dendritic cells (DCs) have been the focus of intense investigation in regards to

T cell activation, while macrophages have received little attention. We have previously shown that a combination of CD4⁺ and CD8⁺ T cells generated using DCs as APCs *ex vivo* effectively controls B16 melanoma growth. Here we compared the ability of DCs and macrophages to further enhance ACT through the *ex vivo* expansion of tumour-specific T cells, using ovalbumin (OVA) as a model tumour antigen. In our model, naïve OVA-specific CD4⁺ and CD8⁺ T cells were expanded for 10 days using bone marrow-derived DCs, re-stimulated with either DCs or macrophages and cultured for a further 10 days before adoptive transfer into mice bearing B16-OVA tumours. ACT using a combination of CD4⁺ T cells re-stimulated with macrophages and CD8⁺ T cells re-stimulated with DCs achieved 100% complete tumour-rejection and provided full protection following tumour re-challenge. Future experiments will investigate the differences in antigen uptake and processing by DCs and macrophages and their effects on T cell generation for ACT.

18 Identification of new genes that enhance effector function of chimeric antigen receptor T cells

Li, P., Lai, Y., Qin, L.

Guangzhou Institutes of Biomedicine and Health, Chinese Academy of Sciences, Guangzhou, China

Chimeric antigen receptor (CAR) T cell immunotherapy has shown unprecedented success in the treatment of leukemia, but not solid tumors. And a large number, usually $> 10^9$ cells, of CAR T cells are needed for clinical trials and a long time (>20 d) is needed for in vitro expansion. To further improve the effector function of CAR T cells in both leukemia and solid tumors, we performed a genetic screening and identified that insertion of the intracellular signaling domain of a gene, N1, to the C end of 2nd generation CARs was able to significantly enhance effector function of CAR T cells. T cells expressing α CD19-28zN1 showed enhanced cytotoxicities against CD19⁺ cell lines NALM6, REH and K562-CD19 compared with T cells expressing α CD19-28z. Similarly, T cells expressing α MSLN-28zN1 exhibited stronger cytotoxicities against MSLN⁺ lung cancer cell lines A549 and H23 compared with T cells expressing α MSLN-28z. Also, in xenograft models, T cells expressing α CD19-28zN1 showed enhanced cytotoxicities against CD19⁺ NALM6 cells; and T cells expressing α MSLN-28zN1 showed stronger cytotoxicities against subcutaneous tumor of A549 cells compared with T cells expressing α MSLN-28z. Importantly, we are conducting a clinical trial with α CD19-28zN1 T cells in which the infusion of 4.5×10^6 CAR T cells achieved CAR T cell expansion and B-ALL remission in the patient. Our results revealed N1 as a contributing component in CAR T cell immunotherapy whose incorporation simplifies the production of CAR T cells by infusing fewer CAR T cells for therapy and potentially reduces the cytokine releasing syndrome in patients.

19 NFkB acts as a central integrator of cell extrinsic signals to regulate CD8⁺ T cell fate and tumor efficacy

Shrikant, P., Myles, A., Vardham-Kaur, T.

Mayo Clinic, Immunology, Scottsdale, United States

Exploiting mechanisms underpinning integration of antigen and cytokine generated signals to produce tumor-antigen specific CD8⁺ T cells with low proinflammatory profile and memory functions can boost efficacy of adoptive cell therapy (ACT) of cancer. Herein, we show that IL-21 via STAT3 induces the atypical IKK family member, Bcl3, to dampen antigen driven NF- κ B (p65/p50) activation. IL-21 decreases antigen induced CD8⁺ activation and proliferation, but enhances clonal expansion due to reduction in apoptosis in a Bcl3 dependent manner. Strikingly, Bcl3 mediated NF κ B dampening skews expression of master transcriptional factors including T-bet, Eomesodermin, Bcl6, Blimp-1 and FoxO1 to facilitate transition of antigen induced polyfunctional CD8⁺ effector cells to memory precursor cells (MPCs) that retain cytotoxicity but produce reduced IFN γ and IL-2. Moreover, ex vivo IL-21 conditioned CD8⁺ T cells are persistent and produce greater tumor efficacy upon adoptive transfer into intact syngeneic recipients. Our results reveal a pivotal role for NF- κ B to integrate antigen and cytokine signals

and control differentiation as well as survival to establish fate of antigen stimulated CD8⁺ T cells. We submit that new strategies to regulate T cell responses for durable tumor immunity should target NF κ B activity.

20 Activity of engineered antigen-specific T cells as a function of the relationship between affinity, avidity and antigen density

Greenman, R., Oren, R., Haus-Cohen, M., Reiter, Y.

Technion, Biology, Haifa, Israel

The use of engineered Ag-specific T cells in adoptive cell transfer therapies has recently gained significant focus due to initial clinical success. Such engineered cells are generated using a chimeric Ag receptor (CAR) based on common formats composed from Ag-recognition elements, such as $\alpha\beta$ -TCR genes or Ab variable domain fragments, fused with T cell-signaling moieties. We recently combined these recognition elements using Abs that recognize peptide-MHC (TCR-like Abs), and compared such a high-affinity TCR-like Ab CAR to a native low-affinity TCR. Unexpectedly, the high-affinity CAR was less effective than the low-affinity TCR, suggesting an upper affinity threshold for TCR-based effective functional outcomes of engineered T cells. That is, exceeding this threshold leads to reduced functionality. To further characterize this affinity threshold and to achieve optimal T cell function, we characterized a series of anti-Tyr single chain fragment binding domains, ranging from 4nM to 1000nM Kd, and constructed Tyr-specific second generation CARs with ranging affinities. The interplay between CAR affinity, Ag density and CAR expression (i.e. avidity) and their effect on T cell functionality will then be studied. Hence, the precise combination of affinities and avidities (termed functional avidity) of T cells that leads to optimized functional outcome can be of crucial importance in adoptive cell transfer immunotherapies that utilize CARs.

21 Blockade of PD-1 enhances the cytotoxic function of ex vivo expanded CD8⁺ T-cells in EpCAM⁺ PDL-1⁺ cancer

Kumar, R.¹, Fang, Y.², Zhen, Y.-H.³, Bo, L.⁴, Yuan, Y.⁴, Ge, H.-X.⁵, Hu, P.¹, Zin, X.¹

¹Affiliated Hospital of Guizhou Medical University, Clinical Research Center/Cancer Immunology and Immunotherapy Center, Guiyang, China, ²Affiliated Hospital of Guizhou Medical University, Clinical Research Center, Guiyang, China, ³Affiliated Hospital of Guizhou Medical University, Department of Colorectal Surgery, Guiyang, China, ⁴Affiliated Hospital of Guizhou Medical University, Cancer Immunology and Immunotherapy Center, Guiyang, China, ⁵Affiliated Hospital of Guizhou Medical University, Department of Surgery, Guiyang, China

Background: In recent years, adoptive cell therapy has proven to be an encouraging modality for treating cancer patients. The increased expression of inhibitory receptors (iRs) on T cells in the tumour microenvironment is a major obstacle in tumour rejection. Programmed cell death protein-1 (PD-1) negatively

regulates the function of CD8+ T cells during *ex vivo* expansion, which is responsible for reduced killing. Here, we investigated whether the blockade of PD-1 on CD8+ T cells can potentiate tumour rejection in cancer patients.

Methods: We investigated the tumour-killing activity of CD8+ T cells after PD-1/PD ligand-1 (PDL-1) blockade. CD8+ T cells were co-cultured with EpCAM+ tumour cells such as Tumour Epithelial Cells (TECs), DLD-1, SW480 and SW620 for cytotoxicity activity, ELISpot was used to detect IFN- γ and GrB, and CD107a mobilisation was quantified by flow cytometry.

Results: We found a dramatic increase in PD-1 expression on the surface of CD8+ T cells during *ex vivo* expansion. PD-1 was downregulated by ~40% after using PD-1 mAb, which induced apoptosis in tumour cells during co-cultured with CTLs. Secreted cytolytic molecules, such as IFN- γ and GrB, and CD107a mobilization also increased upon PD-1/PDL-1 blockade during co-culture, which enhanced CD8+ T cells tumour interactions, as well as cytosolic exchange between effector and target cells.

Conclusion: Our findings suggest that PD-1/PDL-1 blockade increased the killing efficiency of CD8+ T cells and the secretion of functional cytolytic granules and cytokines during tumour invasion. These findings advance the clinical investigation for a more effective approach to cell-based adoptive immunotherapy.

Using Merkel cell polyomavirus specific TCR gene therapy for treatment of Merkel cell carcinoma

Lyngea, R.¹, Wulff Pedersen, N.¹, Linnemann, C.², Schrama, D.³, Ibrani, D.⁴, Met, Ö.⁵, thor Straten, P.⁵, Nghiem, P.⁴, C. Becker, J.³, Reker Hadrup, S.¹

¹Veterinary Institute, DTU, Section of Immunology and Vaccinology, Fredriksberg C, Denmark, ²Netherlands Cancer Institute, Dept. of Immunology, Amsterdam, Netherlands, ³Medical University of Graz, General Dermatology, Graz, Austria, ⁴University of Washington, Departments of Medicine/Dermatology, Pathology, Seattle, United States, ⁵University Hospital Herlev, Center for Cancer Immune Therapy, CCIT, Department of Hematology, Herlev, Denmark

T cell receptor gene-therapy has entered the clinic and shown potential for successful cancer treatment. However, the clinical evaluation has also highlighted the need for selection of truly cancer-specific targets. Merkel cell carcinoma (MCC) is a highly aggressive skin cancer associated with Merkel cell polyomavirus (MCPyV). Due to the clear viral correlation CD8+ T cells specific for viral epitopes could potentially form cancer-specific targets in MCC patients. We have identified MCPyV specific T cells using a high-throughput platform for T-cell enrichment and combinatorial encoding of fluorescence-labeled major histocompatibility complex (MHC) class I multimers. We identified 35 T cell epitopes among 398 MCPyV derived peptides analyzed. Strikingly, T-cell responses against the two oncogenic MCPyV proteins Large T antigen and small T antigen were exclusively present in blood of MCC patients when compared to healthy donors. We demonstrate both the processing and presentation of oncoprotein-derived epitopes, as well as lytic activity of specific T cells towards MHC-matched MCC cells. Demonstrating the presence of oncoprotein-specific

T cells among tumor infiltrating lymphocytes *ex vivo* further substantiated the relevance of the identified epitopes. The viral epitopes represents specific targets and should be ideal for TCR-gene therapy approaches. We have isolated and sequenced MCPyV oncogenic protein specific

T cell receptors and are currently testing *in vitro* transduction systems with the purpose of introducing the TCRs into human PBMC, injecting them into immune deficient NOG mice carrying HLA matched MCPyV positive tumor to investigate the tumor rejection capacity of these gene-modified T cells.

23

Selection process of the optimal T-iPSC clone from among clones derived from T cells specific to melanoma antigen MART-1

Nagano, S., Maeda, T., Shimazu, Y., Masuda, K., Kawamoto, H. Institute for Frontier Medical Sciences/Kyoto University, Department of Immunology, Kyoto, Japan

We have previously reported that iPSC cells (iPSCs) were established from mature cytotoxic T cells specific to MART-1 antigen from a melanoma patient, and that CD8+ mature T cells were generated from these iPSCs (Cell Stem Cell, 2013). This method represents a novel tool for the cloning and expansion of T cells that can be applied for cell therapy against cancer. Whereas this approach has been based on the idea of autologous transplantation, we are also thinking of applying this method to the allogeneic transplantation settings.

In this study, we tried to established a method to select optimal T-iPSC clone from multiple clones. We firstly expanded MART-1 specific CD8+ T cells from a healthy donor, and then reprogrammed these cells using Yamanaka factors. A total of 8 iPSC clones were established, and regenerated T cells from these clones were found to express different T cell receptor (TCR). We found that the affinity of these TCR varied very widely, and accordingly the difference was observed in the cytotoxic activity of regenerated T cells. We also found that these iPSC clones were intrinsically very heterogeneous in terms of the efficiency in the *in vitro* regeneration of T cells. These findings propose that selection process of the best clone among multiple T-iPSC clones is required for this strategy. We are now testing allo-reactivity of regenerated T cells, which would be a risk in allogeneic transplantation setting. Such information in total will be very important for the development of fundamental technology in this strategy.

24

Using agonist anti-4-1BB to enhance CART cell responses against cancer

Mardiana, S.^{1,2}, John, L.B.^{1,2}, Beavis, P.A.^{1,2}, Henderson, M.A.^{1,2}, Giuffrida, L.^{1,2}, Slaney, C.Y.^{1,2}, Cross, R.S.^{1,2}, Haynes, N.M.^{1,2}, Trapani, J.A.^{1,2}, Johnstone, R.W.^{1,2}, Kershaw, M.H.^{1,2}, Darcy, P.K.^{1,2}

¹University of Melbourne, Cancer Immunology Research Program, Sir Peter MacCallum Department of Oncology, Melbourne, Australia, ²University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia

Adoptive immunotherapy involving the genetic modification of T cells with Chimeric Antigen Receptor (CAR) is a promising strategy for targeting tumor-specific T cells to cancer. Clinical trial results have revealed that CART cell therapy is most successfully employed in hematological cancers, but less successful against solid cancers. Therefore new approaches to enhance CAR T cell function are required. Activation of the CD137 (4-1BB) pathway has been shown to provide important co-stimulation to T cells, and the use of an agonistic α -4-1BB antibody has been reported to have potent effects in improving T cell function. We hypothesized that the combination of CAR T cells and agonistic α -4-1BB would act synergistically to increase anti-tumor responses. We found significantly enhanced tumor growth inhibition following the combination therapy compared to either treatment alone against two different Her2⁺ solid tumors. Investigation into the mechanism *in vivo* revealed increased expression of the proliferation marker Ki67 and IFN γ production by CAR T cells following α -4-1BB administration. Interestingly, α -4-1BB also affected host endogenous immune cells favoring CD8⁺ T cell expansion with a concomitant decrease in CD4⁺ Treg cell frequency. This data suggests that the administration of α -4-1BB may have a dual effect of enhancing anti-tumor responses from both Her2-specific CAR T cells and host CD8⁺ T cells. In summary, the addition of exogenous α -4-1BB antibody is a potentially promising strategy for enhancing adoptive T cell immunotherapy for cancer patients.

25

Human gingiva-derived mesenchymal stromal cells inhibit Graft-versus-host disease through CD39 and IDO

Wang, J., Olsen, N., Zheng, S.G.

Penn State University, Medicine, Hershey, United States

Mesenchymal stem cells have the capacity to maintain immune homeostasis and prevent autoimmunity. However, it is unclear whether GMSCs can suppress human T cell-mediated diseases. GMSC were isolated from human gingival tissues. GMSC were cultured with allogenic T cells labeled with CFSE, and the T cell proliferation and cytokine production was evaluated by CFSE dilution and cytokine staining in FACS. Mouse xenogenic Graft-versus-host-disease (GVHD) was induced in NOD/SCID mice. GMSC, human fibroblast (negative control) or human bone marrow mesenchymal stem cells (positive control) were co-transferred with human PBMC into NOD/SCID mice. Weight loss and symptoms of xeno-GVHD were assessed. We observed that GMSCs potently suppressed the proliferation and cytokine production by T cells *in vitro*, and that co-transfer of GMSC and human PBMC significantly prolonged mouse survival. We also demonstrated that GMSC is even better than MBSC on treating xeno-GVHD. We further revealed that GMSCs inhibited human PBMCs-initiated xeno-GVHD *via* CD39 and IDO signals. Thus, GMSC can suppress human immune responses and immune system-mediated diseases, offering a potential clinical option to be used for modulating GVHD and other autoimmune diseases.

CD4⁺CD26⁺ T cells exhibit enhanced persistence and antitumor activity *in vivo*

Bailey, S.^{1,2}, Nelson, M.^{1,2}, Butcher, A.³, Majchrzak, K.^{1,2}, Bowers, J.^{1,2}, Meek, M.^{1,2}, Neal, L.^{1,2}, Paulos, C.^{1,2}

¹Medical University of South Carolina, Microbiology & Immunology, Charleston, United States, ²Medical University of South Carolina, Surgery, Charleston, United States, ³College of Charleston, Charleston, United States

Adoptive T cell transfer has been an impressive therapy for treating cancer patients, but can be inconsequential if the transferred cells are unable to engraft and persist. Our lab has found that human CD4⁺ T cells that express intermediate or high levels of CD26—termed CD26^{intermediate} and CD26^{high}

T cells, respectively—display striking antitumor activity in NSG mice bearing large, established mesothelioma. Importantly, these cells also exhibit increased engraftment and persistence compared to mice treated with bulk CD4⁺ or CD26^{negative} T cells. While the multi-functional nature (IL-17, IFN- γ , IL-2, TNF- α , IL-22) and heightened cytotoxicity (CD107A, Granzyme B) of CD26^{high} T cells can help explain their antitumor activity *in vivo*, their ability to persist long-term despite their differentiated phenotype (CD45RO⁺) is intriguing. After further evaluation, we found that both CD26^{intermediate} and CD26^{high} T cells express elevated β -catenin and BCL-2, as well as decreased Caspase 3 cleavage, compared to CD4⁺ and CD26^{negative} T cells. Gene array analysis revealed that CD26^{high} T cells also express heightened levels of CEBPD and ATF5. Excitingly, both CD26^{intermediate} and CD26^{high} T cells displayed enhanced

T cell persistence and significantly delayed tumor growth when transferred into mice bearing established PANC1 pancreatic tumors. Furthermore, PANC1-bearing mice treated with bulk CD26⁺ T cells also displayed a better antitumor response and persistence than those treated with bulk CD4⁺ or CD26^{negative} T cells. Overall, this data suggests that the presence of CD26 on transferred CD4⁺ T cells could be crucial for an effective antitumor response and can be utilized to enhance future immunotherapy strategies.

27

Manipulating PD-1 axis to generate melanoma-specific high avidity CD8 T cells for adoptive cell transfer for

Simon, S.^{1,2,3,4}, Vignard, V.^{1,2,3,5}, Florenceau, L.^{1,2,3,4,5}, Khammari, A.^{1,2,3,5}, Dréno, B.^{1,2,3,5}, Lang, F.^{1,2,3,4}, Labarrière, N.^{1,2,3,4}

¹University of Nantes, Nantes, France, ²INSERM, U 892, Nantes, France, ³CNRS 6299, Nantes, France, ⁴LabEx IGO, Nantes, France, ⁵Nantes Hospital, Nantes, France

Therapeutic strategies using anti-PD-1 blocking antibody reported unparalleled effectiveness for cancer immunotherapy, in terms of clinical response rates. Nonetheless, the search for biomarkers unequivocally associated with clinical efficiency remains a crucial issue to improve patients' management. Despite its negative role in anti-tumor immunity, PD-1 also identifies reactive tumor-infiltrating T cells. Starting from this ambiguous observation, we documented for the first time the existence of melanoma specific T cell clones unable to express

PD-1. This stable feature was due to the persistent methylation of the *PDCD1* promoter. These PD-1^{neg} clones were globally of lower avidity than their PD-1^{pos} counterparts, suggesting that in physiological conditions, high affinity specific T cell clones negative for PD-1 expression are not or rarely present in peripheral blood, as they are probably eliminated by negative selection, due to a too high reactivity. This strongly suggests the implication of PD-1 in shaping an antigen-specific repertoire. We further demonstrated *in vitro* that the blockade of PD-1 signaling during the selection and amplification process of melanoma specific T cells from patients' PBMC, resulted in the proliferation of specific T cells with a biased TCR Vbeta repertoire exhibiting a better functional avidity (Simon *et al.*, *Oncoimmunol*, 2016, *in press*). This phenomenon likely occurs *in vivo* in anti-PD-1 treated patients and may represent a marker of clinical efficiency. These results offer new prospects for monitoring immune responses of cancer patients treated with anti-PD-1 antibody and for the selection of optimal effector T cells for adoptive cell transfer treatments.

28

Ex vivo expansion of cytolytic natural killer cells in combined immune therapy for relapsed and refractory neuroblastoma

Shen, S.^{1,2,3}, Dolnikov, A.^{1,2,3}, O'Brien, T.^{1,2,3}

¹Sydney Children's Hospital, Kids Cancer Centre, Sydney, Australia,

²University of New South Wales, Faculty of Medicine, Sydney, Australia,

³Children's Cancer Institute for Medical Research, Sydney, Australia

Neuroblastoma (NB) is an aggressive childhood malignancy with limited treatment options for relapsed and refractory disease. Natural Killer (NK) cells are part of innate immune system; they detect and destroy virally-infected transformed cells and have anti-tumor activity. NB is sensitive to NK-mediated cytotoxicity suggesting the possibility of NK cell infusions as a treatment. Human tumours harbour numerous genetic and epigenetic alterations, and develop multiple resistance mechanisms to evade immune destruction. Thus, combining NK therapy with immune-modulatory agents might be beneficial. In this study, we investigated the cytolytic activity of ex vivo expanded NK cells against NB, either as a mono-agent or in combination with histone deacetylase inhibitor (HDACi) and/or Programmed death 1 (PD-1/PD-L1) blocker. NK cells were readily expanded from peripheral blood mononuclear cells by co-culture with K562-mbIL15-41BBL cells (from Prof. Campana, National University of Singapore), with an average 81.9±28.4 fold-expansion after 10-14 days culture. Expanded NK cells expressed activating receptors NKG2D and NKp30 & 46. Co-culture of NK cells with NB cells SK-N-SH, SK-N-AS and SK-N-Be2 resulted in robust cytotoxicity against NB. Treatment of NB cells with HDACi entinostat up-regulated cell surface expression of NKG2D ligand MIC-A/B and increased NK cell killing. Activation of NK cells up-regulated PD-1 expression; blockade of PD-1/PD-L1 axis via neutralizing mAb against PD-1 increased cytotoxicity of NK cells. We speculate that the use of HDACi and/or PD-1/PD-L1 blockade will act to increase the efficacy of NK cell therapy against NB. Effects of such combined treatments in an *in vivo* model is currently being investigated.

29

A rapid and efficient single-cell manipulation method using microwell array chip (ISAAC) technology for screening antigen-specific cytokines-secreting T-cells

Ozawa, T., Kishi, H., Hamana, H., Tajiri, K., Lyu, F., Muraguchi, A.

University of Toyama, Department of Immunology, Toyama, Japan

Identification of antigen-specific T-cells and obtaining their T-cell receptor (TCR) cDNA is becoming important as T-cell adoptive therapy and TCR gene therapy are expected as a promising next generation therapy for tumor or infectious diseases. The interaction of TCRs on T-cells and peptide/MHC on antigen-presenting cells initiates T-cell activation. Using immunospot array assay on a chip (ISAAC) technology with a microwell array chip, we have recently shown that TCRs and peptide/MHC molecules on a single CD8+ T-cells can interact and induce cytokine secretion. ISAAC technology with a microwell array chip enables direct identification of antigen-specific antibody-secreting cells from human peripheral blood lymphocytes, rapid cloning of antibody cDNA, and efficient and rapid production of human monoclonal antibodies. In this study, we applied ISAAC technology to detect antigen-specific T-cells and cloning their TCR cDNA.

To detect antigen-induced cytokine-secretion on the chip, we prepared CD8+ cells from HLA-A24(+) healthy donors, arrayed them on an anti-IFN-gamma antibody-coated chip and stimulated them with Epstein-Barr virus BRLF1-peptide (TYPVLEEMF) that binds to HLA-A*2402 molecules. After 6 h, IFN-gamma immunospots were detected using fluorescence-labeled anti-IFN-gamma antibody. We retrieved the IFN-gamma-secreting cells from the chip and amplified TCR alpha and beta-chain variable region cDNAs using single-cell RT-PCR. We then expressed the cloned TCRs on a T-cell line. Flow cytometry analysis revealed that the cloned TCRs bound to BRLF1-peptide/MHC tetramer. These results demonstrated that ISAAC technology could detect antigen-specific T-cells and yield antigen-specific TCRs. This novel method may provide a powerful tool for the analysis of antigen-specific T-cells.

30

Influence of TCR and pMHC structure on the polyfunctional phenotypes of TCR gene-modified T cells

As the quality of a T cell's functional response has been most closely attributed to the affinity between the TCR-pMHC interaction, strategies to enhance TCR affinity through random alterations by yeast/phage display develop a presumably "better" TCR for adoptive cell transfer. Yet increasing evidences suggests this relationship may not be so straightforward. We examined TCR-pMHC structure-function relationships using a panel of 9

naturally occurring HCV NS3:1406-1415 pMHC variants, NS3⁺ hepatocellular carcinoma cells, and T cells gene-modified with a cross-reactive A2-restricted TCR. We demonstrated inconsistent correlations between variant TCR-pMHC binding measurements (surface plasmon resonance, tetramer binding curves, and tetramer dissociation rates) with biological responses (target lysis, cytokine secretion, and 7-dimensional intracellular cytokine production). Recognition of multiple peptides were CD8-independent, but lost independence in the context of natural processing by tumor cells. Surprisingly, dependence on CD8 required both affinity enhancement (MHC α 3 binding domain) as well as intracellular signaling contributions (Ick-binding domain). TCR pairing competition also influenced biological responses as TCR-engineered Jurkats lacking an endogenous TCR exhibited broader cross-reactivity and reduced CD8-dependence. Stark differences in polyfunctional responses existed between peptide and tumor stimulations, and hierarchical clustering analysis of polyfunctional populations did not always "relate" responses with affinity. Having solved the crystal structure of the WT TCR-pMHC interaction, we can now rationalize these inconsistencies. We propose that modifications in therapeutic TCRs should be rationally designed rather than randomly affinity-enhanced, and that optimal T cell polyfunctionality relies on a more complex cooperation of affinity, ligand and receptor densities, co-receptor signaling components, and structural integrity.

Immunodeficiency

31

The effects of CD247 deficiency on activating NK cell receptors

Blázquez-Moreno, A., Valés-Gómez, M., Reyburn, H.T.
National Center for Biotechnology, Immunology and Oncology Department, Madrid, Spain

Immunoreceptor complexes expressed at the cell surface are composed of single-pass transmembrane subunits, responsible for extracellular ligand-binding, coupled to signal transducing adaptor molecules. One of the most important signalling adaptors, present in both T and Natural Killer (NK) cells is CD247 (CD3 ζ , TCR ζ). We have recently studied NK cells in a new case of inherited CD247 deficiency, where we observed that expression of CD16a (TM form) was reduced in function of the CD247 genotype, with residual expression on CD247-deficient patient cells, presumably due to Fc ϵ R γ adaptor molecule. Expression of the NKp30 (NCR3) receptor was also markedly reduced in heterozygous relatives and essentially absent in patient NK cells, suggesting that NKp30 expression is more dependent on CD247 than Fc ϵ R γ , whereas, surprisingly, NKp46 (NCR1) expression did not vary with CD247 genotype. These observations have led us to analyse in detail the organisation and assembly of complexes containing the different activating NK cell receptors and CD247 or Fc ϵ R γ . Our results show that CD16a surface expression is totally dependent on association with either CD247 or Fc ϵ R γ . Expression of NKp30 isoform b, the most common isoform present in the patient, was also entirely dependent on association with adaptors, particularly CD247. Finally, NKp46

was able to reach the cell membrane by itself, independently of either CD247 or Fc ϵ R γ . A better understanding of the regulation of these receptors, key for NK cell function in tumour clearing and killing of virally infected cells, will aid manipulation of NK recognition for therapeutic benefit.

32

Stem cell based strategies for re-establishing T cell immunity

Wong, K., Hun, M., Barsanti, M., Hammett, M., Lepletier, A., Alsharif, A., Boyd, R., Chidgey, A.
Monash University, Anatomy and Developmental Biology, Melbourne, Australia

Thymic epithelial cells (TEC) provide most of the specialist functions in the thymus and are critical for the establishment of a microenvironment competent to induce development of self-tolerant T cells and T regulatory cells. From early in life, the thymus gradually atrophies due to a loss in TEC number, precipitating a progressive decline in T cell specificities and immune system function. Further damage to the thymus from aggressive cytoablative treatments associated with cancer therapies and hematopoietic stem cell transplantation can lead to a protracted period of severe immune deficiency in adults/elderly.

We recently identified and characterized thymic epithelial stem cells (TESC) in young adult mice (Wong et al, 2104) which express low levels of major histocompatibility complex II (MHCII) and Ly51, high levels of α 6 integrin, Sca1 and epithelial stem cell associated genes. We found reduced colony forming efficiency of adult TESC during ageing, which implicates TESC loss-of-function as a significant mechanism behind the profound loss in lineage specific progenitors and mature epithelial cells. To identify candidate molecules and pathways that could potentially modulate TESC regeneration and differentiation, we have undertaken a systematic transcriptome analysis of fetal mouse thymus development and adult TECs, spanning thymic primordium (E9.5; 3rd pharyngeal pouch endoderm), TESC (E10.5 - E11.5), transitioning TESC-TEC (E12.5-13.5) and adult/aged TECs. Candidates included factors such as fibroblasts growth factors (FGFs), insulin like growth factors (IGFs), bone morphogenic proteins (BMPs) and members of the R-spondin family, involved in Wnt signaling, previously associated with Foxn1 expression and TEC lineage commitment.

33

NFKB2 mutations in CVID: variability in clinical and immunologic phenotypes

Slade, C.^{1,2,3}, Scerri, T.¹, Bahlo, M.^{1,3}, Douglass, J.^{2,3}, McLean, C.⁴, Hodgkin, P.^{1,3}, Bryant, V.^{1,3}

¹Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, ²Royal Melbourne Hospital, Parkville, Australia, ³University of Melbourne, Parkville, Australia, ⁴The Alfred Hospital, Prahran, Australia

Common variable immune deficiency (CVID) is the most common form of primary immune deficiency, affecting up to 1 in 25,000 individuals worldwide. We, and others have shown defects

of both canonical and non-canonical NF κ B signaling cause common variable immune deficiency in humans. In addition to early-onset hypogammaglobulinaemia and B lymphopaenia, individuals with *NFKB2* mutations have been reported to suffer from central adrenal insufficiency, and autoimmune conditions, especially alopecia areata. Here, we report a family with a novel *NFKB2* mutation that demonstrates significant heterogeneity in their clinical and immunologic phenotypes. The proband was diagnosed with CVID at the age of 9, having suffered from failure to thrive, recurrent pneumonia and severe molluscum contagiosum. Her younger sister was diagnosed with CVID at age 7. Their healthy father was also identified to harbor the mutation. Despite receiving replacement immunoglobulin since diagnosis, at the age of 28 the proband succumbed to enteroviral meningoencephalitis. Although extensive investigations for infectious agents were performed during the illness, the cause was unidentified until post-mortem cerebral tissue was examined. Histologic analysis of secondary lymphoid tissue revealed an absence of B cells and germinal centre formation. In contrast the sister had normal naive, but reduced memory B cell counts, and the father normal naive and memory B cell counts. The varied immunologic and clinical phenotypes observed within this pedigree highlight both the challenges of diagnosis and management of this autosomal dominant form of CVID, and the need to identify the mechanisms by which the variability in phenotype occurs.

34

Susceptibility to cryptococcosis due to anti-granulocyte-macrophage colony-stimulating factor autoantibodies in the absence of pulmonary alveolar proteinosis

Yeh, C.-F.¹, Kuo, C.-Y.², Tu, K.-H.³, Shih, H.-P.⁴, Ding, J.-Y.⁴, Lin, C.-H.⁴, Huang, W.-C.⁵, Ho, M.-W.⁶, Chi, C.-Y.⁶, Ku, C.-L.⁴

¹Chang Gung Memorial Hospital, Infectious Disease, Taoyuan, Taiwan, Republic of China, ²Chang Gung Memorial Hospital, Pediatric Infectious Diseases, Taoyuan, Taiwan, Republic of China, ³Chang Gung Memorial Hospital, Nephrology, Taoyuan, Taiwan, Republic of China, ⁴Chang Gung University, Graduate Institute of Clinical Medical Science, Taoyuan, Taiwan, Republic of China, ⁵Chang Gung Memorial Hospital, Infectious Disease, Kaohsiung, Taiwan, Republic of China, ⁶China Medical University Hospital, Infectious Disease, Taichung, Taiwan, Republic of China

Background: Anti-cytokine autoantibodies have emerged as a cause of immunodeficiency in healthy adults without human immunodeficiency virus infection. Granulocyte-macrophage colony-stimulating factor (GM-CSF) regulates the function of phagocytes and pulmonary alveolar macrophages. Anti-GM-CSF autoantibodies have been reported in patients with pulmonary alveolar proteinosis. The patients are concurrent susceptible to cryptococcal infection.

Methods: We reviewed the clinical histories and performed immunologic evaluation and screening of anti-cytokine autoantibodies in patients with cryptococcal infection. The impact of autoantibodies on immune function was assessed by intranuclear staining of GM-CSF-induced STAT5 phosphorylation and inhibit macrophage inflammatory protein 1 alpha (MIP-1 α) production.

Results: A total of eleven patients with cryptococcal infection was examined. We identified neutralizing anti-GM-CSF autoantibodies from two patient with disseminated cryptococcal infection, [one involved central nervous system (CNS), lung and skin; one involved CNS and lung], one patient with cryptococcal infection of eyes, and one patients with cryptococcal infection with meningitis and encephalitis. The existence of anti-GM-CSF autoantibodies could block GM-CSF signaling and further inhibit STAT5 phosphorylation and production of MIP-1 α .

Conclusions: GM-CSF is critical in the host defense mechanism against *Cryptococcus*. Anti-GM-CSF autoantibodies will increase cryptococcal susceptibility in host. In the face of patients with severe cryptococcal infection, it is important to consider the existence of neutralizing anti-GM-CSF autoantibodies even without the concurrent presence of pulmonary alveolar proteinosis.

35

Analysis of the NT5E (ecto-5'-nucleotidase) gene in Common Variable Immunodeficiency

Shields, D.^{1,2,3}, Smith, A.², Hissaria, P.⁴, Al-Kindi, M.⁴, Ferrante, A.^{1,2,3}, Quach, A.^{2,3}

¹University of Adelaide, Department of Molecular and Cellular Biology, Adelaide, Australia, ²SA Pathology at the Women's and Children's Hospital, Department of Immunopathology, Adelaide, Australia, ³Robinson Research Institute, Department of Paediatrics, Adelaide, Australia, ⁴Flinders Medical Centre, Immunology and Allergy Unit, Adelaide, Australia

Common variable immunodeficiency (CVID) is a primary immunodeficiency characterised by low serum IgG and IgA levels. Attempts to elucidate the causes of this heterogeneous disorder have identified several genetic mutations that are associated with CVID, but in the vast majority of cases the cause remains unknown. Approximately 10% of CVID cases described in the literature have been associated with variants within the TNFRSF13B gene encoding TACI, a protein involved in B cell activation. Our group has recently discovered that a further 25% of CVID express a specific TACI haplotype associated with a decrease in B cell surface TACI expression. Recently it has been reported that expression of CD73, an ecto-5'-nucleotidase associated with immunoglobulin class switch recombination, is significantly decreased in a proportion of CVID patients. To our knowledge, genetic analysis of NT5E, the gene that encodes this protein, has not been performed in relation to CVID. We have examined the coding regions and identified several single nucleotide polymorphisms and one 3' UTR 5' nucleotide deletion in our CVID patient cohort (n=37). A case control comparison with a healthy population (n=61) of the frequency of these anomalies revealed no significant association with CVID. These data imply that decreased CD73 expression reported previously in CVID patients is unlikely due to mutations in the NT5E gene.

36**Super-resolution imaging reveals the role of WASP in the ultrastructure of LFA-1 and actin cytoskeleton at the lytic synapse**

Guipouy, D.^{1,2,3}, Houmadi, R.^{1,2,3}, Vasconcelos, Z.⁴, Valitutti, S.^{1,2,3}, Allart, S.^{1,2,3}, Dupré, L.^{1,2,3}

¹Centre de Physiopathologie de Toulouse Purpan, Inserm UMR 1043, Toulouse, France, ²Université Toulouse III Paul Sabatier, Toulouse, France, ³CNRS, UMR 5282, Toulouse, France, ⁴Fernandes Figueira Institute, Fiocruz, Rio de Janeiro, Brazil

CD8⁺ cytotoxic T lymphocytes (CTL) require LFA-1 to adhere to target cells and deliver the lethal hit. LFA-1 activation is controlled via conformational changes, which depend on anchorage to the actin cytoskeleton. How these synaptic events are coordinated at a nanoscale remains to be explored. Super-resolution microscopy approaches (dSTORM and SIM) revealed that LFA-1 was distributed into a few thousands of nanoclusters at the interface between primary human CTL and planar surfaces coated with ICAM-1 and anti-CD3 mAbs. Costaining with antibodies specific of different LFA-1 conformations revealed that each cluster contained LFA-1 under a predominant conformation, with active nanoclusters being excluded from the outer ring of the synapse. Rather than being anchored to actin filaments, LFA-1 nanoclusters were preferentially positioned on the side of actin filaments in areas of intermediate meshwork density. To decipher the link between LFA-1 topology and the actin cytoskeleton, we studied CTL from Wiskott-Aldrich syndrome (WAS) patients, which lack WASP, a key actin regulator. WAS CTL displayed a global reduction of LFA-1 activation, an unstable lytic synapse and a reduced killing activity. In WAS CTL, the outer lamellipodia was replaced by arrays of microspikes, while the synapse center was sustained by an actin meshwork of reduced density. Active LFA-1 nanoclusters were abnormally localized to the edge of the synapse. In conclusion, our work reveals the nano-architecture of LFA-1 at the CTL synapse and its association to the actin cytoskeleton meshwork. The WASP-deficiency model highlights how spatial control of LFA-1 activation tunes synapse stability and cytotoxic activity.

37**Subcutaneous gammaglobulin replacement therapy in chronic lymphocytic leukemia - 5 years of experience**

Grywalska, E., Rolinski, J.

Medical University of Lublin, Department of Clinical Immunology and Immunotherapy, Lublin, Poland

Introduction and aim: In patients with chronic lymphocytic leukemia (CLL) who are at high risk of infection due to secondary hypogammaglobulinemia, subcutaneous immunoglobulin (SCIg) may be administered every week to reduce the risk of serious infection. Weekly SCiG therapy is an alternative to intravenous immunoglobulin (IVIg) in the treatment of patients with secondary antibody deficiencies. The objective of this study was to investigate for the first time the efficacy, safety, quality of life and cost effectiveness of SCiG in patients with CLL. Materials and methods: The study included 20 patients with CLL receiving SCiG. Median age was 64.84 years. Obtained data were

compared with those from the last year with IVIg.

Results: The median trough serum IgG level was 526 mg/dl with IVIg. In patients in whom the SCiG dose was maintained or reduced compared to IVIg, the median trough serum IgG level was 674 mg/dl ($p < 0.001$). Annual rate of infection was lower in comparison to IVIg (32 vs. 69, $p = 0.004$). In 5-year observation, there were 8 treatment-related local adverse events (AE) reported with SCiG. IgG4 levels, undetectable in 11 patients, increased substantially during SCiG treatment ($p < 0.001$). Switching to SCiG treatment led to significant improvements in quality of life and substantial cost savings.

Conclusions: We conclude that subcutaneous administration of 1.65% SCiG is a safe and cost-effective alternative to IVIg for replacement therapy of CLL-related antibody deficiency. Median trough serum IgG levels were higher with SCiG. Local AE were rare and mild. Quality of life is significantly improved.

38**The efficacy of different programs of the interferon- and immunotherapy in children with combined secondary immunodeficiencies associated with recurrent respiratory infections**

Nesterova, I.¹, Malinovskaj, V.², Kovaleva, S.³, Chudilova, G.³, Lomtatidze, L.³

¹People' Friendship University of Russia, Department of Allergology and Immunology, Moscow, Russian Federation, ²Federal Research Center of Epidemiology and Microbiology. N.F. Gamalei, Department of Ontogenesis of Interferon System, Moscow, Russian Federation, ³Kuban State Medical University, Department of Clinical and Experimental Immunology, Krasnodar, Russian Federation

The restoration of defects of immune and interferon systems in immunocompromised children suffering from recurrent viral and viral-bacterial infections is the actual problem. We studied 3 groups of immunocompromised children 5-8 years suffering from recurrent respiratory infections. Group I included 13 children with recurrent acute respiratory viral infections (ARVI), group II - 14 children with recurrent ARVI, group III - 20 children with recurrent ARVI and chronic bacterial infections of upper respiratory tract (URT). Mono- or mixed herpes viral infections were detected in all groups. Immune and interferon (IFN) systems were investigated: T-, B-chains, NK, neutrophilic granulocytes (NG), serum IFN α and IFN γ . Immunodeficiencies (ID) with the predominant defects of NG and IFNs were identified. 3 different programs of IFN- and immunotherapy were created: **in group I** local and system therapy recombinant IFN α 2 (viferon) was used;

in group II IFN therapy and for correction of defects of NG - glyukozoaminilmuramildipeptid (likopid) were used; **in group III** - IFN therapy and for the correction of humoral immunity - IRS-19 were used; in children of all 3 groups inosine pranobex was used for elimination of herpesviruses.

The study demonstrated: reducing the frequency of ARVI in 3,2 (group I), in 5,8 times (group II), exacerbations of chronic diseases of URT in 4 times, increasing the period of "days free from diseases" from 7-10 to 100-150 days. IFN restored levels of IFN α in all groups. Likopid corrected defects of NG in group

II, IRS-19 restored the humoral immunity in group III. Created programs shown high clinical and immunological efficiencies.

39

Impact of a gain-of-function mutation in CXCR4 on haematopoiesis in mice

Nguyen, J.¹, Freitas, C.¹, Wittner, M.², Biajoux, V.¹, Gaudin, F.¹, Bachelerie, F.¹, Dalloul, A.¹, Donadieu, J.³, Louache, F.², Balabanian, K.¹

¹Université Paris-Saclay, Laboratoire 'Cytokines, Chimiokines et Immunopathologie', UMR_S996, Inserm, Clamart, France,

²Université Paris-Saclay, Laboratoire 'Hématopoïèse Normale et Pathologique', U 1009, Inserm, Villejuif, France, ³Service d'Hématologie Pédiatrique, Hôpital Trousseau, AP-HP, Registre Français des Neutropénies Chroniques Sévères, Paris, France

The Warts, Hypogammaglobulinemia, Infections and Myelokathexis Syndrome (WS) is a rare immunohaematological disorder characterized by a chronic lymphopenia. It is mostly caused by inherited heterozygous autosomal gain-of-function mutations in CXCR4, which engender a distal truncation in the C-tail domain and lead to a desensitization-resistant receptor. We hypothesized that WS-associated circulating lymphopenia arises from altered CXCR4-mediated signaling that skews tissue distribution and differentiation of lymphocytes. For this purpose, we generated a knock-in mouse strain harboring a WS-linked heterozygous *Cxcr4* mutation. Mutant mice displayed lymphocytes with enhanced migration to *Cxcl12* and phenocopied severe lymphopenia. To determine the origin of the lymphopenia, we explored the biological impact of the gain-of-*Cxcr4*-function on haematopoiesis in the bone marrow (BM). In mutant mice, the number of haematopoietic stem cells (HSCs) was not altered in the BM, while those of multipotent (MPP) and lymphoid-biased (LMPP and CLP) progenitors were decreased in an allele dose-dependent manner. In contrast, the myeloid lineage was preserved. Long-term BM reconstitution assays revealed that these alterations involve both intrinsic (HSC) and extrinsic (stroma) defects. In line with this, deregulated expression of *Cxcl12* was observed in the BM of mutant mice. Together, these findings identify the MPP stage as defective in mutant mice and this could account for the lymphopenia. As the BM microenvironment is also altered in mutant mice, we currently investigate the impact of a gain-of-*Cxcr4*-function on the maintenance of BM niches and determine their capacity to support lymphoid-biased MPP localization and differentiation.

40

Woodsmoke inhalation injury causes pulmonary recruitment of neutrophils and alters cytokine production late after injury

Kartchner, L.¹, Dunn, J.¹, Stepp, W.², Sjeklocha, L.², Glenn, L.³, Maile, R.^{1,3}, Cairns, B.A.^{1,3}

¹University of North Carolina at Chapel Hill, Microbiology and Immunology, Chapel Hill, United States, ²University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States, ³University of North Carolina at Chapel Hill, Surgery, Chapel Hill, United States

Patients who suffer inhalation injury following severe burn trauma experience up to a 20% increase in mortality, increased comorbidities, and severe immune dysregulation. Currently, there are few models that recapitulate the immune dysfunction following burn plus acute inhalation injury and test potential therapeutic targets. Our lab created a clinically relevant murine model in which C57BL/6 mice (female, 8-12 weeks, >18g) were intubated and subjected to a woodsmoke inhalation injury, burn injury (20% total body surface area), or combined injury (burn+inhalation). We observed 50% increased mortality following combined injury when compared to sham treated mice. Immune cells were isolated from digested whole lung and bronchioalveolar lavages (BAL) collected 14 days post-injury and stimulated using PMA and ionomycin. Inhalation and combined injury caused neutrophil recruitment to airways, observed by neutrophil infiltration into the BAL and digested lung. Cells isolated from inhalation, burn and combined injury treated animals and stained for intracellular flow cytometric analysis revealed increased levels of IL-10 (macrophages) and IL-12 (neutrophils) upon stimulation. In our model, inhalation injury and combined injury cause cellular recruitment to the lungs and stimulation causes increased production of both pro- and anti-inflammatory cytokines as is often found in patient populations who suffer similar injuries. We propose to use this model as a means to determine if changes in neutrophil and macrophage populations contribute to increased susceptibility to bacterial infections and poor outcomes following inhalation or combined injury.

41

Effect of BAY 41-2272, a soluble guanylate cyclase agonist, in lymphocytes

Uchoa Wall Barbosa de Carvalho, M.¹, Vendramini Ferreira Rosa, P.¹, Soeiro Pereira, P.V.², Antunes, E.³, Condino Neto, A.⁴

Our group has studying new therapies with potential therapeutic chemical components for Primary immunodeficiencies, which are disorders that predispose individuals to recurrent infections and other immune manifestations. Recently, our studies has been shown that BAY 41-2272, a soluble guanylate cyclase agonist (sGC), has proven to exert an effect in modulation of monocytes, leading to infection control. In T cells, activation of sGC by NO, increasing the levels of cyclic guanosine monophosphate (cGMP), selectively induces expression of IL-12 β 2 receptor or induced calcium influx and IL-4 production. Thereby, BAY 41-2272, and its pathway, has a potential for activation of T cells. Thus we evaluate the potential of BAY 41-2272 and its pathway as a tool for modulating of lymphocytes. To this end, pharmacological treatments were performed with BAY 41-2272 to evaluate cytokine production by ELISA, expression of CD69, FOXP3 and ROR γ T. It was observed that BAY 41-2271, as direct activator did not induce the production of IFN γ , IL-4 and IL-10 and expression of CD69, FOXP3 e ROR γ T in lymphocytes ($p < 0,001$, ANOVA with Tukey post-test). However, pretreatment

for 24 hours with BAY 41-2272, with subsequent activation with 90 nM of phorbol myristate acetate (PMA), has showed inhibitory effect on IFN γ production and expression of CD69 in lymphocytes ($p < 0,05$), but did not interfere on expression of transcription factors FOXP3 and ROR γ T. These results suggests a immunomodulator effect of BAY 41-2272 in patients with PIDs, which have autoimmunity and phagocytes deficiency, since it shows an improvement of microbicidal response of monocytes and inhibits lymphocytes.

42

A nation-wide study of clinical phenotypes and *TACI* mutations in patients with common variable immunodeficiency (CVID) and IgA deficiency (IgAD) in Greece

Kapoussouzi, A.¹, Sevdali, E.¹, Farmaki, E.², Taparkou, A.², Tsinti, G.¹, Kakkas, I.³, Paterakis, G.⁴, Germenis, A.E.¹, Speletas, M.¹, on behalf of the Study Group of Primary Immunodeficiencies of the Hellenic Society of Haematology

¹University of Thessaly, School of Health Sciences, Faculty of Medicine, Larissa, Greece, ²Aristotle University of Thessaloniki, Hippokraton General Hospital, Thessaloniki, Greece,

³Evangelismos General Hospital, Athens, Greece, ⁴Gennimatas General Hospital, Athens, Greece

CVID and IgAD represent the most common immunodeficiencies in humans. This study is an updated record of the clinical presentation and *TACI* mutations of both diseases in Greece. Medical records of 93 patients (85 families), 47 with CVID (male/female:24/23, mean age of analysis: 34.2y, range: 4-70), and 46 with IgAD (male/female:26/20, mean age: 21.2y, range: 5-79), were evaluated. *TACI* was amplified and sequenced by standard protocols. In CVID patients, a remarkable delay of diagnosis (mean: 9.2y, range: 0-34) was observed. Recurrent infections of the upper and lower respiratory track, complicated also by bronchiectasis, were the most common clinical manifestations (78.7%, 65.9% and 29.6% of patients, respectively). Lymphoproliferation was observed in 26 patients (55.3%), and autoimmunity in 22 (46.8%), with thrombocytopenia and thyroid disease representing the most common manifestations (27.7% and 17.0%, respectively). Enteropathy was observed in 25.5% and granulomatous disease in 8.5% of patients, while neoplasia in 4 patients (8.5%; 3 lymphoma, 1 NSCL). Autoimmunity was the most common manifestation in IgAD patients (23, 50.0%), followed by recurrent infections (18, 39.1%) and allergy (6, 13.1%). *TACI* mutations were detected in 7 CVID patients (14.9%; all except one in heterozygous state); p.C104R was the most common defect, associated with splenomegaly ($p=0.022$) and neoplasia ($p < 0.001$). Only 2 asymptomatic IgAD patients displayed *TACI* defects (p.C104R & p.P151L). Our study was in accordance with previous ones in Caucasian patients providing further evidence that *TACI* mutations are associated with a more aggressive CVID phenotype, representing a marker for a higher awareness in patients' management.

43

Conserved IL-2R signalling in zebrafish

Sertori, R., Liongue, C., Ward, A.

Deakin University, School of Medicine, Geelong, Australia

The interleukin 2 receptor (IL-2R) family of class I cytokine receptors plays important roles in lymphocyte development and function. The mammalian IL-2R family utilize the shared signalling component interleukin 2 receptor gamma common (IL-2R γ c) that signals via JAK3. Mutations of this receptor chain in humans or mice leads to severe combined immunodeficiency (SCID). The aim of this research project is to investigate the evolution of the il-2r family and analyse the role of key components in zebrafish lymphopoiesis. Using morpholino-mediated knockdown, pharmacological inhibition and genome editing with Transcription Activator-Like Effector Nucleases (TALENs), we demonstrate that the zebrafish *il-2ryc.a* paralogue has a conserved role in T-lymphopoiesis mediated via jak3 and other downstream pathways, consistent with human T-B+ SCID observed in humans with defective IL-2R γ c.

44

Recurrent Infected lymphangioma in hyper-IgE syndromes

Sari, N.I.N.

Harapan Kita Women and Children Hospital, Pediatric, Jakarta, Indonesia

Introduction: Hyper-immunoglobulin E Syndrome (HIES) is a rare primary immunodeficiency disease which is characterized by high serum of IgE levels, eczema, and recurrent bacterial infections. We present the case of a patient with HIES from our hospital.

Method: Case Presentation.

Results: A 5 year-old girl was admitted to our hospital due to recurrent infected lymphangioma in cervical area. She was born full term without perinatal problems. She had a history of recurrent skin and respiratory tract infections such as skin abscess, otitis media, sinusitis and pneumonia since 6 months of age. There is no genetic relationship between her parents. Her father has history of recurrent abscesses. Her brother died with severe pneumonia in the first year of age with the IgE serum was 16.764 IU/ml. On physical examination, we found chronic eczematous skin rashes on the whole body and infected lymphangioma caused by *S. aureus*. Laboratory tests revealed a WBC count of 19,660 /uL, elevated eosinophil count 860/uL and high level of Ig E (16,452 IU/ml). Chest radiography revealed interstitial pneumonia. The patient's National Institutes of Health (NIH) Score for HIES was 61 means suggestive of autosomal dominant-HIES. The genetic examination should be done to verified. Antimicrobial prophylaxis to prevent *S. aureus* was started (2.5 mg/kg of the trimethoprim-sulfamethoxazole twice daily), and had a good response.

Conclusion: HIES should be considered in patients with recurrent bacterial infections. NIH-HIES scoring system help to distinguish HIES patients from patients with suspected primary immunodeficiency disease.

Keywords: Lymphangioma, Hyper IgE Syndrome (HIES), Immunodeficiency

45**Delayed puberty and gonadal failure in patients with HAX 1 mutation**Cekic, S.¹, Saglam, H.², Tarim, O.², Kilic, S.S.¹¹Uludag University Medical Faculty, Pediatric Immunology, Bursa, Turkey, ²Uludag University Medical Faculty, Pediatric Endocrinology, Bursa, Turkey

Purpose: Severe congenital neutropenia (SCN) comprises a heterogeneous group of disorders characterized by early childhood onset of profound neutropenia and recurrent life-threatening infections. Hypergonadotropic hypogonadism has been reported in two female patients with SCN due to P.Glu190X mutation in Hax-1 gene which is known to play a role in apoptosis and cell migration. In this investigation, gonadal development and function of patients with Hax-1 mutation in our clinic are evaluated.

Method: Detailed history, pubertal development, physical, and laboratory findings of 8 patients with SCN due to P.Trp44X mutation in HAX1 gene are evaluated retrospectively.

Results: The pubertal development of the only male patient was normal and complete. Four of the remaining 7 female patients were diagnosed with hypergonadotropic hypogonadism and hormone replacement therapy was prescribed. The rest of the three patients had small ovaries. One patient had small ovaries and menstrual irregularity, but gonadotropin levels were not elevated. One patient had small ovaries, but hypergonadotropic hypogonadism was not diagnosed, because she had normal menarche and gonadotropin concentrations. Although ovaries could not be visualized in one patient, puberty had just started and hypergonadotropic hypogonadism was not established. They are being followed up with gonadal dysfunction.

Conclusion: These results demonstrate that female patients with HAX1 mutation may develop primary ovarian failure. It is crucial to follow and evaluate the gonadal development of functions of female patients with HAX 1 mutation.

46**Mutations underlying autosomal dominant hyper-IgE syndrome impair distinct stages of STAT3 signaling**Pelham, S.J.^{1,2}, Lenthall, H.¹, Deenick, E.K.^{1,2}, Tangye, S.G.^{1,2}¹Garvan Institute of Medical Research, Immunology Division, Sydney, Australia, ²University of New South Wales, St Vincent's Clinical School, Sydney, Australia

Autosomal dominant hyper IgE syndrome (AD-HIES) is a primary immunodeficiency caused by heterozygous dominant negative mutations in the gene encoding Signaling transducer and activator of protein 3 (STAT3). These mutations cause a multisystem disorder, characterized immunologically by susceptibility to infection with pathogens such as *C. albicans* and *S. aureus* due to defective Th17 responses, and a failure to generate effective humoral immune responses. Interestingly, disease-causing mutations have been identified throughout all functional domains of STAT3 including the DNA binding, SH2 and transactivation domains. However, no phenotype-genotype correlations have been observed. To better understand how different mutations all result in the same

clinical and functional outcome we sought to characterize which stage(s) of STAT3 signaling was impaired by each of these mutations and if this was consistent for mutations in different domains. We used B-cell lines from AD-HIES patients or cell lines transfected with mutant STAT3 to determine the abilities of the mutant STAT3 proteins to undergo phosphorylation, cytokine receptor docking, dimerization, nuclear translocation, bind DNA and induce gene transcription. This revealed that while all mutations resulted in a distal impairment in STAT3 binding to DNA the block occurred at different proximal stages in signaling: transactivation domain mutant had reduced phosphorylation, SH2 domain mutants either were not phosphorylated or had reduced dimerization, and DNA binding domain mutants had defective nuclear translocation or DNA binding. Thus, this study reveals the mechanism underlying dysfunctional STAT3 signaling in AD-HIES and also identifies residues and regions of domains that are critical for normal STAT3 function.

47**Alteration of T cell responses in adult-onset immunodeficiency with acquired anti-interferon-γ autoantibodies**Pata, S.¹, Sirikul, C.², Chruewkamlow, N.¹, Mahasongkram, K.¹, Chaiwarith, R.³, Salee, P.³, Supparatpinyo, K.^{3,4}, Kasinrerak, W.¹¹Biomedical Technology Research Center, National Center for Genetic Engineering and Biotechnology, National Science and Technology Development Agency at the Faculty of Associated Medical Sciences, Chiang Mai University, Department of Medical Technology, Chiangmai, Thailand, ²Biomedical Technology Research Center, National Center for Genetic Engineering and Biotechnology, National Science and Technology Development Agency at the Faculty of Associated Medical Sciences, Chiang Mai University, Chiangmai, Thailand, ³Faculty of Medicine, Chiang Mai University, Department of Internal Medicine, Chiangmai, Thailand, ⁴Research Institute for Health Sciences, Chiang Mai University, Chiangmai, Thailand

Autoantibodies to IFN-γ can cause immunodeficiency syndrome in adults and are associated with various opportunistic infections. We speculate that, besides the presence of the anti-IFN-γ antibodies, T cell dysfunction may also be befallen in these patients. Upon TCR activation, T cell proliferation and expression of interleukin 2 receptor (CD25) of the patients remained intact. In comparison with the healthy subjects, the percentage of degranulating CD8 T cells was unchanged. However, the percentage of degranulating cytotoxic CD4 T cells was up-regulated in patients with anti-IFN-γ autoantibodies. Furthermore, the enhancement of Th1 cytokine (IFN-γ and TNF-α) production was observed, the production of Th2 (IL4) and Th17 (IL-17) cytokines were at the same level as healthy controls. We suggest that, in addition to the presence of anti-IFN-γ autoantibodies, alterations in T cell functions may also contribute to this adult-onset immunodeficiency.

48

Memory B cells and plasmablasts in patients after splenectomy

Kral, V.¹, Pohorska, J.¹, Jilkova, E.², Zizkova, J.¹, Jilek, D.¹, Richter, J.¹

¹Institute of Public Health, Centre of Immunology and Microbiology, Ústí nad Labem, Czech Republic, ²Institute of Public Health, Centre of Health Services, Ústí nad Labem, Czech Republic

The spleen is crucial in regulating immune homeostasis through its ability to link innate and adaptive immunity and in protecting against infections. Patients after splenectomy are lifelong susceptible to the risk of bacterial infections mainly with encapsulated bacteria. Existing studies have reported the reduction of memory B cells in these patients.

Aim of the study was to perform more detailed analysis of B cells population subsets and monitoring their representation depending on vaccination.

B cells immunophenotyping was done by flow cytometry with CD19, CD27, CD38, IgM and IgD in the splenectomized patients suffering with hereditary spherocytosis (HS, n=15), immune thrombocytopenic purpura (ITP, n=10), injury (I, n=57) and with healthy control (HC, n=12).

Reduction of CD27⁺ memory B cells and more profoundly CD27⁺IgM⁺ immunophenotype was found in all splenectomized groups in comparison to HC group (p < 0,01). These results correlate with significantly increased levels of naive B cells in all patients groups (p < 0,01). Higher proportions of plasmablasts (IgM⁺CD38^{hi}) and transitional B cells (IgM⁺CD38^{hi}) were found in all groups of splenectomized patients, significantly in HS group (p < 0,01 when compared to HC group), despite the fact that last vaccination was done more than one year ago.

Our data affirm that splenectomy is associated with diminished numbers of peripheral memory B cells, mainly IgM⁺CD27⁺ subset. There has been also shown increased proportion of transient B cells and plasmablasts in periphery without any relation to previous vaccination history.

Our results could support the view of the fundamental importance of the spleen marginal zone in IgM memory B cells development.

Innate Lymphoid Cells

49

Innate lymphoid cells contribute to allergic airway disease exacerbation by obesity

Everaere, L.¹, Ait Yahia, S.¹, Molendi-Coste, O.², Vorng, H.¹, Quemener, S.², Le Vu, P.², Fleury, S.², Bouchaert, E.², Fan, Y.¹, Duez, C.¹, de Nadai, P.¹, Staels, B.², Dombrowicz, D.², Tsigopoulos, A.¹

¹Inserm U 1019, Institut Pasteur de Lille, Pulmonary Immunity, Lille, France, ²Inserm U 1011, Institut Pasteur de Lille, EGID, Lille, France

Background: Epidemiological and clinical observations identify obesity as an important risk factor for asthma exacerbation, but the underlying mechanisms remain poorly understood. Type 2 and 3 Innate Lymphoid Cells (ILC2 and ILC3) have been implicated respectively in asthma and adipose tissue homeostasis, and in obesity-associated airway hyperresponsiveness (AHR).

Objective: To determine the potential involvement of ILC in

allergic airway disease exacerbation by high fat diet- (HFD) induced obesity.

Methods: Obesity was induced by HFD feeding and allergic airway inflammation was subsequently induced by intranasal administrations of house dust mite (HDM) extract. AHR, lung and visceral adipose tissue (VAT) inflammation, humoral response, cytokine and innate and adaptive lymphoid populations were analysed in the presence or absence of ILC.

Results: HFD feeding exacerbated allergic airway disease features including humoral response, airway and tissue eosinophilia, AHR, and Th2 and Th17 pulmonary profiles. Notably, non-sensitized obese mice already exhibited increased lung ILC and tissue eosinophil infiltration compared with lean mice in the absence of AHR. The number of total and cytokine-expressing lung ILC2 and ILC3 further increased in HDM-challenged obese mice compared to HDM-challenged lean mice and was accompanied by high levels of IL-33 and IL-1 β and decreased ILC markers in VAT. Furthermore, depletion of ILC with an anti-CD90 antibody, followed by T cell reconstitution, led to a profound decrease of allergic airway inflammatory features in obese mice, including Th2 and Th17 infiltration.

Conclusion: These results indicate that HFD-induced obesity may exacerbate allergic airway inflammation by mechanisms involving ILC2 and ILC3.

50

T-bet regulates IL-33-induced airway inflammation by suppressing IL-9 production from innate lymphoid cells

Matsuki, A., Takatori, H., Makita, S., Yokota, M., Tamachi, T., Suto, A., Suzuki, K., Hirose, K., Nakajima, H.

Graduate School of Medicine, Chiba University, Allergy and Clinical Immunology, Chiba, Japan

Thy1⁺ CD25⁺ Lineage⁻ group 2 innate lymphoid cells (ILC2s) are a subset of immune cells that produce large amounts of Th2 cytokines such as IL-5 and IL-13 in T-cell-independent allergic inflammation and helminth infection. Recent studies have shown that T-box expressed in T cells (T-bet), which is well known as a master regulator of Th1 cells, plays pivotal roles in the development of ILC3s and ILC1s. However, the role of T-bet in lung ILC2s remains unknown. In this study, we examined the roles of T-bet in the development and the function of lung ILCs and airway inflammation induced by IL-33 administration. At steady-state conditions, the development and cytokine production of lung ILCs were normal in T-bet^{-/-} mice. On the other hand, IL-33-induced accumulation of lung ILC2s and eosinophilic airway inflammation were exacerbated in T-bet^{-/-} mice and T-bet^{-/-} RAG2^{-/-} mice as compared with those in wild-type (WT) mice and RAG2^{-/-} mice, respectively, suggesting that T-bet expressed in non-T/non-B cells regulates the development of eosinophilic inflammation. Transcriptome analysis revealed that IL-9 expression was up-regulated in IL-33-stimulated T-bet^{-/-} ILCs as compared with that in IL-33-stimulated WT ILCs. Moreover, enforced expression of T-bet suppressed IL-9 production in lung ILC2s. Furthermore, anti-IL-9 antibody attenuated IL-33-induced lung inflammation in T-bet^{-/-} mice. Taken together, these results suggest that T-bet suppresses IL-9 expression in lung ILC2s and thereby inhibits IL-33-induced eosinophilic inflammation.

51**Systemic and airway derived Th2 cells and ILC2s in asthmatics susceptible to virus triggered exacerbations***Malmhäll, C., Johansson, K., Lötvall, J., Rådinger, M.**University of Gothenburg, Sahlgrenska Academy, Krefting Research Centre, Gothenburg, Sweden*

Background: Asthma is a chronic inflammatory disease, in which Th2 cells and type 2 innate lymphoid cells (ILC2) play roles. These cells express the interleukin-33 receptor (IL-33R), and/or the prostaglandin D2 (PGD2) receptor CRTH2. IL-33 serves as a barrier guardian, and PGD2 induces cellular migration. The expression of these receptors on Th2 cells and ILC2s in subgroups of asthmatics has not been studied.

Aim: Our aim was to determine the expression of IL-33R/CRTH2 on blood versus airways derived Th2 cells and ILC2s obtained from asthmatics reporting recurrent viral exacerbations or not, and healthy volunteers.

Method: Bronchial lavage and blood were obtained from participants selected from an epidemiological cohort (West Sweden Asthma Study). Th2 cells (Lin+CD45+CD4+and IL-33R+ and/or CRTH2+), ILC2s (Lin-CD45+CD127+and IL-33R+ and/or CRTH2+) were analyzed by flow cytometry.

Results: Th2 cells express IL-33R and CRTH2 similarly in blood and airways. IL-33R expression was seen on a majority of airway ILC2s, but only half of blood ILC2s expressed IL-33R. CRTH2+ILC2s demonstrated an opposing pattern with more CRTH2 positive ILC2s in blood vs airways. Th2 cells were found in higher quantities in blood vs bronchial lavage. However, the number of ILC2s were comparable in blood and bronchial lavage. Asthmatics and healthy volunteers demonstrated similar distribution of Th2 cells and ILC2s in blood and airways at baseline.

Conclusion: ILC2s display highly distinct compartment-specific phenotypes, suggesting a more IL-33-responsive but less migration-prone phenotype in airways compared to blood. In contrast, our data suggest a shared Th2 phenotype in circulating blood and in airway lumen.

52**Soluble fibrinogen-like protein 2 regulates differentiation and enhances immunosuppressive function of myeloid-derived suppressor cells in allograft immunity***Yang, C.**Shanghai Key Laboratory of Organ Transplantation, Shanghai, China*

Soluble fibrinogen-like protein 2 (sFGL2) is a novel immunoregulatory molecule, secreted mainly by regulatory T cells. CD11b⁺ Gr1⁺ myeloid-derived suppressor cells (MDSCs) are an important regulatory innate cell population and have significant inhibitory effect on T cell-mediated responses. Here, we synthesized murine full length sFGL2 by eukaryotic expression system, and investigated the impact on differentiation and function of MDSCs. Bone marrow cells from BABL/c mice were cultured with or without 10 µg/ml sFGL2 for 3 days and 5 days under 10 ng/ml GM-CSF stimulation. Compared with PBS, sFGL2 significantly induced CD11b⁺Ly6G⁺Ly6C^{high} MDSC (MO-MDSC) differentiation but inhibited CD11b⁺Ly6G⁺Ly6C^{low}

MDSC (PMN-MDSC) differentiation. The sFGL2-induced MO-MDSCs significantly inhibited T cells proliferation compared with those induced by PBS. Besides, sFGL2-induced MO-MDSCs demonstrated higher expression of arginase-1 and iNOS at both mRNA and protein level. Furthermore, adoptive transfer sFGL2-induced MO-MDSCs prolonged the skin allograft survival in mice. In the sFGL2-induced MO-MDSCs infusion group, the transplanted skin allograft showed mild inflammatory immune cell infiltration, less apoptosis and necrosis, and lower pro-inflammatory cytokines expression. T cells in the recipient mouse displayed a lower autoimmune phenotype (lower TCR⁺ CD44^{high} CD62^{low} cells). Taken together, our results indicate sFGL2 prompts MO-MDSCs differentiation and enhances their immunosuppressive function.

53**A novel effect of extracellular histones released by innate immune cells on erythrocyte fragility***Kordbacheh, F.¹, O'Meara, C.H.^{1,2}, Coupland, L.A.¹, Lelliott, P.M.³, Parish, C.R.¹**¹Australian National University, John Curtin School of Medical Research, Cancer Biology and Therapeutics, Canberra, Australia,**²The Canberra Hospital, ENT Unit, Canberra, Australia, ³Australian National University, John Curtin School of Medical Research, Immunology and Infectious Disease, Canberra, Australia*

Extracellular histones are released from activated immune cells by extracellular traps. Extracellular traps are first observed in activated neutrophils (NETs) in response to pathogens and tissue injury and exhibit very effective anti-microbial activity. Uncontrolled formation of NETs can, however, become pathogenic particularly via their associated histones that can be cytotoxic in the vasculature causing endothelial cell death, systemic vascular obstruction and multiple organ failure. They can also initiate coagulation by both activating platelets and damaging erythrocytes such that they become pro-thrombotic. Recently we discovered an additional effect of histones on erythrocyte, which is to enhance their fragility when they are subjected to sheer stress associated with blood flow through the vascular system and spleen in particular. The spleen is the largest blood filter and is composed of branching arterial vessels that prevent old, damaged or abnormal erythrocytes from returning to the bloodstream. We have used a novel mechanically-induced sheer stress method as well as an *in vitro* spleen filtration model to investigate the effects of NETS and mammalian histones, over a wide concentration range, on RBC fragility under both isotonic and hypotonic conditions. Our results revealed that free histones bind to erythrocytes with high affinity and render erythrocytes susceptible to lysis by sheer stress in a dose-dependent manner. Based on these data we propose that erythrocytes can capture histones in the circulation and transport them to the spleen for disposal. Overload of this disposal system could cause the unexplained anaemia associated with sepsis, cancer and other pathological conditions.

54

Human and murine fibroblastic reticular cells play specialized roles in innate immune cellular crosstalk

D'Rozario, J.^{1,2,3}, Knoblich, K.³, Roberts, D.³, Dias De Campos, J.⁴, Astarita, J.⁵, Mansell, A.⁶, Denton, A.⁷, Fearon, D.^{8,9}, Withers, D.³, Barone, F.⁴, Turley, S.⁵, Boyd, R.L.¹, Heng, T.^{1,10}, Fletcher, A.L.^{3,10}

¹Monash University, Department of Anatomy and Developmental Biology, Clayton, Australia, ²Monash Biomedicine Discovery Institute, Infection and Immunity Program, Clayton, Australia, ³University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom, ⁴University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom, ⁵Genentech, 1 DNA Way, Department of Cancer Immunology, San Francisco, United States, ⁶Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia, ⁷University of Cambridge, Department of Medicine and Cancer Research UK Cambridge Institute, Cambridge, United Kingdom, ⁸Cold Spring Harbor Laboratory, New York, United States, ⁹Weill Cornell Medical School, Department of Microbiology and Immunology, Joan and Sanford I. Weill Department of Medicine, New York, United States, ¹⁰These authors contributed equally to this work, Clayton, Australia

Fibroblastic reticular cells (FRCs) are a subset of lymph node stromal cells which have evolved to play important structural and immunoregulatory roles within the lymph node. While structurally they form the mesenchymal backbone of the lymph node, and surround the reticular network, FRCs have also been found to facilitate leukocyte migration and priming via the secretion of chemokines, cytokines and growth factors to regulate immune responses within the periphery. Furthermore, new studies have demonstrated additional capabilities of FRCs including deletional tolerance, antigen presentation and T cell suppression mediated via cellular crosstalk mechanisms.

Here we focus on the immunological crosstalk that occurs between FRCs and the innate immune system. Human and mouse transcriptomic expression profiles indicate that FRCs constitutively produce factors associated with the innate immune response and innate cell chemotaxis. FRCs express CCL2 and CXCL12, providing stimuli for the chemoattraction of macrophages and monocytes. FRCs also express functional TLR3 and TLR4, as stimulation with LPS or Poly I:C led to p38 phosphorylation and upregulation of chemotactic and growth factors by FRCs, inducing the maturation of monocytes to macrophages. Furthermore, ablation of FRCs in FAP-/- DTR mice led to the depletion of innate immune cell types within the lymph node and impairment of the immune response. Our data suggest that FRCs have the capacity to respond to bacteria and viruses and support a novel role for FRCs in the regulation of the innate immune system.

55

Regulation in the production of natural antibody by innate lymphoid cells

Flores-Vázquez, J.C., Jiménez-Zamudio, L.A., Carnalla-Cortés, M., García-Latorre, E.A., Domínguez-López, M.L.
Instituto Politécnico Nacional, Escuela Nacional De Ciencias Biológicas, Ciudad de México, Mexico

Introduction: B1 lymphocytes are responsible of the production of natural antibody, essential in the defense against infectious agents but maybe dangerous in large quantities because of their autoreactivity. Moro et al. described the type II innate lymphoid cells (ILC2s) as lymphocyte stimulator of B1 cells to parasitic infections; so we asked if they would be responsible not only of stimulation in infection, but also to have a role in the spontaneous function of B1 cells.

Materials and methods: BALB/c healthy mice were used, and to develop the murine plasmacytoma at 9 months after induction with pristane. They were divided in two groups: the control group and a group that was treated with monoclonal antibody anti c-kit to deplete the ILC2s. Serum and peritoneal fluid were obtained to analyze antibody titers of IgM and IgA by ELISA.

Results: An increased of IgM and IgA production was observed in both serum and peritoneal fluid from mice treated with anti c-kit compared to healthy mice control group; however in the plasmacytoma group no significant difference was observed.

Conclusions: The increase in the production of IgM and IgA in the c-kit treated groups suggested a regulatory role by ILC2s. These cells not only are responsible for detecting danger signals to increase production of natural antibody, but are also responsible for regulation; however in the pristane induced animals, the depletion was not seen, probably because of the increase of ILC2s during the inflammatory process.

56

Peyer's patch innate lymphoid cells regulate commensal bacteria expansion

Hashiguchi, M., Kobayashi, A., Kashiwakura, Y., Kojima, H., Kanno, Y., Kobata, T.
Dokkyo Medical University School of Medicine, Department of Immunology, Tochigi, Japan

The mammalian intestinal tract is colonized by trillions of bacteria comprising thousands of different species and anatomical containment of commensal bacteria in the intestinal mucosa is promoted by innate lymphoid cells (ILCs). However, the mechanism by which ILCs regulate bacterial localization to specific regions remains unknown.

Flow cytometric analyses revealed distinct cytokine profiles of ILCs from various tissue. Especially, Peyer's patch (PP) ILCs robustly produce IL-22 and IFN- γ , even in the absence of exogenous stimuli. The IL-22-producing ILCs showed typical phenotypes of group 3 ILCs; the IFN- γ -producing ILCs showed phenotypes of group 1 ILCs. Antibiotic treatment of mice decreased both IL-22⁺ and IFN- γ ⁺ cells in PPs. Blockade of both IL-2 and IL-23 signaling *in vitro* lowered IL-22 and IFN- γ production. Combination of IL-2 and IL-23, and IL-12 alone partly restored IL-22, and IFN- γ production of PP ILCs from Antibiotic-treated PP ILCs, respectively. PP ILCs induced mRNA expression of the antibacterial proteins RegIII β and RegIII γ in intestinal epithelial cells. PP contains large numbers of Proteobacteria and small parts of Bacteroidetes and Firmicutes by 16s rRNA analyses. *In vivo* depletion of ILCs rather than T cells altered bacterial composition from Proteobacteria-dominant to Bacteroidetes-dominant. qPCR revealed that ILC depletion also allowed Bacteroidetes and Firmicutes expansion in PPs. Collectively, our results show that ILCs regulate the expansion of commensal bacteria in PPs.

57**Dysregulation of ERK signaling in CD4-expressing cells induces osteochondromas**

Wehenkel, M.¹, Corr, M.², Guy, C.¹, Edwards, B.¹, Calabrese, C.³, Pages, G.⁴, Pouyssegur, J.⁴, Vogel, P.⁵, McGargill, M.¹

¹St. Jude Children's Research Hospital, Immunology, Memphis, United States, ²UCSD, Division of Rheumatology, Allergy and Immunology, La Jolla, United States, ³St. Jude Children's Research Hospital, Small Animal Imaging, Memphis, United States,

⁴University of Nice Sophia-Antipolis, Institute for Research of Cancer & Aging (IRCAN), Nice, France, ⁵St. Jude Children's Research Hospital, Pathology, Memphis, United States

ERK1 and ERK2 are serine/threonine kinases critical for the proliferation and development of many cell types. Mice with a conditional deletion of *Erk1* and *Erk2* mediated by *CD4cre* (DKO^{CD4} mice) exhibit a profound block in T cell development. Surprisingly, the DKO^{CD4} mice spontaneously developed osteochondromas by 28 weeks of age. Histological analysis of these lesions revealed excessive accumulation of hypertrophic chondrocytes originating from the growth plates in the bone, but no mononuclear infiltrate indicative of inflammation. As the majority of CD4⁺ cells are T cells, we investigated whether these lesions were caused by deletion of *Erk* in T cells. Unexpectedly, osteochondromas still appeared in DKO^{CD4} mice in the absence of T cells. In fact, osteochondromas developed faster and were more severe in DKO^{CD4} mice that lacked T cells, indicating that T cells play an important role in regulating cartilage homeostasis, and deletion of *Erk* in other cell types mediates excess cartilage accumulation. Furthermore, the development of the osteochondromas was influenced by changes in the microbiota, as DKO^{CD4} mice treated with an antibiotic cocktail had a delay in osteochondroma development, while mice housed in non-specific pathogen free conditions had accelerated onset of tumors. Together these data suggest that *Erk* plays a critical role in a CD4⁺ cell type other than T cells, possibly an innate lymphoid cell, to alter cartilage growth. In addition, we present a novel role for T cells in regulating cartilage homeostasis.

58**The role of dietary antigens on homeostasis and functional activity of innate lymphoid cells (ILCs) in the small intestine**

Lee, M.J., Kim, K.S., Hong, S.-W., Ko, H.-J., Jung, J., Lee, J.-Y., Surh, C.D. Academy of Immunology and Microbiology (AIM), Institute for Basic Science (IBS), Pohang, Korea, Republic of

ILCs are found in increased numbers in the mucosal tissues and mediate local tissue homeostasis. ILCs lack an Ag-specific receptor, but closely resemble effector CD4⁺ T cell subsets in terms of cytokine profiles and transcription factors. The precise role of commensal microbiota and dietary Ags in the intestinal immune homeostasis of ILCs is poorly understood. In order to address this issue we have examined small intestinal ILCs in B6 mice raised under germ-free (GF) conditions and also in antigen-free (AF) conditions whereby GF mice were raised on an elemental diet deprived of dietary macromolecules. We found that a fraction of Type3 ILCs was depleted in GF mice, and more strikingly, AF mice have a dramatically elevated number of Type2

ILCs that produced considerably higher amounts of TH2 effector cytokines than Type2 ILCs in SPF and GF mice. Moreover, Type3 ILCs in AF mice were severely depleted compared to that in SPF and GF mice. Accordingly, while the basal proliferation rate of Type3 ILCs was similar in SPF and GF mice, it was minimal in AF mice. Various experiments confirmed the role of dietary Ags in modulating Type2 and Type3 ILCs. Notably, we found markedly increased mRNA expression levels of TSLP and IL-25, but not IL-33, in the intestinal epithelial cells from AF mice compared to SPF and GF mice. We are currently investigating how dietary Ags from normal chow diet block strong expansion of ILC2s and promote normal ILC3 homeostasis in the steady state.

59**Mucosal BCG vaccination promotes function and accumulation of innate lymphoid cells in murine lungs**

Steigler, P., McCulloch, T., Kirman, J.R.

University of Otago, Department of Microbiology and Immunology, Dunedin, New Zealand

Tuberculosis (TB) has surpassed human immunodeficiency virus as the deadliest infectious disease. The intradermally applied TB vaccine, Bacille Calmette-Guérin (BCG), prevents disseminated childhood TB but fails to protect against pulmonary TB, the most prevalent form. TB vaccines currently in clinical trials target conventional T cells; innate cells are neglected in these vaccine approaches. New evidence suggests that some innate cell subsets exhibit features of immunological memory. In keeping with this concept, epidemiological studies show that BCG can protect against unrelated diseases. Located at mucosal entry sites and able to secrete cytokines rapidly, innate lymphoid cells (ILCs) are crucial in defense against many pathogens; however their role in protection against TB and ability to exhibit features of memory are as yet unexplored. Several studies have shown that mucosal BCG delivery enhances immunity against pulmonary TB infection compared to parenteral administration. We hypothesised that intranasal BCG vaccination would enhance the number and function of ILCs within lungs. Using a new multicolour flow cytometry panel, we measured ILC phenotype and function in murine lung and secondary lymphoid tissues post intradermal, intranasal or subcutaneous BCG vaccination or in unvaccinated controls. We found increased numbers of all ILC subsets in lungs and increased interferon-gamma production by natural killer cells, ILC1s and ILC3s compared to other delivery routes; implying that intranasal delivery leads to enhanced accumulation and effector function of ILCs in lungs. Mucosal BCG delivery might be the required vaccination route for effective induction of ILC immunity in lungs to mediate early protection against TB.

60**STAT4 modulates innate lymphoid cell effector function and early responses to intestinal infection**

Dulson, S., Harrington, L.

University of Alabama at Birmingham, Cellular Developmental and Integrative Biology, Birmingham, United States

Innate Lymphoid Cells (ILCs) are a newly discovered subset of cells primarily found at barrier surfaces that serve both protective and pathogenic roles in intestinal health. ILCs are subdivided into distinct groups and perform effector functions similar to CD4 T cells, but lack a specific receptor and are activated early during an immune response. Since the initial events following intestinal infection dictate the course of the immune response, it is critical to know what molecules regulate ILC function both during homeostasis and in disease. Signal transducer and activator of transcription 4 (STAT4) is important for driving many pro-inflammatory responses and phenotypes in T cells, but its effects on ILC development and function remain unclear. Contrary to its known role in Th1 cell biology, we find STAT4 to be dispensable in Group 1 ILC development. However, we observe that STAT4 is critical for IFN- γ production by Group 1 ILCs, thus influencing the capacity of this subgroup to mount an effector response. Whereas STAT4 deficiency did not impact IL-22 or IL-17 production by Group 3 ILCs, this transcription factor specifically modulates the secretion of IFN- γ by plastic Tbet⁺ ILC3s, a subgroup that is greatly expanded during inflammation. Importantly, STAT4 signaling is critical early for survival against gastrointestinal infection with a genetically modified strain of *Listeria monocytogenes* that is capable of binding mouse E-cadherin on the intestinal epithelium. These results indicate that STAT4 has the potential to directly influence responses by ILCs, thereby contributing to host protection against intestinal infection.

61

Interferon- γ negatively regulates cytokine production of group 2 innate lymphoid cells

Kudo, F., Takaki, S.

National Center for Global Health and Medicine, Research Institute, Department of Immune Regulation, Ichikawa, Japan

Group 2 innate lymphoid cells (ILC2s) contribute to type 2 immune responses in response to allergic inflammation and tissue repair by producing high amounts of IL-5 and IL-13. IL-5 supports eosinophil responses in various tissues. IL-13 induces mucus production and contributes to tissue repair or fibrosis. ILC2s are activated by alarmins, such as IL-33 released from epithelia, macrophages and NKT cells in response to infection and allergen exposure, leading to epithelial injury.

To get insight for regulations operating in ILC2s, we conducted SAGE analysis and found that ILC2s expressed *Ifngr1*, the receptor for Th1 cytokine. IFN- γ severely inhibited IL-5 and IL-13 production by lung and kidney ILC2s in culture. In order to evaluate the effects *in vivo*, we used α -galactosylceramide (α -GalCer) to induce NKT cells to produce IL-33 and IFN- γ . Intraperitoneal injection of α -GalCer in mice induced NKT cell activation resulting in IL-5 and IL-13 production by ILC2s. Administration of anti-IFN- γ together with α -GalCer significantly enhanced the production of IL-5 and IL-13 by ILC2s in lung and kidney. Conversely, cytokine production from ILC2s was markedly suppressed after injection of exogenous IL-33 in *Il33*^{-/-} mice pre-treated with α -GalCer. Our findings demonstrate that IFN- γ directly inhibits IL-5 and IL-13 production by ILC2s, and that blocking IFN- γ restored the ability of activated ILC2s to produce IL-5 and IL-13. IFN- γ antagonizes ILC2 function

similar to the way IFN- γ impacts Th2 cells and constrains type 2 immune responses.

62

Characterising the role of group 1 innate lymphoid cells during malaria

Ng, S.S.^{1,2}, Guimaraes, F.^{3,4}, de Labastida Rivera, F.¹, Amante, F.H.¹, Smyth, M.³, Engwerda, C.R.¹

¹QIMR Berghofer Medical Research Institute, Immunology and Infection, Herston, Australia, ²Griffith University, School of Natural Sciences, Nathan, Australia, ³QIMR Berghofer Medical Research Institute, Immunology of Cancer and Infection, Herston, Australia, ⁴Walter & Eliza Hall Institute, Molecular Immunology Division, Parkville, Australia

Innate lymphoid cells (ILCs) resemble T helper (Th) cells in terms of transcription factor requirements and cytokine profiles, but do not express antigen-specific receptors. Group 1 ILCs consist of natural killer (NK) cells and ILC1s. Together, they share many characteristics with Th1 cells such as a requirement for T-bet and the ability to produce IFN γ . However, the developmental relationship between NK cells and ILC1s is still a matter of debate. An ILC1 subset that is liver-resident has recently been described. Given the resemblance between ILC1s and Th1 cells, and the importance of Th1 cells in the immune response during *Plasmodium* infection, we aimed to characterise the role of ILCs during malaria. Initial findings suggested that ILC1s and NK cells have a limited role in conferring protection or causing pathology during *P. chabaudi chabaudi* AS (PcAS) infection. However, in a controlled human malaria infection study, we showed that the frequencies of circulating ILC1s and NKs were decreased at the peak of infection, compared to frequencies before infection. A similar observation was made for liver and splenic ILC1s in PcAS-infected mice. The decrease in liver ILC1 frequencies in mice was associated with increased apoptosis but did not directly relate to blood parasitaemia. Together, our results show that ILC1s are lost early during rodent and human malaria, and this observation may explain the limited role for ILC1s and NK cells in controlling blood stage malaria.

63

The role of c-Kit in the activation of innate lymphoid cell and respiratory viral infection-induced acute asthma

Lai, A.¹, Wu, H.-C.¹, Chuang, Y.-T.², Wu, Y.-H.¹, Baumgarth, N.³, Umetsu, D.², Chang, Y.-J.¹

¹Academia Sinica, Institute of Biomedical Sciences, Taipei, Taiwan, Republic of China, ²Children's Hospital, Harvard Medical School, Division of Immunology and Allergy, Boston, United States, ³University of California, Center for Comparative Medicine, Davis, United States

Asthma, which is characterized by airway inflammation and airway hyperreactivity (AHR), is thought to be mediated by allergen-specific Th2 cells, adaptive immunity and allergic inflammation. Current treatments for asthma generally focus on minimizing the Th2-driven eosinophilic inflammation with the use of anti-inflammatory therapies such as corticosteroids.

However, this approach, targeting the adaptive Th2 cell immunity with corticosteroids, has not reduced the high rates of hospitalizations for acute asthma, most often caused by acute viral infection, including influenza. Recently, type 2 innate lymphoid (ILC2) cells expressing c-Kit have been shown to expand during influenza infection and to directly cause airway hyperreactivity (AHR), a cardinal feature of asthma. We now show that the treatment of *influenza*-infected mice with c-Kit kinase inhibitors blocked the development of AHR and airway inflammation and greatly reduced the number and function of ILC2 cells, whereas the treatment with corticosteroids, commonly used to treat acute asthma, failed to prevent the *influenza*-induced AHR. We also demonstrated that c-Kit function is required for normal ILC2 cell function and for *influenza*-induced AHR, and that c-Kit kinase inhibitor inhibits murine lung ILC2 cell proliferation and cytokine productions *in vitro* and *in vivo*. Furthermore, the treatment of c-Kit inhibitor did not affect *in vivo* viral clearance. Our study provides mechanistic insights into the crucial role of c-Kit in modulating the ILC2 activation in the lungs, particularly in respiratory viral infection induced acute asthma.

Invariant & $\gamma\delta$ T Cells

Comparison of IFN- γ production of peripheral blood $\gamma\delta$ T cells between latent tuberculosis infections and patients with active pulmonary tuberculosis

Li, B.¹, Sheng, L.-L.^{1,2}, Chen, C.¹, Jin, H.², Wang, Z.³, Tang, J.¹, Xia, H.¹
¹Bengbu Medical College, Department of Immunology, and Anhui Key Laboratory of Infection and Immunity, Bengbu, China, ²The First Hospital of Taizhou, Taizhou, China, ³The Infectious Disease Hospital of Bengbu City, Department of Lung Disease, Bengbu, China

Aim: The Interferon- γ (IFN- γ) release assays (T-SPOT.TB), which based on the re-activation of *M. tuberculosis* (*M. tb*) antigen specific memory CD4 T cells, are specific for diagnosis of *M. tb* infection, but not sufficient for discrimination of active tuberculosis (TB) patients from latent TB infection (LTBI). This study was to investigate the difference of IFN- γ producing $\gamma\delta$ T cells between the LTBI and active pulmonary TB patients.

Methods: Eighteen healthy donors without *M.tb* infection (HD), 17 subjects with LTBI, and 22 active pulmonary TB patients were enrolled in this study. Peripheral mononuclear cells were separated from whole blood, and cultured with phosphoantigens (DMAPP, or IPP) and *M.tb* heat resistant antigen (Mtb-Hag) for 20 hours and added monesin during last 6 hours. The antigen stimulated cells were stained with anti cell surface molecule fluorescence monoantibodies (mAb), followed with anti IFN- γ fluorescence mAb. The proportions of IFN- γ producing $\gamma\delta$ T cells, and $\alpha\beta$ T cells were measured by flow cytometry.

Result: The proportions of IFN- γ producing $\alpha\beta$ T cells stimulated with phosphoantigen, or Mtb-HAg, among HD, LTBL and TB groups were from 0.13% to 0.25%, there were no differences among groups. The proportions of IFN- γ producing $\gamma\delta$ T cells that stimulated with phosphoantigen and Mtb-HAg among

LTBI group (7.53%, and 5.82%, respectively), were significantly higher than that among active TB patients (3.36%, and 2.32%, respectively) (both $p < 0.05$).

Conclusion: IFN- γ release assays by $\gamma\delta$ T cell specific antigens are potential means to differentiate LTBI from active TB patients.

65

MAIT cells in *Helicobacter* induced gastritis

Dsouza, C.^{1,2}, Chen, Z.¹, Every, A.², Scheerlinck, J.P.², Corbett, A.J.¹, McCluskey, J.¹

¹University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ²University of Melbourne, Centre for Animal Biotechnology, Melbourne, Australia

Mucosal Associated Innate T (MAIT) cells are type of innate like T lymphocytes that express a semi-invariant TCR and are restricted by the non-classical MHC class I-related molecule, MR1. These cells can recognize a novel class of antigens, intermediates of the riboflavin synthesis pathway that are only produced by certain class of bacteria and yeasts.

Helicobacter pylori is a bacterium that infects the human stomach and is associated with causing gastritis, duodenal ulcers and gastric cancer. We have examined whether MAIT cells play a role in the pathology of chronic *H. pylori* infection. We have recently developed highly specific MR1 tetramers that have been used to detect and characterize MAIT cells in mice. Our studies show that MAIT cells play a key role in the regulation of gastric inflammation in *H. pylori* infection. Using a mouse model that first enriches MAIT cells in the lung, we show repopulation of MAIT cells to other mucosal sites including the stomach. On challenge with *H. pylori*, these mice develop an accelerated inflammatory response leading to atrophic gastritis. In our model, MAIT cells have a pathogenic rather than protective effect. We are working to understand their role with a view to therapeutic intervention.

66

CAR $\gamma\delta$ -T cell for solid tumor immunotherapy based on tumor specific CDR3 δ

Teng, D., Chen, H., Zhang, J., He, W.

Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

The adoptive transfer of engineered T cells that express artificial chimeric antigen receptor (CAR) which target CD19 has shown impressive antitumor efficacy in B cell malignancies. But current CAR-T cell therapy has less therapeutic effects in solid tumors, mainly because the limited antigen specificity of single-chain antibody (scFv) expressed on CAR-T cell, is not suitable for highly heterogeneous solid tumors. T cell receptor (TCR) $\gamma\delta$ can recognize stress-induced antigens highly expressed on several tumor cells and the antigen specificity of TCR $\gamma\delta$ solely depends on CDR3 δ . Previously, we found tumor-specific CDR3 δ sequence named OT3 derived from tumor infiltrated lymphocytes. TCR $\gamma\delta$ 2 (OT3)-Fc fusion protein triggered an ADCC response against series of solid tumors including ovarian epithelial carcinoma, hepatic carcinoma, lung carcinoma, etc. Moreover, TCR $\gamma\delta$ 2 (OT3) engineered $\alpha\beta$ T cells also revealed significant

antitumor reactivity both *in vitro* and *in vivo*. In this study, we found several tumor-specific CDR3 δ sequences by immune repertoire technology. Then designed series of third generation CAR $\gamma\delta$ molecules, extracellular domain of which were composed of single chain of V γ and V δ (tumor-specific CDR3 δ grafted), instead of scFv. These molecules were then transferred to CD8⁺T cell by lentivirus and detected the cytotoxicity of CAR $\gamma\delta$ -T cells to tumor cells. Considering the characteristics of solid tumor, we combined heparanase, PD-1 antibody, IL-12, soluble IL-6 receptor with CAR $\gamma\delta$ -T cells, which might enhance the anti-tumor activity and reduce adverse reactions of CAR $\gamma\delta$ -T cells *in vivo*. Based on TCR $\gamma\delta$ broad-spectrum recognition, CAR $\gamma\delta$ -T cells is expected to provide perspective on the development of adoptive immunotherapy against solid tumor.

67

TCR-ligand interactions are required for murine epidermal V γ 3V δ 1 T cell development

Witherden, D.A., Garijo, O., Kelly, R., Komori, H.K., Havran, W.L. Scripps Research Institute, Department of Immunology and Microbial Science, La Jolla, United States

Dendritic epidermal T cells (DETC), which bear the V γ 3V δ 1 T cell receptor (TCR), are the exclusive T cell population resident in the murine epidermis where they act as sentinels for neighboring keratinocytes. $\gamma\delta$ T cells differentiate from lymphoid precursors largely within the thymic microenvironment in a highly organized manner. Cellular selection processes are also believed to be involved and indeed several lines of evidence suggest that proper development and homing of the V γ 3V δ 1 subset does require positive selection events in the fetal thymus. To evaluate the role of TCR interactions with cognate ligand in V γ 3V δ 1 T cell development and maturation, we used a soluble DETC TCR tetramer to characterize ligand expression in the fetal thymus and skin. We show that temporal expression of ligand in the thymus closely mimics the window of DETC intrathymic development. Ligand expression is independent of Skint1, a molecule shown to be important for thymic maturation of DETC and their subsequent residence in the epidermis. Furthermore, using the soluble DETC TCR tetramer as a ligand blocking reagent, we show that in fetal thymic reaggregation cultures, TCR-ligand interactions are essential for DETC development and maturation. Current experiments are investigating the nature of the ligand-expressing thymic epithelial cell population. Understanding TCR-ligand interactions involved in DETC development may provide important insight into identifying the enigmatic DETC antigen.

68

Dynamic expression of CCR6 and CCR2 balances homeostatic and inflammatory trafficking of $\gamma\delta$ T17 cells

McKenzie, D.¹, Kara, E.¹, Tyllis, T.¹, Bastow, C.¹, Fenix, K.¹, Gregor, C.¹, Kallies, A.^{2,3}, Nutt, S.^{2,3}, Comerford, I.¹, McColl, S.¹

¹University of Adelaide, Department of Molecular & Cellular Biology, Adelaide, Australia, ²Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, ³University of Melbourne, Department of Medical Biology, Parkville, Australia

Successful detection and eradication of invading pathogens requires collaboration between appropriately placed immune sentinels in barrier tissue and infiltrating inflammatory cells. Fulfilling both roles are interleukin 17-producing $\gamma\delta$ T cells ($\gamma\delta$ T17), which exhibit unique migratory characteristics. While most $\gamma\delta$ T17 cells reside in mucocutaneous tissues at homeostasis, these cells also expand in lymphoid organs during inflammation and then infiltrate inflammatory sites. While crucial for various rapid protective responses, $\gamma\delta$ T17 cells have been shown to be detrimental in models of autoimmunity and cancer. Therefore, investigating the poorly understood migratory cues regulating their homeostatic positioning and inflammatory trafficking is of clinical significance. We show that $\gamma\delta$ T17 cells constitutively express the chemokine receptors CCR6 and CCR2. $\gamma\delta$ T17 cell positioning in the dermis at homeostasis is CCR6-dependent, while CCR2 drives recruitment of $\gamma\delta$ T17 cells to the central nervous system in experimental autoimmune encephalomyelitis and into B16 melanomas. We find no requirement for CCR6 in $\gamma\delta$ T17 cell homing to inflammatory lesions despite its established inflammatory role in other cell types. Accordingly, upon activation $\gamma\delta$ T17 cells quickly extinguish CCR6 expression in an IRF4- and BATF-dependent manner, which inhibits their recruitment to uninfamed skin. These findings suggest a novel paradigm of cell migration, whereby $\gamma\delta$ T17 cells constitutively express chemokine receptors that drive recruitment into non-inflamed (CCR6) and inflamed (CCR2) tissues, but rapidly downregulate the homeostatic regulator CCR6 upon activation to avoid recruitment to uninfamed skin. This allows CCR2 to efficiently drive $\gamma\delta$ T17 cells to sites of inflammation and orchestrate early immunity.

69

Identification of CD1b-autoreactive T cells using tetramers

Ross, F.J.¹, Souter, M.¹, Pellicci, D.G.¹, Uldrich, A.P.¹, Rossjohn, J.², Godfrey, D.I.¹

¹The Peter Doherty Institute for Infection and Immunity, The University of Melbourne, Microbiology and Immunology, Melbourne, Australia, ²School of Biomedical Sciences, Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia

The ability of conventional T cells to recognize peptide antigens presented by MHC has been well characterized. However, there also exist T cell populations that interact with lipid antigens presented by CD1. Four CD1 isoforms are expressed in humans, and include CD1a-d. Of the lipid-reactive T cell populations, CD1d-reactive Natural Killer T cells have been the most thoroughly described, largely due to the fact that CD1d is the only isoform present in mice and that the antigen, α -GalCer, loaded into CD1d tetramers permits clear identification of these cells.

One difficulty in investigating T cells specific to CD1a-c is a lack of reagents to identify them. In spite of this, it has been demonstrated that at least a subset of these cells can be identified by *in vitro* stimulation assays due to their ability to recognize both self-lipids and bacterial lipids. We utilized endogenous antigen-loaded tetramers to probe for CD1b-autoreactive cells within healthy human blood samples. Following *in vitro* expansion of

rare tetramer+ T cells, a defined population could be identified and further examined using single cell abTCR sequencing. Five distinct clones were identified across two donors, each of which was CD4⁺ CD8⁻. The TCR chains expressed by these cells were TRAV12-3/TRBV28, TRAV13-2/TRBV19, TRAV27/TRBV5-8, TRAV27/TRBV5-4, and TRAV41/TRBV6-2, suggesting diverse TCR usage. Generation of retrovirally transduced TCR+ cell lines confirmed CD1b-reactivity, and allows us to investigate their reactivity to a large panel of lipid-based antigens. This work is helping to shed light on the poorly understood autoreactive CD1b-restricted T cell population.

70

Visualising MAIT and NKT cells in colorectal tumours

Kelly, J.^{1,2}, Toohey, B.², Gray, D.³, Kannourakis, G.², Berzins, S.P.^{1,2}

¹Federation University Australia, Ballarat, Australia, ²Fiona Elsey Cancer Research Institute, Ballarat, Australia, ³The Walter and Eliza Hall Institute of Medical Research (WEHI), Molecular Genetics of Cancer, Immunology, Melbourne, Australia

Unlike conventional T cells, which have a diverse T cell receptor repertoire and recognize antigen presented on MHC, several unconventional T cell subsets have a semi-invariant TCR α -chain and are restricted by non-MHC antigen presenting molecules, such as MR1 (MAIT cells) and CD1d (NKT cells). The role of these cells is not yet fully defined, but their responsiveness to microbes suggests they may have important roles in immune regulation within mucosal tissues. As colorectal cancers involve a breach of the mucosal barrier and an interaction between colorectal tissue and the gut microbiota, we investigated where, if any, MAIT and NKT cells were located in relation to these lesions, and whether their activity in these locations contribute to cancer evolution and progression. We have previously identified NKT and MAIT cells in colorectal tissue using flow cytometry and molecular analysis and, utilizing convention immunohistochemistry and immunofluorescence staining of formalin-fixed paraffin-embedded archived tissue blocks, we have now identified the location of these cells in both normal and cancerous regions of patients with colorectal cancers.

71

Circulating mucosal-associated invariant T (MAIT) cell levels and their functional capacity in healthy individuals and patients with chronic lymphocytic leukemia (CLL)

Alcantara, M.^{1,2}, Wallace, M.¹, Kannourakis, G.^{1,2}, Berzins, S.^{1,2,3}

¹Federation University, Biomedical Science, Ballarat, Australia,

²Fiona Elsey Cancer Research Institute, Ballarat, Australia,

³Melbourne University, Melbourne, Australia

Chronic Lymphocytic Leukemia (CLL) is a malignancy characterized by the accumulation of mature B cells and is the most common form of adult leukemia in the western world. The progression of CLL is unpredictable; patients can remain stable for variable periods (1- 20 years), before rapidly progressing to aggressive and symptomatic disease.

Immune regulation may play an important role in the progression of CLL, with increased numbers of Foxp3+ T regulatory cells

correlated with disease progression. Other regulatory subsets such as NKT cells, $\gamma\delta$ T cells and MAIT cells may also be important but are not as well characterized in patients. MAIT cells are a regulatory T cell population with a semi-invariant TCR repertoire and an anti-microbial role. Their significance in cancer has not been well studied but they interact with B cells and may therefore influence immune activity in CLL patients.

Our preliminary characterization of MAIT cell subsets in CLL patients at different stages of the disease, including enumeration and analysis of cytokines and cell surface molecules have identified a deficiency of MR1 restricted MAIT cells in patients with CLL, within the well-studied CD161+CD8⁺ subset, as well as the CD161-CD8⁺ and CD161+CD8⁻ subsets. In addition, our results also indicate a correlation between patient group characteristics and deficiencies in these cells. We are looking forward to providing important insights on the role of MAIT cells in the immune regulation of CLL patients and potentially how this may be used to improve current treatments or provide new targets for immune therapy.

72

The role of the CD8 co-receptor on MAIT cells

Souter, M.N.T., Chen, Z., Pellicci, D.G., Godfrey, D.I., Eckle, S.B.G.,

McCluskey, J.

University of Melbourne, Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia

T cells have historically been characterized by their ability to recognize peptides presented by the major histocompatibility complex (MHC) molecules.

These 'conventional' T cells express either CD4 or CD8 $\alpha\beta$ co-receptors and can be reliant on these molecules for the recognition of MHC-II and MHC-I respectively. In the last two decades, T cells bearing receptors reactive to lipid and small molecule antigens have been discovered. These include Mucosal-Associated Invariant T (MAIT) cells, which are restricted by the monomorphic MHC molecule MR1.

Using MR1-tetramers we showed that MAIT cell co-receptor expression is discordant with conventional T cells. MAIT cells predominantly express CD8 $\alpha\alpha$ or to a lesser extent can be deficient of co-receptor molecules. The high frequency of CD8⁺ MAIT cells suggests that the CD8 co-receptor may influence immune outcomes in this population of cells. Using a CD8 α transduced cell line, we have determined that CD8 $\alpha\alpha$ is capable of binding to MR1-tetramers in the absence of a T cell receptor (TCR) and fails to bind to MR1-tetramers mutated at residues shown to abrogate the CD8 interaction with MHC-I. Our observations suggest that MAIT cells use the CD8 co-receptor in a similar manner as conventional T cells to bind MHC-I, whereby CD8 can bind MR1 to enhance the overall avidity of the MAIT TCR interaction with MR1. We aim to characterize the CD8 interaction with MR1 quantitatively and determine its importance in MAIT cell biology.

73 TCR $\gamma\delta^+$ CD8 $\alpha\beta^+$ T cell in health and disease: a novel and functionally active subpopulation of T cells enriched within the gut

Kadivar, M.¹, Petersson, J.¹, Bekiaris, V.², Marsal, J.³, Svensson, L.¹

¹Lund University, Medical Faculty, Immunology, Lund, Sweden,

²Technical University of Denmark, DTU Vet., Copenhagen,

Denmark, ³Lund University, Skane University Hospital, Gastroenterology, Lund, Sweden

$\gamma\delta$ T-cells have been implicated in the pathogenesis of immune-mediated diseases such as inflammatory bowel disease (IBD). However, a potential role of different immune cell subsets in IBD and also in the process of mucosal healing upon treatment is unknown. $\gamma\delta$ T-cells have been divided into CD8 $\alpha\alpha^+$ and CD8 $\alpha\beta^+$ T-cells. By using flow cytometry and RT-PCR, we described for the first time a novel subset of human $\gamma\delta$ T-cells expressing CD8 $\alpha\beta$ heterodimers on their surface. We found that these TCR $\gamma\delta^+$ CD8 $\alpha\beta^+$ T-cell subset exist in both human peripheral blood as well as in the gut, however they were differentially enriched within the gut. TCR $\gamma\delta^+$ CD8 $\alpha\beta^+$ T-cells displayed high cytotoxic activity by expressing Fas Ligand on their surface and also producing Granzyme B and Perforin. We showed that these cells can produce INF γ and TNF α but they did not show the ability to produce IL-17 in healthy individuals. In patients with IBD, we found a decrease in the percentage of intestinal CD8 $\alpha\beta^+$ $\gamma\delta$ T-cells compared to healthy controls. Moreover, the percentage of TCR $\gamma\delta^+$ CD8 $\alpha\beta^+$ T-cells out of $\gamma\delta$ T-cells showed a negative correlation with Crohn's disease activity. Three months of anti-TNF α (adalimumab) therapy increased the percentage of TCR $\gamma\delta^+$ CD8 $\alpha\beta^+$ T-cells close to the level of healthy controls. These results suggest that TCR $\gamma\delta^+$ CD8 $\alpha\beta^+$ T-cells might possibly play a role in gut inflammation and also intestinal wound healing after anti-TNF α treatment. These results are likely to have implications for the development of novel therapies to treat mucosal inflammatory diseases.

74 A broad family of MR1-restricted T cells

Gherardin, N.A.^{1,2,3}, Keller, A.N.^{4,5}, Woolley, R.E.^{4,5}, Le Nours, J.^{4,5}, Ritchie, D.S.^{2,6}, Neeson, P.J.², Birkinshaw, R.W.^{4,5}, Eckle, S.B.¹, Waddington, J.N.¹, Liu, L.^{7,8}, Fairlie, D.P.^{7,8}, McCluskey, J.¹, Pellicci, D.G.^{1,3}, Uldrich, A.P.^{1,3}, Rossjohn, J.^{4,5,9}, Godfrey, D.I.^{1,3}

Immunity, Cardiff University School of Medicine, Heath Park, Cardiff, United Kingdom

MR1 is an MHC class Ib molecule that presents a series of small metabolite antigens derived from vitamin B metabolism. Conserved microbial ligands derived from microbial riboflavin (Vitamin B2) biosynthesis have been shown to be T cell agonists, activating a unique subset of T cells called mucosal-associated invariant T (MAIT) cells. MAIT cells are highly abundant in humans, accounting for up to 10% of circulating T cells. They are defined by expression of a semi-invariant T cell receptor (TCR) that imbues pattern-recognition-like detection of MR1-presented microbial riboflavin metabolites. Thus MAIT cells are emerging as key players in antimicrobial immunity. Beyond MAIT cells however, little is known about MR1-mediated immunity, including the breadth of antigens presented by MR1 and the repertoire of T cells that recognise them. Very recently, we showed that human MAIT cells can recognise non-microbial antigens derived from folate (Vitamin B9), and furthermore that a second population of 'atypical' MR1-restricted T cells exists, characterised by a surface phenotype and transcription factor profile distinct to that of MAIT cells, and a diverse TCR repertoire¹. Thus, MAIT cells represent only a subset of a broader population of MR1-restricted T cells.

We subsequently extend upon these findings and provide further detail on the phenotypic features and functional capacity of these atypical MR1-restricted T cells. We provide novel insight into the TCR and antigenic repertoires of these cells and show that they use a variety of docking modes atop MR1 to mediate MR1-Ag recognition.

75 Differentiation and expansion of $\gamma\delta$ T-cells by Zoledronic acid efficiently activates cytotoxicity *in vitro*

Thunberg, S.^{1,2}, Uhlin, M.², Önfelt, B.¹

¹Science for Life Laboratory and Royal Institute of Technology, Applied physics, Stockholm, Sweden, ²Karolinska Institute, Oncology and Pathology, Stockholm, Sweden

Between 1-10 % of circulating T-cells express the $\gamma\delta$ T-cell receptor. Dissimilar to conventional $\alpha\beta$ -T-cells recognizing peptide antigens, the $\gamma\delta$ -T-cells recognize phosphorylated antigens expressed by various pathogens and tumours. Metabolites of zoledronic acid (ZOL), a bisphosphonate, can stimulate proliferation and expansion of $\gamma\delta$ -T-cells. The aim of the study was to expand $\gamma\delta$ -T-cells using ZOL and evaluate their cytotoxic function.

Peripheral mononuclear cells (PBMCs) (n=10) was stimulated without or with 2.5 μ M ZOL and 200 U/mL of IL-2 for up to 18 days. T-cell differentiation and expansion was followed with flow cytometry. Cytotoxic function of $\gamma\delta$ - and $\alpha\beta$ -T-cells were evaluated using 4 h co-cultures in 1:1 and 5:1 ratios with the cell lines K562, HL-60 and KU812, all lacking MHC-expression, as targets.

The median frequency of $\gamma\delta$ -T-cells at day 0 was 3.6, increasing with ZOL to 37, 79 and 89 % at day 3, 9 and 13 respectively and absolute number increased between 2 to 4 times per week.

The majority of $\gamma\delta$ -T-cells were NKG2A positive and displayed a mature and activated T-cell phenotype, defined by CCR7-CD45RA-HLA DR+. Both $\gamma\delta$ - and $\alpha\beta$ -T-cells effectively killed K562 and HL-60 cells, while KU812 was predominately killed by $\gamma\delta$ -T-cells. Moreover, the cytotoxicity by $\gamma\delta$ -T-cells was not due to degranulation, since only an average of 0.69 % expressed CD107a, compared to 8.35 % of the $\alpha\beta$ -T-cells.

ZOL are able to expand and activate $\gamma\delta$ -T-cells to become effective killers for potential use in immunotherapy. However, the mechanism of their cytotoxic function remains to be elucidated.

Immunological role of alternatively spliced isoforms of MR1

Li, S.^{1,2}, McWilliam, H.E.G.^{1,3}, Smith, J.M.¹, Meehan, B.¹, Herold, M.^{4,5}, Villadangos, J.^{1,3}, Rossjohn, J.^{6,7,8}, Eckle, S.B.G.¹, Uldrich, A.P.^{1,2}, McCluskey, J.¹, Godfrey, D.I.^{1,2}

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Department of Immunology and Microbiology, Melbourne, Australia, ²University of Melbourne, Department of Microbiology and Immunology, Australian Research Council Centre of Excellence in Advanced Molecular Imaging, Melbourne, Australia, ³University of Melbourne, Bio21 Molecular Science and Biotechnology Institute, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ⁴Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia, ⁵University of Melbourne, Department of Medical Biology, Melbourne, Australia, ⁶Monash University, Department of Biochemistry and Molecular Biology, School of Biomedical Sciences, Melbourne, Australia, ⁷Monash University, Department of Biochemistry and Molecular Biology, Australian Research Council Centre of Excellence in Advanced Molecular Imaging, Melbourne, Australia, ⁸Cardiff University, Institute of Infection and Immunity, School of Medicine, Cardiff, United Kingdom

Mucosal-associated invariant T (MAIT) cells are a subset of T-cells restricted by the MHC-related protein 1 (MR1). While the full-length transcript of MR1, (MR1A), is conserved across all mammalian species, MR1 is also alternatively spliced into species-specific isoform variants. In humans, three isoforms; MR1A, MR1B/D and MR1C are ubiquitously transcribed. MR1A, the most well characterised isoform, encodes for a heavy chain with three extracellular domains (α 1- α 3), a transmembrane domain and a cytoplasmic domain. In contrast, MR1B/D encodes for a truncated membrane bound protein lacking the α 3-domain, and MR1C for a soluble MR1B/D variant. It has recently been shown that MR1A has the capacity to present riboflavin (vitamin B2) and folate (vitamin B9) derivatives as antigens. In contrast, less is known about the function of the other isoforms. Like MR1A, MR1B/D has been suggested to express on the cell surface and activate MAIT cells. Thus, MR1B/D may act as an antigen-presenting molecule although presented antigens and antigen presentation pathways may be distinct.

To address the physiological role of alternative splice forms of MR1 we embark on verifying the existence of and quantifying alternative splice forms in various human cell types and tissues at the transcriptional and translational levels. Initial transcriptional analysis has suggested that MR1 isoforms are

differentially expressed in a tissue and cell type specific manner. Furthermore, in contrast to MR1B/D, MR1A was virtually undetectable in blood cells from all donors. More strikingly, it appears MR1B/D is the dominant MR1 transcript in both human thymus and blood.

77

Role of TCR γ enhancer 'Ey4' for the development and function of $\gamma\delta$ T cells

Tani-ichi, S., Ikuta, K.

Institute for Virus Research, Kyoto University, Kyoto, Japan

Development of lymphocytes requires functional receptor gene rearrangements which generate the diversity of lymphocyte repertoire. Whereas the enhancers in the TCR α , β , and δ loci are critical for their V(D)J recombination, a previous study showed that simultaneous deletion of two TCR γ enhancers, Ey1 and HsA, only marginally blocks some V-J rearrangements in the TCR γ locus. We previously reported that the transcription factors Stat5 and Runx bind to not only Ey1 and HsA but also Ey4 and increase its activity *in vitro*. However, the function of Ey4 *in vivo* remains unknown. In this study, we generated mice lacking Ey4 (Ey4^{-/-}), the most 3' located TCR γ enhancer. In Ey4^{-/-} thymus, V γ 1.1⁺ $\gamma\delta$ T cells were almost completely disappeared, and V γ 1.2⁺ and V γ 5⁺ $\gamma\delta$ T cells were also reduced. Analysis of Ey4^{-/-} thymus revealed that Ey4 is essential for V γ 1.1-J γ 4 rearrangement and, to a lesser extent, for V γ 1.2-J γ 2, but not for other V γ -J γ rearrangements. Ey4 was also required for transcription of entire TCR γ genes in the thymus and specific V γ -J γ transcription in peripheral tissues. In addition, effector function of these $\gamma\delta$ T cells in peripheral tissue was changed in Ey4^{-/-} mice. This study suggests that Ey4 has a non-redundant role in the development and function of $\gamma\delta$ T cell subsets.

78

Universal immunity against influenza: human $\gamma\delta$ T cells

Sant, S.¹, Crowe, J.², Thomas, P.³, Lappas, M.⁴, Loh, L.¹, Kedzierska, K.¹

¹Peter Doherty Institute for Infection and Immunity, The University of Melbourne, Melbourne, Australia, ²Deeplene Surgery, Melbourne, Australia, ³St Jude Children's Research Hospital, Memphis, Department of Immunology, Memphis, United States, ⁴The University of Melbourne, Department of Obstetrics and Gynaecology, Melbourne, Australia

$\gamma\delta$ T cells link innate and adaptive immunity, exhibiting myriad of effector functions, thus implicating they might provide universal immunity to influenza across throughout life. Studies with *in vitro* expanded human $\gamma\delta$ 2 T cells have shown their protective role against influenza infection, however the potential role of peripheral blood $\gamma\delta$ T cells directly *ex vivo* and their TCR dynamics are understudied. To investigate this, we utilised a single-cell multiplex-nested-RT-PCR to study the TCR γ/δ repertoire in healthy individuals across three major age groups (neonates, adults and elderly donors). Neonatal $\gamma\delta$ T cells displayed diverse TCR γ/δ repertoires, while healthy adults showed an enrichment of $\gamma\delta$ 2 TCR pair with diverse CDR3 region. Furthermore, the elderly donors displayed different

dynamics with clonal expansion of CDR3 regions. To investigate the role of $\gamma\delta$ T cells on the early onset of influenza virus infection, we established an *in vitro* co-culture model of virus infection, in which peripheral blood mononuclear cells were co-cultured with influenza-infected (H1N1) human lung epithelial cells. Following infection, IFN- γ producing cells were isolated via IFN- γ secretion assay for paired CDR3 γ/δ analysis. Healthy adult PBMCs showed enrichment of $\gamma9\delta2$ subset T cells. Preliminary results show that lack of monocytes in A549-PBMC culture abrogated IFN- γ by $\gamma\delta$ T cells. Our study provides insights into the composition and diversity of TCR γ/δ repertoires responding to human influenza viruses. Future investigations are required to understand the level of $\gamma\delta$ T cell cross-reactivity across different influenza viruses and accessory function of monocytes in amplifying $\gamma\delta$ T immune responses.

79

Triple costimulation via CD80, 4-1BB and CD83 ligand elicits the long-term growth of V γ 9V δ 2 T-cells in low levels of IL-2

Cho, H.-W.¹, Kim, S.-Y.², Sohn, D.-H.¹, Park, M.-Y.², Sohn, H.-J.², Cho, H.-I.^{2,3}

¹The Catholic University of Korea, Department of Microbiology, Seoul, Korea, Republic of, ²The Catholic University of Korea, Hematopoietic Stem Cell Bank, Seoul, Korea, Republic of, ³The Catholic University of Korea, Cancer Research Institute, Seoul, Korea, Republic of

Human $\gamma\delta$ T-cells play important roles in the regulation of infection and cancer. To understand the roles of costimulatory signals in activation and expansion *ex vivo*, V γ 9V δ 2 T-cells were grown with artificial antigen presenting cells that express CD83, 4-1BBL, and/or CD32, which allowed a loading of α CD3 and α CD28 antibodies. The costimulatory signals through CD80, 4-1BB, CD83L in low levels of IL-2 triggered an explosive *ex vivo* proliferation of V γ 9V δ 2 T-cells capable of secreting high levels of IL-2, IFN- γ , and TNF- α . Moreover, the triple costimulatory signals cause augmented cell viabilities for long-term growth of V γ 9V δ 2 T-cells, resulting in phenotypic changes to CD27⁺CD45RA⁺ effector memory-like cells. Notably, we observed that CD83L signaling is crucial to promote *ex vivo* expansion, survival, and cytolytic effector functions of V γ 9V δ 2 T-cells. In contrast, 4-1BB signaling is moderately important in up-regulating surface molecules on V γ 9V δ 2 T-cells. Consequently, $\gamma\delta$ T-cells stimulated in the presence of triple costimulatory signals have diverse cytolytic effector molecules including perforin, granzyme A, granzyme B, and Fas ligand eliciting potent cytolytic activities against tumor cells. Overall, our results provide insights the roles of costimulatory signals in manufacturing long-lived and fully functional V γ 9V δ 2 T-cells, which could be useful against cancers.

80

Mucosal associated invariant T cells are deficient in human airways diseases

Hinks, T.^{1,2,3}, Wallington, J.², Williams, A.^{2,3}, Djukanovic, R.^{2,3}, Staples, K.^{2,3}, Wilkinson, T.²

¹University of Melbourne, Microbiology and Immunology, Melbourne, Australia, ²University of Southampton, Clinical and

Experimental Sciences, Faculty of Medicine, Southampton, United Kingdom, ³University of Hospital Southampton, NIHR Respiratory Biomedical Research Unit, Southampton, United Kingdom

Mucosal associated invariant (MAIT) cells have not been studied in the human airways. Infection with non-typeable haemophilus influenzae (NTHi) is linked to recurrent exacerbations and disease progression in COPD.

We hypothesised airway MAIT-cells may be dysregulated in asthma and COPD and contribute to susceptibility to infection.

Methods: Using bronchoscopy we analysed airway MAIT-cell frequencies by flow-cytometry in 93 adults with asthma, COPD and health. Subgroups underwent trials of inhaled and oral corticosteroids. *In vitro* monocyte derived macrophages (MDM) were infected with NTHi.

Results: CD3+TCR-V α 7.2+CD161+ MAIT cells comprise up to 10% of airway T cells. There was a striking deficiency of MAIT-cells in asthma in blood (P=.005), sputum (P=.002) and biopsies (P=0.02). This deficiency was related to disease severity and chronic treatment with inhaled corticosteroids. Blood MAIT cell frequencies were markedly reduced by 7 days of treatment with oral prednisolone (P=.03). There is significant seasonal variation in MAIT-cell frequencies (R²=0.16, P< 0.0001) which is specific to MAIT cells. 28% of the variability in MAIT cell frequencies was attributable to variation in serum vitamin-D3 concentrations. MAIT cells are also deficient in blood and biopsies (P< .05) in steroid-treated COPD.

In vitro, lung macrophages express MR1. Infection with live NTHi induced expression of MR1 on MDM and MAIT-cell IFN- γ expression. Corticosteroids reduce bacterially-induced MR1 surface expression and IFN- γ production.

Conclusions: Airway MAIT-cells are numerically and functionally deficient in severe asthma and COPD, likely due to corticosteroids. This may contribute to susceptibility to bacterial infection, and to changes in the airway microbiome.

81

Innate memory formation of dermal IL-17-producing $\gamma\delta$ T cells in a mouse model of psoriasis

Hartwig, T.¹, Pantelyushin, S.², Croxford, A.¹, Kulig, P.¹, Becher, B.¹

¹University of Zurich, Zurich, Switzerland, ²University of Geneva, Geneva, Switzerland

Subsets of dermal $\gamma\delta$ T cells rapidly produce pro-inflammatory cytokines after challenge with Aldara, an immunostimulatory substance inducing psoriasis-like lesions in murine skin. The ability of 'experienced' innate-like $\gamma\delta$ T cells to form a long-lasting immunological memory is an emerging concept. Using fate mapping studies, we observed long term persistence of V γ 4⁺V δ 4⁺IL-23R⁺IL-7R⁺ T cells after Aldara-induced inflammation. These cells exhibit enhanced cytokine production compared to unchallenged controls, and elicit an exacerbated skin inflammation upon re-challenge. We also describe that longevity of V γ 4⁺V δ 4⁺ T cells in the skin is dependent on IL-7 signaling. In addition to identifying a unique feature of $\gamma\delta$ T cells during inflammation, our results have direct relevance to the human disease as this quasi-innate memory provides a mechanistic insight into relapses and chronification of psoriasis.

82

Herpes simplex virus (HSV) attracts resident $\gamma\delta$ T cells to the epidermal and dermal junction of human neonatal skin

Yu, U.^{1,2}, Fernandez, M.A.^{1,2}, Kim, M.³, Harman, A.N.³, Holland, A.J.^{1,2,4}, Li, Z.⁵, Maitz, P.⁵, Cunningham, A.L.³, Alexander, S.I.^{1,2}, Jones, C.A.^{1,2}

¹The Children's Hospital at Westmead, NSW, Australia, ²The University of Sydney, Discipline of Paediatrics and Child Health / Marie Bashir Institute for Infectious Diseases and Biosecurity, NSW, Australia, ³Westmead Institute for Medical Research, NSW, Australia, ⁴Westmead Private Hospital, NSW, Australia, ⁵Concord Repatriation General Hospital, NSW, Australia

$\gamma\delta$ T cells are a small population of innate effectors predominantly located in the skin and mucosa, the main sites of HSV entry. Our aim here was to determine the effects of HSV on human neonatal skin $\gamma\delta$ T cells. We observed that neonatal skin $\gamma\delta$ T cells accumulated to the site of HSV infection 6 hours post infection, peaking at 24 hours post infection, compared to mock controls. Localizations of $\gamma\delta$ T cells changed from the epidermal-dermal junction to the deep dermis from 6 hours to 48 hours after HSV infection, associated with increased expressions of inflammatory chemokines CXCL8, CXCL9, CCL2, and CXCL10 in infected neonatal skin. We observed that HSV infected neonatal skin explants showed clusters of cells formed by inflammatory cells including $\gamma\delta$ T cells, Langerhans cells (LCs), neutrophils, and IL-17A-expressing non- $\gamma\delta$ T cells. Our results suggest that $\gamma\delta$ T cells contribute to the cellular response in neonatal skin after HSV infection but their roles is to be determined.

Neuroimmunology

83

STING modulates neuro-inflammation in acute neural injury

Abdullah, A.D.I., Zhang, M., Taylor, J.M., Crack, P.J.
University of Melbourne, Pharmacology and Therapeutics,
Melbourne, Australia

Traumatic brain injury (TBI) represents a major cause of disability and death worldwide with sustained neuro-inflammation a key driver of cellular damage. STING-induced type-1 interferon (IFN) signaling is known to modulate the innate immune response in the periphery, however its role in the CNS remains unclear. We previously identified the type-1 IFN pathway as a key mediator of neuro-inflammation and neuronal cell death in TBI (Karve *et al.*, 2016). This study investigated the role of STING in modulating the type-1 IFN mediated neuroinflammatory response following TBI.

WT and STING^{-/-} mice (male, n=6) were subjected to controlled cortical impact (CCI) injury and brains removed 2h or 24h for QPCR, western and immunohistochemical analysis. QPCR identified increased STING expression (4.45 ± 0.93 fold) in WT mice at 24h that was confirmed by western blot and immunohistochemistry. Elevated TNF- α , IL-6, i-NOS and IFN- β levels were also detected in the WT mice. Significantly, pro-inflammatory gene expression was suppressed in the STING^{-/-} mice with a smaller infarct volume identified at 24h (WT; 4.16 ± 0.27mm³, STING^{-/-} ; 3.20 ± 0.17 mm³; p < 0.05) as assessed by

triphenyl tetrazolium chloride (TTC) staining. Supporting a role for STING in human TBI, a significant upregulation in STING expression (2.25 ± 0.50 fold; p < 0.0001) was detected in late trauma human brain samples as compared to the control group. These studies have identified STING as a novel mediator of neuroinflammation in TBI and therefore a potential new therapeutic target.

84

Transgenic expression of H-2Db class I molecules influences the development of brain atrophy during picornavirus infection

Huseby Kelcher, A.¹, Atanga, P.², Gamez, J.², Cumba-Garcia, L.¹, Willenbring, R.³, LaFrance, S.¹, Macura, S.⁴, Johnson, A.J.¹

¹Mayo Clinic, Immunology, Rochester, United States, ²Mayo Clinic, Neurology, Rochester, United States, ³Mayo Clinic, Virology, Rochester, United States, ⁴Mayo Clinic, NMR Core Facility, Rochester, United States

Brain atrophy is a common feature of numerous neurological diseases in which the role of neuroinflammation remains poorly defined. We have previously demonstrated the development of brain atrophy in the Theiler's murine encephalomyelitis virus (TMEV) model of multiple sclerosis. However, cellular and molecular mechanisms of brain atrophy remain poorly understood. We therefore evaluated the contribution of major histocompatibility (MHC) class I molecules in atrophy development during TMEV infection. To accomplish this, we created a novel transgenic FVB/NJ mouse by introducing the H-2Db (Db) class I molecule. Expression of Db class I molecule confers resistance to persistent TMEV infection and demyelination in the normally susceptible FVB/NJ strain (H2-Dq class I haplotype). Next, we compared the development of brain atrophy, assessed by volumetric analysis of T2-weighted MRIs, in FVB/Db to FVB/NJ wild-type mice following viral infection. Significant brain atrophy was observed in the FVB/Db mice over a four-month period. FVB/Db mice also developed a significant increase in the overall number of CNS infiltrating CD8 T cells and a strong CD8 T cell response towards an immunodominant Db TMEV epitope, VP2121-130. Several CD8 T cells were also observed in close proximity to virus infected neurons. We therefore propose a hypothesis that class I restricted CD8 T cell responses promote the development of brain atrophy. This model provides a unique opportunity to analyze the contribution of immune cells to neuronal loss and brain atrophy in a system where persistent virus infection and demyelination are not confounding variables.

85

Characterising B cells in multiple sclerosis

Rathbone, E.¹, Durant, L.¹, Douglas, M.^{1,2,3}, Curnow, S.J.¹

¹University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom, ²Dudley Group NHS Foundation Trust, Department of Neurology, Dudley, United Kingdom, ³Aston University, School of Life and Health Sciences, Birmingham, United Kingdom

Multiple Sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS). In addition to the presence of intrathecal immunoglobulin, clonally expanded, hypermutated B cells are found in many compartments of the MS brain including the cerebrospinal fluid (CSF). The presence of ectopic meningeal B cell follicles in late disease suggests a sustained immunopathological B cell response, however the relative contributions of recently recruited peripheral B cells versus long-lived CNS-expanded B cells remains unclear.

We investigated the phenotype of B cells and antibody-secreting cells in the blood and CSF of MS patients using flow cytometry, recruiting patients with a clinically isolated syndrome (the first clinical event suggestive of MS), relapsing-remitting MS, MS patients ceasing chronic natalizumab (anti- $\alpha 4$ integrin monoclonal antibody) treatment and control patients with other neurological diseases.

We demonstrated that both B cells and antibody-secreting cells display a more activated phenotype in the CSF versus those in the blood and are more prevalent in MS patients than controls. Antibody-secreting cells in the CSF almost exclusively expressed IgG, compared to the predominant IgA expression seen in the blood, whereas B cells displayed similar immunoglobulin expression profiles in both compartments. Furthermore, antibody-secreting cells in the CSF of MS patients demonstrated a higher degree of kappa light chain restriction compared to B cells.

This suggests that in the CNS of MS patients, B cells arise predominantly from non-specific recruitment from the periphery, whereas antibody-secreting cells are involved in a persistent antigen-driven immune response and are likely involved in disease maintenance.

86

Effects of clioquinol on the aggregation of beta-amyloid peptides in the presence and absence of metal ions and astrocyte-mediated inflammation

Tahmasebinia, F., Emadi, S.

Institute for Advanced Studies in Basic Sciences, Biochemistry, Zanjan, Iran, Islamic Republic of

Amyloid β (A β) fibrils, amorphous aggregates and oligomers are found in the brain of patients with Alzheimer's disease (AD). Amyloid plaques in the brains are mainly composed of Amyloid β -(1-40) and β -(1-42). These plaques are surrounded by activated astrocytes and microglia which participate in the inflammatory process in the brain. Metal imbalance is also the leading cause for AD, owing to the fact that A β aggregation takes place in the synaptic cleft where A β , Cu(II) and Fe(III) can be found together in abnormally high concentration. Recent studies show that metal dyshomeostasis is involved in aggregation and inflammation. In addition, at the early stage of AD, small diffusible oligomers (or protofibrils) activate microglia leads to inflammation, particularly early inflammatory responses. On the other hand, fibrillar A β showed less increase of pro-inflammatory molecules and sustain the chronic inflammation associated with AD. In this work, first, we examined the formation of all types of A β 40 and A β 42 aggregates (oligomers, fibrils, and amorphous aggregates) in the presence of the added metal ions, Fe(III) and

Cu(II), by using fluorescence spectroscopy and atomic force microscopy (AFM). Second, we studied the ability of Clioquinol, to bind these metal ions in order to prevent A β accumulation. We found that A β 42 may be more oligomerogenic than A β 40 and may have higher effects in inflammation at early stage of AD and Cu(II) induces oligomeric formation. Fe(III) were found to be involved in fibril formation. So it may be more involved in sustaining the chronic inflammation associated with the AD.

87

Protective role of interferon-gamma during the chronic phase of experimental autoimmune encephalomyelitis

Arellano, G., Tichauer, J.E., Acuña, E., Castillo, C., Naves, R.

University of Chile, Faculty of Medicine, Program of immunology, Biomedical Sciences Institute, Santiago, Chile

Several studies have described opposing effects of Interferon (IFN)- γ in the pathogenesis of multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE). We have shown that IFN- γ has a stage-specific role in EAE: pathogenic during the inductive phase but protective in the effector acute phase. In this study, we analyzed the protective effects of IFN- γ in the chronic phase of EAE. Clinical symptoms of EAE were significantly ameliorated in mice treated with IFN- γ compared with PBS-treated control mice. Histological analysis revealed that EAE suppression was associated with less CNS inflammation and demyelination. Furthermore, IFN- γ -treated mice showed a lower frequency of CD4⁺ T cells but a significantly higher frequency of regulatory T cells infiltrating the CNS, compared to control mice. Spinal cords and CNS infiltrating mononuclear cells obtained from mice treated with IFN- γ produced higher IL-10 than those from PBS-treated mice. Overall, these results indicate that IFN- γ plays a protective role in the chronic phase of EAE suppressing CNS inflammation by inhibiting CD4⁺ T cell infiltration and inducing regulatory T cell activity.

Supported by FONDECYT 1140049 (RN) and 3150133 (JET), and CONICYT Doctoral fellowship 21130452 (GA).

88

Differentially expressed genes in iron-induced prion protein conversion

Kim, M.-S.¹, Choi, B.-R.², Kim, E.-H.¹, Woo, H.-J.¹

¹Seoul National University, Immunology, College of Vet Medicine, Seoul, Korea, Republic of, ²Johns Hopkins University, Neuroscience, Baltimore, United States

The conversion of the cellular prion protein (PrP^C) to protease-resistant isoform is the key event in prion diseases. Increase of iron in prion disease has been observed with the prion protein-ferritin complex. The accumulation and conversion of recombinant PrP (rPrP) is specifically derived by Fe(III) but not by Fe(II). Fe(III)-mediated PK-resistant PrP (PrP^{res}) conversion is a more complex cellular environment than a direct contact between rPrP and Fe(III). We identified the differentially expressed genes that correlate with the prion degeneration depending on Fe(II) and Fe(III) using Affymetrix microarrays. In

Fe(III)-treated environment, we detected 97 genes that were differentially expressed (≥ 1.5 -fold change in expression). The 85 were upregulated and 12 were downregulated as compared with negative controls. However, Fe(II)-treated environment produced moderately altered gene expression level and did not induce a profound alteration of gene expression profile. Moreover, Gene Set Enrichment Analysis indicated that the differentially regulated genes were highly associated with cell growth and maintenance, immune response and cell-cell interaction system. These findings show that Fe(III) might specifically influence the expression of genes involved in many cellular processes. The identification of genes with altered expression patterns in neural cells may provide an insight to the PrP conversion mechanisms in prion disease development and progressing.

89

Immunological markers as risk factors in clinically isolated syndrome (MS)

Posova, H.¹, Horakova, D.², Hrušková, Z.¹, Čapek, V.¹, Havrdová, E.¹
¹1st Medical Faculty, Charles University in Prague, Institute of Immunology and Microbiology, Prague, Czech Republic, ²1st Medical Faculty, Charles University in Prague, Department of Neurology and Centre of Clinical Neuroscience, Prague, Czech Republic

Clinically isolated syndrome (CIS) represents first neurological symptoms suggestive of demyelinating lesion in CNS according to MRI with the risk of multiple sclerosis (MS) development. So far there are no sufficient immunological markers predicting disease activity and potential disability or efficiency of registered CIS treatment - interferon beta. The aim of our study was to evaluate immunological predictors of CIS conversion into MS.

Method: 212 patients with CIS treated with interferon beta have been followed for 4 years. Lymphocyte subsets (CD3+, CD4+, CD8+, CD19+, CD3+CD16+56+ and chemokine receptors CXCR3+ and CCR5) were analyzed by flow cytometry at the time of first relaps, after 1-2 month before therapy and after 6, 12, 24, 36 and 48 months. 88 patients converted to MS and switched to another therapy. Multivariate Cox proportional hazard regression were used to compare this group with patients who did not develop clinically defined MS.

Results: Higher levels of B lymphocytes predicted relapse-free status. On the other hand a decrease of NK cells was associated with an increased risk of relapse activity. Decreases of the naïve subset of cells (CD45RA+ in CD4+) after 12, 24, and 36 months of follow-up were associated with increased risk of a new relapse activity and increase expression of chemokine receptors on CD4+ T lymphocytes increase signals a clinical deterioration.

Conclusion: Our data point to the importance of regular examination of B lymphocytes, NK cells and naïve T helper cells; a decrease of these subpopulations increases the risk of relapse or clinical worsening.

90

Distinct cytokine profiles differentially induce white and grey matter inflammation in the experimental autoimmune encephalomyelitis model of multiple sclerosis

Orian, J.M., Dang, P.T., D'Souza, C.

La Trobe Institute for Molecular Science, Biochemistry and Genetics, Melbourne, Australia

Progress in the elucidation of mechanisms underlying neurodegeneration in the central nervous system (CNS) autoimmune disorder multiple sclerosis (MS) has demonstrated distinct pathological processes in grey matter (GM) and white matter (WM). To identify WM and GM-specific mechanisms multiple approaches were applied to WM and GM separately, in the experimental autoimmune encephalomyelitis MS model and resident CNS cell responses and axonal/neuronal survival, in relation to lesion development evaluated in each compartment, over the disease course. These include

- (a) laser microdissection of defined WM and GM regions, followed by expression profiling of pro-inflammatory and apoptosis/anti-apoptosis molecules,
- (b) quantitative immunochemistry and
- (c) in-situ hybridization.

Results showed that in the spinal cord, distinct pro-inflammatory profiles evolve in WM and GM from pre-clinical times, where WM disease is driven by IFN-gamma, but GM disease by TNF-alpha. Secondly, upregulation of the extrinsic apoptosis pathway is observed in neuronal cell bodies; this is in opposition to evidence of mitochondrial dysfunction as the cause of axonal degeneration. However, concurrent upregulation of anti-apoptosis molecules is observed in neuronal cell bodies, without significant neuronal loss. We conclude

- (1) that the microenvironment generated within WM or GM in response to circulating inflammatory mediators is determined by resident CNS cells,
- (2) each microenvironment drives a unique apoptosis mechanism and
- (3) neurons exhibit innate survival mechanisms in early disease. These data are in agreement with evidence of different cytokine/chemokine profiles along the neuraxis during neuroinflammation, but also highlight differences between WM and GM responses which may underlie the divergence in pathophysiological pathways.

91

To investigate the immunological role of chemokine decoy receptor ACKR2 in experimental autoimmune encephalomyelitis

Chen, J.W.¹, Lin, G.-J.², Chen, S.-J.^{3,4,5}

¹National Defense Medical Center, Graduate Institute of Life Science, Taipei, Taiwan, Republic of China, ²National Defense Medical Center, Graduate Institute of Biology and Anatomy, Taipei, Taiwan, Republic of China, ³National Defense Medical Center, Graduate Institute of Medical Sciences, Taipei, Taiwan, Republic of China, ⁴National Defense Medical Center, Department of Pediatrics, Tri-Service General Hospital, Taipei, Taiwan, Republic of China, ⁵National Defense Medical Center, Department of Microbiology and Immunology, Taipei, Taiwan, Republic of China

Experimental autoimmune encephalomyelitis (EAE) is an animal model of multiple sclerosis, which is inflammatory demyelinating disease of central nervous system (CNS). Astrocytes and microglial cells were stimulated by damaging stress, they secrete inflammatory chemokines, like the CCL2 and CCL5. These inflammatory chemokines stimulate leukocytes activation, and the activating leukocytes transmigrate to brain parenchyma. Atypical chemokine receptor 2 (ACKR2) is a chemokine decoy and scavenger receptor, which has been proven express on lymphatic endothelial cells and some immune cells. ACKR2 through binding inflammatory chemokine, internalization and degradation regulate chemokine-driven inflammatory response. Lack ACKR2 has been proven to increase the cutaneous inflammation, colitis and colon cancer. In addition, high expression level of ACKR2 had also been shown to slow down skin tumor and type 1 diabetes. Despite the role of ACKR2 in the peripheral system has clearly understood, the role of the CNS is not clear. In this study, we investigate the immunological functions of ACKR2 in EAE. The expression level of ACKR2 on immune cells was detected through flow cytometry. In the PBMC from patients, there was high expression on the CD4+ T cell. In addition, splenic B220+ B cells, from the EAE, expressed higher ACKR2 than wild type on the early phase of EAE. The mRNA expression of ACKR2 will be measured by real-time PCR. Furthermore, the protein expression of ACKR2 will be detected by western blot and immunohistochemistry.

92

Adrenoreceptor signalling influences T cell responses during viral infection

Loi, J.K.^{1,2}, Devi, S.^{1,2}, Sloan, E.³, Mueller, S.N.^{1,2}

¹The University of Melbourne and The Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Parkville, Australia, ²ARC Centre of Excellence in Advanced Molecular Imaging, The University of Melbourne, Melbourne, Australia, ³Monash Institute of Pharmaceutical Sciences, Monash University, Parkville, Australia

T cells express adrenergic receptors (AR) that enable them to respond to neurotransmitters including those of the sympathetic nervous system (SNS), noradrenaline (NA) and adrenaline. These neurotransmitters bind to α and β AR inducing downstream signalling and modulating cell functions, although whether this is stimulatory or inhibitory in T cells during the context of immune responses to virus infection remains unclear. We confirmed that naive CD4 and CD8 T cells expressed predominantly b2AR that induced cyclic AMP production upon stimulation *in vitro*. We examined the role of adrenoceptor signals via treatment of mice with the bAR agonist isoprenaline early during acute and chronic lymphocytic choriomeningitis virus (LCMV) infection. While the magnitude of antigen-specific CD4 and CD8 T cell responses to LCMV clone 13 infection was unchanged by 5 days of isoprenaline treatment, viral clearance in the spleen and blood was impaired and mice displayed increased morbidity and mortality. Using 2-photon microscopy we found that T cell migration was altered by indirect bAR signals, suggesting that adrenoceptor signals may influence T cell responses to infection by influencing behaviour in tissues.

93

Tolerogenic activity of IFN- γ on macrophages/microglia in experimental autoimmune encephalomyelitis

Tichauer, J., Arellano, G., Acuña, E., Naves, R.

Universidad de Chile, Program of Immunology, Biomedical Sciences Institute, School of Medicine, Santiago, Chile

During experimental autoimmune encephalomyelitis (EAE) development, leukocytes are recruited into the CNS mediating a destructive inflammatory response. Resident microglia and infiltrating macrophages present myelin peptides to reactive T cells inducing activation or tolerance. This process is regulated by inflammatory cytokines, such as IFN- γ . Our previous results have shown that IFN- γ has a stage-specific dual activity in EAE: pathogenic during the inductive phase but protective in the effector phase. We hypothesized that as part of its protective role, IFN- γ might exert a tolerogenic activity on innate immune cells in the CNS. Here, we evaluated the effect of IFN- γ on the activation of macrophages/microglia during the chronic phase of EAE. Flow cytometry analysis of CNS cells revealed that IFN- γ -treated EAE mice had a significantly lower frequency of CD11b⁺ cells than PBS-treated control mice. However, CD11b⁺ cells from IFN- γ -treated EAE mice showed significantly higher expression of IL-10 than those from controls. Remarkably, IFN- γ -treated EAE mice had a significantly lower frequency of CD11b⁺CD45^{hi} (activated) cells but a significantly higher frequency of CD11b⁺CD45^{low} (resting) cells associated with higher expression of IL-10, compared with controls. Moreover, CD11b⁺CD45^{hi} cells obtained from CNS of PBS-treated EAE mice were induced to downregulate CD45 expression and to increase IL-10 expression upon *ex vivo* IFN- γ treatment. In addition, macrophages/microglia from IFN- γ -treated EAE mice exhibited lower expression of CD80 costimulatory molecule without affecting MHC-II and CD86 expression, compared to control mice. Overall, our results indicate that IFN- γ induces a tolerogenic phenotype in macrophages/microglia during EAE effector phase.

Functional effects of antibodies specific for myelin proteolipid protein in multiple sclerosis

Greer, J.M.¹, Muller, D.M.¹, Beasley, S.J.¹, Trifilieff, E.², Pender, M.P.³

¹The University of Queensland, UQ Centre for Clinical Research, Brisbane, Australia, ²Université de Strasbourg, Institut de Physique Biologique, Strasbourg, France, ³The University of Queensland, School of Medicine, Brisbane, Australia

Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease of the central nervous system (CNS). Autoimmune T cells are critical for the pathogenesis of MS, but it is also likely that autoantibodies play a role, although this remains to be proven. We have found that a high proportion of MS patients have elevated levels and titres (compared to healthy controls and patients with other neurological diseases (OND)) of autoantibodies specific for the second extracellular loop of myelin proteolipid protein (PLP), the most abundant CNS

myelin protein. The aim of the current study was to investigate these antibodies further, in order to determine if they could play a functional role in MS. Most PLP-specific antibodies from MS patients showed evidence of isotype-switching to IgG and thus of an ongoing active response; in contrast, anti-PLP antibodies detected in healthy controls and OND patients were almost all IgM. Serum from MS patients opsonized human myelin for uptake by macrophages, whereas antibodies from healthy individuals or OND patients did not; and for 65% of MS sera, pre-adsorption of sera with PLP peptides could remove the opsonizing activity. Anti-PLP antibodies could also label and kill oligodendrocytes in culture. In an animal model of MS, anti-PLP antibody was able to shift the location of lesions within the CNS in a complement-dependent manner. These findings show that antibodies directed against extracellular epitopes of PLP have the potential to induce pathogenic effects in patients with MS, and suggest that specifically removing anti-PLP antibodies might be clinically indicated.

95

Trehalose administration inhibits inflammatory responses in the brain of Lewy body disease model mice

Tanji, K., Maruyama, A., Matsumiya, T., Miki, Y., Mimura, J., Mori, F., Itoh, K., Wakabayashi, K.

Hirosaki University, School of Medicine, Hirosaki, Japan

Lewy body disease (LBD) such as Parkinson's disease and dementia with Lewy bodies is a neurodegenerative disorder accompanied by abnormal protein aggregation and inflammatory responses. Actually increased levels of pro-inflammatory cytokines such as TNF, IL-1 β , and IL-6 are observed in postmortem brain and cerebral spinal fluid from patients with LBD. Trehalose is a natural disaccharide composed of two glucose units, and found in a wide range of eukaryotic microorganisms, plants, fungi and insects. Interestingly, trehalose serves as a scaffold molecule that inhibits protein aggregation by direct interaction. Giving this property of trehalose, it can modulate inflammatory responses in the brain. We therefore investigated the effect of trehalose on abnormal aggregation and inflammatory responses in the brains of LBD model mice. Regarding abnormal aggregation of α -synuclein, immunohistochemical studies showed that any differences were not observed between mice with orally trehalose- and maltose-intake. Whereas, GFAP and Iba1 immunoreactivity was weaker in trehalose mice compared with maltose one. Further analyses using real time PCR revealed that the levels of several cytokines were inhibited in the brain with trehalose compared with maltose. In addition, trehalose increased the levels of several chaperone molecules, such as HSP90 and SigmaR1, in the brain of LBD model mice. These findings suggest that trehalose together with chaperone molecules suppresses inflammatory responses in the brain of LBD model mice. Oral administration of trehalose could be used as a safe therapeutic approach for sustained inflammatory responses.

96

Role of T cells accumulated in the brain at the late onset of stroke

Ito, M., Shichita, T., Yoshimura, A.

Keio University School of Medicine, Microbiology and Immunology, Tokyo, Japan

Stroke causes ischemic brain injury, which is a leading cause of neurological disability and death worldwide. Post-ischemic inflammation is a hallmark of ischemic stroke pathology. Although intensive efforts have been devoted to understanding innate immunity after stroke, pathogenic significance of adaptive immunity and its long-term effects on the post-ischemic brain remain unclear. In this study, we demonstrated the roles of CD4⁺T cells in adoptive immune response to ischemic brain injury using a transient middle cerebral artery occlusion (MCAO) model induced by means of an intraluminal suture. The infiltration of antigen-specific CD4⁺T cells into the infarct region in the brain was drastically increased on day 7 to 21 after stroke onset. These T cells were mainly composed of IFN- γ ⁺ Th1 and Foxp3⁺ Tregs. By using Rag-deficient mice and transfer experiments, we found that T cells played a crucial role for the formation of astrocytic gliosis which recruits inflammatory cells from uninjured brain cells. We also observed that such delayed T cell accumulation in the infarct area ameliorated neurological dysfunction. Moreover, the T cells from ischemic mice had suppressive effects on infarct volume growth by suppressing inflammatory response and by promoting the activation of astrocytes. These results suggest that the delayed accumulation of CD4⁺T cells is important for the neurological recovery after ischemic brain injury and induction of brain-specific Tregs could be a useful therapy for alleviation of neurological symptoms.

97

Blimp-1 deficiency exacerbates experimental autoimmune encephalomyelitis in mice by impairing the suppressive function of Treg cells and enhancing the encephalogenicity of Th1 cells

Lin, M.-H.¹, Sytwu, H.-K.^{2,3}

¹Kaohsiung Medical University, College of Medicine, Institute of Medicine, Department of Microbiology and Immunology, Kaohsiung, Taiwan, Republic of China, ²National Defense Medical Center, Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan, Republic of China, ³National Defense Medical Center, Graduate Institute of Life Sciences, Taipei, Taiwan, Republic of China

Recently, we demonstrated that B lymphocyte-induced maturation protein 1 (Blimp-1) has a role in regulating the differentiation and effector function of Th1 and Th17 cells. Since these cells play critical roles in the induction and pathogenesis of experimental autoimmune encephalomyelitis (EAE), we further investigate whether the potential role of T cell Blimp-1 in modulating the pathogenesis of MOG₃₅₋₅₅-induced EAE. We currently established T cell-specific Blimp-1 conditional knockout (CKO) non-obese diabetic (NOD) mice to further dissect the roles of Blimp-1 in EAE using loss-of-function mouse model. Our results indicated that EAE severity is dramatically

exacerbated in Blimp-1 CKO mice. The numbers of CNS-infiltrating Th1, Th17, IFN- γ ⁺IL-17A⁺, and IL-21⁺IL-17A⁺ CD4⁺ T cells are remarkably increased in brain and spinal cord of CKO mice. Moreover, the ratio of regulatory T cells (Tregs)/effectors and IL-10 production of Tregs are significantly downregulated in CNS of CKO mice. The frequency and expression of GM-CSF (granulocyte-macrophage colony-stimulating factor) in Th1 cells are massively upregulated in CNS of Blimp-1 CKO mice with EAE induction. In summary, we concluded that Blimp-1 suppresses autoimmune encephalomyelitis, at least, via downregulating the pathogenicity of Th1 and Th17 cells and enhancing the effector function of Treg cells.

98

A choroid-forebrain-lymphatic pathway for the maintenance of CNS immune tolerance

Mohammad, M.G.¹, Tsai, V.², Li, H.², Hassanpour, M.^{2,3}, Hart, P.⁴, Breit, S.², Sawchenko, P.⁵, Brown, D.^{2,6}

¹University of Sharjah, Department of Laboratory Sciences, Faculty of Health Sciences, Sharjah, United Arab Emirates, ²St Vincent's Hospital Center for Medical Research, Inflammation and Cytokine Research Group, Sydney, Australia, ³University of New South Wales, St. Vincent's Clinical School, Darlinghurst, Australia, ⁴University of Western Australia, Telethon Institute for Child Health Research, Centre for Child Health Research, Perth, Australia, ⁵Salk Institute for Biological Studies, Laboratory of Neuronal Structure and Function, La Jolla, United States, ⁶Westmead Hospital, Department of Immunology/Immunopathology, Sydney, Australia

The ability of the central nervous system (CNS) to maintain immune privilege is well known, but poorly understood. However, it appears that in multiple sclerosis and its animal model, experimental autoimmune encephalomyelitis (EAE), the cervical lymph nodes (CxLNs) may participate in this process. We therefore wished to establish whether there was immune cellular traffic from the CNS to the CxLNs, as well as its functional significance. Using IHC, dendritic cells (DCs) were more prominent throughout the rostral migratory stream (RMS), a pathway of neural stem cells. Further, DCs migrated from the RMS to the CxLNs, a process interrupted by Fingolimod treatment. This treatment led to the accumulation of DCs along the RMS and to severer actively induced EAE. The same treatment of 2D2 mice, a T-cell receptor transgenic mice, induced spontaneous with accumulation of antigen specific T-cells in the spinal cords of these EAE-resistant mice. In these mice, spinal cord T-cell infiltration was proportional to the ratio of anti-inflammatory T-regulatory cells (Tregs) to pro-inflammatory T-effector cells in their CxLNs. Investigating this phenomenon showed that RMS-Fingolimod treatment compromised CxLN Treg function. Using a delayed type hypersensitivity model, we demonstrate that the same treatment leads to fewer regulatory DCs in CxLNs. Combined; these data suggest that DCs migrate from the CNS to the CxLNs and regulate anti-CNS immunity representing a novel target for the treatment of CNS autoinflammatory disease.

99

TREM-2 promotes amyloid plaque formation and modulates microglia oxidative stress adaption in an experimental Alzheimer's disease mouse model

Yang, F.-C., Chou, N.-Y., Lin, Y.-H., Chen, N.-J.

National Yang-Ming University, Institute of Microbiology and Immunology, Taipei, Taiwan, Republic of China

Alzheimer's disease (AD) is a common neurodegenerative disease characterized with abnormal deposition of amyloid A β plaques in brain. A phagocytic receptor TREM-2 expressed on microglia was recently found interacts with oligo A β and plays roles in AD pathogenesis. We examined the role of TREM-2 in AD by intercrossing J20 A β -transgenic mouse model and *Trem-2* deficient (KO) mouse model. Interestingly, less amyloid A β plaques and fewer infiltrating Iba-1 (+) microglia cells were observed in the brain samples of 12 month-old J20/*Trem-2* KO mice in comparison with those from J20 mice. Further investigation on the inflammatory changes upon AD revealed a significant reduction of iNOS activity, accompanied with a drastic decrease of A β nitration in the brain sections of J20/*Trem-2* KO. Accordingly, the iNOS expression, NO induction and the NO-mediated A β nitration were defective in primary TREM-2 deficient microglia cells and TREM-2 knockdown BV2 cells. Moreover, depleting TREM-2 in BV-2 significantly exacerbates the stimuli-induced intracellular oxidative stress consequently leads to enhanced cell death. In conclusion, in an experimental AD mouse model, TREM-2 plays a motive role on enhancing the amyloid plaque formation via regulating A β nitration. TREM-2 may also contribute to the adaption of microglia on overflowed oxidative stress in response to inflammatory stimuli upon AD.

Behavioural and cellular effects of immunomodulatory compounds in the cuprizone model

Templeton, N.¹, La Flamme, A.², Kivell, B.², Webster, G.³, Connor, B.⁴

¹Victoria University of Wellington, Biology, Wellington, New Zealand, ²Victoria University of Wellington, Wellington, New Zealand, ³Innate Immunotherapeutics, Auckland, New Zealand, ⁴University of Auckland, Auckland, New Zealand

Multiple Sclerosis (MS) is a disorder of the central nervous system that affects approximately 2.5 million people worldwide. Disease pathology is characterised by the formation of demyelinating lesions in the central nervous system (CNS) which lead to cognitive and motor impairments associated with disease. These CNS lesions can be classified as those with immune cell involvement or those without immune cell infiltrate. To investigate the effect of immune-modulating therapies on lesions without immune cell infiltrate, the cuprizone model of non-immune demyelination was used to determine the effect of the immunomodulatory compounds, MIS416 and clozapine, both of which have been shown to reduce disease burden in an immune-driven animal model of MS. We found that treatment with MIS416 and clozapine led to improved performance on behavioural assays over control, with the cellular changes underlying this difference still being characterised. Protective effects provided by either of these compounds could aid in the

development of unique combination therapies to target both the immune component and the cellular components seen at different stages of MS.

101

Mast cell-nerve interactions in the colonic mucosal of *Trypanosoma cruzi*-infected individuals with chagasic megacolon

Martins, P.^{1,2}, Martinelli, P.¹, Oliveira, E.³, d'Avila Reis, D.¹

¹Universidade Federal de Minas Gerais, Morphology Department, Belo Horizonte, Brazil, ²University of Melbourne, Anatomy and Neuroscience, Melbourne, Australia, ³Universidade Federal de Goias, Goiania, Brazil

Chagas disease is an endemic infection in Latin America caused by the parasite *Trypanosoma cruzi*. Nowadays, it affects millions of people worldwide including thousands in Australia and New Zealand. Chagasic megacolon is the most frequent complication of the digestive chronic form. It is characterized by a dilation of the colon, due to lesions of enteric nervous system, followed by motility disorders. The mechanism to induce neuronal lesions is still unknown; nevertheless, several evidences support a role for the immune system. Mast cells (MCs), in particular, participate in the bidirectional communication between the immune and nervous systems. Tryptase released by MCs is a pro-inflammatory protease that through linkage to its protease activated receptor 2 (PAR2) on neurons can induce hyperexcitation or neuronal death, which could contribute to denervation of the megacolon. Accordingly, we investigated the relationship between MCs and enteric nerves in infected individuals with and without megacolon and controls, by immunohistochemistry and ultrastructural studies in the colonic mucosal. The number of tryptase-MCs increased in patients with megacolon. The percentage of PAR2-neurons and the area of PGP 9.5 nerve fibers in individuals with megacolon were lower when compared to controls. Ultrastructural analysis showed that in controls, 59% of the MCs were without signals of degranulation, while 93% of MCs were degranulated and 75% of MCs were in close proximity or contact, located within 5 µm of nerve fibers in infected individuals with megacolon. These data provide evidences about the communication between the immune and nervous systems in the chagasic megacolon.

102

Neuromyelitis optica spectrum disorder: a patient with a symptomatic third ventricular floor lesion, anti-aquaporin-4 antibodies and remission with methotrexate

Berry, R.^{1,2}, Panegyres, P.K.^{1,2}

¹Joondalup Health Campus, Neurology Service, Perth, Australia, ²Neurodegenerative Disorders Research Pty Ltd, Perth, Australia

Neuromyelitis optica is a rare severe inflammatory demyelinating disease of the central nervous system previously described to affect only the optic nerves and spinal cord. Since the detection of the highly specific autoantibody to Aquaporin-4 (anti-AQP4), lesions are now recognised outside of these regions. We present a patient with severe debilitating

symptoms resulting from a lesion within the diencephalon, which manifested with abnormal circadian rhythms, autonomic dysfunction, behavioural disturbance and unusual visual phenomenon. Centrally driven sick sinus syndrome resulted in permanent cardiac pacemaker insertion. Disease activity has been suppressed with methotrexate. This experience teaches us of the clinical spectrum of Neuromyelitis Optica Spectrum Disorder and provides evidence that methotrexate might be a useful immunomodulating substance and steroid sparing agent for anti-AQP4 related pathology.

103

Immunophenotypic studies in transgenic reporter mice reveal that the uveal tract, but not the neural retina, contains populations of resident dendritic cells

Dando, S., McMenamin, P.

Monash University, Department of Anatomy and Developmental Biology, Clayton, Australia

The question of whether dendritic cells (DCs) reside in the normal mouse retina has been hotly debated for many years. Early studies in rodents failed to identify MHC class II⁺ cells in the quiescent retina, suggesting an element of 'immune-privilege'. Nonetheless, the retina is affected by numerous diseases with an inflammatory or autoimmune nature, such as uveoretinitis, suggesting that resident antigen presenting cells (APCs) may interact with autoreactive T cells to initiate disease. We hypothesised that candidate APCs reside within the uveal tract of the eye (choroid, iris and ciliary body), but not the neural retina. Using transgenic reporter mice (CD11c-eYFP *Crb1^{wf/wf}*, CD11c-DTR-GFP and CX3cr1^{GFP/GFP}) we examined the distribution and phenotype of putative DCs within the uveal tract and retina. *In vivo* imaging revealed an extensive network of CX3cr1^{GFP/GFP+} and CD11c-eYFP⁺ cells within the retina, but no CD11c-DTR-GFP⁺ cells were observed. Retinal CX3cr1^{GFP/GFP+} and CD11c-eYFP⁺ cells were identical in both morphology and phenotype to resting Iba-1⁺ microglia (CD45^{int}, F4/80⁺, CD11b⁺, CD115⁺), but did not express APC or DC markers including I-A/I-E, CD11c, CD103, CD8α, CD80, CD86, CD135, DEC205, 33D1 or Zbtb46. In contrast, CX3cr1^{GFP/GFP+} and CD11c-eYFP⁺ cells within the iris and ciliary body were stout in appearance with few, short processes and expressed APC, DC and macrophage markers. These findings demonstrate that the retina, unlike the iris and ciliary body, is devoid of DCs. Therefore, putative APCs in the uveal tract are most likely involved in the initiation of autoimmune responses of the uvea and retina.

104

Immune privilege in the central nervous system revisited: are there dendritic cells in the brain?

Dando, S.¹, Chinnery, H.², Ruitenber, M.³, McMenamin, P.¹

¹Monash University, Department of Anatomy and Developmental Biology, Clayton, Australia, ²University of Melbourne, Department of Optometry and Vision Sciences, Parkville, Australia, ³University of Queensland, School of Biomedical Sciences, St Lucia, Australia

The central nervous system (CNS) was considered to be 'immune

privileged' due to a lack of antigen presenting cells (APCs) and the absence of traditional lymphatics. However, these concepts were recently challenged due to the discovery: (i) of putative dendritic cells (DCs) in the brain parenchyma of CD11c-eYFP mice and (ii) that brain interstitial fluid may be partly absorbed by lymphatic vessels in the dura mater. These findings suggest that afferent communication may exist within the CNS, which has implications for our understanding of immune regulation at this site. However, recent data from our laboratory questioned whether the putative 'brain DCs' described within the brain parenchyma of CD11c-eYFP mice do indeed fit the profile of DCs. We microdissected brains from CD11c-eYFP *Crb1^{wt/wt}* mice and determined the phenotype of CD11c-eYFP⁺ cells within the brain parenchyma, meninges and choroid plexus. CD11c-eYFP⁺ cells within the brain parenchyma (CD45^{int}, F4/80⁺, CD11b⁺, I-A/I-E, CD11c, CD115⁺, CD103⁻, CD8α⁻, CD80⁻, CD86⁻, CD135⁻, DEC205⁻, 33D1⁻, Zbtb46⁻) did not display the immunophenotype of DCs or their precursors and were phenotypically indistinguishable from microglia. Thus we challenge the notion that CD11c-eYFP⁺ cells within the brain parenchyma are 'brain DCs'. In contrast, CD11c-eYFP⁺ cells within the pia mater and choroid plexus (non-parenchymal, supportive tissues of the brain) contained rich populations of macrophages and DCs. These data confirm that the brain parenchyma is devoid of DCs and suggest that autoimmune responses may be initiated in the meninges and/or choroid plexus. Studies are currently underway to determine the functional capacity of these cells.

105

Infection driven inflammation severely attenuates influenza specific immunity in a chronic model of spinal cord injury

Andreansky, S., Valerie Bracchi-Ricard, Ji Zha, Annalise S. Barnette, Darlah Rodriguez-Lopez, John R. Bethea
University of Miami, Pediatrics (D-820), Miami, United States

Crosstalk between the nervous system and the immune system plays a pivotal role in maintaining homeostasis of the host. This coordination is achieved via the sympathetic nervous system (SNS) and the hypothalamic-pituitary-axis (HPA), which regulates a variety of cytokines, hormones and neurotransmitters. Thus direct injury to the neural pathways innervating the spinal cord contributes to functional deficit in the peripheral immune response and renders patients with spinal cord injury (SCI) more susceptible to viral and bacterial infections and account for 50% mortality. We therefore hypothesized that chronic SCI causes 'immune paralysis' and impairs virus specific host immunity. A low-level (T9) thoracic contusion injury model was utilized as it minimally disrupts the innervations from preganglionic sympathetic neurons to lymphoid organs. Comprehensive analysis of virus specific immunity was performed at various time points post-infection in comparison to uninjured controls. We demonstrate that infection of chronically injured mice with influenza A virus causes severe morbidity and mortality, which was driven by virus induced inflammation at the site of infection. Analysis of adaptive immunity demonstrated severe deficits in virus specific antibody and CD8T cell responses. Furthermore we provide evidence that chronic injury also regulates the formation of immunological memory in a secondary virus infection model.

To our knowledge, this is the first comprehensive analysis of virus specific immunity against a clinically relevant respiratory pathogen in a chronic SCI preclinical model. Our goal is to develop more effective therapies and reduce mortality due to complications from infections in chronic SCI patients.

106

Brain mast cells evoke central nervous system inflammation by inducing microglial activation

Zhang, S., Dong, H., Zhang, X., Wang, Y., Zhou, X., Qian, Y.
The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Brain inflammation has a critical role in the pathophysiology of brain diseases. Microglia, the resident immune cells in the brain, plays an important role in brain inflammation. While brain mast cells are the "first responder" in the injury rather than microglia. Functional aspects of mast cell-microglia interactions remain poorly understood. Our results demonstrated that site-directed injection of the "mast cell degranulator" compound 48/80 (C48/80) in the hypothalamus induced mast cell degranulation, microglial activation and inflammatory factors production, which initiated the acute brain inflammatory response. "Mast cell stabilizer" disodium cromoglycate (cromolyn) inhibited this effect, including decrease of inflammatory cytokines, reduced microglial activation. We also demonstrated that C48/80 had no effect on microglial activation in mast cell-deficient KitW-sh/W-sh mice. In vitro study, we found that the conditioned medium from activated HMC-1 could stimulate microglial activation and subsequent production of pro-inflammatory factors TNF-α and IL-6. The antagonists of H1R, H4R, PAR2 or TollR4 reduced HMC-1-induced pro-inflammatory factors production and MAPK and PI3K/AKT pathway activation. These results implicate that activated mast cells could trigger microglial activation and CNS inflammation, and interactions between mast cells and microglia could constitute a new and unique therapeutic target for CNS immune inflammation-related diseases.

107

Attenuation of pro-inflammatory parameters and memory impairment by erythropoietin in experimental pneumococcal meningitis

Barichello, T.¹, Simões, L.R.², Generoso, J.S.², Sangiogo, G.², Danielski, L.G.², Florentino, D.³, Domingui, D.², Comim, C.M.⁴, Petronilho, F.³, Quevedo, J.¹

¹University of Texas Health Science Center at Houston, Houston, United States, ²Universidade do Extremo Sul Catarinense, Criciúma, Brazil, ³Universidade do Sul de Santa Catarina, Tubarão, Brazil, ⁴Universidade do Sul de Santa Catarina, Palhoça, Brazil

Pneumococcal meningitis is characterized by a severe inflammatory reaction in the subarachnoid and ventricular space of the brain, disruption of the blood-brain barrier, hearing loss, and neurologic sequelae in as many as 27% of surviving patients. Several experimental studies have shown that erythropoietin (EPO) and its receptor are expressed in the central nervous system and have neuroprotective properties through the inhibition of apoptosis, as well as anti-inflammatory,

antioxidant, angiogenic, and neurotrophic effects. In the current study, we demonstrated the effect of erythropoietin (EPO) on lipid peroxidation, protein carbonylation, superoxide dismutase (SOD), catalase (CAT), myeloperoxidase (MPO), and behavioral parameters in rats with pneumococcal meningitis. EPO decreased lipid peroxidation and protein carbonylation, and it prevented protein degradation in the hippocampus and frontal cortex. MPO activity was decreased, and both SOD and CAT activity were increased in the first 6 hours after pneumococcal meningitis induction. Novel object recognition memory was impaired in the meningitis group; however, adjuvant treatment with EPO prevented memory impairment during both the short- and long-term retention tests. The meningitis group showed no difference in motor and exploratory activity between training and test sessions in the open-field task, which indicates that habituation memory was impaired; however, adjuvant treatment with EPO prevented habituation memory impairment. Although there are some limitations with respect to the animal model of pneumococcal meningitis, this study suggests that adjuvant treatment with EPO contributed to decreased oxidative stress and prevented cognitive impairment.

108

Pain is an inducer for relapse in multiple sclerosis models via the sensory-sympathetic nerve activation

Arima, Y., Higuchi, K., Nishikawa, N., Stofkova, A., Ohki, T., Kamimura, D., Murakami, M.

Hokkaido University, Division of Molecular Neuroimmunology, Institute of Genetic Medicine, Graduate School of Medicine, Sapporo, Japan

Pain is a common symptom in many diseases, but is considered as one of their by-products. Because a large proportion of multiple sclerosis patients experiences remission and relapse during the course of disease progression with the frequent association of pain, we assessed whether pain induces the relapse of experimental autoimmune encephalomyelitis (EAE), which is an animal model of multiple sclerosis. EAE symptoms relapsed in mice that had recovered from the initial episode of EAE after pain induction. The pain-induced excitation of sensory neurons activated the anterior cingulate cortex (ACC) in the brain, followed by the activation of sympathetic neurons that specifically control the ventral vessels of the whole spinal cord. The activation of sympathetic neurons caused the release of norepinephrine around the ventral vessels, which led to the expression of chemokine CX3CL1 from activated monocytes and further accumulation of activated monocytes at the ventral vessels. Because the numbers of activated monocytes increased in L5 cord, pain-mediated EAE relapse was induced from L5 cord. Importantly, the activated monocytes had an ability to present myelin antigens to autoreactive T cells for the induction of IL-17A and IL-6, which are important cytokines for the inflammation amplifier, a chemokine inducing mechanism in endothelial cells. Indeed, their neutralizing antibody treatments inhibited the pain-induced relapse. Thus, we concluded that pain-induced sensory-sympathetic neural activation triggers EAE relapse via the inflammation amplifier activation. These results provide the possibility that suppressing pain-mediated

regional neural signaling may prevent the relapse of CNS diseases, including MS.

109

Intrahepatic development of liver-resident NK cells

Tian, Z., Peng, H., Tang, L., Sun, R.

University of Science and Technology of China, Hefei, China

Natural killer (NK) cells are an important component of the innate immune system and play critical roles in host defense against infections and tumors. Accumulating studies have shown that the NK cell pool is highly heterogeneous, consisting of different cell subsets with distinct phenotypic and functional features. Recently, in collaboration with Professor Wayne Yokoyama, we showed that a novel NK cell subset expressing CD49a and lacking DX5 rarely recirculates and selectively resides in the liver, that is, liver-resident NK cells. While bone marrow (BM) cells are efficient in generating conventional NK (cNK) cells, the frequency of liver-resident NK cells is significantly reduced after BM transplantation. Conversely, lethally irradiated mice adoptively transferred with fetal liver cells exhibit normal frequency of liver-resident NK cells. Further analyses reveal that the adult liver retains hematopoietic potential and contains a few hematopoietic progenitor cells (HPCs), which are phenotypically distinct from BM lineage (Lin)-negative progenitor cells but resemble fetal liver counterparts. Moreover, adoptive transfer of these adult liver HPCs have the capacity to generate liver-resident NK cells, but not cNK cells. Finally, Liver HPCs express higher levels of the transcription factors that are essential for liver-resident NK cell development than their BM counterparts. Thus, our studies suggest an alternative development pathway for liver-resident NK cells.

NK Cells

Introduction: Combination antiretroviral therapy (cART) does not effectively target inflammation or innate immune activation in HIV+ individuals, leading to increased risk of inflammatory non-AIDS co-morbidities. Understanding how cART impacts innate immune activation is required for better long-term management of HIV patients.

Methods: Blood was analysed from 20 HIV+ men who have sex with men (MSM) pre-cART and 6, 12 and 24 months post-cART, and 15 HIV- MSM controls. NK, T and monocyte populations and

activation were measured using whole-blood flow cytometry. Antibodies to HCMV glycoprotein B (gB) and lysates from infected human foreskin fibroblasts (HFF) were measured in plasma. Changes of individual parameters over time were modeled using latent growth-curve modeling.

Results: CD56dimFcyR γ - adaptive NK cells were elevated at baseline in HIV+ compared to HIV- MSM ($p=0.003$) and our modelling revealed that their proportion did not change after at least 14 months of cART ($p=0.128$). Expansion of adaptive NK cells was associated with persistently elevated CMV Ab although there was no correlation between the two in HIV+ MSM ($p=0.858$ for HFF; $p=0.477$ for gB). NK activation assessed with the early activation marker CD69 decreased ($p=0.003$) whereas HLA DR+CD38+ NK cells did not ($p=0.103$). In contrast, T cell activation (HLA DR+CD38+ CD4 and CD8 both $p < 0.001$) and expansion of the proportions of intermediate ($p < 0.001$) and non-classical ($p=0.001$) monocytes significantly decreased.

Conclusions: cART reduces NK, CD4 and CD8 T cell activation at different rates. The expansion of the adaptive NK cell population following HIV infection was not altered by cART.

Effects of resveratrol on cytotoxicity of human NK cells in vitro

Shao, D., Di, Y., Li, Q., Wang, Y., Ren, H., Shi, J., Huang, Q.

Northwestern Polytechnical University, School of Life Sciences, Xi'an, China

Resveratrol (RES), a natural compound in plants, possesses obvious immune modulation activities, such as anti-tumor. Natural killer (NK) cells are important in host defense against tumors and Res may influence the cytotoxicity of NK cells through affecting the NKG2D receptor on NK cells or NKG2D-ligands on tumor cells. The effects of RES on NK cytotoxicity through its influence on NK cells and tumor cells were assessed in this study, respectively.

RES with different concentrations (3 μ M, 6 μ M, 12 μ M, 25 μ M and 50 μ M) were used in the present study. Results showed that when directly treated to NK cells, RES exhibited concentration dependent biphasic effects on the cytotoxicity of NK cells to K562 cells. At high concentration (50 μ M), RES lowered the NK cells cytotoxicity by down-regulating the expression of NKG2D. However, contrary results were obtained when at low concentration (3 μ M). On the other hand, after K562, HepG2, Caco2 and Hela cells were pre-treated with RES, there were no significant change on the sensitivity of K562, Caco2 and Hela cells to NK cells. However, 50 μ M RES treated HepG2 cells were resistant to NK cells with 15% decreased cytotoxicity than that of control. It was found to be because of the decrease in the gene expression of some NKG2D ligands (MICA, MICB, MICC, ULBP1 and ULBP2) in the HepG2 cells with 50 μ M RES treatment. The results demonstrated it was selective for RES to tumor cells. Our results may provide a new perspective of sight into RES function on immuno-cells and tumor cells.

112

Ascites containing ovarian cancer cells impair NK cells functionality and hinder their activation after IL-2 stimulation

da Silva, R.E.¹, Yoshida, A.¹, Cardoso, D.M.², Jales, R.M.¹, Derchain, S.¹, Guimarães, F.³

¹University of Campinas / Facult of Medical Sciences, Tocogynecology, Campinas, Brazil, ²University of Campinas / Facult of Medical Sciences, Campinas, Brazil, ³University of Campinas / CAISM, LCE, Campinas, Brazil

Peritoneal ascites is a unique feature of patients with advanced ovarian cancer that displays soluble factors and cells consistent with the tumor microenvironment. The goal of this study was to evaluate the NK cells functionality and their possible suppressive mediators in ascites from ovarian cancer patients. Healthy donor's ($n=12$) and patient's blood ($n=21$), and ascites without (Asc, $n=11$) and with cancer cells (AscCA, $n=6$) were collected after signed consent. Functionality of NK cells resting and IL-2 stimulated (overnight) were evaluated against K562 (1:1 ratio) by the expression of CD107a, together with the expression of DNAM-1, NKp30, NKG2D and CD16, and soluble cytokines IL-2, IL-4, IL-5, IL-10, TNF, IFN- γ and TGF- β in the serum and ascites were also quantified. The functional activation of NK cells from Asc increased significantly ($p < 0.05$) after IL-2 stimulation, (median/range, resting=17.60/6.29-29.55 to IL-2=37.07/11.20-49.50), however, the increase of the functional activation of NK cells from AscCA was not significant (resting=9.81/6.04-18.40 to IL-2=15.45/11.75-18.50). All activating receptors observed in AscCA samples were significantly ($p < 0.05$) down-regulated in respect to healthy donor's blood samples. TNF was the only cytokine in which increased significantly from Asc to AscCA. Furthermore, the population of T-regs in AscCA was significantly higher than in Asc, within the CD4⁺ population (Asc T-regs=3.36/1.38-9.58, AscCA T-regs=6.05/3.58-14.95). NK cells functionality and their response to IL-2 is impaired in ascites containing ovarian cancer cells. This effect is associated to the down-regulation of NK cells activating receptors and a higher percentage of T-regs.

Natural killer activating receptors in Behcet disease

Sallakci, N.¹, Aktas Cetin, E.², Tahrali, I.², Kucuksezer, U.C.², Yilmaz, A.², Gul, A.³, Deniz, G.²

¹Akdeniz University, Medical Faculty, Hematology Laboratory, Antalya, Turkey, ²Istanbul University, Institute of Experimental Medicine, Immunology, Istanbul, Turkey, ³Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Behcet's disease (BD) is a systemic inflammatory disorder of unknown etiology. Besides genetic predisposition, immune dysregulation in Natural Killer (NK) cells are reported to be involved in the pathogenesis of BD. NK cells have activating receptors that can be modulate adaptive immune system. NK activating receptors can shape immune responses, but very limited studies have reported about NK cells and their receptors.

In this study, expression of NKp30, NKp46, NKG2D receptors and proliferative capacity of NK cells in BD were investigated.

Peripheral blood mononuclear cells (PBMCs) were isolated from Behcet's patients (n=8) and healthy subjects (n=4). PBMCs were incubated with various human recombinant cytokine combinations including IL-12, IL-15, IL-18 and IL-23. After culturing for 40 hours, cells were stained with fluorochrome labeled antibodies and analyzed by 8-color flow cytometer. Proliferative activity were evaluated by CFSE staining.

Compare to healthy donors, CD16⁺ cells in lymphocyte population were significantly diminished in BD patients when stimulated with IL-12+IL-15 and IL-15+IL-23. Expression of CD16⁺NKp30⁺, CD16⁺NKp46⁺ and CD16⁺NKG2D⁺ cells were also lower when stimulated with IL-12+IL-13 in Behcet's patients. But on unstimulated conditions, there was borderline differences both CD16⁺NKp46⁺ and CD16⁺NKp30⁺ expression. When the stimulation with cytokine combinations including IL-12+IL-15, IL-18+IL-15 and IL-23+IL-15, proliferative capacity of CD3⁺CD56⁺ cells of Behcet's patients were significantly increased compared to healthy subjects.

Combination of the cytokines could be playing a role immune dysregulation of BD. Expression of low activating receptors in Behcet's patients might be contributed disease pathology. Excessive proliferative capacity of Behcet's patients might be a factor IL-15.

114

Tumor therapeutics work as stress inducers to enhance tumor sensitivity to NK cell cytotoxicity by upregulating NKp30 ligand B7-H6

Cao, G., Wang, J., Zheng, X., Wei, H., Tian, Z., Sun, R.

University of Science and Technology of China, Hefei, China

Immune cells are believed to participate in initiating anti-tumor effects during regular tumor therapy such as chemotherapy, radiation, hyperthermia and cytokine injection. One of the mechanisms underlying this process is the expression of so-called stress-inducible immunostimulating ligands. Although the activating receptor NKG2D has been proven to play roles in tumor therapy through targeting its ligands, the role of NKp30, another key activating receptor, is seldom addressed. In this study, we found that the NKp30 ligand B7-H6 was widely expressed in tumor cells and closely correlated to their susceptibility to NK cell lysis. Further studies showed that treatment of tumor cells with almost all standard tumor therapeutics, including chemotherapy (cisplatin, 5-fluorouracil), radiation therapy, non-lethal heat shock, and cytokine therapy (TNF- α), could upregulate the expression of B7-H6 in tumor cells and enhance tumor sensitivity to NK cell cytotoxicity. B7-H6 shRNA treatment effectively dampened sensitization of tumor cells to NK-mediated lysis. Our study not only reveals the possibility that tumor therapeutics work as stress inducers to enhance tumor sensitivity to NK cell cytotoxicity but also suggests that B7-H6 could be a potential target for tumor therapy in the future.

115

HLA haplotype homozygous iPSC-derived cells can be rejected by haploidentical recipient in NK cell dependent manner

Ichise, H., Kawamoto, H.

Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan

iPSC stock project are planned to be produced from donors with homozygous HLA haplotype (HLA-homo) in Japan. It is expected that HLA-homo iPSC-derived cells can be transplanted to recipients who have identical haplotype in one of alleles (HLA-hetero). In homo-to-hetero transplantation, rejection by allo-reactive T cells may not occur. However, recipient NK cells may attack the graft, by the mechanism called missing-self. In recent years, NK cell-mediated rejection has been suggested to occur in some organ transplantation cases in human. The aim of this study is to examine whether NK cell mediated rejection occurs against human iPSC-derived regenerated tissue in homo-to-hetero transplantation setting. NK cells express inhibitory receptors called killer cell immunoglobulin-like receptors (KIRs), and HLA-C serve as major ligands for KIRs. HLA-C are divided into two groups (C1 and C2), each of them binds to different KIRs (2DL3, 2DL1). We established iPSCs from HLA-homo and hetero donors, and those iPSCs were differentiated into T cells and endothelial cells. NK cells from a HLA-hetero donor (C1/C2) were cultured with regenerated T cells or endothelial cells from a HLA-homo donor (C1/C1), and production of inflammatory cytokine and cytotoxic activity were measured. We found that NK cells expressing C2 specific KIRs (2DL1) were selectively activated and produced IFN- γ . More importantly, regenerated HLA-homo T cells were found to be killed by HLA-hetero NK cells. We further found that such cytotoxic activity was suppressed by transducing HLA-homo iPSCs with HLA-C2 gene.

MiR-146a negatively regulates NK cell functions via STAT1 signaling

Xu, D.¹, Han, Q.¹, Zhang, C.¹, Zhang, J.²

¹Shandong University, School of Pharmaceutical Sciences, Jinan, China, ²Shandong University, School of Pharmaceutical Sciences, Jinan, China

It is known that NK cell function is down-regulated in chronic hepatitis B virus infection (CHB) and hepatic carcinoma (HCC). However, the mechanisms underlying this functional down-regulation are largely unclarified. In this study, microRNA (miR)-146a expression increased in NK cells from CHB and HCC patients compared to NK cells from healthy donors, while miR-146a levels were negatively correlated to NK cell functions. Overexpression of miR-146a diminished NK cell mediated cytotoxicity and production of IFN γ and TNF α , observations which were reversed upon inhibition of miR-146a. MiR-146a in NK cells was induced by cytokines IL-10 and TGF- β , but reduced after treatment with IL12, IFN α , and IFN β . We further revealed that miR146a targeted STAT1 and thereby regulated NK cell functions. Taken together, the up-regulated miR146a expression attributes to, at least partly, the NK cell dysfunction in CHB and HCC patients. So, miR-

146a may become a therapeutic point with great potential to ameliorate NK cell functions in liver disease.

117

Differential phenotypic and functional properties of liver-resident NK cells and mucosal ILC1s

Tang, L.¹, Peng, H.¹, Zhou, J.¹, Chen, Y.¹, Wei, H.¹, Sun, R.¹, Yokoyama, W.M.², Tian, Z.¹

¹University of Science and Technology of China, Institute of Immunology and The CAS Key Laboratory of Innate Immunity and Chronic Disease, Hefei, China, ²Washington University School of Medicine, Department of Medicine, St. Louis, American Samoa

Group 1 innate lymphoid cells (ILCs) consist of conventional natural killer (cNK) cells, tissue-resident NK cells and mucosal ILC1s. Recently identified liver-resident NK cells, which can mount contact hyper-sensitivity responses, and mucosal ILC1s that are involved in pathogenesis of colitis are distinct from cNK cells in several aspects, but the issue of how they are related to each other has not been clearly clarified. Here, we show that liver-resident NK cells and mucosal ILC1s have different phenotypes, as evidenced by distinct expression patterns of homing-associated molecules. Moreover, mucosal ILC1s exhibit tissue residency akin to liver-resident NK cells. Importantly, liver-resident NK cells express relative high levels of cytotoxic effector molecules, which are poorly expressed by mucosal ILC1s, and exhibit stronger cytotoxic activity compared with mucosal ILC1s. These results demonstrate differential phenotypic and functional characteristics of liver-resident NK cells and mucosal ILC1s, shedding new light on the diversity of ILC family.

The role of natural killer cells in graft versus leukaemia following T cell deplete allogeneic stem transplant

Maggs, L., Kinsella, F., Zuo, J., Moss, P.

University of Birmingham, Birmingham, United Kingdom

Leukaemic relapse is the major cause of treatment failure after reduced intensity T cell deplete haematopoietic stem cell transplant (HSCT). A graft versus leukaemia (GvL) effect derived from cells co-transferred with a donor's stem cell population eliminates residual tumour. Natural killer (NK) cells are purported to contribute to this effect but their precise function remains to be properly identified. Here we assessed whether 18 patients who relapsed following T cell deplete HSCT received different NK cell populations compared to 56 patients who did not relapse by immunophenotyping donor apheresis product samples and comparing these to patient outcomes. Apheresis product NK cell CD56^{dim} proportions as well as activation receptors NKp46, NKG2D and DNAM expression were decreased compared to healthy individuals, but not between the different outcome groups. Patients who relapsed received a lower percentage, as well as a lower total dose, of NK cells in their apheresis product. Further functional analysis of apheresis product NK cell cytotoxic potential, via killing of 721.221 cells, found no difference between patients who relapsed and those who did not. The phenotype and function of NK cells in

the apheresis products of allogeneic stem cell transplants did not differ between patients who go on to relapse and those who did not. However the overall number of NK cells in the transplant may be important for the success of the GvL effect in a reconstituted haematopoietic environment.

119

Heat killed *Helicobacter pylori* increases NK cell cytotoxicity through induction of NKG2DL surface expression on gastric adenocarcinoma cells

Hernández, C.J.¹, Garrido-Tapia, M.², Kramm, K.², Ribeiro, C.H.², Molina, M.C.²

¹Universidad de Chile, Escuela de Tecnología Médica, Facultad de Medicina, Santiago, Chile, ²Universidad de Chile, Programa disciplinario de Inmunología, Facultad de Medicina, Santiago, Chile

The Natural Killer Group 2, member D (NKG2D) is an activating receptor present on the surface of cytotoxic cells. Its ligands (NKG2DLs) are expressed on the cell surface in response to cellular stress. *Helicobacter pylori* can induce cellular damage on gastric cells through HSP60 and lipopolysaccharide (LPS), which are recognized by Toll like receptors (TLR). Our aim was to evaluate NKG2DLs expression on gastric adenocarcinoma cell lines in response to *H. pylori* through TLRs activation and its effect on NK cell cytotoxicity activation. NKG2DL expression was assessed at the protein and mRNA levels in MKN-45 cells upon heat killed *H. pylori* (HKHP) treatment by flow cytometry and real time PCR, respectively. NK cells degranulation and cytotoxicity on target cells was evaluated, respectively, by CD107a surface expression, by flow cytometry, and lactate dehydrogenase release assay after co-culture with MKN-45 cells previously treated with HKHP. HKHP induced a selective modulatory effect on MICA, ULBP2/5/6, ULBP4 and TLR4 cell surface expression and mRNA levels on MKN-45 cells. Both, LPS from *Rhodobacter sphaeroides*, a TLR4 antagonist, and a peptide that inhibits the dimerization of MyD88, reversed the effect of HKHP. Accordingly, increased MICA, ULBP2/5/6 and ULBP4 expression on target cells upon HKHP stimulus resulted in increased NK cell cytotoxicity, mainly through NKG2D receptor activation. Our results suggest that an inflammatory microenvironment could be associated to induction of NKG2DL expression through TLR stimulation on gastric epithelial cells, which may contribute to the maintenance of epithelial tissue damage. Characterising natural killer cell subset responses to a herpes simplex virus (HSV) lipopeptide

Truong, N.^{1,2}, Kim, M.^{1,2}, Zeng, W.³, Esparon, S.⁴, Wines, B.⁴, Hogarth, M.⁴, Jackson, D.³, Cunningham, A.^{1,2}

¹The Westmead Institute for Medical Research, Sydney, Australia, ²University of Sydney, Sydney Medical School, Sydney, Australia, ³University of Melbourne, Department of Microbiology and Immunology, Parkville, Australia, ⁴Burnet Institute, Melbourne, Australia

There are two subsets of human natural killer (NK) cells. In

circulation, >95% are CD56^{dim}CD16⁺, which are highly cytolytic against infected target cells. < 5% are CD56^{bright}CD16^{-/dim}, which have decreased cytolytic capacity, but increased production of cytokines. We are investigating HSV vaccine development using a Toll-like receptor-2 (TLR-2) stimulating lipid-conjugated HSV peptide, "Pam2Cys-30-5". Previously, we observed that this lipid conjugation enhanced CD4 T lymphocyte responses to Pam2Cys-30-5 in coculture with NK cells and dendritic cells. Furthermore, NK cells were directly activated by Pam2Cys-30-5 and could activate CD4 T lymphocytes in the absence of other antigen presenting cells, so their responses to Pam2Cys-30-5 were further investigated. Both cultured NK cell subsets were activated by Pam2Cys-30-5 as shown by increased CD69 expression, and CD16 expression on CD56^{dim} NK cells decreased over 18 hours. The two stimulated subsets showed different patterns of cytokine and chemokine production. Furthermore, this emerging CD56^{dim}CD16^{-/dim} population showed highest expression of IFN- γ . CD16 involvement in NK cell TLR-2 responses has not been explored. Hence, we began investigating the mechanism of CD16 downregulation induced by Pam2Cys-30-5. CD16 can be cleaved, so shedding into the supernatant was measured by Cytometric Bead Array. Direct binding between Pam2Cys and CD16 was not observed by ELISA, and CD16 only infrequently interacted with TLR-2 by proximity ligation assay. Finally, CD16⁺ cytolytic NK cells selectively infiltrated the HSV infected epidermis of initial herpetic lesion biopsies. Therefore they may play a role in innate control of initial genital HSV infection and should be considered in vaccine development.

121

Flow cytometric multicolor NK cell phenotyping as a potential tool for donor selection and NK cell reconstitution analysis in different hematopoietic stem cell transplantation setups

Pflitsch, S., Huppert, V., Richter, A., Siewert, C., Dose, C. Miltenyi Biotec GmbH, Research & Development, Bergisch Gladbach, Germany

Natural killer (NK) cells are lymphocytes of the innate immune system and show the capacity to kill cancer cells. Their function is regulated by the balance of inhibitory and activating signals transmitted mainly by killer-cell immunoglobulin-like (KIR), killer-cell lectin-like (KLR) and natural cytotoxicity (NCR) receptors. Genotyping, phenotyping and haplotyping of NK cell receptors are discussed in different haploidentical and allogeneic hematopoietic stem cell transplantation settings to predict the incidence of Graft-versus-Host-Disease (GvHD), Graft-versus-Leukemia effects (GvL), graft rejection and relapse, and therefore to improve donor selection. Furthermore NK cell receptor phenotyping is a potent tool to analyze NK cell reconstitution after haploidentical and allogeneic hematopoietic stem cell transplantation to further improve the understanding of the complex NK cell biology. Here we present four robust multicolor flow cytometry NK cell receptor phenotyping panels (up to 8 colors) with the focus on a) inhibitory KIRs recognizing HLA-C2 (CD158a - KIR2DL1), HLA-C1 (CD158b - KIR2DL2/3) and HLA-Bw4 (CD158e - KIRDL1/DS2) alleles of the HLA class I molecules,

b) other inhibitory and activating KIRs, c) KLRs and NK cell maturation markers and d) NCRs. Panels were compiled by including recombinant antibodies (REAFinity™ Antibodies), which provide the advantages of high purity, lot-to-lot consistency for greater reproducibility and high specificity, so that FcR blocking is no more required. Additionally, the brighter VioBright™ FITC fluorophore is used to substitute the conventional FITC fluorochrome, where feasible.

122

Natural killer cytotoxicity and single nucleotide polymorphisms in transient receptor potential ion channels and acetylcholine receptors of isolated natural killer cells in chronic fatigue syndrome

Marshall-Gradisnik, S.^{1,2}, Huth, T.^{1,2}, Chacko, A.^{1,2}, Johnston, S.¹, Smith, P.¹, Staines, D.¹

¹Menzies Health Institute Queensland, National Centre for Neuroimmunology and Emerging Diseases, Parklands, Australia, ²Griffith University, School of Medical Science, Parklands, Australia

Nucleotide polymorphisms (SNPs) and genotypes in transient receptor potential (TRP) ion channels and Acetylcholine receptors (AChRs) in isolated NK cells from CFS patients.

Methods: Thirty-nine Fukuda defined CFS patients (age = 51.69±2.00 years) and 30 non-fatigued controls (age = 47.60±2.39 years) were included. Flow cytometric protocols were used to examine NK cytotoxic activity. A total of 678 SNPs from isolated NK cells were examined for 21 TRP ion channel genes and for 9 AChR genes using Agena Biosciences iPLEX Gold assay. SNP association and genotypes were determined using ANOVA and PLINK analysis.

Results: CFS patients had a significant reduction in NK% lysis (17±4.68) compared to non-fatigued controls (31±6.78). Eleven SNPs for TRP ion channel genes were identified in the CFS group. Five of these were associated with TRPM3 and the remainder were associated with TRPM8, TRPC2 and TRPC4. Fourteen SNPs were associated with nicotinic and muscarinic AChRs: six were nAChR α 3, while the remainder were nAChR α 2, nAChR β 4, nAChR α 5 and nAChR epsilon. Sixteen genotypes were identified from SNPs in TRP ion channel and AChR for TRPM3, TRPM, TRPC4, TRPC2, nAChR epsilon, nAChR α 2, nAChR α 3 and nAChR β 4.

Conclusions: We identified SNPs and genotypes for TRP ion channels and AChRs from isolated NK cells in patients with CFS, which may be involved in changes in NK cell function and development of CFS pathology.

123

Generation, characterization and functional analysis of HLA-DR-positive NK cells

Erokhina, S., Streltsova, M., Kanevskiy, L., Kovalenko, E. M.M. Shemyakin and Yu.A. Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation

Activated NK cells are able to express HLA-DR. However, HLA-DR-positive subpopulation and functional significance of HLA-

DR on NK cells are still not fully characterized. In this work, we investigated HLA-DR-positive NK cells generated in the in vitro activation system using IL-2 and K562 cells with membrane-bound IL-21 (K562-mbIL-21). This cytokine combination is very promising for NK cells expansion for adoptive immunotherapy. Stimulation of NK cells for 6 days significantly increased the proportion of HLA-DR⁺ subpopulation, with combination of IL-2 and K562-mbIL-21 causing the highest rates (93% of HLA-DR⁺ NK cells). IL-2 only, unmodified K562, soluble IL-21, and their various combinations also led to a certain increase in HLA-DR⁺ cells proportion, but to a lesser extent (less than 45% of NK cells). This phenomenon resulted from the induction of HLA-DR expression on NK cells, rather than propagation of HLA-DR-positive subpopulation: proportion of HLA-DR⁺ cells increased in the pre-sorted HLA-DR-negative subpopulation too.

HLA-DR⁺ cells, obtained after 6 days of stimulation with IL-2 and K562-mbIL-21, demonstrated higher IFN γ production and cytotoxicity than HLA-DR⁻ cells, along with higher expression of NKG2C, NKG2D, CD86 and degranulation marker CD107a. At the same time, we found out a significant increase in proportion of HLA-DR-positive NK cells in the peripheral blood of tuberculosis-infected patients comparing to healthy donors. This might be the clue to elucidating the physiological role of HLA-DR-positive NK cells, but further investigation is needed, including the potential to use these cells with elevated effector functions in adoptive immunotherapy.

Killer cell immunoglobulin-like receptor genes and allelic polymorphism from natural killer cells in chronic fatigue syndrome/myalgic encephalomyelitis patients

Huth, T.^{1,2}, Brenu, E.^{1,2}, Staines, D.^{1,2}, Marshall-Gradisnik, S.^{1,2}

¹National Centre for Neuroimmunology and Emerging Diseases, Menzies Health Institute Queensland, Gold Coast, Australia, ²School of Medical Sciences, Griffith University, Gold Coast, Australia

Variations in *Killer cell immunoglobulin-like receptor (KIR)* gene content and allelic polymorphism have been identified to influence KIR surface expression and receptor ligation required to initiate NK cell cytotoxic activity. NK cell cytotoxic activity has consistently been reported to be reduced in patients with Chronic Fatigue Syndrome/ Myalgic Encephalomyelitis (CFS/ME). The aim of this study was to investigate *KIR* gene content and allelic polymorphism to determine if genetic variations may contribute to reduced NK cell activity in an Australian population of CFS/ME patients. NK cells were isolated by magnetic separation and deoxyribonucleic acid was extracted from CFS/ME patients and non-fatigued controls (NFC). NK cell DNA was sequenced on an Illumina MiSeq platform and the data generated was aligned the Immuno Polymorphism-KIR Database to determine *KIR* content and allelic polymorphism for each participant. A total of 20 CFS/ME patients and 20 non-fatigued controls (NFC) were included in this study. The frequency of individual activating and inhibitory *KIRs* were compared between CFS/ME patients and NFC and no significant differences were observed. *KIRs* alleles were also compared between CFS/ME patients and NFC and no significant differences

were reported. As the frequencies of *KIR* genes and allelic polymorphisms were not significantly associated with NK cells from CFS/ME patients, this suggests that individual *KIR* genes and allelic polymorphism may not contribute to reduced NK cell cytotoxic activity. Further investigations in a larger sample size are required to ensure there is enough statistical power to identify differences between CFS/ME patients and NFC.

125

ERK1/2 significantly reduced in CD56^{dim}CD16⁺ NK cells from chronic fatigue syndrome/myalgic encephalomyelitis patients

Huth, T.^{1,2}, Brenu, E.^{1,2}, Staines, D.^{1,2}, Marshall-Gradisnik, S.^{1,2}

¹National Centre for Neuroimmunology and Emerging Diseases, Menzies Health Institute Queensland, Gold Coast, Australia, ²School of Medical Sciences, Griffith University, Gold Coast, Australia

Intracellular signals for Natural Killer (NK) cell effector function are propagated through a phosphorylation cascade by a family of mitogen-activated protein kinases (MAPKs). Extracellular signal-regulated kinase (ERK)1/2 has been identified as a critical signalling molecule required for the secretory granule in cytotoxic NK cells to polarise towards and release lytic proteins into the target cell. Reduced cytotoxic function of NK cells has consistently been reported in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) patients, and the MAPK signalling pathway remains to be investigated. Therefore, the purpose of this study was to examine phosphorylated ERK1/2 in NK cells from CFS/ME patients as a potential mechanism for reducing NK cell cytotoxic function. Peripheral blood mononuclear cells (PBMCs) were isolated from each participant by density gradient centrifugation and incubated with K562 cells at an effector to target ratio of 25:1 for 15 minutes to induce phosphorylation. The PBMCs were subsequently fixed, permeabilised, stained for ERK1/2 with a monoclonal antibody and analysed using flow cytometric methods on CD56^{dim}CD16⁺ NK cells. 14 CFS/ME patients and 11 non-fatigued controls were included in the study. In CFS/ME patients, ERK1/2 was significantly reduced in CD56^{dim}CD16⁺ NK cells following stimulation with K562 cells compared to the non-fatigued controls. The MAPK pathway may contribute to reduced NK cell cytotoxic activity in CFS/ME patients. The significant reduction of ERK1/2 in CD56^{dim}CD16⁺ NK cells from CFS/ME patients may disrupt intracellular signals required for polarisation of the secretory granule towards the target cell.

126

MAPK signalling and NK cell cytokine production in chronic fatigue syndrome/myalgic encephalomyelitis patients

Huth, T.^{1,2}, Brenu, E.^{1,2}, Staines, D.^{1,2}, Marshall-Gradisnik, S.^{1,2}

¹National Centre for Neuroimmunology and Emerging Diseases, Menzies Health Institute Queensland, Gold Coast, Australia, ²School of Medical Sciences, Griffith University, Gold Coast, Australia

Natural Killer (NK) cells elicit cytotoxic activity and cytokine

production to remove target cells infected with viruses, bacteria or cells which have been malignantly transformed. Intracellular signalling through the mitogen activated protein kinase (MAPK) pathway induces cytokine production. Interferon gamma (IFN- γ) from NK cells in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) patients has previously been reported to be increased and the purpose of this study was to investigate if signalling molecules in the MAPK pathway may contribute to increased cytokine production in CFS/ME patients. Peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation. To induce phosphorylation, the PBMCs were stimulated with K562 cells at an effector to target ratio of 25:1 for 15 minutes. The PBMCs were subsequently fixed, permeabilised, stained with monoclonal antibodies for MAPK Kinase1/2 (MEK1/2), p38 and c-Jun N-terminal kinase (JNK) and analysed on CD56^{bright}CD16^{-dim} NK cells using flow cytometric methods. 14 CFS/ME patients and 11 non-fatigued controls were included in the study. CD56^{bright}CD16^{-dim} NK cells from CFS/ME patients expressed significantly increased amounts of p38 and MEK1/2 following stimulation with K562 cells compared to the non-fatigued controls. Phosphorylation of p38 and MEK1/2 activates tyrosine kinase molecules which translocate into the nucleus to regulate cytokine production at the transcriptional level. Therefore, increased levels of phosphorylated p38 and MEK1/2 in CD56^{bright}CD16^{-dim} NK cells may contribute to increased production of IFN- γ in CFS/ME patients.

127

SNPs rs4656317 and rs12071048 located within an enhancer in *FCGR3A* are in strong linkage disequilibrium with SNP rs396991 and influence ADCC by transcriptional regulation

Oboshi, W., Yukimasa, N.

Kagawa Prefectural University of Health Sciences, Department of Medical Technology, Takamatsu, Japan

Responses to NK cell-mediated ADCC have been shown to depend on a SNP at CD16 (Fc γ R11a) receptor amino acid position 158. However, a consensus has not yet been reached regarding differences in the structure and expression levels of the CD16 molecule among Fc γ R11a-F158V genotypes. The aim of the present study was to further investigate the relationship between ADCC activity and functional SNPs in the *FCGR3A* gene. SNP analyses were performed on 101 healthy Japanese volunteers (46 males and 55 females). Direct sequencing using *FCGR3A* gene sequence-specific primers were conducted for SNP rs396991 (T>G; F158V) and other SNPs located within an enhancer, i.e., rs10917571 (G>T), rs4656317 (C>G), and rs12071048 (G>A). Twenty-four volunteers participated in measurements of NK cell-mediated ADCC activity, the binding affinity of CD16 to the Fc region, *FCGR3A* transcripts, and cell-surface CD16 expression. The results obtained showed that SNP rs396991 was in strong linkage disequilibrium with SNPs rs4656317 and rs12071048. NK cell-mediated ADCC activity was significantly different in the genotypes of their SNPs. Binding affinity for SNP rs396991 was significantly greater in G/G subjects than in G/T or T/T subjects. *FCGR3A* transcript levels and surface CD16 expression levels indicated a significant

difference in the genotypes of SNPs rs4656317 and rs12071048, respectively. We revealed a detailed relationship between ADCC activity and functional SNPs in NK cells obtained from Japanese subjects. In conclusion, two regulatory SNPs are in strong linkage disequilibrium with SNP rs396991 in *FCGR3A* and influence NK cell-mediated ADCC by transcriptional regulation.

128

Deficiency of autophagy resulted in high cytotoxicity activity and strong anti-tumor effect in NK (natural killer cells)

Yang, J., Wang, X., Zhang, Y., Chen, W.

Zhejiang University, Institute of Immunology, School of Medicine, Hangzhou, China

Macroautophagy (hereafter referred to autophagy) is an evolutionary conserved self-homeostasis mechanism. It has been demonstrated that autophagy played an important role in the development, survival and function of immune cells. However, the role of autophagy in the function of NK cells remained unknown. Here, we utilized Atg3 and Atg7 conditional knock-out mice with ER-Cre, which could induce Atg gene knockdown in mature NK cells without affecting cell development. We found that the NK cells from both of Atg3-deficient and Atg7-deficient mice showed higher expression levels of perforin and granzyme B compared with NK cells from control mice, and therefore possessed increased cytotoxicity activity in vitro. We also found that these autophagy-deficient mice exhibited more obvious anti-tumor effect on the NK-sensitive RAM-S tumor in vivo. Furthermore, the expression of killer activatory receptors (KAR) and killer inhibitory receptors (KIR) on surface of NK cells did not change after Atg7 gene knockdown. In addition, the release of cytolytic granules detected by CD107a staining was not impaired in NK cells from Atg7 knockout mice. These data indicated that autophagy controlled the cytotoxicity activity of NK cells by regulating the expression levels of perforin and granzyme B, and KAR/KIR on surface of NK cells as well as the release of lytic granule remained unchanged.

NKT Cells

129

Increase in NKT cell numbers protects mice from central nervous system autoimmunity

Gemiarto, A., Xuyen Dinh, T., Jordan, M., Baxter, A.

James Cook University, Molecular and Cell Biology, Townsville, Australia

Natural killer T (NKT) cells are a distinct subset of T lymphocytes that expresses both TCR and natural killer cell receptors. NKT cells require the presentation of glycolipid antigen by CD1d and they express an invariant TCR- α chain Va14-Ja18. They rapidly produce an array of cytokines upon stimulation, including IFN- γ , IL-4, and IL-10. In this study, we examined the role of NKT cells in an animal model of central nervous system (CNS) autoimmunity, Experimental Autoimmune Encephalomyelitis (EAE).

We compared the progression of EAE in wild-type C57BL/6, NKT cell-deficient C57BL/6.CD1d^{-/-} (CD1dKO) and NKT cell-abundant C57BL/6.Va14 transgenic (Va14tg) mice. Mice were immunised with myelin oligodendrocyte glycoprotein 35-55 in complete Freund's adjuvant and supplemented with pertussis toxin. Mice were scored for signs of CNS damage for 30 days, after which the CNS was harvested for histological analysis. The proportions of NKT cells in the lymphoid organs were determined using flow cytometry.

There was no significant difference in disease severity of CD1dKO mice compared to the wild-type strain. Conversely, Va14tg mice developed a significantly milder form of EAE. Histological analysis confirmed a lower degree of inflammation in the CNS of Va14tg mice compared to wild-type and CD1dKO mice. We also observed significantly milder symptoms in wild-type mice following transfer of NKT cells from Va14tg mice, compared to PBS-injected control mice.

These findings support a role for NKT cells in suppressing autoimmune disease and may lead to the development of a novel MS therapy.

130

Role of killer-associated protein NKG7 in NK and NKT cells

Baxter, A.G.¹, Gemiaro, A.¹, Oliaro, J.², Dinh, T.X.¹, Smith, L.¹, Godfrey, D.I.³, Jordan, M.A.¹

¹James Cook University, Comparative Genomics Centre, Townsville, Australia, ²Peter MacCallum Cancer Centre, Cancer Immunology, Melbourne, Australia, ³University of Melbourne, Microbiology and Immunology, Melbourne, Australia

NKG7 is a poorly characterised integral membrane protein expressed on cytotoxic granules of quiescent NK and CD8 T cells and is translocated to the plasma membrane of cytotoxic cells following target engagement. It is expressed on expanded populations of cytotoxic CD4 T cells in patients with effective antiviral responses to HIV and CMV. In a transcriptional analysis of NKT cell development, we found that *Nkg7* is one of the most strongly up-regulated transcripts (35-fold) in NKT cells at the point of lineage commitment, suggesting it plays an important role in NKT cell activities. We have produced B6.*Nkg7*^{-/-} mice and found a decrease in NK cell-mediated cytotoxicity on a per cell basis *in vitro*, but not an effect on numbers of peripheral NK cells. B6.*Nkg7*^{-/-} mice had fewer thymic resident NK1.1⁺ NKT cells but increased numbers in spleen and liver. The expression of the NK1.1 marker in NKT cells was associated with a "killer transcriptional program," including strong expression of *Nkg7*, *Gzma*, *Gzmb*, *Prf1*, *Fasl* and a wide range of NK cell markers that were not expressed on other subsets.

131

Phenyl glycolipids with different glycosyl groups exhibit marked differences in murine and human iNKT cell activation

Huang, J.-R.¹, Wu, T.-N.^{2,3}, Hung, J.-T.¹, Lin, K.-H.^{2,4}, Wu, Y.-T.², Wu, J.-C.¹, Wong, C.-H.^{2,3,4}, Yu, A.L.^{1,2}

¹Chang Gung Memorial Hospital, Institute of Stem Cell and Translational Cancer Research Center, Taoyuan, Taiwan, Republic

of China, ²Academia Sinica, Genomics Research Center, Taipei, Taiwan, Republic of China, ³National Taiwan University, Institute of Biochemical Sciences, Taipei, Taiwan, Republic of China, ⁴National Taiwan University, Department of Chemistry, Taipei, Taiwan, Republic of China

Phenyl glycosphingolipids (GSLs) bearing α -galactosyl head group (α Gal) and acyl-chain terminated with a phenyl derivative were found to be more potent than α -galactosylceramide (α GalCer) to stimulate both murine and human invariant natural killer T (iNKT) cells. Their activities have a strong correlation with the binding avidities and stability of the ternary interaction between iNKT T-cell receptor (TCR) and CD1d-GSL complex. In this study, we replaced the galactosyl group with glucose (α Glc) or mannose (α Man), and showed that GSLs with α Glc were stronger than those with α Gal in human but weaker in mice in inducing cytokines and expansion/activation of immune cells. However, addition of fluoride on the 4' or 6'-glucose-head phenyl-glycolipids could rescue the IFN- γ secretion in mice to comparable level as induced by GSL with α -galactosyl head. Using Ja18 knockout (KO) mice, we showed that most cytokines/chemokines induced by GSLs with either α Glc or α Gal were iNKT-dependent. On the other hand, it was the binding of GSLs to iNKT-TCR rather than CD1d that dictated the species-specific responses, as demonstrated by mCD1d vs. hCD1d swapping assay. Computer modeling of the ternary complex suggested that a H-bond interaction between Glc-GSL and human iNKT-TCR is lacking in murine TCR, which may attribute to the species differences in their iNKT responses to GSLs. Thus, our studies have not only uncovered a species specific immune response to GSLs with different glycosyl groups, due to differences in the TCR-glycolipid interactions but also provided a new insight for designing new generation of GSL for human use.

132

Induction of adipocyte resident NKT cells can be instructed by non ligand-binding motifs of the TCR β chain

Vieih, J., Das, J., Ranaivoson, F., Comoletti, D., Denzin, L., Sant'Angelo, D.

Robert Wood Johnson Medical School, Rutgers University, The Child Health Institute of NJ, New Brunswick, United States

Invariant Natural Killer T (NKT) cells, a CD1d-restricted subset of ab T cells, have been increasingly recognized for their role in a wide variety of functions associated with autoimmunity, cancer, infection, tolerance, and obesity. The semi-invariant TCR expressed by NKT cells is unique in its recognition of glycolipids presented by CD1d, heterodimer rigidity, and limited binding footprint compared to conventional TCR:MHC interactions. This distinctive interaction has been studied extensively *in vitro*, though the role of the rigid $\alpha\beta$ heterodimer in the selection and development of NKT cells remains elusive. We investigated a hydrophobic patch on the b chain of the NKT TCR, suggested to play a role in heterodimer stability. Partial disruption of this patch, while permissive of ligand binding, resulted in decreased populations of NKT cells, diminished development, and effector function. Complete disruption of the patch resulted in the ablation of the NKT cell compartment entirely, while still

accommodating of conventional T cell development. NKT cells expressing the mutant NKT TCR acquired an adipose-resident NKT phenotype while in the thymus, and accumulated in the adipose tissue in mice. Hence, we show that *in vivo*, non-ligand binding regions of the NKT TCR are critical for the development of these important immune cells, and mediate the selection of adipose-resident NKT cells.

133

A novel epigenetic regulator of early NKT cell development

Inoue, M.¹, Okamoto, K.¹, Negishi-Koga, T.², Nakashima, T.³, Takayanagi, H.¹

¹University of Tokyo, Tokyo, Japan, ²Showa University School of Dentistry, Tokyo, Japan, ³Tokyo Medical and Dental University, Tokyo, Japan

Natural killer T (NKT) cells are differentiated from CD4⁺CD8⁺ double positive (DP) cells that recognize CD1d-glycolipid complexes. After commitment to the NKT cell lineage, NKT cells undergo differentiation from stage 0 to stage 3 cells in thymus, in which several transcription factors such as PLZF and T-bet are involved. However, no epigenetic regulators that contribute to NKT cell development were reported. Here we identified a histone modifying enzyme (termed Himez) as an essential regulator of NKT cell development. Himez epigenetically regulates the expression of various genes related to cell cycle and survival in many tissues. Since Himez is highly expressed in T cells, we newly generated Himez-floxed mice and then crossed Himez-floxed mice with *Cd4-Cre* mice to generate T cell-specific Himez knockout mice. These mice possessed normal thymic cellularity. The Treg cell number was mildly decreased in thymus and spleen of Himez^{flox} *Cd4-Cre* mice. On the other hand, NKT cell number was markedly reduced in the thymus, spleen and liver of Himez^{flox} *Cd4-Cre* mice, due to an impaired differentiation in stage 1. Mixed bone marrow chimera experiments demonstrated that Himez regulates NKT cell development in a cell intrinsic manner. The transcriptome analysis using NKT stage 1 cells indicated that Himez is necessary for expression of several genes associated with NKT cell development. Collectively, Himez plays an essential role in early NKT cell development by regulating gene transcriptions. We would like to discuss the epigenetic modifications by Himez that influence NKT cell generation.

134

Characterization of sulfatide-reactive type II NKT cells in mouse lungs

Kato, S.¹, Pasquet, L.¹, Adams, T.¹, Sharrow, S.¹, Davies-Hill, T.¹, Jaffe, E.¹, Xia, Z.¹, Suzuki, M.², Kovalovsky, D.¹, Berzofsky, J.¹, Terabe, M.¹

¹National Cancer Institute, National Institute of Health, Bethesda, United States, ²National Heart, Lung and Blood Institute, National Institute of Health, Bethesda, United States

Type II NKT cells are CD1d-restricted T cells that do not express an invariant TCR α expressed on all type I NKT cells. Similar to type I NKT cells, type II NKT cells have been reported to play a critical role in many disease models including autoimmune diseases and cancer. However, in contrast to type I NKT cells

much less is understood about type II NKT cells because of lack of widely available tools to identify them. Although there is no known antigen that can be recognized all type II NKT cells, sulfatide is a relatively well-defined self-antigen recognized by a fraction of type II NKT cells. By creating sulfatide-loaded CD1d-tetramers, we analyzed distribution of sulfatide-reactive type II NKT cells among different organs of mice and found a significant number in lungs. Characterization of lung sulfatide-reactive type II NKT cells revealed a strong contrast with type I NKT cells. They consisted of CD4⁺ and CD8⁺ populations while type I NKT cells are either CD4⁺ or double-negative. Lung sulfatide-reactive type II NKT cells do not express PLZF, which is a master regulator of type I NKT cell development. This result was confirmed with the observation that sulfatide-reactive type II NKT cells could develop in PLZF^{-/-} mice. Their V β repertoire was diverse like conventional T cells. Unexpectedly we also found that a significant fraction of sulfatide-reactive type II NKT cells express CD11b and Ly6C although they had lymphocytic morphology. Altogether, lung type II NKT cells have very unique characteristics.

135

TAC1 is required for maintaining the numbers and functions of invariant NKT (iNKT) cells

Quah, P.S.¹, Fairfax, K.², Andrews, D.¹, Mackay, F.^{1,3}

¹Monash University Central Clinical School, Department of Immunology and Pathology, Melbourne, Australia, ²Walter and Eliza Hall Institute of Medical Research (WEHI), Parkville, Australia, ³University of Melbourne, Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia

Invariant NKT (iNKT) cells are innate-like T lymphocytes which co-express the invariant Ja18 T cell receptor and NK cell markers. Murine iNKT cells recognize lipid antigens presented on CD1d. The primary function of NKT cells is cytokine production where CD4⁻ iNKT cells produce Th1 cytokines while CD4⁺ iNKT cells produce both Th1 and Th2 cytokines. Among all antigen presenting cells that express CD1d, marginal zone (MZ) B cells express the highest levels. MZ B cells also express high levels of B cell activating factor (BAFF) receptor (BAFF-R) and transmembrane activator and calcium modulator and cyclophilin ligand interactor (TAC1). BAFF-R binds only to BAFF whereas TAC1 binds to both BAFF and a proliferation inducing ligand (APRIL). The purpose of this study is to investigate the role of BAFF, APRIL and their receptors in regulating iNKT cell numbers and functions. Comparing the numbers of iNKT cells in BAFF^{-/-}, BAFF Tg (overexpress BAFF), BAFF-R^{-/-} and TAC1^{-/-} mice to wildtype mice, we observed a significant reduction of iNKT cell numbers in TAC1^{-/-} mice. In addition, the level of IL-4 was significantly decreased in the sera of TAC1^{-/-} mice injected intraperitoneally with α -galactosylceramide. Our results show that TAC1 is important for maintaining the number and function of iNKT cells. iNKT cell defects have been observed in human patients with common variable immunodeficiency (CVID) and autoimmune disorders. Some of these patients are also TAC1 deficient. Therefore, studying the link between TAC1 and iNKT cells might provide a better clinical outcome for these patients.

136**c-Maf positively regulates IL-17A production in invariant NKT cells**

Yu, J.-S.¹, Hamada, M.², Ohtsuka, S.³, Yoh, K.⁴, Takahashi, S.², Miaw, S.-C.¹

¹College of Medicine, National Taiwan University, Graduate Institute of Immunology, Taipei, Taiwan, Republic of China, ²Faculty of Medicine, University of Tsukuba, Department of Anatomy and Embryology, Tsukuba, Japan, ³Graduate School of Comprehensive Human Sciences, University of Tsukuba, Department of Respiratory Medicine, Tsukuba, Japan, ⁴Faculty of Medicine, University of Tsukuba, Department of Nephrology, Tsukuba, Japan

c-Maf, a member of the large Maf family transcription factors, plays an important role in regulation of cytokine production and differentiation in Th2, Th17, Tfh and Tr1 cells. Many studies have shown that invariant natural killer T (iNKT) cells can produce Th-related cytokines such as IFN- γ , IL-4 and IL-17A. However, the role of c-Maf in iNKT cells and iNKT cells-mediated diseases is poorly understood. In this study, we demonstrate that α -galactosylceramide (α -GalCer)-stimulated iNKT cells express c-Maf transcript and protein. We further show that c-Maf-deficient iNKT cells produce less IL-17A, but not IFN- γ and IL-4, than their WT counterparts after α -GalCer stimulation by using c-Maf-deficient fetal liver cells-reconstituted mice both *in vitro* and *in vivo*. c-Maf deficiency does not affect the development and activation state of iNKT cells. In addition, induction of IL-17-producing iNKT (iNKT17) cells by IL-6, TGF- β and IL-1 β is also positively regulated by c-Maf *in vitro*. Furthermore, c-Maf-deficient iNKT17 cells lose the ability to recruit neutrophils to the lungs. Taken together, c-Maf is a positive regulator for IL-17A production in iNKT cells and potential therapeutic target in iNKT17 cells-mediated inflammatory diseases.

137**Repeated activation of lung invariant NKT cells results in chronic obstructive pulmonary disease-like symptoms**

Chuang, Y.-H.

National Taiwan University, Department of Clinical Laboratory Sciences and Medical Biotechnology, Taipei, Taiwan, Republic of China

Chronic obstructive pulmonary disease (COPD) is characterized by chronic airway inflammation, mucus hypersecretion, and emphysema, which lead to reduced lung function and breathlessness. The pathologies of COPD are due to an abnormal immune response. Invariant natural killer T (iNKT) cells are important population of innate lymphocytes and have been implicated in the regulation of immune responses associated with a broad range of diseases including COPD. We have here analyzed the role of iNKT cells in a model of COPD induced by repeated intranasal administration of iNKT cell agonist α -galactosylceramide (α -GalCer). Our results demonstrated that mice received repeated intranasal administration of α -GalCer had molecular and inflammatory features of COPD including airway inflammation with significant increases in infiltration of macrophages and lymphocytes, CD8⁺ T cells, as well as proinflammatory cytokines IL-6 and TNF- α . In particular, these mice also showed the presence of pulmonary emphysema,

mucus production, and pulmonary fibrosis. Furthermore, neutralization of IL-4 reduced α -GalCer induced emphysema. This study indicates the importance of iNKT cells in the pathogenesis of COPD by an IL-4 dependent mechanism.

138**CD1d-dependent lipid antagonist DPPE-PEG attenuates atherosclerosis**

Li, Y.^{1,2}, Kanellakis, P.¹, Hosseini, H.¹, Cao, A.¹, Deswaerte, V.¹, Tipping, P.², Toh, B.-H.², Bobik, A.^{1,3}, Kyaw, T.^{1,2}

¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Southern Clinical School, Faculty of Medicine, Nursing and Health Sciences, Monash University, Centre for Inflammatory Diseases, Department of Medicine, Melbourne, Australia, ³Central Clinical School, Faculty of Medicine, Nursing and Health Sciences, Monash University, Department of Immunology, Melbourne, Australia

Atherosclerosis is responsible for heart attacks and stroke-leading causes of global mortality. As current lipid-lowering statins reduces risk of cardiovascular events by only one-third in patients with atherosclerosis. Thus, additional therapies to reduce atherosclerosis-related deaths are urgently needed. In this study, we investigate pharmacological effect of DPPE-PEG₃₅₀ that can prevent NKT atherogenicity in development and progression of atherosclerosis.

To test its effect in the development of atherosclerosis, DPPE-PEG350 was administered to ApoE^{-/-} mice at the beginning of 8 week high fat diet (HFD). We found that DPPE-PEG350 reduced aortic root atherosclerosis as well as lesion lipid content and macrophage accumulation without affecting NKT cells or other lymphocyte numbers. CD4/CD8 T cells and B cells in atherosclerotic lesions and lesion contents of MCP-1 and VCAM-1 proteins were decreased in DPPE-PEG350-treated mice. Necrotic core size, not lesion smooth muscle and collagen content were also reduced in DPPE-PEG350-treated mice. In progression experiment, 6 week HFD-fed ApoE^{-/-} mice were treated with DPPE-PEG350 for 6 weeks. DPPE-PEG350-treatment also showed reduced atherosclerosis in similar fashion. To confirm if DPPE-PEG350 reduces atherosclerosis by preventing CD1d-dependent lipid antigen presentation to NKT cells, we treated mice with DPPE-PEG₃₅₀ followed by NKT agonist, α -GalCer. We found that α -GalCer failed to aggravate atherosclerosis in DPPE-PEG₃₅₀-treated mice. In conclusion, our data suggest that DPPE-PEG₃₅₀ treatment attenuates both development and progression of atherosclerosis by preventing CD1d-dependent activation of NKT cells. DPPE-PEG₃₅₀ in combination with current lipid lowering statins has a therapeutic potential to reduce atherosclerosis-related mortality.

Tumour Immunology

139

Characterization of the antitumor and immunomodulatory properties of new HDAC inhibitors as targeted anti-cancer drugs

Veloso Caixeta, A.¹, Soares Romeiro, L.A.², Grace Magalhães, K.¹

¹University of Brasilia, Laboratory of Immunology and Inflammation, Brasilia, Brazil, ²University of Brasilia, Laboratory of Development and Therapeutic Innovation, Brasilia, Brazil

The chemotherapy still remains the treatment of choice in the clinic against cancer. However its toxicity and side effects are limiting factors for its use. Immunotherapy is also often used in combination with other anticancer drugs. Currently there is a difficulty in obtaining drugs that have both antitumor and immunomodulatory effects. Inhibitors of histone deacetylases (HDACi) represent a new drug target class in which the histone acetylation associated with chromatin is changed, thereby modulating a gene transcription and factors involved in proliferation, migration, inflammation and cell death. HDACs appear to have a role in innate immunity and adaptive immunity. Thus, new drugs that target HDAC (LD 536, LDT537, and LDT80) were synthesized in order to be verified its antitumor and immunomodulatory properties. Murine macrophages, human monocytes (THP-1), peripheral blood mononuclear cell (PBMC), human breast cancer (MCF-7) and murine (4T1), and leukemia (K562) cell lines were treated in vitro with different HDAC inhibitors (LDT536, LDT537 and LDT80) as targeted anti-cancer drugs at different concentrations. After 24 hours cell viability was analyzed by MTT test. LDT536 and LDT537 compounds induced a significant selective decrease in cell viability non-invasive human breast cancer (MCF-7). The LDT536 decreased the cell viability of THP-1 only in the higher concentration 50 μ M. However, LDT537 showed to be selectively cytotoxic only over leukemia K562 cells. The data show that the drugs LDT536 and LDT537 could be potential drugs to be used in anti-breast and anti-leukemia cancers.

140

Tumour resection in patients with non-small cell lung cancer does not modulate the adaptive immune system in a systemic manner

Cook, A.^{1,2}, Khong, A.^{1,2}, Salmons, J.^{1,2}, Millward, M.^{2,3}, Lake, R.^{1,2}, Nowak, A.K.^{1,2,3}, Robinson, B.W.S.^{1,2}

¹National Centre for Asbestos Related Diseases, Perth, Australia, ²University of Western Australia, School of Medicine & Pharmacology, Perth, Australia, ³Sir Charles Gairdner Hospital, Medical Oncology, Perth, Australia

Tumour resection is widely used to treat patients with early non-small cell lung cancer (NSCLC); however it is often not curative due to subsequent local recurrence or occult distant metastases. We have previously shown in preclinical models that survival outcomes of 75% tumour debulking surgery can be improved by combination with immunotherapy - enabling the adaptive immune system to delay outgrowth of any remaining tumour and having a curative effect in some animals. In the work described

here, our aim was to identify any relevant systemic changes in T cell-mediated immunity resulting from tumour resection in the clinical setting. Pre-surgery (< 1 week) and 1 month post-surgery peripheral blood samples were prospectively collected from 24 consenting adult patients with stage 1a, 1b or 2a operable NSCLC, including adenocarcinoma (15/24) or squamous cell carcinoma (8/24). Peripheral blood mononuclear cells (PBMC) were isolated, cryostored and phenotypically analysed by flow cytometry. Initial results show no significant alterations in the proportion of activated CD8+ T cells or CD4+ regulatory T cells, nor in the expression of activation (ICOS+) or proliferative (Ki67+) markers, after surgical resection. Lymphocyte expression of PD-1 and PD-L1 is currently under investigation and will be reported. We conclude that tumour resection in lung cancer does not modulate systemic adaptive cell-mediated immunity phenotypes, although functional implications remain unknown. This supports the potential for surgery to offer a partnership with immunotherapies such as checkpoint blockade with minimal additional considerations when compared to checkpoint blockade alone.

141

Killed *Klebsiella pneumoniae* activates an organ-specific innate immune response to reduce tumor burden

Costa, A.¹, Perekslis, T.¹, Alexander, M.¹, Sanders, K.¹, Gunn, H.², Fiering, S.¹, Mullins, D.¹

¹Dartmouth College, Microbiology and Immunology, Lebanon, United States, ²Qu Biologics, Vancouver, Canada

Acute infection in a cancer-bearing organ has been associated with improved prognosis and enhanced survival, although the anti-cancer immune mechanisms remain undefined. We hypothesized that stimulating pathogen-specific immunity, using bacteria that have previously infected specific organs, may induce protective anti-cancer immune responses in those target organs. In collaboration with Qu Biologics, we evaluated *Klebsiella*-mediated anti-cancer efficacy in metastatic-like B16 melanoma using heat-killed *Klebsiella pneumoniae* (Qu Biologics' drug product QBKPN Site Specific Immunomodulator [SSI]). Subcutaneous injection of QBKPN SSI significantly reduced tumor burden in mice unexposed to *K. pneumoniae*, and pre-exposure significantly enhanced QBKPN SSI-induced anti-tumor immunity and control of metastatic-like B16 melanoma in the lungs. The anti-tumor efficacy in exposed mice correlated with an influx of monocytes and neutrophils, and is effective in RAG-knockout (lymphocyte deficient) mice, suggesting innate memory may be responsible. Furthermore, subcutaneous treatment with heat-killed *E. coli* (QBECO SSI) reduced lung tumor burden but not as substantially as with QBKPN, suggesting a species-specific response. Collectively, these data suggest pre-exposure to live *K. pneumoniae* may induce an innate memory response that is re-activated upon injection of subcutaneous heat-killed *K. pneumoniae* and induces a potent anti-tumor response in the lungs.

142

Immune escape in primary melanoma*Behren, A.^{1,2}, Paessler, S.¹, Deb, S.¹, Cebon, J.^{1,2,3}, Klein, O.^{1,2}**¹Olivia Newton-John Cancer Research Institute, Cancer Immunobiology, Heidelberg, Australia, ²La Trobe University, School of Cancer Medicine, Heidelberg, Australia, ³Melbourne University, Department of Medicine, Melbourne, Australia*

Tumour infiltrating lymphocytes are prognostic in all stages of melanoma and may also predict as part of an inflamed tumour microenvironment for a response to immunotherapeutic interventions. Melanoma cells can escape the anti-tumour immune response either by immunoselection or immunosuppression, and it is currently not well understood if both processes are mutually exclusive or not. In immune selection, melanoma cells hide from the recognition of CD8⁺ T lymphocytes via downregulation and loss of melanoma specific antigens or components of the HLA class I complex. Alternatively, melanoma cells can escape anti-tumour immune responses by the expression of molecules or immunosuppressive cytokines that inhibit the cytotoxic potential of melanoma-specific T cells by engaging co-inhibitory receptors on their cell surface. One of these molecules, the programmed cell death ligand-L1, PD-L1 has been recognized as an important therapeutic target with monoclonal antibodies blocking the PD-1/PD-L1 interaction demonstrating significant clinical activity in patients with advanced melanoma.

The immune escape mechanisms of melanoma in early stages of the tumour development are currently not well defined. It can be predicted that anti-melanoma immunity is shaped at the initial encounter of the tumour and the host immune system and that this interaction may influence the further disease course and potentially the responsiveness to immunotherapy. Here, we defined the immune microenvironment in early stages of melanoma with a particular focus to discriminate immunoselection and immunoevasion by investigating the expression of PD-L1, HLA-class I and lymphocyte subset infiltration using multi-colour immunofluorescence in a large cohort of primary melanomas (n>50).

143

Regulatory T cells in experimental colon carcinoma: effect of differential ratios of fish oil and corn oil*Malik, R., Agnihotri, N., Bhatnagar, A.**Panjab University, Biochemistry, Chandigarh, India*

The present study highlights effect of different ratios of fish oil (FO) and corn oil (CO) on T regulatory cell populations in rodent model of colon carcinoma.

Male Wistar rats were divided into six groups: Ethylenediamine-tetra acetic-acid (EDTA) treated group, dimethylhydrazine-dihydrochloride (DMH) treated (DMH/week for four weeks), FO:CO(1:1)+EDTA, FO:CO(1:1)+DMH, FO:CO(2.5:1)+EDTA, FO:CO(2.5:1)+DMH. The animals were maintained for 16 weeks after last treatment and sacrificed by cervical dislocation. CD4⁺/CD25⁺/Foxp3 (nTregs), CD4⁺/Foxp3 (iTregs) and intracellular cytokines (IL-6 and IL-10) were analyzed in colonic intraepithelial lymphocytes (IELs).

A significant decrease was observed in nTregs (1.38±0.42%) on DMH treatment whereas iTregs (9.22±2.93%) increased significantly (p<0.001) in this group as compared to control group (8.87±1.96%, 5.35±1.61% respectively). In FO+CO(1:1)+DMH and FO+CO(2.5:1)+DMH both, the Tregs increased significantly as compared to DMH group. In FO+CO(1:1)+DMH group, percentage of nTregs and iTregs was 14.4±2.96 and 13.67±3.15. In FO+CO(2.5:1)+DMH the percentage of nTregs was 16.86±2.58 and iTregs was 16.4±4.15. A significant (p<0.001) increase was observed in IL-10 and IL-6 expression in CD4 cells (13.76±1.96 and 40.37±7.5) on DMH treatment as compared to control group (6.88±0.11 and 9.15±2.3). Treatment with both the ratios of fish oil and corn oil led to a considerable decrease (p<0.001) in IL-10 expression (4.86±0.56 and 1.3±0.31 respectively) and IL-6 expression (25.14±4.8 and 20.05±2.6) with respect to DMH treated group.

The regulatory T cells and their cytokine expression was found to be affected by fish oil & corn oil in isolated IELs from rat colon cancer model in a dose and time dependent manner.

Immunophenotyping breast tissue for the identification of new immune-therapeutic targets for breast cancer*Unsworth, A.¹, Vieusseux, J.¹, Dall, G.^{1,2}, Haynes, N.¹, Anderson, R.¹, Britt, K.¹**¹Peter MacCallum Cancer Centre, East Melbourne, Australia,**²Monash University, Anatomy and Developmental Biology, Clayton, Australia*

Background: Tumor infiltrating lymphocytes have been shown to predict clinical outcome in breast cancer (BCa) patients, leading to the application of several antibody-based immunotherapies for treatment of late stage BCa. The specific immune cell subtypes within the breast tissue responsible for predicting outcome, and their role in the early stages of breast cancer initiation however, has not been addressed. Investigating this area will determine whether currently available immunotherapies are applicable to BCa patients, and may also identify new immunotherapeutic targets for BCa.

Materials and methods: Using the transgenic MMTV-neuT spontaneous model of HER2+ BCa, we assessed the timing of breast cancer progression from hyperplasia through to DCIS and metastatic disease. We developed a mammary specific immunophenotyping FACS panel and used this to assess the immune cell compartment present in the mammary gland during hyperplasia and DCIS.

Results: Our immune profiling revealed an increase in the number of macrophages present in MMTV-neuT mice throughout hyperplasia and DCIS compared to WT mice. These changes are also evident prior to the histological appearance of hyperplasia. Furthermore, dendritic cells are also increased in MMTV-neuT mice during DCIS. We are currently treating these MMTV-neuT mice with anti-CSF-1R monoclonal antibody to deplete macrophages, and block the early stages of breast cancer development. This will allow us to determine the role of macrophages in the initiation and progression of BCa.

Conclusions: This research has identified macrophages and dendritic cells, as new potential targets for the use of immune-based therapeutics to treat early stage HER2+ breast cancer.

145

IFN- γ exposure augments immunoinhibition caused by ganglioside enrichment of dendritic cells*Dillinger, B.¹, Ahmadi, S.¹, Erhart, F.¹, Lau, M.¹, Hölzl, M.A.¹, Jürgens, B.¹, Fuchs, D.², Heitger, A.¹, Ladisch, S.³, Dohnal, A.M.¹**¹Children's Cancer Research Institute, Tumor Immunology, Vienna, Austria, ²Innsbruck Medical University, Division of Biological Chemistry, Innsbruck, Austria, ³Children's National Medical Center, Center for Cancer and Immunology Children's Research, Washington, United States*

Gangliosides, known as biologically active molecules, are shed by tumor cells into their microenvironment (TME). There they can bind and inhibit the function of infiltrating dendritic cells (DCs), central for effective anti-tumor cellular immune responses. We posed the question, whether interferon-gamma (IFN- γ), capable both of priming and boosting DC function, is able to counteract ganglioside inhibitory effects on DCs. Dissecting the effects, we found:

- (i) DC ganglioside exposure reduced LPS/p38 signaling, explaining the previously observed strong down-modulation of factors that drive cellular immune responses including CD80, TNF- α and IL-12.
- (ii) IFN- γ , while strongly increasing LPS-dependent DC responses, did not overcome the inhibitory effect of GD1a.
- (iii) Instead, IRF-1 expression and LPS-independent induction of immunosuppressive indoleamine 2,3-dioxygenase (IDO) indicated that the immunoinhibitory IFN- γ /STAT1-signaling axis was active and unaffected by GD1a ganglioside enrichment.
- (iv) IFN- γ exposure reinforced the strong immune inhibition of LPS/GD1a-treated DCs, resulting in markedly impaired DC potential to stimulate CD8⁺ T-cells.

This combination--potent ganglioside inhibition of IFN- γ -boosted LPS immune stimulation of DCs and retained integrity of IFN- γ -induced immunosuppressive IDO activity--may contribute in creating a tolerogenic microenvironment *in vivo*. These factors, both released by tumors such as glioma, may play a keyrole in triggering clinically relevant immunosuppression. As future work we will validate the interplay of IFN- γ with gangliosides in clinical samples.

Transgenic CAR mice for cancer immunotherapy*von Scheidt, B.^{1,2}, Yong, C.S.M.^{1,2}, Davenport, A.J.^{1,2}, Slaney, C.Y.^{1,2}, Darcy, P.K.^{1,2,3}, Kershaw, M.H.^{1,2,3}**¹Peter MacCallum Cancer Centre, Cancer Immunology Program, East Melbourne, Australia, ²University of Melbourne, Sir Peter MacCallum Department of Oncology, Parkville, Australia, ³Monash University, Department of Immunology, Clayton, Australia*

Adoptive immunotherapy using genetically modified lymphocytes has shown great promise in the treatment of blood cancers in the clinic. However, the challenge of eradicating solid tumours still remains. We developed a transgenic mouse model using a pan-haematopoietic promoter (*vav*) to drive the expression of a chimeric antigen receptor (CAR) specific for the tumour antigen human epidermal growth factor receptor 2 (Her2). This mouse model allows us to study the ability of

different subsets of CAR⁺ cells to mediate anti-tumour activity and their potential role in enhancing immunotherapy against cancer. We also describe two transgenic mouse models which generate dual-specific CAR T cells. T cells in these mice express a Her2-specific CAR as well as either a T cell receptor (TCR) specific for the pre-melanocyte antigen (pMEL, gp100) (CARaMEL) or alternately an OT-I TCR, recognising the ovalbumin peptide SIINFEKL (CAR.OT-I). We found that CAR⁺ cells in all three mouse models were functional and mediated robust antigen-specific responses through proliferation, cytokine release and cytotoxicity, *in vitro* and *in vivo* against Her2-expressing tumours. Our data show that expression of an antigen-specific TCR by dual-specific CAR T cells can induce the expansion of CAR⁺ T cells in the tumour in response to vaccination, thereby enhancing the anti-tumour response. These new CAR mouse models provide a ready source of CAR expressing immune cells for further studies to improve the adoptive immunotherapy against solid cancers.

147

System-level effects of ectopic galectin-7 reconstitution in cervical cancer and their microenvironment*Rincon-Orozco, B.¹, Higareda, J.², Rabinovich, G.³**¹Universidad Industrial de Santander, School of Microbiology, Bucaramanga, Colombia, ²Helmholtz Zentrum München Deutsches Forschungszentrum für Gesundheit und Umwelt, Institute for Diabetes and Cancer, Neuherberg, Germany, ³Instituto de Biología y Medicina Experimental (IBYME), Laboratorio de Inmunopatología, Buenos Aires, Argentina*

Cancer can be conceived as a complex cross talk of molecular networks that are shaped by a particular microenvironment in a spatio-temporal fashion. However, our understanding of how these networks adapt in response to a specific gene expression remains largely unexplored. Such knowledge would be critical to comprehend the role of galectin-7, which is negatively regulated in cervical cancer, and appears to be a link between the apoptotic response triggered by cancer and the surveillance of the immune system to annihilate the malignant cell.

148

Immune cell composition in human non-small cell lung cancer*Stankovic, B.¹, Korsmo, H.A.¹, Müller, E.^{1,2}, Aamodt, H.^{3,4}, Beraki, K.¹, Bækkevold, E.⁵, Woldbæk, P.R.³, Jahnsen, F.³, Øynebråten, I.¹, Corthay, A.^{1,2}**¹Oslo University Hospital-Rikshospitalet, Department of Pathology, Tumor Immunology Group, Oslo, Norway, ²University of Oslo, Department of Biosciences, Oslo, Norway, ³Oslo University Hospital Ullevål, Department of Cardiothoracic Surgery, Oslo, Norway, ⁴Oslo University Hospital-Rikshospitalet, Oslo, Norway, ⁵Oslo University Hospital, Rikshospitalet, Liipat, Department of Pathology, Oslo, Norway*

Lung cancer is the most common cause of cancer related death worldwide. Non-Small Cell Lung Cancer (NSCLC) is the most frequent type, representing about 85% of all lung cancer patients. Presently, the TNM staging, which is based on tumor size and localization, is used for diagnosis and prognosis in

NSCLC. However, previous reports suggest that the analysis of tumor-infiltrating immune cells may represent a more accurate prognostic tool. The aim of this project was to perform comprehensive analysis of tumor-infiltrating immune cells in NSCLC using flow cytometry, as a first step to understanding the relationship between tumor-infiltrating immune cells and clinicopathological parameters. We used 10-color flow cytometry to investigate immune cells in tumors, distant lung tissue, lymph node, and peripheral blood, from 67 patients with primary NSCLC. The following populations of tumor-infiltrating immune cells were identified: CD4⁺ T cells, CD8⁺ T cells, each with memory and naive phenotypes; CD19⁺ B cells, with naive, memory, germinal center and plasma cell subsets; CD14⁺ macrophages, CD123⁺ plasmacytoid dendritic cells, CD11c⁺CD1c⁺ dendritic cells (DCs), and CD11c⁺CD141⁺ DCs, CD3⁺CD56⁺ natural killer T cells (NKT), CD56⁺ natural killer (NK) cells, with CD16⁺ and CD16⁻ subsets, and all four granulocyte populations. Statistical analysis revealed increased percentage of CD45⁺ leukocytes within tumors compared to distant lung tissue. Among leukocytes, B cells showed increased frequency in tumor compared to the distant lung ($p=0.0001$). This suggests that the tumor microenvironment of NSCLC recruits immune cells and has a different immunological structure compared to normal lung tissue.

149

Distribution of the potential target for immunotherapy BTN2A1 in cancer and normal tissues

Tutuka, C.¹, Hudson, C.¹, Woods, K.¹, Prato, S.², Panousis, K.², Maraskovsky, E.², Cebon, J.¹, Behren, A.¹

¹Olivia Newton-John Cancer Research Institute, Cancer Immunology, Heidelberg, Australia, ²CSL Limited, Parkville, Australia

Cancer immunotherapy targets immune-regulatory signal molecules such as the programmed cell death receptor PD-1 or its ligand PD-L1 and cytotoxic T lymphocyte antigen CTLA4. Clinical trials have shown encouraging outcomes including durable responses first seen in melanoma. However, a subset of patients does not respond.

With the success of these therapies and the deeper understanding of the immune-system and its regulation in the context of cancer, more and more potential immune-regulatory molecules are being discovered and examined. We recently discovered one of these molecules following a high-throughput screen for novel tumor antigens in melanoma in collaboration with CSL Limited. The screening outcome led to the discovery of a protein belonging to the Butyrophilin (BTN) family on the surface of melanoma cells called BTN2A1. BTN2A1 shares sequence and structure similarity to the B7 family of immune-regulatory molecules, which include B7-1 and B7-2 in mice. The purpose of this project was to evaluate BTN2A1 expression in human cancers. We have found that BTN2A1 was generally more highly expressed in cancer cells compared to their normal tissue counterparts. BTN2A1 had high levels of membrane expression in 8/10 melanomas tested and was over expressed in 9/9 pancreatic adenocarcinomas, 8/15 hepatocellular carcinomas, 14/24 breast and 6/14 prostate cancers.

Multiplex fluorescent immunohistochemical staining with

the VECTRA (Perkin Elmer®) system also enables staining of multiple immune markers. In ongoing studies we are evaluating the expression patterns and spatial relationships of different immune-regulatory molecules such as BTN2A1 and PD-L1 within the same tumour samples.

Reduction of gastric cancer proliferation and invasion by miR-15a mediated suppression of Bmi-1 translation

Wu, C.¹, Zheng, X.², Li, X.³, Fesler, A.⁴, Hu, W.¹, Chen, L.², Xu, B.², Wang, Q.², Tong, A.⁵, Burke, S.⁴, Ju, J.⁴

¹The Third Affiliated Hospital of Soochow University, Department of Oncology, Changzhou, China, ²The Third Affiliated Hospital of Soochow University, Department of Biological Treatment, Changzhou, China, ³The Third affiliated Hospital of Soochow University, Department of Oncology, Changzhou, China, ⁴Stony Brook University, Translational Research Laboratory, Department of Pathology, New York, United States, ⁵BioGenex Inc, Fremont, United States

B-cell specific moloney leukemia virus insertion site 1 (Bmi-1) gene plays important roles in gastric cancer, but the epigenetic regulatory mechanism by microRNA (miRNA) and the functional significance of Bmi-1 inhibition in gastric cancer remains elusive. In this study, we systematically investigated the functional roles of miRNA mediated Bmi-1 suppression in gastric cancer. Our results show that the expression of miR-15a is significantly reduced in gastric cancer and the protein expression levels of Bmi-1 are inversely correlated with miR-15a ($P=0.034$) in gastric cancer patientsamples. Functional studies revealed that ectopic expression of miR-15a decreased Bmi-1 in gastric cancer cell lines with reduced proliferation and tumor invasion. High levels of Bmi-1 in gastric cancer patients are significantly associated with better overall survival ($P=0.02$) based on the Kaplan-Meier survival analysis.

High-dose vitamin C modulates CXCR4/CXCR7/CXCL12 chemokine receptor/ligand axis in MDA-MB-231 breast cancer cells

Akekawatchai, C.¹, Changsri, K.¹, Soymanee, T.¹, Fungkrajay, M.¹, Tuntipopipat, S.²

¹Faculty of Allied Health Sciences, Thammasat University, Department of Medical Technology, Pathumthani, Thailand, ²Institute of Nutrition, Mahidol University, Nakornpathom, Thailand

High-dose ascorbic acid as a treatment for cancer has recently been reexamined and mechanisms underlying its anti-tumor activity are still unclear. CXCR4/CXCR7/CXCL12 chemokine system has been demonstrated to participate in natural selection of breast cancer cells in invasion and metastasis. Functional CXCL12 expression appears to promote invasiveness and apoptosis in the cells. Therefore, this study aimed to examine an effect of high-dose ascorbic acid, potentially achieved by clinical intravascular injection, on expression and function of CXCR4/CXCR7/CXCL12 system in MDA-MB-231 breast cancer cells. The cells were characterized for their response to ascorbic acid in

clinical relevant conditions and expression of CXCR4, CXCR7 receptors and CXCL12 ligand by real-time PCR, immunostaining and flow cytometry, and ELISA. The data showed that there was up to approximately 50% reduction of viability of the treated-MDA-MB-231 cells. Analysis by annexin V-PI stain and flow cytometry, and activated caspase detection assay indicated that the decrease of cell survival was due to apoptosis. In this cell line, a strong constitutive expression of CXCR4 was observed whereas CXCR7 and CXCL12 were weakly expressed. Ascorbic acid treatment caused a significant increase of CXCL12 secretion and induction of CXCR7 expression, while CXCR4 remained highly expressed in the treated cells. Blocking CXCL12 ligands by the selective inhibitor chalcone 4 decreased ascorbic acid-induced apoptosis of the cells. Our findings indicated that high-dose ascorbic acid modulates CXCR4, CXCR7 and CXCL12 expression, potentially affecting the selection processes in metastasis of breast cancer cells, and are useful for therapeutic application of high-dose vitamin C in cancer.

152

The role of NADPH oxidase 2 on M2 tumor-associated macrophages differentiation in pancreatic cancer progression

Chen, C.-J.¹, Hou, Y.-C.¹, Wang, H.-C.¹, Shieh, C.-C.^{1,2}, Shan, Y.-S.^{1,3}
¹National Cheng Kung University, Tainan, Taiwan, Republic of China, ²National Cheng Kung University Hospital, Pediatrics, Tainan, Taiwan, Republic of China, ³National Cheng Kung University Hospital, Surgery, Tainan, Taiwan, Republic of China

M2 Tumor-associated macrophages (M2-TAMs) are a dominant component of inflammatory cells in the tumor microenvironment and have been shown to promote tumor development and progression. Reactive oxygen species (ROS) have been reported essential for differentiation of TAMs. In this study, we aimed to explore the role of NADPH oxidase 2 (NOX2) in M2-TAMs differentiation. After orthotopically inoculated cancer cells (KPC) from Pdx-Cre Kras^{G12D/+}p53^{-/-} mice into the pancreas of *Cybb*^{-/-} and wild type mice, the tumor size was significantly smaller in *Cybb*^{-/-} mice than in wild type mice. Interestingly, the expression of mouse M2-TAM markers CD206 and YM1 was also reduced in pancreatic tumors of *Cybb*^{-/-} mice, suggesting that knockout of *Cybb* gene to downregulate NOX2 function could impede M2-TAMs formation and inhibit tumor growth. Then bone marrow cells isolated from the *Cybb*^{-/-} mice were stimulated using GM-CSF to differentiate into macrophages. After co-cultured with KPC cells, the *Cybb*^{-/-} mice-derived macrophages failed to skew M2-TAMs. In conclusion, our study demonstrates that CYBB gene function is required for M2-TAMs differentiation and may be a potential therapeutic target for pancreatic cancer treatment.

Modulating T-cell cholesterol metabolism to treat cancer

Yang, W., Bai, Y., Xu, C.

Institute of Biochemistry and Cell Biology Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China

CD8+ T cells play a central role in antitumour immunity, but their activity is suppressed in the tumour microenvironment. Reactivating the cytotoxicity of CD8+ T cells is of great clinical interest in cancer immunotherapy. Here we report a new mechanism that the antitumour response of CD8+ T cells can be potentiated by modulating cholesterol metabolism. Upon activation, T cells undergo a reprogramming of cholesterol metabolism to support acquisition of effector function and fast proliferation. Inhibiting cholesterol esterification leads to potentiated effector function and enhanced proliferation of CD8+ T cells. This is attributed to the elevation of the plasma membrane cholesterol level of CD8+ T cells that causes enhanced T-cell receptor clustering and signalling as well as more efficient formation of immunological synapse. CD8+ T cells with impaired cholesterol esterification showed better effect in controlling melanoma growth and metastasis in mice than wild-type CD8+ T cells. We further show that a small molecule inhibitor of cholesterol esterification has good antitumour effect in preclinical models. A combined therapy of the inhibitor and α -PD-1 antibody showed better efficacy than monotherapies in controlling tumour progression. Modulating T-cell cholesterol metabolism is therefore a promising new strategy to treat cancer.

154

Immunotherapy of solid tumours using complete Freund's adjuvant

Carroll, C.S.E.¹, Andrew, E.R.¹, Neeman, T.², Fahrer, A.M.¹

¹Australian National University, Research School of Biology, Acton, Australia, ²Australian National University, ANU Statistical Consulting Unit, Acton, Australia

The field of cancer immunotherapy aims to modulate immune responses to enhance tumour destruction. The aim of this project is to investigate the efficacy of an immunotherapeutic cancer vaccine. The hypothesis is that injecting a strong immunostimulant directly into tumours can induce an anti-tumour immune response (Fahrer, 2012). Mice bearing subcutaneously injected tumours were treated with intratumoural CFA. Tumours were measured regularly, and immune infiltrates in tumours were collected at pre-determined time points by fine needle aspiration and analysed by flow cytometry. Fine-needle aspiration allowed us to investigate the time course of immune cell infiltration and then correlate it to survival data. CFA treatment of P815 mastocytomas resulted in a statistically significant survival increase and a reduction in tumour growth rate (p-value < 0.0001, < 0.0001 respectively). CFA treatment also resulted in a reduced incidence of mice with observable liver metastases at necropsy (p-value 0.0121). In the P815 model, increased survival was correlated to increased infiltration of neutrophils into tumours on days 1-5 post-treatment. Neutrophil depletion abrogated CFA treatment efficacy.

155

Tim-3, a negative player in liver tumor microenvironment*Ma, C.**Shandong University School of Medicine, Jinan, China*

Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide that accounts for half a million deaths per year. Accumulated data highlighted the important role of tumor microenvironments in the progression of HCC. Liver is rich of innate immunes such as NK cells and macrophages which constitute the important stromal components of tumor microenvironments. T cell immunoglobulin and mucin-domain containing protein-3 (Tim-3) has been recognized as a key negative regulator of

T cell-mediated responses, and abundant Tim-3 expression has also been demonstrated in both NK cells and macrophages. In the present study, we investigated the expression pattern and the roles of Tim-3 in tumor infiltrated macrophages and NK cells in HCC. Augmented Tim-3 expression was detected on tumor associated macrophages (TAMs) and tumor infiltrated NK cells (TINK) from HCC patients and orthotopic transplanted mice model of liver tumor. The increased Tim-3 expression on TAM negatively correlated with survival of HCC patients. Interference of Tim-3 expression in NK cells or macrophages suppressed HCC growth. In vitro study showed that Tim-3 expression was promoted by TGF- β . Tim-3 blocking greatly enhanced NK cells cytotoxicity and IFN- γ /TNF- α production. Moreover, Tim-3 enhanced the TGF- β mediated alternative activation of macrophages, which might be due to the reduced production of IL-6 in macrophages. These data suggest Tim-3 as the potential target in HCC immunotherapy which might both booster NK cells-mediated antitumor immunity and revise macrophages-induced immunosuppression in tumor microenvironments.

The impact of microbiota on the efficacy of immune checkpoint blockade*Duong, C.^{1,2}, Vétizou, M.^{1,2}, Zitvogel, L.^{1,2,3,4}*

¹Gustave Roussy Cancer Campus, Villejuif, France, ²INSERM Unit U 1015, Villejuif, France, ³Université Paris-Saclay, Faculté de Médecine, Le Kremlin-Bicêtre, France, ⁴Center of Clinical Investigations in Biotherapies of Cancer, Villejuif, France

The curative potential of immunotherapy has been demonstrated through the combined targeting of the immune checkpoints CTLA4 and PD1. Accordingly, ipilimumab and nivolumab have recently been approved in metastatic melanoma following reported clinical response rates of 60%. However, reports of immune-related adverse events are concerning, these often occurring at sites exposed to commensal microbiota. Recent studies have demonstrated the importance of gut microbiota to the efficacy and toxicity of CTLA4 and PDL1 blockade. Therefore, we hypothesise that the efficacy and toxicity of combined CTLA4 and PD1 blockade is also dependent on microbiota. To test this, mice were treated with or without a cocktail of antibiotics (ATBx),

inoculated with either MCA205 sarcomas or the melanoma cell line RET, and treated with α -CTLA4, α -PD1, or a combination of both Abs. Interestingly, we also observed a decrease in overall survival (MCA205) and tumour growth (RET) in ATBx-treated mice receiving the combination therapy. We will next determine whether specific bacteria identified to improve the efficacy of CTLA4 and PDL1 blockade in mice are able to compensate for the lack of microbiota in our combination. Various organs, including lymph nodes and spleen will be analysed by flow cytometry to assess changes in the immune status and gut pathology will be assessed for toxicity by immunohistochemistry. This project will evaluate which species of microbiota are involved in the efficacy and toxicity of immune checkpoint inhibitors and will enhance our understanding of their mechanism of action, enabling better prediction of patients susceptible to treatment-related toxicity.

157

Transmissible cancers and the immunogenic role of *Trypanosoma cruzi* calreticulin*Cruz, P.¹, Torres, C.², Ferreira, A.¹*¹University of Chile, Faculty of Medicine, Immunology, Santiago, Chile,²University of Chile, Faculty of Veterinary Medicine, Santiago, Chile

Transmissible cancers are important due to both their capacity to be easily transmitted among allogenic individuals, and their significant potential of endangering wildlife. Canine transmissible venereal tumor (CTVT) and the devil facial tumor disease (DFTD) are transmissible cancers naturally occurring in dogs (*Canis lupus familiaris*) and Tasmanian devils (*Sarcophilus harrisi*), respectively. CTVT cells evade the host immune system by secreting TGF- β 1 and downregulating the expression of MHC class I molecules in tumor cells. Furthermore, tumor-secreted TGF- β 1 downregulates cell-mediated cytotoxicity by impairing IFN- γ secretion by T and natural killer cells. Treatments of CTVT and DFTD are complex (e.g. vincristine treatment is effective only in CTVT and recurrences are frequent). Therefore, in order to promote tumor rejection, new therapeutic or prophylactic alternatives are needed, especially in Tasmanian devils, which are under severe conservation threat due to DFTD. We have determined that *Trypanosoma cruzi* (the agent of American trypanosomiasis) calreticulin (TcCRT), an endoplasmic reticulum (ER) resident chaperone, is a potent anti-angiogenic and anti-tumor agent. (Indeed, TcCRT can be translocated from the ER to the parasite exterior). We have also cloned and expressed recombinant TcCRT (rTcCRT). Currently we investigate whether TcCRT promotes tumor rejection by increasing the immunogenicity of CTVT cells. We now assess the rTcCRT binding to the surface of cultured CTVT cells, with subsequent and consequent binding of complement component C1q, which opsonizes cancer cells for engulfment by dendritic cells (DCs). In the regional lymph nodes these DCs will promote cytotoxic

T cell responses will resulting significant tumor growth inhibition.

158

The critical role of macroautophagy for MHC class II presentation of tumor antigens by dendritic cells

Oh, D.S., Lee, H.K.

KAIST, Daejeon, Korea, Republic of

Autophagy has been implicated in the presentation of cytoplasmic and viral antigens on MHC class II molecules. However, the role of the autophagic process in the presentation of phagocytized tumor associated antigens (TAAs) *in vivo* remains unclear. Following administration of apoptotic tumor antigen, mice with a dendritic cellspecific deletion of Atg5, which is a key autophagy gene, exhibited reduced CD4+ cell priming, but not CD8+ cytotoxic T cell priming. Atg5 deficient dendritic cells have a defect in the MHC class II processing and presentation of phagocytized tumor antigens. In contrast, Atg5 is not essential for crosspresentation of peptides on MHC class I molecules in dendritic cells or macrophages. Further, Atg5 deficient dendritic cells and macrophages had elevated mRNA expression of class A scavenger receptors and showed increased phagocytosis of apoptotic tumor cells. Thus, our study demonstrated that dendritic cells utilize autophagic machinery to process and present apoptotic tumor antigens for MHC class II presentation.

159

Autologous bone marrow Th cells can support multiple myeloma cell proliferation *in vitro* and *in vivo*

Wang, D.^{1,2}, Fløisand, Y.³, Tveita, A.⁴, Bürgler, S.⁵, Parente-Ribes, A.⁴, Hofgaard, P.⁴, Schjesvold, F.⁴, Szodoray, P.⁴, Nakken, B.⁴, Bogen, B.^{2,4,6}, Tjønnfjord, G.^{2,3}, Dalgaard, J.^{3,7}, Munthe, L.^{2,4}

¹Oslo University Hospital-Rikshospitalet, Institute of Immunology/Centre for Immune Regulation, Oslo, Norway, ²Institute of Clinical Medicine, University of Oslo, Oslo, Norway, ³Oslo University Hospital, Dept. of Hematology, Oslo, Norway, ⁴Centre for Immune Regulation, Oslo University Hospital, Dept. of Immunology, Oslo, Norway, ⁵Swiss Experimental Infectious Diseases and Cancer Research, University Children's Hospital, Zurich, Switzerland, ⁶KG Jebsen Centre for Influenza Vaccine Research, Institute of Clinical Medicine, University of Oslo, Oslo, Norway, ⁷Vestre Viken Trust, Drammen Hospital, Dept. of Medicine, Oslo, Norway

Multiple myeloma (MM) is a cancer of end-differentiated B cells (plasma cells). MM cell growth is supported by the microenvironment by poorly defined cellular and molecular mechanisms. MM cells express CD40, a receptor known to activate autocrine secretion of cytokines and proliferation. However, the source of CD40 ligand has been unclear. Here we show that activated autologous T helper (Th) cells can support MM cell growth *in vitro* and *in vivo*. CD40-activated MM cells secreted cytokines that attracted Th cells, suggesting that MM cells actively recruit Th cell partners. MM cells had retained sufficient antigen presentation function to activate Th cells and engage in a MM cell - Th cell collaboration. The results suggest that Th cells may support the expansion of MM cells in patients and that such a mechanism may be a caveat in terms of treatment of multiple MM patients with check-point inhibitors.

Inhibitory activity and major effective compounds of the products converted from glucose by *Phomopsis sp.* XP-8 resting cells

Shi, J.¹, Li, Q.¹, Zhang, Y.², Wang, Y.¹, Huang, Q.¹, Shao, D.¹

¹Northwestern Polytechnical University, School of Life Sciences, Xi'an, China, ²Northwest A&F University, College of Food Science and Engineering, Yangling, China

Resting cells of *Phomopsis sp.* XP-8, an endophytic fungus isolated from *Eucommia ulmoides* Oliver, were previously found to have capability to convert glucose into pinoresinol (Pin), a plant-derived lignin that has multiple functions including potential of anti-tumor. Inhibition effects on HepG-2 and K562 cells of the culture broth of *Phomopsis sp.* XP-8 resting cells in glucose solution were assessed and the major effective compounds were identified in this study. As results, the culture broth significantly inhibited HepG-2 and K562 cells by decreasing their viability and inducing apoptosis via up-regulated the expression of apoptosis related genes. It also significantly inhibited HepG-2 cells adhere to the plate, and inhibited them migrate by blocking the expression of MMP-9. After separately evaluating the inhibitory activity of each compound detected in the culture broth, Pin and pinoresinol monoglucoside were identified as the major effective components. Methoxyquercetin also found in a high amount but did not show inhibitory effects on tumor cells. The results indicated the potential application of *Phomopsis sp.* XP-8 in producing anti-tumor products by bioconversion of glucose.

Tumor-infiltrating T-cells of ovarian cancer express markers associated with functional impairment

Rådestad, E.¹, Klynning, C.², Mattsson, J.^{1,3}, Norström, M.M.⁴, Sundberg, B.¹, Levitsky, V.⁵, Uhlin, M.^{1,3,6}

¹Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden, ²Karolinska University Hospital, Department of Gynaecology, Stockholm, Sweden, ³Karolinska University Hospital, Centre for Allogeneic Stem Cell Transplantation, Stockholm, Sweden, ⁴Pharmaceutical Sciences (PS), Roche Pharmaceutical Research and Early Development (pRED), Roche Innovation Center, Basel, Switzerland, ⁵Molecular Partners AG, Schlieren-Zurich, Switzerland, ⁶Royal Institute of Technology, Department of Applied Physics, Stockholm, Sweden

Suppression of immune reactivity by increased expression of co-inhibitory receptors has been discussed as a major reason as to why the immune system fails to control tumor development. Elucidating the co-inhibitory pattern of tumor-infiltrating lymphocytes in different cancer types is of great importance for development of future treatment strategies.

We performed an extracellular characterization with primary focus on coinhibitory and co-stimulatory receptors on T-cells freshly isolated from blood, tumor-associated ascites, and metastatic tumor tissue from ovarian cancer patients (n=24) at late-stage disease (III-IV).

The results showed significantly higher frequencies of T-cells expressing co-inhibitory receptors LAG-3 (median 9.4%), PD-1 (62.6%), TIM-3 (7.5%), and CTLA-4 (4.0%) in tumor tissue

compared to T-cells isolated from blood (0.8%, 13.4%, 0.1%, and 0.7% respectively). The frequency of T-cells lacking expression of LAG-3, PD-1, and TIM-3 were decreased in tumor tissue (35.4%) and ascites (59.5%) compared to blood (87.0%). A significantly higher frequency of potential regulatory T-cells (CD4⁺/CD25^{high}CD127^{-low}) was observed in both tumor tissue (24.1%) and ascites (12.6%) compared to blood (5.7%). Analysis of soluble factors by Luminex revealed higher concentrations of G-CSF, IL-5, IL-6, IL-8, IL-10, IP-10, MCP-1, MIP1a, MIP1b, and TNF- α in ascites compared to blood.

Our data confirms that the late stage metastatic ovarian tumor environment exhibits an inflammatory milieu with abundant presence of infiltrating immune cells expressing co-inhibitory receptors. Clinical data and functional studies are necessary to obtain insight into the anti-tumor reactivity of these cells, elucidate the observed heterogeneity between patients, and evaluate possible novel treatment strategies such as checkpoint inhibitors.

162

Assessment of checkpoint blockade combined with NKT cell-dependent glycolipid-peptide vaccines

Petley, E.V.^{1,2}, Osmond, T.L.¹, Farrand, K.J.¹, Tang, C.¹, Ancelet, L.R.¹, Anderson, R.J.³, Painter, G.F.³, Hermans, I.F.¹

¹Malaghan Institute of Medical Research, Wellington, New Zealand, ²Victoria University of Wellington, School of Biological Science, Wellington, New Zealand, ³Ferrier Research Institute, Wellington, New Zealand

While inhibition of immune checkpoints treatments have validated the concept of enhancing T cell-mediated immune responses for cancer treatment, it is clear that not all patients respond. Therefore, there is considerable interest in whether the use of vaccines can improve responses to checkpoint blockade, particularly in patients that do not have pre-existing anti-tumour immunity. Here we generated a new synthetic cancer vaccine conjugating the tumour-associated antigen survivin to an isomer of α -Galactosylceramide (α -GalCer), a potent invariant natural killer T (iNKT) cell agonist with documented adjuvant activity. Upon antigen encounter, activated iNKT cells are capable of licensing dendritic cells (DCs) through CD40-CD40L interaction to stimulate potent anti-tumour CD8⁺ T cell responses. Conjugation of α -GalCer to the survivin-derived peptide was achieved via an enzymatically cleavable linker sensitive to cathepsin B activity. This strategy thereby favours the co-presentation of both active components on the same DC. We combined our vaccine with the immune-checkpoint blockade inhibitors α -PD-1, α -CTLA-4, α -LAG-3 and α -CD40, in an implantable mouse model of glioma, to fully reveal the immunogenicity of our vaccine. Our preliminary data demonstrates that combining the conjugate vaccine with α -CTLA-4 improved tumour clearance compared to α -CTLA-4 monotherapy in an implantable mouse model of glioma, suggesting that this combination may be a useful therapy for patients with glioma.

163

Immune infiltrates in murine solid tumour models treated with bacterial based cancer immunotherapies

Andrew, E.¹, Carroll, C.¹, Schulte, K.-M.², Neeman, T.³, Fahrer, A.¹

¹The Australian National University, Research School of Biology, Acton, Australia, ²The Australian National University, The John Curtin School of Medical Research, Acton, Australia, ³The Australian National University, Statistical Consulting Unit, Acton, Australia

Our lab is testing a novel, simple cancer immunotherapy: intra-tumoural injection of Complete Freund Adjuvant (CFA). CFA contains heat-killed mycobacteria in oil which is emulsified into a water-in-oil emulsion. Our hypothesis is that, due to the Pathogen-associated Molecular Patterns (PAMPs) present on the mycobacterium, CFA will stimulate a strong anti-tumour immune response when injected directly into the solid tumour. Coley's toxins, heat-killed preparations of *Streptococcus pyogenes* and *Serratia Marcescens* used by Dr William Coley in the early 19th Century, may also work by this mechanism. Previous work in the Fahrer lab analysing the anti-tumour effect of CFA on a murine mastocytoma model revealed that CFA increases survival of treated mice. Using the novel technique of repeated fine needle aspiration (FNA) combined with flow cytometry we are able to monitor tumour infiltrates in individual mice over time. Currently we can analyse the distribution of 7 immune cell subtypes for 8 time points per mouse, thus linking changes of immune cell subtypes with the survival of our mice. This technique allows us to distinguish the immune infiltrates resulting from bacterial based immunotherapies in multiple solid tumour types. We have associated survival with high levels of neutrophils between 1-5 days after CFA injection in mastocytoma. The aim of this study is to analyse the immune infiltrates and compare the efficacy of CFA and Coley's toxins in multiple murine tumour models. The results of this study are presented.

164

Simple and effective tumour immunotherapy using intratumoural complete Freund's adjuvant

Fahrer, A.¹, Carroll, C.¹, Andrew, E.¹, Orange, M.², Allavena, R.³

¹The Australian National University, Research School of Biology, Acton, Australia, ²Arlesheim Klinik, Onkologie, Arlesheim, Switzerland, ³University of Queensland, School of Veterinary Science, Gatton, Australia

We demonstrate that intra-tumoural injection of Complete Freund's Adjuvant can result in a potent anti-tumour immune response.

In order to test the efficacy of this treatment, we have initiated pre-clinical trials in three species: mice, dogs and horses. Efficacy has been demonstrated in a range of solid tumours, including mastocytoma, mammary tumours and melanoma. Complete tumour regressions have been observed in all three species. Evidence of systemic immune responses (regression of non-injected metastases) have also been observed. We characterise the immune cells infiltrating mouse tumours after treatment. Finally we provide case reports on the treatment of four human cancer patients; suffering from lung cancer, metastatic

osteosarcoma, or breast cancer, with one patient having a partial response to treatment with intra-tumoural Complete Freund's Adjuvant.

Taken together, our data demonstrate that our treatment has major anti-tumour effects in a proportion of treated animals, and is safe for use in human cancer patients. Further trials in human cancer patients are therefore strongly warranted. Our novel treatment provides a simple and inexpensive cancer immunotherapy, applicable to a wide range of solid tumours, and of potential benefit to cancer patients around the world, including patients from developing countries.

165

Cancer vaccine design based on tumor cell lysates and adjuvants

Salazar-Onfray, F.

Universidad de Chile, Facultad de Medicina, Santiago, Chile

Dendritic cells (DCs) loaded with tumor-associated antigens (TAAs) have emerged as promising immunological tools for cancer therapy due to their abilities to stimulate the antitumor response and trigger immunological memory in cancer patients. Nevertheless, an important percentage of patients treated with DCs remain refractory. The optimal delivery of antigens (Ags) to DCs is a relevant aspect for vaccine success. Indeed, antigen peptides, tumor-associated proteins, tumor cells, autologous tumor lysates, and tumor-derived mRNA have been tested as antigen sources. We have previously shown that DCs loaded with allogeneic tumor cell lysates can induce a potent immunological response in melanoma and prostate cancer patients. This strategy provides a reproducible pool of almost all potential Ags, suitable to be used in a broad number of patients independently of their MHC haplotypes or the availability of autologous tumor tissue. However, the development of an optimal autologous tumor cell lysate preparation is crucial to enhance the efficacy of these approaches. Additionally, Ag-presenting cells, used as DC-vaccines, possess innate-related receptors that sense molecular signatures derived from pathological microenvironments as well as stressed cancer cells, thus helping in triggering anti-cancer immune responses. Calreticulin cell surface mobilization, and HGBM1 release during stress are close related to DCs activation through TLR4. Combination of stressed tumor cell lysates together with different adjuvants is strongly immunogenic, as we show in a melanoma model using immunological competent mice. This approach may constitute a useful strategy for melanoma, prostate and gallbladder cancer vaccines that can be associated with prolonged survival of cancer patients.

166

Effect of new oncogene-targeted therapies on NK cell function

Manzini, C.¹, Venè, R.², Cossu, I.¹, Queirolo, P.², Moretta, L.³, Mingari, M.C.⁴, Pietra, G.⁴

¹IRCCS Istituto G. Gaslini, Genova, Italy, ²IRCCS San Martino/IST, Genova, Italy, ³IRCCS Bambin Gesù Hospital, Roma, Italy, ⁴University of Genova-IRCCS AOU San Martino-IST, DIMES, Genova, Italy

Oncogene-targeted therapies based on mutant BRAF-specific inhibitors and/or MEK inhibitors have recently been developed for melanoma treatment. Although these targeted drugs induce tumor regression in a high percentage of patients, clinical responses are frequently narrow in time. Understanding the impact of these targeted therapies on immune cell function is an important area of research as the oncology field moves to combinations of targeted drugs with immunotherapies. Natural killer (NK) cells are suitable effector cells in tumor immunotherapy. Thus in this study, we investigated whether Vemurafenib (a BRAF^{V600} inhibitor) and PD0325901 (a MEK inhibitor) could interfere with NK cell function.

Vemurafenib has no effect on the phenotypic and functional properties of peripheral blood NK cells cultured in the presence of IL-2 or IL-15. In contrast, the PD0325901-induced MEK inhibition reduces NK cell proliferation and down-regulates the main activating NK receptors resulting in inhibition of NK cell function. However, interestingly, the inhibitory effect of PD0325901 can be overridden if NK cell are activated in the presence of IL-15+IL-18, or pre-activated with IL-2 or IL-15. Finally, given that BRAF/MEK co-inhibition is a possible clinical practice, the combination of BRAF and MEK inhibition was also tested in this study.

Our data may offer a rationale for future trials that combine IL-15/IL-18 cytokine administration with MAPK inhibitors. In addition, they suggest that both these drugs may represent synergistic tools to improve the efficacy of NK cell-based adoptive therapy.

167

Andosan™ extract of the immunomodulating and antitumor mushroom *Agaricus blazei*, protects against development of intestinal cancer in the APC Min^{+/-} mouse model for colorectal cancer

Hetland, G.¹, Eide, D.M.², Tangen, J.M.³, Haugen, M.H.⁴, Mirlashari, M.R.³, Paulsen, J.E.⁵

¹Oslo University Hospital, Immunology, Oslo, Norway, ²Norwegian Institute of Public Health, Oslo, Norway, ³Oslo University Hospital, Oslo, Norway, ⁴Oslo University Hospital -The Norwegian Radium Hospital, Tumor Biology, Oslo, Norway, ⁵Norwegian University of Life Sciences, Food Safety and Infection Biology, Oslo, Norway

Similar to human Familial Adenomatous Polyposis, APC^{Min/+} mice have a deletion in the *apc* gene, giving spontaneous rise to multiple intestinal polyps that develop into adenocarcinomas. *Agaricus blazei* Murill (AbM) is an edible *Basidiomycetes* mushroom used in traditional medicine against cancer and other diseases. The mushroom is rich in immunomodulating β-glucans and has antitumor effects in murine models for fibrosarcoma, ovarian-, lung - and prostate cancer. Andosan™ is a water extract based on AbM (82%), also containing medicinal *Basidiomycetes* mushrooms, *Hericeum erinaceus* and *Grifola frondosa*. Tap water with 10% Andosan was provided as drinking water for 4.5 months to APC^{Min/+} mice and wild-type mice, which then were exsanguinated, their intestines preserved in formaldehyde and the serum frozen. The intestines were examined blindly by microscopy and also stained for the pro-inflammatory and metastasis-promoting protease, legumain. Serum cytokines (pro- and anti-inflammatory, Th1-, Th2 -and

Th17 type) were measured by Luminex analysis. Andosan treated APC^{Min+/-} mice had significantly fewer adenocarcinomas in both the small intestines and colon, and a 60% significantly reduced tumor load (# tumors x size). There was also reduction in legumain content in intestines from Andosan-treated animals. Moreover, Andosan had a significant cytotoxic effect in vitro on the human cancer colon cell line, CaCo2. However, there were no differences in serum cytokine levels between treated and untreated APC^{Min+/-} mice, and no correlations between cytokine level and tumor load. Interestingly, there was an increase in pro-inflammatory cytokine levels in Andosan-treated wild type mice that was not observed for the APC^{Min+/-} mice.

168

Pediatric B- and T-ALL minimal residual disease levels in Turkey

Cinar, S., Yilmaz, A., Gelmez, M.Y., Tahrali, I., Ozcit, G., Deniz, G. Institute of Experimental Medicine, Istanbul University, Immunology, Istanbul, Turkey

In patients with acute lymphoblastic leukemia (ALL), treatment response is increasingly evaluated with minimal residual disease (MRD) assays. Assessment of MRD by flow cytometry is faster and cheaper when compared to molecular methods and it is the main reason for utilization in many centers.

In this study, paired bone marrow samples from diagnosis and early follow up from 454 consecutive B-cell precursors ALL and 71 consecutive T-ALL cases were analyzed. Blasts were detected in bone marrow samples of ALL patients on the 15th day of treatment and MRD ratio and relapse risk were evaluated. For B-ALL MRD detection, CD10, CD11a, CD19, CD20, CD34, CD38, CD45 and CD58 expression levels were determined by 4-color flow cytometry. For T-ALL MRD detection CD45, CD3, CD4, CD5, CD7, CD8, CD99, cytoplasmic CD3 and cytoplasmic TdT antigen expressions in samples were detected by 8-color flow cytometry. According to MRD risk in B-ALL diagnosis of 153 cases was FLR (33.70%), 232 cases were FMR (51.10%) and 69 cases were FHR (15.20%); In T-ALL 24 cases were FLR (33.80%), 27 cases were FMR (38.03%) and 20 cases were FHR (28.17%).

MRD is now used in several clinical trials for risk assignment and to guide clinical management overall. Further studies, to investigate relationship between prognosis and survival or correlation of PCR and MRD findings in more detailed studies with contribution of clinics will be more supportive to apply sensitive and accuracy therapy in either B-ALL or T-ALL patients.

169

CTLA-4 positive breast cancer cells inhibit dendritic cells function and the reverse effect of anti-CTLA-4 antibody therapy

Chen, X., Hao, S., Shao, Q., Zhao, Z., He, Y., Gao, W., Mao, H. Qi Lu Hospital, Shandong University, Institute of Basic Medical Sciences, Jinan, China

Cytotoxic T lymphocyte-associated antigen 4 (CTLA-4) expressed by T lymphocytes is traditionally known as a potent immunoregulatory molecule that down-regulates T-cell activation and thus inhibits the anti-tumor immune response.

Antibodies that specifically block the binding of CTLA-4 with its ligands can enhance immune response. In the present study, we have discovered that cytoplasmic and surface expression of CTLA-4 in human breast cancer cells (BCCs) is also detectable by flow cytometry and immunohistochemical staining. Moreover, CTLA-4⁺ breast cancer cells could inhibit dendritic cells (DCs) maturation and function. LPS-stimulated human DCs decreased the expression of major histocompatibility complex class II (HLA-DR) and co-stimulatory molecules (CD40, CD80, CD83 and CD86) following coculture with human CTLA-4⁺ BCCs. Also, the suppressed DCs further inhibited the proliferation of CD4⁺ T lymphocytes and promoted the secretion of Th2 cytokines, such as IL-4, IL-6. However, the addition of functional anti-CTLA-4 antibody in coculture system could recover LPS-stimulated DC maturation and DC-elicited allogeneic T-cell proliferation. In addition, anti-CTLA-4 antibody therapy also significantly inhibited the proliferation of CTLA-4⁺ BCCs. Collectively, our findings that CTLA-4 molecule is expressed and functional on human breast cancer cells suggest a new sight into the role of CTLA-4 as a negative regulator to influence the maturation and function of DCs in tumor milieu, and anti-CTLA-4 antibody therapy not only recovers the antigen-presenting function of DCs and T lymphocytes activation but also suppresses breast cancer cells proliferation. This study highlights the clinical application of anti-CTLA-4 antibody therapy in breast cancer.

Characterization of immune cell phenotypes in response to Ras activation in the mouse intestinal epithelium

Henn, S.J.¹, Gutting, T.¹, Janssen, K.-P.², Ebert, M.¹, Burgermeister, E.¹ ¹University of Heidelberg, Department of Medicine II, Universitätsklinikum Mannheim, Mannheim, Germany, ²Technical University Munich, Department of Surgery, Munich, Germany

Evidence for the importance of the role of immune cells in the tumor microenvironment has increased over recent years. The priming of the immune system by oncogenic stimuli and the transition of inflammation to malignancy has not yet been fully elucidated and is of significant importance regarding disease prevention and therapy in patients with inflammatory bowel disease. In the intestine and other organs, constitutively active mutant Ras stimulates multiple interconnecting pathways resulting in tumor initiation and progression. These pathways act not only directly on epithelial cells, but also stimulate the release of chemotactic cytokines and chemokines, known to result in immune cell infiltration. However, specific immune cells targeted by oncogenic *ras*-activated epithelial cells and the subsequent change in immune cell phenotypes during *ras*-specific tumor initiation and progression have not been previously characterized. Using a mouse model with an activating *ras* mutation specific to intestinal cells, we characterized the subsets of T cells and macrophage phenotypes in the intestine involved in the initiation and progression of cancer compared to wildtype mice and *ras*-inhibitor treated mice. Techniques included flow cytometry, immunohistochemistry and RTqPCR. Our data indicate that transgenic overexpression of the mutated *ras* oncogene in the intestinal epithelium promotes a chronic inflammatory state, a precondition to malignant transformation.

171

Significance of INHBA expression in EBV-infected nasopharyngeal carcinoma*Fong, H.L., Lee, H.F.**University of Hong Kong, Hong Kong, China*

Nasopharyngeal carcinoma is common in Asia and Africa, especially in southern China. The cause of NPC is a combination of factors which can be environmental influences, genetic susceptibility, and including the viral influence associated with the infection of Epstein-Barr virus (EBV). The relationship between NPC and EBV has not been fully understood yet, meanwhile it is also suggested to be associated with human papillomavirus (HPV).

Inhibin beta A, INHBA as a member of the transforming growth factor β superfamily, it is known to have association with several human cancer. However, the significance of INHBA in NPC has not been evaluated. There were clinical data showed that a poorer overall survival rate was resulted in the group of patients with high INHBA expression comparing to the group of patients with low INHBA expression

($P < 0.05$). Moreover, we found that INHBA was able to enhance the ability of growth, metastatic, migratory and invasive capabilities of NPC cell lines in vitro.

This study can give us a new insight in the viral oncogenesis of INHBA in NPC and in order to contribute to its early diagnosis and effective treatment.

172

Chitosan hydrogel vaccine generates CD8⁺ T cell memory protective in a mouse tumour model of colorectal cancer*Highton, A., Niemi, V., Hook, S., Kemp, R.**University of Otago, Dunedin, New Zealand*

Vaccination generating a robust memory population of CD8⁺ T cells may provide protection against cancer. We investigated the generation of murine memory CD8⁺ T cells using a sustained antigen release vaccine vehicle (chitosan gel; Gel+OVA) containing a model antigen, ovalbumin, or conventional dendritic cell vaccination (DC+OVA) using the same protein antigen. The aims of this work were to evaluate the efficacy of Gel+OVA in generating memory CD8⁺ T cells at peripheral and gut associated lymphoid sites; and to determine whether this vaccination provided protection in murine tumour challenge models.

Mice were euthanised at memory time points following subcutaneous vaccination and cell populations were phenotypically assessed in peripheral and gut-associated lymphoid tissues using flow cytometry. Following vaccination with Gel+OVA, CD8⁺ T cell memory populations specific for ovalbumin protein were detected in both peripheral and gut-associated lymphoid organs. A subcutaneous melanoma model and an orthotopic colorectal cancer model were used to assess the protective capacity of Gel+OVA vaccination at peripheral and gut sites. Vaccination with Gel+OVA or DC+OVA increased survival of mice following subcutaneous tumour challenge compared to unvaccinated controls. Only vaccination with Gel+OVA gave decreased tumour burden compared to unvaccinated or DC+OVA-

vaccinated mice in the colorectal cancer challenge model. This protection was associated with IL-2 production by antigen-specific cells.

These results indicate that subcutaneous vaccination with Gel+OVA generates a population of functional CD8⁺ memory T cells in peripheral and gut-associated lymphoid tissue able to protect against tumour challenge.

173

Myeloid STAT3 promotes hepatocarcinogenesis by inactivating natural killer T cells*Wang, H.¹, Yin, S.², Li, J.³, Gao, B.⁴**¹Department of Oncology, The First Affiliated Hospital of Anhui Medical University, Hefei, China, ²Department of Geriatrics,**Affiliated Provincial Hospital of Anhui Medical University, Hefei,**China, ³Institute for Liver Diseases, Anhui Medical University, Hefei,**China, ⁴NIAAA, National Institutes of Health, Rockville, United States*

Background/objectives: Activation of signal transducer and activator of transcription 3 (STAT3) occurs virtually in most liver diseases, but how STAT3 links liver inflammation and cancer remains elusive.

Methods and results: Using cell-specific STAT3 deletions mouse strains, we have investigated the interplay of myeloid and hepatic STAT3 in controlling hepatocarcinogenesis induced by diethylnitrosamine (DEN). We show that in DEN model hepatic STAT3 plays an important role in mediating a cytoprotective action and enhancing tumor growth, while myeloid STAT3 also significantly affects tumor growth via its anti-inflammatory effect. We further revealed that higher natural killer T cells expansion in liver tumor microenvironment of DEN-treated myeloid cells specific STAT3 knockout mice when compared with that in the wild-type mice.

Conclusions: Orchestral crosstalk between hepatic and myeloid STAT3 enables survival of mutagenized cells and subsequent tumor promotion in DEN-induced hepatocarcinogenesis. Myeloid STAT3 promotes hepatocarcinogenesis by inactivating natural killer T cells.

174

Zoledronic acid induces dose-dependent increase of antigen-specific CD8 T-cell responses in combination with peptide/poly-IC vaccine*Cho, H.-I.¹, Park, H.-M.², Shin, C.-A.³, Shon, H.-J.², Kim, T.-G.⁴**¹The Catholic University of Korea, Catholic Hematopoietic Stem Cell Bank, Cancer Research Institute, Seoul, Korea, Republic of,**²The Catholic University of Korea, Catholic Hematopoietic Stem Cell Bank, Seoul, Korea, Republic of, ³The Catholic University of**Korea, Department of Microbiology, Seoul, Korea, Republic of,**⁴The Catholic University of Korea, Department of Microbiology, Catholic Hematopoietic Stem Cell Bank, Seoul, Korea, Republic of*

Zoledronic acid (ZA) is used for treating osteoporosis and for preventing skeletal fractures in cancer patients suffering from myeloma and prostate cancer. It is also reported to directly

induce cancer cell apoptosis and indirectly modulate T-cell immune response as an antitumor agent. In this study, the effect of ZA following peptide/ polyinosinic-polycytidylic acid (poly-IC) vaccination was investigated in a murine tumor model. The combination of ZA with peptide/poly-IC vaccine showed a synergistic effect on the induction of antigen-specific CD8 T-cell response. Three consecutive intravenous administrations of ZA was defined to induce the highest CD8 T-cell response. Further, total splenocyte counts and antigen-specific CD8 T-cell response gradually increased depending on the dose of ZA. In tumor-bearing mice, ZA showed a dose-dependent decrease of growth and prolonged survival. Treatment with ZA only decreased the number of CD11b⁺Gr1⁺ myeloid cells in blood. Our results demonstrate that the use of ZA could improve antitumor immune responses induced by the peptide/poly-IC vaccine.

175

Activin-A potentiates anti-tumor immunity and protects against lung cancer progression in vivo

Morianos, I., Semitekoulou, M., Stellas, D., Xanthou, G.

Biomedical Research Foundation of the Academy of Athens, Athens, Greece

Activin-A is a pleiotropic cytokine that shapes T cell-mediated responses in allergic and autoimmune disorders. Pertinent to cancer, activin-A exerts both anti-tumorigenic and pro-tumorigenic functions, depending on the cell type and activation status. Activin-A is overexpressed at the tumor site in patients with lung cancer; still, its *in vivo* role in tumor progression remains elusive. Our aim was to decipher whether activin-A can enhance T cell-mediated anti-tumor responses and inhibit lung cancer progression. To address this, we administered recombinant activin-A, in mice which were intravenously inoculated with either Lewis Lung Carcinoma or B16F10 melanoma cells and studied its effect on lung tumor development and induction of anti-tumor immune responses. Our data demonstrated a significant increase in activin-A serum levels in lung tumor-bearing mice. Immunohistochemical studies revealed that activin-A was increased in bronchial epithelial cells at the tumor site. Notably, *in vivo* administration of activin-A in preventive and therapeutic protocols induced a marked regression in lung tumor development, evidenced by macroscopic, PET/CT imaging studies and leukocytic infiltration observations of lung tissue sections, followed by an extended overall survival. Activin-A anti-tumor effects were associated with a striking increase in effector T cell populations in the lung and decreased expression of the immune checkpoint inhibitors, PD-1 and CTLA-4. Administration of activin-A also enhanced the immunostimulatory potential of lung-infiltrating CD11c⁺DCs, reflected by increased MHCII, CD80 and CD86. Collectively, our studies uncover activin-A as a novel anti-cancer agent that may be utilized for enhancing anti-tumor immune responses leading to effective lung tumor regression.

176

Role of intestinal CD103⁺CD11b⁻ dendritic cells in colorectal cancer

Soncini, L., Sheng, J., Ruedl, C.

Nanyang Technological University (NTU), SBS, Singapore, Singapore

The tumor microenvironment is comprised of proliferating neoplastic cells, tumor stroma, blood vessels and infiltrating immune cells such as T lymphocytes, occasional B and NK cells as well as effectors of innate immunity, including dendritic cells (DC), macrophages and granulocytes.

We have recently characterized at least nine distinct colon intra-tumoral myeloid cells including dendritic cells, resident macrophages, monocyte-derived macrophages, neutrophils/MDSCs and eosinophils.

Since the intestinal DCs represent a heterogeneous cell family that mediates diverse immune functions, we studied which DC subset regulates the integrity of the epithelial barrier and contributes to the development of colitis-associated malignancies. To unravel the function of the CD103⁺CD11b⁻ DC subset in promoting or repressing intestinal tumor development, Clec9A-DTR mice were backcrossed with the APC^{Min/+} mouse strain, widely used as mouse model for colon cancer. The conditional *in vivo* ablation of CD103⁺CD11b⁻ DCs in Clec9A-DTR APC^{Min/+} mice resulted in a higher adenomas formation when compared to the wild-type APC^{Min/+} mice, suggesting an anti-tumoral function of this DC subset. A higher infiltration of myeloid cells such as neutrophils and monocytes was observed, which could contribute to the enhanced tumor progression. In order to untangle the role of the intra-tumoral CD103⁺CD11b⁻ DCs, other parameters such as T cell activation state, were evaluated.

This work was supported by MOE Academic Research Fund grant MOE2014-T2-1-011 to C.R.

⁵Hudson Institute of Medical Research, Clayton, Australia, ⁶La Trobe

Institute for Molecular Science, Bundoora, Australia

Metastatic disease accounts for almost all breast cancer related deaths. The mechanisms that dictate this spread to key sites such as the lung and bone are only now emerging. Our recent work supports a role for the host immune system in restricting breast cancer metastasis, and that the balance between pro- and anti-metastatic immune responses is a critical determinant of metastatic progression. Previous studies in our laboratory have shown that breast tumour cells suppress their intrinsic type-I interferon (IFN) pathway, and hence type-I IFN secretion, in order to evade host immunosurveillance and colonise distant organs. These findings are supported by our recent

work showing that breast cancer patients who present with tumours expressing low levels of key IFN pathway members had a much greater risk of developing metastatic disease. These data argued for the re-examination of type-I IFN therapies in the prevention of disseminated disease using our unique models of spontaneous breast cancer metastasis. We show that the induction of endogenous type-I IFN (through the administration of TLR agonists) provided superior anti-metastatic protection than the use of recombinant type-I IFN alone. We also show that the efficacy of such therapies depends on their administration early in tumour dissemination, and, through the use of models of innate immunodeficiency, uncover the importance of NK cells in this anti-metastatic immune response. These data, together with our recent and comprehensive review of IFN clinical trials in breast cancer, form a compelling basis for re-visiting this cytokine pathway in the prevention of metastatic breast cancer.

Antibodies pay Toll to improve their therapeutic efficacy: improving antibody-mediated anti-cancer treatment via co-activation of Fc-receptors and Toll-like receptors

Ganzevles, S.¹, Stigter-van Walsum, M.¹, Schilham, M.², Tuk, K.³, van Egmond, M.³, Leemans, R.¹, Brakenhoff, R.¹, Bakema, J.¹

¹VUMC, Department of Otolaryngology/Head-Neck Surgery, Amsterdam, Netherlands, ²LUMC, Department of Pediatrics, Leiden, Netherlands, ³VUMC, Molecular Cell Biology and Immunology, Amsterdam, Netherlands

The development of immunotherapies aiming to employ the patient's own immune system to fight cancer has increased dramatically in the last decades. Unfortunately, malignant cells have evolved various immune escape mechanisms to suppress anti-tumor immune responses, which hampers clinical success of anti-cancer therapeutic antibodies in most patients. Many of these harmful suppressive mechanisms of the tumor are, in fact, based on natural regulators that resolve inflammatory immune responses once pathogens have been cleared.

We now aim to re-activate the inflammatory immune response during antibody mediated immunotherapy to overcome the immune suppressive tumor microenvironment. We recently demonstrated that simultaneous activation of antibody binding Fc-receptors (FcRs) and pathogen recognizing Toll-like receptors (TLRs) on various immune cells induces unique and robust pro-inflammatory immune responses. We therefore explored the synergistic properties of a combined treatment with cetuximab, an antibody targeting the epidermal growth factor receptor (EGFR), and synthetic ligands for TLRs to target EGFR positive tumors.

We demonstrated that simultaneous activation of TLRs during cetuximab treatment improved the tumor killing capacity of natural killer (NK) cells of healthy donors as well as NK cells from cancer patients. Furthermore, analyzing various cytokines and chemokines we could demonstrate that a profound pro-inflammatory immune response was evoked when cetuximab treatment was combined with TLR agonists. These results show that combined activation of TLRs and FcRs during cetuximab treatment can overcome the immunosuppressive tumor environment and as such improve the tumoricidal capacity

of immune effector cells. This strategy may improve various immunotherapies targeting patient's own immune system.

179

Lactococcus lactis as a new vehicle in delivering tumoricidal recombinant human protein tumor necrosis factor-related apoptosis-inducing ligand (TRAIL)

Wieckiewicz, J., Ciacma, K., Baran, J.

Jagiellonian University Medical College, Clinical Immunology, Krakow, Poland

Introduction: TRAIL (Tumour Necrosis Factor-Related Apoptosis-Inducing Ligand) has a unique ability to induce apoptosis of tumour cells in vitro and in vivo without cytotoxic effect on normal cells. Recombinant TRAIL developed for clinical application (Dulanermin®) was found to be well tolerated, however without therapeutic effect, indirectly caused by the form of its administration. *Lactococcus lactis* is a non-pathogenic and endotoxin-free bacteria, which might serve a new vehicle for TRAIL administration and expression.

Objective: To assess if our genetically engineered *Lactococcus lactis* bacteria, harbouring constructed recombinant plasmid pUSP45TRAIL3, can efficiently express bioactive hsTRAIL.

Methods: Recombinant hsTRAIL-cDNA was synthesized using RT-PCR, inserted to plasmid vector pTrc99A and transformed into the *E.coli* DH5α host strain. The screening of hsTRAIL antitumour activity in vitro and its effect in combination with chemotherapeutics (puromycin, 5-Fluorouracil) were performed by incubation of broth supernatant from *E.coli* DH5α culture with human pancreatic adenocarcinoma HPC-4 cell line. The final hsTRAIL-secretable vector (pUSP45TRAIL3) was obtained by insertion of hsTRAIL-cDNA (cut from constructed *E.coli* plasmid) and cDNA of *L.lactis* usp45 gene coding signal peptide, into plasmid vector for *L.lactis* pNZ8148 and was transformed into the *L.lactis* NZ9000 host strain. The presence of the protein in lysates from *L.lactis* was examined by Western blot.

Results: Supernatants from culture of *E.coli* DH5α expressing hsTRAIL exhibited strong antitumour activity onto HPC-4 cells in a dose dependent manner. The addition of chemotherapeutics enhanced hsTRAIL-induced apoptosis of cancer cells. Identification of hsTRAIL protein in the lysates of *L.lactis* NZ9000 proved production of this protein by transformed strain.

180

The role of T cells in the immune regulation of Langerhans cell histiocytosis (LCH)

Mitchell, J.^{1,2}, Pellicci, D.G.³, Berzins, S.^{1,2}, Kannourakis, G.^{1,2}

¹Federation University Australia, Ballarat, Australia, ²Fiona Elsey Cancer Research Institute, Ballarat, Australia, ³Peter Doherty Institute, University of Melbourne, Dept. Microbiology and Immunology, Parkville, Australia

LCH is characterised by lesions containing CD1a⁺ and/or CD207⁺ histiocytes as well as inflammatory cells, including T and B cells. New treatment options are required for the large proportion of patients who remain unresponsive to current standards. FOXP3⁺ regulatory T cells (Tregs) are present in high

numbers in LCH lesions (suggestive of an immune-suppressive environment), but the frequency and importance of other T cells with regulatory functions, such as mucosal associated invariant T (MAIT) cells and type I natural killer T (NKT) cells is not known. We have characterised blood and LCH lesions using 13-colour flow cytometry, and *in vitro* assays of T cell function. We report that MAIT cells and type I NKT cells are altered in LCH patients compared with healthy donors and we have established a method to isolate FOXP3⁺ Tregs from LCH patients to conduct *in vitro* functional studies. Immune regulation may be defective in LCH and changes in these and other regulatory T cell subsets could be important factors in LCH onset and progression. Targeting regulatory T cell subsets could therefore be a promising avenue of investigation in the development of new immune based therapies.

Novel regulators of CD8⁺ T-cell functions in the skin

Bridge, J.A., Overgaard, N.H., Cruz, J.L.G., Veitch, M., Frazer, I.H., Steptoe, R.J., Wells, J.W.

The University of Queensland Diamantina Institute, Woolloongabba, Australia

Cancer Council statistics show that Australia has the highest rate of skin cancer in the world (twice that of the USA and UK), and predicts 2 in 3 Australians will be diagnosed with skin cancer before the age of 70. Tumour-specific CD8⁺ T-cells are well-recognised for their importance in eliciting tumour-rejection, however, in many cases tumour-specific CD8⁺ T-cells within the tumour microenvironment are dysfunctional. The regulation of CD8⁺ T-cell activity in the tumour microenvironment is poorly understood. This study aimed to explore the mechanisms involved in the regulation of CD8⁺ T-cells in the skin as a prelude to tumour studies. We have generated a new experimental mouse model in which activated CD8β⁺ T-cells from donor mice were introduced into RAG1KO mice in order to assess CD8⁺ T-cell deregulation in the absence of conventional-regulatory T-cells (Treg). When RAG1KO mice subsequently received CD4-depleting antibody, CD8⁺ T-cell-mediated destruction of the ear skin occurred. However, this did not occur in mice administered control-antibody. Analysis of lymph nodes 30 days post CD8β⁺ T-cell transfer showed no evidence of classical CD4⁺FoxP3⁺ Treg indicating regulation is mediated by a separate, distinct cell type. Using the model, we have identified CD4⁺ cells, which are distinct from classical-Treg, and we are subsequently defining the mechanism by which these cells exert control of CD8⁺ T-cell function in the skin. Uncovering novel pathways of CD8⁺ T-cell regulation will shed new light onto regulatory influences of CD8⁺ T-cell function within tumours and yield opportunities to develop better treatment options for cancer patients.

182

Eliciting regression by combination of therapeutic vaccine STDENVANT and PD-L1 blockade in a glioma mouse model

Zhu, S.¹, Zhang, X.¹, Lv, X.¹, Zang, G.¹, Chen, W.², Liu, Y.-J.³, Chen, J.¹

¹The First Hospital of Jilin University, Institute of Translational Medicine, Chuangchun, China, ²University of Minnesota

Medical School, Department of Hematology-Oncology and BMT Department of Pediatrics, Minneapolis, United States, ³MedImmune, Gaithersburg, United States

Glioblastoma multiforme (GBM) is the most malignant primary type of brain tumor in adults. Glioma stem cells (GSCs) are resistant to radiotherapy and chemotherapy, and are responsible for glioblastoma recurrence. In order to develop an immunotherapy for GBM treatments, we explored a cancer vaccine called STDENVANT, which combined with lysate of glioma stem-like cells, dendritic cells (DCs), and Toll-like receptor 9 agonist CpG ODN and studied its anti-tumor effects in an intracranial glioma mouse model. The mouse model was generated with luciferase-expressing GL261 or GL261-derived GSCs in C57BL/6 mice. STDENVANT vaccine was injected every seven days for three times after tumor inoculation. Mice were monitored for immune responses. Our data showed that STDENVANT vaccine inhibited tumor growth, prolonged survival and increased lymphocyte infiltration in mouse model. The STDENVANT vaccine performed anti-tumor effects in both GL261 and GL261-derived GSCs groups. Furthermore, we found that PD-L1 expression was upregulated in GL261-derived GSCs. Administration of a PD-L1 blocking antibody with STDENVANT elicited complete regression of established tumors. Taken together, the current study demonstrated that PD-L1 blockade could promote STDENVANT to kill the GL261-derived GSCs in mouse glioma model, and the combination of PD-L1 blockade and STDENVANT could provide a feasible immune therapeutic approach against GBM.

183

PD-1 blockade boosts radiofrequency ablation-elicited adaptive immune responses against tumor

Jiang, J.¹, Shi, L.¹, Chen, L.¹, Zhu, Y.¹, Wu, C.¹, Lu, B.²

¹Third Affiliated Hospital of Soochow University, Department of Tumor Biological Treatment, Changzhou, China, ²University of Pittsburgh, Department of Immunology, Pittsburgh, United States

Purpose: Radiofrequency ablation (RFA) has been shown to elicit tumor-specific T cell immune responses but is not sufficient to prevent cancer progression. Here we investigated immune suppressive mechanisms limiting the efficacy of RFA. Experimental design: We performed a retrospective case-controlled study on patients with synchronous colorectal cancer liver metastases who had received primary tumor resection with or without pre-operative RFA for liver metastases. Tumor infiltrating T cells and tumoral PD-L1 expression in human colorectal cancer tissues were analyzed by immunohistochemistry. T cell immune responses and PD-1/PD-L1 expression were also characterized in a RFA mouse model. In addition, the combined effect of RFA and PD-1 blockade was evaluated in the mouse RFA model.

Results: We found that RFA treatment of liver metastases increased not only T cell infiltration but also PD-L1 expression in primary human colorectal tumors. Using mouse tumor models, we demonstrated that RFA treatment of one tumor initially enhanced a strong T cell-mediated immune response in tumor. Nevertheless, tumor quickly overcame the immune

responses by inhibiting the function of CD8+ and CD4+T cells, driving a shift to higher Treg to Teff ratio, and up-regulating of PD-L1/PD-1 expression. Furthermore, we established that the combined therapy of RFA and anti-PD-1 antibodies significantly enhanced T cell immune responses, resulting in stronger antitumor immunity and prolonged survival.

Conclusions: The PD-L1/PD-1 axis plays a critical role in dampening RFA-induced antitumor immune responses. And this study provides a strong rationale for combining RFA and the PD-L1/PD-1 blockade in the clinical setting.

Heterogeneity of immune response within single melanoma metastases

Mathy, J.E.^{1,2}, Dunbar, P.R.^{1,2}

¹University of Auckland, School of Biological Sciences, Auckland, New Zealand, ²Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand

Numerous cellular and molecular mechanisms can block tumour-directed immune responses within the tumour microenvironment. Determining optimal immune therapy for each cancer patient will ultimately depend on reading out which mechanisms are active in available tumour samples, using histological or molecular diagnostic techniques. However, the potential heterogeneity of immune responses within metastases remains under-studied -despite the growing recognition of cancer cell heterogeneity.

We are using four-colour immunofluorescence microscopy on tissue sections spanning entire human melanoma metastases to determine the activation status of tumour-infiltrating leukocytes, and their distribution relative to both the melanoma cells and the other immune and stromal cells within each microenvironment. Preliminary results have revealed remarkable heterogeneity within single tumour sections, with distinct microenvironments bearing contrasting markers for T cell activity, e.g. cytotoxic granule markers in one zone, and high FoxP3 expression in another. Heterogeneity of macrophage populations in these microenvironments is also striking. In follow up studies, contrasting microenvironments from single tumours are being sampled using laser capture microdissection for differential gene expression analysis.

Our preliminary data are consistent with the concept that immune status within tumours is highly dynamic, resulting in microenvironments in close proximity showing sharp contrasts in T cell activity and in the cellular and molecular mechanisms that influence that activity. Our results also suggest that highly localised approaches for patient biopsy, such as single point fine-needle aspiration, may be insufficient for comprehensive assessment of the immune response status of a patient's tumours in order to select or modify therapy.

185

T cell phenotype and receptor expression in pleural effusions associated with malignant mesothelioma

McDonnell, A.¹, Chee, J.¹, Nowak, A.^{1,2}, Robinson, B.^{1,3}, Lake, R.¹

¹University of Western Australia, National Centre of Asbestos

Related Diseases, School of Medicine and Pharmacology, Nedlands, Australia, ²Sir Charles Gairdner Hospital, Department of Medical Oncology, Nedlands, Australia, ³Sir Charles Gairdner Hospital, Department of Respiratory Medicine, Nedlands, Australia

Cancer of mesothelial cells that line the pleural cavity is known as malignant pleural mesothelioma. A common feature of the disease is abnormal build-up of fluid in the cavity as a pleural effusion. The effusion contains erythrocytes, leukocytes and malignant cells. It is often drained for palliation and diagnostic tests. However, the importance of cells in the pleural effusion is still relatively unknown. We postulated that the pleural effusion is a site that reflects the immunological status of the tumour, i.e. that T cells detected in the effusion would represent those that infiltrate the tumour. If so, the pleural effusion will be an excellent source of immune cells for further analysis of tumour immunity.

We characterised T cells from pleural effusions of mesothelioma patients by multi-parameter flow cytometry, and compared them with concurrently drawn T cells from blood. Notably, we observed increased expression of T cell inhibitory receptors (PD1, LAG3), similar to the phenotype of tumour-infiltrating lymphocytes (TILs). We performed TCR sequencing on T cells isolated from a pleural effusion and compared receptor usage with the relevant blood sample. There was no clear bias in the usage of any Vb gene families in either CD4+ or CD8+ compartments, but we noted several clonotypes differentially expressed in the antigen-experienced (PD1+) compartment between the sites. Our initial studies reveal that T cells in the effusion have a similar phenotype to TILs. The specificity of T cells and the importance of TCR repertoire diversity in the effusion still need to be further tested.

186

Inhibition of osteoclast differentiation by NDRG2 expression in breast cancer cells

Kim, B.¹, Nam, S.¹, Lee, H.G.², Lim, J.-S.¹

¹Sookmyung Women's University, Department of Biological Science, Seoul, Korea, Republic of, ²Korea Research Institute of Bioscience and Biotechnology, Medical Genomics Research Center, Daejeon, Korea, Republic of

Bone matrix is properly maintained by osteoclasts and osteoblasts. In the tumor microenvironment, osteoclasts are increasingly differentiated by the various ligands and cytokines secreted from the metastasized cancer cells at the bone metastasis niche. The activated osteoclasts generate osteolytic lesions. For this reason, studies focusing on the differentiation of osteoclasts are important to reduce bone destruction by tumor metastasis. The N-myc downstream-regulated gene 2 (NDRG2) has been known to contribute to the suppression of tumor growth and metastasis, but the precise role of NDRG2 in osteoclast differentiation induced by cancer cells has not been elucidated. In this study, we demonstrate that NDRG2 expression in breast cancer cells has an inhibitory effect on osteoclast differentiation. RAW 264.7 cells, which are monocytic preosteoclast cells, treated with the conditioned media (CM) of murine breast cancer cells (4T1) expressing NDRG2 are less

differentiated into the multinucleated osteoclast-like cells than those treated with the CM of 4T1-WT or 4T1-mock cells. Interestingly, 4T1 cells stably expressing NDRG2 showed a decreased mRNA and protein level of intercellular adhesion molecule 1 (ICAM1), which is known to enhance osteoclast maturation. Osteoclast differentiation was also reduced by ICAM1 knockdown in 4T1 cells. In addition, blocking the interaction between soluble ICAM1 and ICAM1 receptors significantly decreased osteoclastogenesis of RAW 264.7 cells in the tumor environment. Collectively, these results suggest that the reduction of ICAM1 expression by NDRG2 in breast cancer cells decreases osteoclast differentiation, and demonstrate that excessive bone resorption could be inhibited via ICAM1 down-regulation by NDRG2 expression.

187

Expression of OCT4 and EMT-associated factors in invasive breast cancer and its relationship with clinicopathological features and prognosis

Ai, J.

The Fourth Hospital of Hebei Medical University, Research Center, Shijiazhuang, China

Objective: In order to investigate the correlation between EMT and cancer stem cells, this experiment is about the expression of EMT related factors E-cadherin, vimentin and stem cells factor OCT4 in breast cancer.

Method: Quantitative real-time PCR and immunohistochemical staining were used to detect the mRNA and protein expression of OCT4, E-cadherin and vimentin in invasive breast cancer tissue and the corresponding adjacent tissues. Furthermore, the correlation between OCT4 and EMT-related proteins and the survival of breast cancer patients were analyzed.

Results: In invasive breast cancer tissues, the expression rate of OCT4, E-cadherin and vimentin were 30% (12/40), 55% (22/40) and 65% (26/40) respectively. OCT4 gene expression levels was correlated with the age, histological grade, lymph node metastasis and the expression in Her-2 of breast cancer patients. The expression of OCT4 mRNA and protein negatively correlated with the expression of E-cadherin mRNA and protein. And the expression of E-cadherin mRNA and protein correlated negatively with the expression of vimentin mRNA and protein. The survival rate of OCT4 positive expression breast cancer patients was lower than patients with OCT4 negative expression significantly.

Conclusion: Stem cells factor OCT4 may promote the metastasis of breast cancer cells via EMT and is an independent prognostic factor for breast cancer.

Emergence of a neutrophil precursor population that serves as granulocytic myeloid-derived suppressor cells in cancer

Kim, M.-H.¹, Yang, D.², Kim, M.³, Kim, S.-Y.³, Kim, D.², Kang, S.-J.¹

¹Korea Advanced Institute of Science and Technology (KAIST), Biological Sciences, Daejeon, Korea, Republic of, ²Korea Advanced Institute of Science and Technology (KAIST), Bio and Brain Engineering, Daejeon, Korea, Republic of, ³Korea Research Institute

of Bioscience and Biotechnology (KRIBB), Medical Genomics Research Center, Daejeon, Korea, Republic of

Hematopoietic alteration is one of the major features of cancer. In particular, cancer progression is often accompanied by dysregulated granulopoiesis. Studies of granulopoiesis dynamics in clinical conditions like cancer have been hampered by technical limitations in defining neutrophil precursors, thus preventing a clearer understanding of the underlying biological process. In cancer, myeloid-derived suppressor cells (MDSCs) arise and contribute to tumor promotion by suppressing anti-tumor immunity. MDSCs are a heterogeneous cell population that is composed of granulocytic and monocytic cells. Immature neutrophil like granulocytic-MDSCs are major T cell suppressive population contributing pro-tumor immunity. However, the maturation stage and differentiation process of MDSCs remains undetermined. Here, we define a population of neutrophil precursor cells with unprecedented purity, which we call NeuPs (Neutrophil Precursors). We demonstrated that NeuPs have the potential to proliferate and differentiate into mature neutrophils both *in vitro* and *in vivo*. By analyzing the gene expression profiles of NeuPs, we identified stage-specific genes and characterized patterns of gene regulation throughout granulopoiesis. Importantly, NeuPs displayed shared but unique modes of granulopoiesis dynamics in different hematopoietic stress settings, indicating that NeuPs are poised at a critical step to regulate granulopoiesis. Significantly, we demonstrate that NeuPs acquire T cell suppressive activity in cancer condition and can serve as granulocytic MDSCs. Our study reveals that MDSC differentiation branches out at the NeuP stage of neutrophil development in cancer.

189

Immunization with glycosylated-MUC1 induces effective humoral responses and suppression of MUC1-expressing carcinoma growth and metastasis

Denda-Nagai, K.¹, Namba, A.², Noji, M.¹, Irimura, T.¹

¹Juntendo University School of Medicine, Tokyo, Japan, ²University of Tokyo, Graduate School of Pharmaceutical Sciences, Tokyo, Japan

Mucin 1 (MUC1) has been considered as a promising target of cancer immunotherapy through the vaccination, and aberrant glycosylation was considered as the basis of immunological distinction between normal and carcinoma-associated MUC1. However, the precise nature of the immune response to the glycoforms of MUC1 was previously unknown. In the present study, we aimed to evaluate the efficacy of MUC1-IgG fusion protein with Tn (GalNAc) or T (Gal-GalNAc) epitopes in the induction of immune response and in the suppression of MUC1-expressing carcinoma growth and metastasis in C57/BL6 mice. Mice immunized with glycosylated MUC1-IgG produced significantly higher levels of anti-MUC1 IgG1 antibodies, especially anti-Tn-MUC1 antibodies, than those with MUC1-IgG without carbohydrate chains. The antibodies after immunization with glycosylated MUC1-IgG also efficiently bound to the surfaces of MUC1-expressing carcinoma cells. Macrophage galactose-type C-type lectins (MGL1 or MGL2 in mice) expressed on dendritic cells were involved in the effective

humoral response at 1 week after immunization of glycosylated MUC1-IgG. Growths at the site of injection (spleen) and liver metastasis of MUC1-transfected mouse colon carcinoma cells were suppressed after immunization with glycosylated MUC1-IgG but those by mock-transfected cells were not. These results strongly suggest that MUC1 with truncated *O*-glycans (Tn and/or T epitopes) induces effective humoral responses and the anti-Tn-MUC1 antibodies contribute to the suppression of carcinoma growth and metastasis.

190

Gamma-interferon-inducible lysosomal thiol reductase is upregulated in human melanoma and halo nevi

In, K.¹, Menon, H.¹, Nguyen, J.¹, Sebastiao, N.², Kang, P.¹, Hu, C.¹, Bernert, R.³, DiCauda, D.⁴, Hastings, K.¹

¹University of Arizona College of Medicine, Phoenix, United States, ²Ventana Medical Systems, Tucson, United States, ³Arizona Dermatopathology, Scottsdale, United States, ⁴Mayo Clinic, Scottsdale, United States

T cell-mediated immunity has the ability to produce durable anti-melanoma responses resulting in improved survival of patients with advanced melanoma. Gamma-interferon-inducible lysosomal thiol reductase (GILT) is critical for MHC class II-restricted presentation of multiple melanoma antigens to CD4⁺ T cells. However, GILT expression in human melanocytic lesions has not been defined. We evaluated GILT and MHC class II expression in human primary and metastatic melanomas and nevi using immunohistochemistry. Both GILT and MHC class II expression were increased in melanocytes of primary and metastatic melanomas compared with nevi ($p < 0.01$ for GILT; $p < 0.001$ for class II). GILT expression was increased in APCs of primary and metastatic melanomas compared to nevi ($p < 0.001$), whereas MHC class II had equivalent high expression in APCs of all melanocytic lesions. GILT, but not MHC class II, expression was increased in keratinocytes of primary melanomas compared to nevi and metastases ($p < 0.01$). To evaluate whether GILT expression was related to inflammation, GILT expression in halo nevi was compared to nevi without lymphocytic infiltrates. A halo nevus is a benign nevus with a lymphocytic infiltrate which results in a zone of depigmentation surrounding the nevus. GILT, but not MHC class II, expression was increased in melanocytes and keratinocytes of halo nevi ($p < 0.05$) compared to nevi without lymphocytic infiltrates, suggesting that GILT expression is induced by the inflammatory environment. GILT expression is anticipated to result in improved presentation of melanocyte antigens and more effective immune-mediated destruction.

191

Mechanisms of Response and Resistance to checkpoint blockade in models of murine colorectal carcinoma

Wiehagen, K., Pizutti, D., DeAngelis, N., Ferrante, C., Yamada, D., Verona, R.

Janssen Research and Development, LCC, Spring House, United States

PD-1 and TIM-3 are inhibitory cell surface molecules that function to limit T cell responses during infection, autoimmunity, or cancer. In tumors, co-expression of PD-1 and TIM-3 promote

an exhausted or dysfunctional state on T cells. This state of exhaustion is reversible, however. Inhibition of PD-1 with function-blocking antibodies can control tumor growth in syngeneic transplantable murine tumor models. Combination of PD-1 and TIM-3 blockade exhibits greater efficacy than monotherapy, although mechanisms underlying this response remain unclear. We profiled the composition and functionality of infiltrating immune cells in CT26 and MC38 tumors treated with anti-PD-1, anti-TIM-3 or combination. Intratumoral CD8⁺ T cells were detected in higher frequencies after PD-1 blockade. More CD8⁺ T cells expressed patterns of cell surface markers associated with effector lymphocytes, including CD62L, LFA-1, and costimulatory receptors CD137 and GITR. Furthermore, expression of inhibitory receptors also increased with PD-1 blockade, suggesting the emergence of mechanisms for acquired resistance to PD-1 immunotherapy. CD8⁺ T cells from anti-PD-1 and combination treated mice expressed higher levels of T-bet and lower Eomesodermin, two transcription factors associated with balancing effector function and exhaustion in T cells. TIM-3 blockade elicited its own effects, extending from T cells to other immune populations. Combination of PD-1 and TIM-3 induced changes consistent with both monotherapies. Analysis of the CD8 T cell transcriptome of infiltrating lymphocytes revealed gene expression changes in response to anti-PD-1 treatment that correlated with the flow cytometry data. Ongoing studies are comparing PD-1 monotherapy to anti-PD-1 combination with other immunotherapies in multiple models.

192

Extracellular pH and hypoxia affect on the function and development of antigen-specific cytotoxic T lymphocytes

Ishii, K., Nakagawa, Y., Negishi, Y., Shimizu, M., Takahashi, M., Takaku, S., Takahashi, H.

Nippon Medical School, Microbiology and Immunology, Tokyo, Japan

CD8⁺ cytotoxic T lymphocytes (CTLs) are the major effector cells in cellular adaptive immunity, which can recognize and kill virus-infected cells or tumor cells. Although CTLs exhibit strong cytolytic ability against target cells in vitro, a number of studies have shown that CTLs function is often impaired within tumors. Nevertheless, CTLs regain their cytotoxic activity after escaping from the tumor environment. These results suggest that the milieu created by growing tumors influence the cytotoxicity of CD8⁺ CTLs. The patho-physiological situation present in vivo has been shown to differ from in vitro regarding the tumor environment. In particular, low pH and hypoxia are the most important microenvironmental factors within growing tumors. To determine the effect of these factors on CTL function in vivo, we examined the cytolytic activity of CTLs against their targets using murine CTL lines and the induction of these cells from memory cells under low pH or hypoxic conditions using antigen-primed spleen cells. The results indicated that both cytotoxic activity and the induction of functional CTLs were markedly inhibited under low pH. On the other, in hypoxic conditions, although cytotoxic activity was almost unchanged, the induction of CTLs in vitro showed a slight enhancement, which was completely abrogated in low pH conditions. Therefore, antigen-specific CTL functions may be more

vulnerable to low pH than to the oxygen concentration in vivo. These findings provide new therapeutic approaches for controlling tumor growth by retaining CTL cytotoxicity through the maintenance of higher pH conditions.

193

Neutrophils as therapeutic targets in metastatic breast cancer

Mouchemore, K.^{1,2}, Swierczak, A.^{1,3}, Haynes, N.¹, Hamilton, J.³, Anderson, R.^{1,4}

¹Peter MacCallum Cancer Centre, Melbourne, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ³Arthritis and Inflammation Research Centre, Department of Medicine, Melbourne, Australia, ⁴The University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia

We have demonstrated that targeting Tumour Associated Macrophages (TAMs) via their growth factor Colony Stimulating Factor-1 (CSF-1) unexpectedly increased metastasis to lung and bone in two mouse models of breast cancer, accompanied by an increase in circulating and Tumour Associated Neutrophils (TANs) and an increase in plasma levels of the neutrophil growth factor Granulocyte Colony Stimulating Factor (G-CSF). Targeting the G-CSF receptor (G-CSFR) overcame this increase in metastasis and neutrophil accumulation. This project now aims to characterize the role of neutrophils and G-CSF signalling in enhancing breast cancer metastasis, and to identifying appropriate chemotherapy regimes suitable for combination with G-CSFR antibody treatment potentially for patients.

Syngeneic mouse models of breast cancer were established by 4T1.2 tumour cell injection into the mammary gland and mice were treated alone or in combination with cytotoxic chemotherapy and G-CSFR antibody. Treatment efficacy was assessed by flow cytometry for changes in immune populations in blood, tumours and lungs. Therapeutic benefit was assessed by survival and level of metastatic burden in lung.

Low dose Doxorubicin alone depletes myeloid (CD11b⁺) cell populations, including neutrophils, that suppress T-cell activity in the 4T1.2 model, resulting in enhanced anti-tumour responses. However, combination with G-CSFR antibody treatment had little therapeutic benefit. The exact mechanism of action by which G-CSFR antibody alone reduces metastasis is still being characterised. In conclusion, G-CSFR antibody treatment may benefit more from combination with radiotherapy or chemotherapy that directly stimulates T-cell infiltration/activity, rather than therapies also affecting neutrophils themselves.

194

The association of lentinan with PD-1/ PD-L1 axis in gastric cancer

Ina, K.¹, Kataoka, T.¹, Ina, H.², Yoneda, M.²

¹Nagoya Memorial Hospital, Nagoya, Japan, ²School of Nursing and Health Aichi Prefectural University, Nagoya, Japan

Background: The outcomes of anticancer therapy for gastric cancer remain unsatisfactory. Aiming at improving the survival, lentinan, beta- (1, 3)-glucan with beta- (1, 6) branches, has been

used in combination with oral fluoropyrimidines such as S-1. We examined the association of lentinan with programmed death (PD)-1/ PD receptor-ligand 1 (PD-L1) axis which may elude immune surveillance.

Methods: The expression of PD-1 and PD-L1 was examined using biopsy samples from chemo-sensitive cases (n=5). Three human gastric cancer cell lines (MKN1, MKN45, Kato III) were used in vitro study. The drug solutions of 5-FU and CDDP and lentinan powder were purchased from commercial sources. All cell lines were cultured in RPMI-1640 supplemented with 10 % fetal bovine serum in the presence of various concentrations of agents. Total RNA was extracted and cDNA was synthesized. Real-time PCR analysis for PD-L1 and b-actin was performed.

Results: PD-L1 expression was demonstrated in gastric cancer cells of chemo-sensitive cases. The exposure to CDDP (0, 0.25, 0.5, 1, 2 microgram/ ml), but not 5-FU, up-regulated PD-L1 expression on gastric cancer cell in a dose-dependent manner, and co-incubation with lentinan down-regulated its expression in vitro.

Discussion: Up-regulated PD-L1 expression should be related to immune escape and chemo-resistance. Lentinan decreased platinum-induced overexpression of PD-L1 on tumor cells in vitro. This effect of lentinan on PD-1/ PD-L1 axis might be related with restoration of chemo-sensitivity, leading to enhance tumor clearance.

195

The novel function of immunoregulatory molecule TIM-4 in non-small-cell lung cancer development

Zhang, Q., Wang, H., Liang, X., Ma, C., Gao, L.

Shandong University School of Medicine, Jinan, China

TIM-4 is a novel cell-surface glycoprotein belonging to TIM family. TIM-4 is exclusively expressed on antigen presenting cells. However, the role of TIM-4 in tumor development and progression remains unclear. This study aims to investigate the role of TIM-4 in lung cancer development and further explore related mechanisms. We found that the expression of TIM-4 in lung cancer tissues was significantly higher than that of adjacent tissues and closely related with lung carcinoma histological differentiation and life span of patients. Although TIM-4 expression was relatively low in lung cancer cell lines, LPS and cytokines increased its expression. Moreover, TIM-4 overexpression promoted lung cancer cell growth and proliferation, accompanied by accumulation of lung cancer cells in S phase. Consistently, TIM-4 overexpression upregulated the expression of PCNA, cyclinA, cyclinB1 and cyclinD1. More importantly, we found that TIM-4 interacted with $\alpha\beta 3$ integrin. Interestingly, Arg-Gly-Asp (RGD) motif mutation of TIM-4 abolished the effect of wild type TIM-4 on growth, proliferation and cell cycle progression of A549 cells. Moreover, TIM-4 mediated promotion of lung cancer growth and proliferation by its RGD motif was further verified by tumor xenografts in mice. These data suggest that TIM-4 might be a potential diagnostic marker and therapeutic target of lung carcinoma.

The role of vasculogenic mimicry vessels in mediating leukocyte recruitment to melanomas

Tan, L.^{1,2}, Sachi, P.¹, Brown, M.^{1,3}, Bonder, C.¹, Ebert, L.¹

¹Centre for Cancer Biology, University of South Australia and SA Pathology, Adelaide, Australia, ²University of South Australia, School of Pharmacy and Medical Sciences, Adelaide, Australia, ³Royal Adelaide Hospital, Department of Medical Oncology, Adelaide, Australia

The endothelial cells of the vasculature act as a gatekeeper between the leukocytes and underlying tissues, including solid tumours such as melanoma. By regulating adhesion molecule expression on the endothelium, tumours can selectively recruit pro-tumourigenic leukocytes to enhance tumour growth. Interestingly, melanoma cells themselves can also form vessel-like structures, a process known as vasculogenic mimicry (VM). The occurrence of VM closely correlates with disease progression in melanoma and other cancers such as breast cancer. While VM vessels appear to function like the conventional endothelium in conducting blood, as indicated by the presence of blood cells within the VM vessels and their connection with the endothelium, whether or not they can recruit leukocytes remains unknown. We and others have shown that melanoma cells can express various adhesion molecules and chemokines, thereby hinting at the potential of these cells to interact with leukocytes. Indeed, preliminary results obtained from parallel plate flow chamber assays and transwell migration assays have revealed that leukocytes, in particular monocytes, could roll, adhere and transmigrate across a melanoma cell monolayer. Interestingly, the capability of the melanoma cells in recruiting leukocytes appeared to correlate with their capability of forming vessel-like structures when subjected to a Matrigel tube formation assay, which reflects their VM capability *in vitro*. Current work focuses on further defining the adhesion molecules and chemokines involved in this process, as well as the detailed phenotype of the recruited leukocytes. Taken together, VM vessels may play an important role in leukocyte recruitment and ultimately dictate melanoma disease outcome.

197

Loss of AIM2 expression promotes hepatocarcinoma progression through activation of mTOR-S6K1 pathway

Ma, X.¹, Guo, P.¹, Qiu, Y.¹, Li, T.², Han, L.¹

¹Shandong University School of Medicine, Department of Immunology, Jinan, China, ²Provincial Hospital Affiliated with Shandong University, Department of Gastroenterology, Jinan, China

Absent in melanoma (AIM2) is recognized as a cytoplasmic DNA sensor playing important role in both innate immunity and tumor pathology. However, the role of AIM2 in the development of hepatocellular carcinoma (HCC) remains to be clarified. We here investigate the mRNA and protein levels of AIM2 expression in liver cancer tissues and corresponding non-cancerous liver tissues from a total of 113 HCC patients. Our data showed that expression of AIM2 was significantly decreased in liver cancer tissues, and this decreased expression was significantly

correlated with more advanced tumor progression. Our *in vitro* and *in vivo* assay showed that loss of AIM2 expression significantly promoted the proliferation, colony formation and invasive capability of these HCC cells. Further analysis showed that mammalian target of rapamycin (mTOR)-S6K1 pathway was significantly activated in the AIM2-absent HCC cells, and treatment with mTOR pathway inhibitor rapamycin verified that this mTOR pathway activation contributed to HCC progression. Thus, these data suggested that AIM2 played a critical role as a tumor suppressor and might serve as a potential therapeutic target for future development of AIM2-based gene therapy for human liver cancer. This study also paves a new avenue to treat AIM2-deficient cancer by suppression of mTOR.

* This study was supported by the National Natural Science Foundation of China (No.81472269, No.81472685, and No. 81172352) and the Science and Technology Development Project of Shandong Province (No. 2015GSF118047).

Metabolic reprogramming of myeloid cells during tumor progression

Huang, L.-R., Jian, S.-L., Zhou, Y.-J., Chen, W.-W.

National Health Research Institutes, Institute of Molecular and Genomic Medicine, Miaoli County, Taiwan, Republic of China

Myeloid-derived suppressor cells (MDSCs) are heterogeneous populations of immature myeloid cells, which expand and differentiate in responses to growth factors, cytokines and chemokines derived from cancer cells and then are released from bone marrow to peripheral tissues including tumor sites. MDSCs play important roles not only in T-cell suppression but also in angiogenesis, lymphangiogenesis and metastasis during tumor progression. The influence of tumor cells on the activation and proliferation of myeloid cells has been extensively studied. However little is known about the metabolic status of MDSCs during tumor progression. We therefore try to elucidate the metabolic changes during differentiation of myeloid cells into MDSCs.

We have found that myeloid cells up-regulated their glycolytic pathway and immunosuppressive features when encountering cancer cells *in vitro*. Results from DNA microarray and real-time PCR also revealed that monocytic and granulocytic MDSCs from primary tumor sites of 4T1 tumor-bearing mice promoted their glycolysis in comparison to their healthy counterparts, monocytes and neutrophils, from bone marrow of healthy mice. We further proved that glycolytic pathway contributed to the survival and immunosuppression of MDSCs *in vitro* and *in vivo* using a hexokinase inhibitor, 2-DG, to block glycolysis. We are currently examining the association of metabolites from glycolysis and differentiation of myeloid cells during tumor progression and expect to identify specific metabolite responsible for driving differentiation of MDSCs.

199 miR-200c regulates migration of breast cancer cell BT549 by targeting slug

*Jia, L., Tian, Y., Shi, Y., Zhang, L., Rong, S., Zhang, Y., Li, J.
Third Affiliated Hospital of Zhengzhou University, Clinical
Laboratory, Zhengzhou, China*

This study regarded breast cancer BT549 cell as the research object and transferred miR-200c into the BT549 to explore the relationship of miR-200c and the expression of Slug and the influence of miR-200c to the migration of BT549 cell in order to provide laboratory basis for clinical diagnosis and treatment.

Method: miR-200c mimic was transfected into a highly metastatic breast cancer cell line BT549 which was cultured through RPMI-1640 medium within 10% fetal bovine serum. The experiment was divided into 3 groups: miR-200c group, miR-control group and blank control group. 3 wells were prepared in each group.

Transwell migration assay, Wound healing assay, Western blot assay and Real time PCR were used in the study process.

Result:

1. Compared with blank control groups and miR-control group, the migratory ability of the BT549 cell in miR-200c group was reduced and the difference had statistical significance ($P < 0.05$).
2. Compared with blank control group and miR-control group, the expression of Slug mRNA in the BT549 cell of miR-200c group was decreased significantly ($P < 0.05$), but the expression of E-cadherin mRNA was increased significantly ($P < 0.05$).
3. Compared with blank control group and miR-control group, the expression of Slug in the BT549 cell of miR-200c group was declined significantly ($P < 0.05$).

Conclusion: The miR-200c in BT549 could reduce the expression of correspondent Slug protein by suppressing the translation of Slug mRNA and subsequently promote the expression of E-cadherin, inhibit EMT (Epithelial-Mesenchymal Transition) and block the migration of BT549 cell.

200 Up-regulated S100A9 in stroma functions as an early recurrence marker for early-stage oral cancer patients through increased tumor invasiveness, angiogenesis, macrophage recruitment and IL-6 expression

*Wu, L.-W.
National Cheng Kung University, Institute of Molecular Medicine,
Tainan, Taiwan, Republic of China*

S100A9 is a calcium-binding protein with two EF-hands and frequently deregulated in several cancer types, however, with no clear role in oral cancer. In this report, the expression of S100A9 in cancer and adjacent tissues from 79 early-stage oral cancer patients was detected by immunohistochemical staining. Although S100A9 protein was present in both tumor and stromal cells, only the early-stage oral cancer patients with high stromal expression had reduced recurrence-free survival. High stromal S100A9 expression was also significantly associated with non-well differentiation and recurrence. In addition

to increasing cell migration and invasion, ectopic S100A9 expression in tumor cells promoted xenograft tumorigenesis as well as the dominant expression of myeloid cell markers and pro-inflammatory IL-6. The expression of S100A9 in one stromal component, monocytes, stimulated the aggressiveness of co-cultured oral cancer cells. We also detected the elevation of serum S100A9 levels in early-stage oral cancer patients of a separate cohort of 73 oral cancer patients. The release of S100A9 protein into extracellular milieu enhanced tumor cell invasion, transendothelial monocyte migration and angiogenic activity. S100A9-mediated release of IL-6 requires the crosstalk of tumor cells with monocytes through the activation of NF- κ B and STAT-3. Early-stage oral cancer patients with both high S100A9 expression and high CD68+ immune infiltrates in stroma had shortest recurrence-free survival, suggesting the use of both S100A9 and CD68 as poor prognostic markers for oral cancer. Together, both intracellular and extracellular S100A9 exerts a tumor-promoting action through the activation of oral cancer cells and their associated stroma in oral carcinogenesis.

201 Mesenchymal stromal cells derived from cervical cancer tumors induce an increase of CD73 expression in cervical cancer cells

*Avila Ibarra, L.R.¹, Mora Garcia, M.D.L.², Hernández Montes, J.²,
Garcia Rocha, R.¹, Weiss-Steider, B.², Monroy Garcia, A.¹

Zaragoza, Mexico City, Mexico*

Mesenchymal stromal cells (MSCs) are important components in the tumor microenvironment and participate together tumor cells in the suppression of antitumoral immune response, via production of immunosuppressive factors such as TGF- β . Since the expression of the ectonucleotidase CD73 in malignant cells is also associated with immunosuppression via adenosine production, and that its expression is dependent of TGF- β production, the aim of this work was to analyze whether MSCs derived from cervical tumors (CeCa-MSCs) increase the expression of CD73 on cervical cancer cells through the production of TGF- β . For this purpose CeCa-MSCs and MSCs obtained from normal cervix (NCx-MSCs), were co-cultured with CaSki and Hela cervical cancer (CeCa) cell lines. After 96hrs, CD73 expression was determined by flow cytometry on tumor cells, as well as, the content of TGF- β in the supernatants by ELISA. Interestingly, we observed that CeCa-MSCs as well as NCx-MSCs, induced an important increase of the expression of CD73 on tumor cells, which was dependent of the amount of MSCs added to the cell co-culture, as well as of the presence of TGF- β in the supernatants, since the addition of anti-CD73 mAb strongly blocked the increased expression. These results provide evidence that MSCs collaborate with CeCa cells to increase their expression of CD73 through the production of TGF- β , providing a potential mechanism for immunosuppression in CeCa. This work was supported by DGAPA-PAPIIT (IN226516), FIS/IMSS/PROT (1314 and 1383) and CONACYT (240635) grants.

202**HBV infection promotes proliferation, migration and invasion of hepatocellular carcinoma via the regulation of miR-181a/362 by targeting HSPA5**

Ma, S., Qin, K., Ouyang, H., Jiang, Q., Li, H., Wu, M., Zhu, H., Lei, P., Shen, G.

Huazhong University of Science and Technology, Immunology, Wuhan, China

HSPA5, which belongs to the heat shock protein 70 family, is a stress-inducible endoplasmic reticulum (ER) chaperone and a major regulator of the unfolded protein response (UPR). Tumors are subjected to ER stress triggered by both intrinsic and extrinsic factors, such as hypoxia, acidosis, viral infection and genetic lesions leading to UPR activation and HSPA5 induction. The up-regulation of HSPA5 in a variety of tumors and its induction after drug therapies has been considered as a main contributor to oncogenesis and therapeutic resistance. Moreover, HSPA5 participates in the process of immunoregulation and tumor escape. Notwithstanding these studies, the molecular mechanism underlying the increased HSPA5 expression in HCC remains poorly understood. Given that microRNAs (miRNAs) are implicated in HCC progression, we explored the potential role of miRNAs in HCC by performing miRNA expression profiling between HepG2 and HepG2.215. We discovered miR-181a/362 as two of the most markedly overexpressed miRNAs and highly associated with HBV-positive HCC. We found the overexpression of miR-181a/362 displayed significantly stimulative effects on the proliferation, migration and invasion potentialities of HCC cell lines. Using an integrated approach, we uncovered that HSPA5, whose expression was obviously increased in HCC specimens in comparison with the adjacent noncancerous hepatic specimens and liver hemangioma specimens, was a novel target of miR-362. Furthermore, we showed an inverse influence on the expression levels of miR-181a/362 and HSPA5 exerted by transfection of HBV related plasmids. Altogether, our findings indicate miR-181a/362 may serve as potential prognostic biomarkers and novel targets in the therapeutic strategies of HCC.

203**Role of immune cells in prostate cancer development and clearance**

Mishra, M.¹, Kumar, S.¹, Singh, U.², Scissum-Gunn, K.¹, Manne, U.³, Ponnazhagan, S.³

¹Alabama State University, Montgomery, United States, ²University of South Carolina School of Medicine, Columbia, United States,

³University of Alabama at Birmingham, Birmingham, United States

Prostate Cancer (PCa) is the most common non-skin malignancy and the most commonly diagnosed cancer in men in the United States. The immunotherapeutic role of immune cells in regulation of PCa has been studied but still the specific interplay between these cells to regulate cancer needs further investigation. In this study, we analyzed the role of immune cells in tumor development and progression using a prostate cancer model. We used TRAMP cells (TRAMP C1, C2 and C3 derived from transgenic adenocarcinoma of mouse prostate) to induce tumor

in C57/B6 mouse. Interestingly, TRAMP-C1 and TRAMP-C2 cells are tumorigenic while TRAMP-C3 cells fail to form tumor. Briefly, tumor induction studies were performed on different groups of mice. Mice were inoculated with these three cell lines, tumors were analyzed at different time points, and the percentage and absolute number of different immune cells such as CD4, CD8, NK, NKT, Macrophages, regulatory T cells, and Dendritic cells were analyzed. Our data demonstrated that the capacity of TRAMP-C1 and TRAMP-C2 cells to form tumors and the inability of TRAMP-C3 cells to induce tumors is mediated by number of different immune cells such as NK, NKT, macrophages and regulatory T cells in the tumor microenvironment. Therefore, the data suggest an understanding of function and effect of immune cells during tumor progression and clearance is needed to successfully develop a targeted therapy to modulate the number of immune cells in the tumor microenvironment.

204**The production of cytokines induced by breast tumor antigens in dendritic cells is modulated by cholinergic activation**

Lombardi, M.G.¹, Oroño, M.², Giambalvo Gómez, D.², Martínez Pulido, P.², Sales, M.E.²

¹Centro de Estudios Farmacológicos y Botánicos, Facultad de Medicina, UBA, Segunda Cátedra de Farmacología, FMED, UBA, CABA, Argentina, ²Centro de Estudios Farmacológicos y Botánicos, Laboratorio de Inmunofarmacología Tumoral, Segunda Cátedra de Farmacología, CABA, Argentina

We have previously described the presence of a functional non neuronal cholinergic system in human dendritic cells (DC). The addition of cholinergic agonists, carbachol and acetylcholine modulates the function of DC. Taking into account that a deficiency in the activity of DC was reported in tumor bearers, we investigated the effect of cholinergic receptors (ChR) activation in human DC cells regarding their cytokine profile. Experiments were performed in the absence or presence of tumor antigens obtained from the human luminal breast adenocarcinoma, MCF-7.

Methods: DC were obtained from human monocytes and were treated during 24h with different concentrations of MCF-7 tumor extract (MTE). Afterwards, DC were stimulated with carbachol during 1 h in the absence or presence of cholinergic antagonists (atropine or mecamylamine). Finally, DC were cultured without or with lipopolysaccharide during 24 h to obtain immature or mature DC (iDC or mDC). The production of cytokines in culture supernatants was quantified by ELISA.

Results: In iDC, the addition of increasing doses of MTE triggered a potent up-regulation of interleukin (IL)-10 production while the effect on IL-12 or tumor necrosis factor alpha (TNF- α) levels was less potent ($495 \pm 19\%^{**}$; $295 \pm 28\%^{*}$; $269 \pm 20\%^{*}$, respectively; $^{**}p < 0.0001$; $^{*}p < 0.01$ vs. control). Carbachol prevented the effect of MTE on IL-10 production by iDC ($p < 0.0001$ vs. MTE). MTE did not modify IL-10 or TNF- α levels in mDC, while the addition of carbachol strongly increased TNF- α production ($125 \pm 18\%$; $p < 0.0001$ vs. MTE).

Conclusions: These results show that the activation of ChR promotes an inflammatory response that could modulate the

tolerogenic/immunosuppressive profile induced during DC-tumor interaction.

205

Time-scale analysis of interplay between occult immunogenic tumor and immune response

Mojic, M.¹, Sato-Matsushita, M.², Tahara, H.², Hayakawa, Y.¹

¹University of Toyama, Institute of Natural Medicine, Division of Pathogenic Biochemistry, Department of Bioscience, Toyama, Japan, ²The University of Tokyo, The Institute of Medical Science, Department of Surgery and Bioengineering, Tokyo, Japan

The implication of controlling cancer growth *in vivo* by immune response has been mostly based on the results obtained by monitoring palpable tumors. Consequently, the time-scale position of specific immune response to control occult tumor remained unclear. To tackle this question, we established a bioluminescence imaging model to monitor the interplay between occult immunogenic tumor and various components of innate and adaptive immunity. By using mouse B16 melanoma cells co-expressing ovalbumin (OVA) and luciferase (B16OVA-Luc cells), we monitored the exact behavior of B16OVA-Luc cells under the different immunological conditions. In mice immunized with tumor antigen ovalbumin (OVA-mice), we observed time-limited immune control of tumor growth that was far more dynamic than detected with caliper measurement. Anti-tumor immune response in OVA-mice was critically dependent on IFN- γ and CD8⁺ T cells, which inhibition/depletion as late as a 5 days after tumor inoculation resulted in abolition of tumor growth inhibition. In the absence of NK cells, tumor growth suppression in OVA-mice was still conceivable, yet time of immune control over tumor growth was significantly shorter. Compared to tumor antigen-naïve group, we observed significantly higher expression of PD-1 and PD-L1 in OVA-specific CD8⁺ T cells and B16OVA-Luc cells, respectively, even during the period of time where immune control over tumor growth was evident. We are now further exploring the mechanism how IFN- γ plays specific role in the maintenance and/or the effector phase of anti-tumor immune response to control occult tumor in the tumor antigen experienced mice.

206

Immunological markers of persistence & regression in cervical intraepithelial neoplasia grade 2 in women under 25

Saito, M.¹, Budhwani, M.¹, Coffey, K.², Sykes, P.³, Hibma, M.¹

¹University of Otago, Department of Pathology, Dunedin School of Medicine, Dunedin, New Zealand, ²University of Otago, Department of Women's and Children's Health, Dunedin School of Medicine, Dunedin, New Zealand, ³University of Otago, Department of Obstetrics and Gynaecology, Christchurch, New Zealand

Cervical cancer is the second most common cause of death from cancer in women. High-risk human papillomavirus (hr-HPV) infection has been recognized as the major risk factor for cervical cancer. The development of cervical cancer, and the

preceding high grade cervical lesions (cervical intraepithelial neoplasia [CIN] 2 and CIN3) is likely to be associated with a lack of an effective immune response against hr-HPV. However, there is a relatively high spontaneous regression rate for CIN2, which is considered to be immune mediated. The aim of this study is to identify immune markers of regression and persistent of CIN2 to identify novel predictive markers of disease outcome.

A range of immunological markers, including CD4, CD8, FoxP3, granzyme, CD1a and Langerin, were used to identify T cell subsets and antigen presenting cell populations in infected lesions from women under 25 with persistent or regressing CIN2 lesions. We found a significant increase in the number of CD8⁺, granzyme positive T cells in regressing lesions when compared with persistent lesions, but no significant difference in the number of Tregs between the two groups.

From these experiments we conclude that granzyme positive CD8⁺ T cells are more likely to be identified in lesions that will regress, even in lesions that contain populations of Tregs. This suggests that the Tregs may not exert a strong suppressive effect on the CD8 T cytotoxic T cells in CIN2 lesions.

207

Prebiotic supplement effect on the response to a mutated PAP-derived vaccine in old mice

McArdle, S.E.¹, Rees, R.C.¹, Pockley, A.G.¹, Gibson, G.R.²

¹Nottingham Trent University, The John van Geest Cancer Research Centre, Nottingham, United Kingdom, ²Reading, Food and Nutritional Sciences, Reading, United Kingdom

Vaccine-based immunotherapy can increase the overall survival of patients with advanced prostate cancer. However, the efficacy of vaccine-elicited anticancer immune responses is heavily influenced by the physical, nutritional, and psychological status of the patient. Given their importance, these parameters should be carefully considered for the design of future clinical trials testing this immunotherapeutic paradigm in prostate cancer patients.

We have recently demonstrated the ability of a prostatic acid phosphatase-derived 15mer peptide (PAP-114) to reduce the growth of established TRAMP C1 tumours in a pre-clinical murine model. These results are encouraging and show the efficacy potential of vaccine based therapy, however these were obtained using relatively young animals (maximum 12 weeks) and therefore might not represent the responsiveness/effectiveness which would be generated in older mice or in prostate patients, the average of which is 65 years. We have since elongated, mutated and patented this PAP-derived sequence and demonstrated its superiority in generating PAP-peptides specific T-cells compared to the wild-type, short or long, PAP-sequences. Moreover, due to its length this sequence contains several peptides with high binding affinity to multiple HLA-haplotypes thereby avoiding the need, in the future, to HLA type patients prior to vaccination.

People over 60 typically exhibit a marked reduction in gut bacteria, however supplementation with pre-biotics (e.g. GOS) can restore it, Here we show that older mice benefited from prebiotic supplementation in their diet two weeks prior to vaccination.

These results have profound consequences for the management of any vaccination trial involving older patients, especially cancer patients.

208

Can IL-25 remove the malignant cells spontaneously? An in vitro evaluation of IL-25 versus IL-17B on breast cancer cell lines

Shokrollahi Barough, M.^{1,2}, Pak, F.¹, Kokhaei, P.^{1,3}, Barati, M.¹, Barabadi, M.⁴

¹Semnan University of Medical Sciences, Department of Immunology and Cancer Research Center, Semnan, Iran, Islamic Republic of, ²Tehran University of Medical Sciences, Immunology, Asthma and Allergy Research Institute, Tehran, Iran, Islamic Republic of, ³Karolinska Institute and Karolinska University Hospital Solna, Immune Gene Therapy Lab, CCK, Stockholm, Sweden, ⁴Tehran University of Medical Sciences, Department of Immunology, Teheran, Iran, Islamic Republic of

Introduction: IL-25 (IL-17E) and IL-17B are two members of IL-17 family, which bind to a unique receptor (IL-25R). IL-25 can induce apoptosis and IL-17B can enhance the survival of tumor cells in breast cancer. IL-25R as a poor diagnostic marker is widely expressed on breast cancer tissue the exact role of these cytokines is unknown.

Materials and methods: MCF-7 (Estrogen receptor (ER) positive), MDA-MB231 (ER-) like malignant cells and MCF-10A as a non-malignant breast cell line (ER-) was treated with recombinant human cytokines (rhIL-25/IL-17E and rhIL-17B). Apoptosis by flow cytometry and the proliferation by MTT assay was evaluated. Gene expression analysis was performed for IL-25R, IL-17B and MMP-1 by Real Time PCR before and after treatment.

Results: IL-25 treatment induced apoptosis up to 20% and IL-17B promoted cell viability in malignant cell lines without effect on MCF-10A cells. In combinational cytokine treatment the apoptosis assay showed antagonistic effect of IL-17B on IL-25. Both cytokines increased expression level of IL-25R only in ER+ cells and IL-17B expression level in both malignant cells. Although IL-17B expression wasn't observed at non-treated MCF-10A cells, IL-17B treatment caused to 105 fold increment of IL-17B expression. Both cytokines induced elevated level of MMP-1 expression in MDA-MB231.

Conclusion: ER status can affect the IL-25R expression in response to IL-25 and IL-17B treatments without effect on MMP-1. IL-25 may promote the apoptosis in malignant cells, however overexpression of IL-17B in response to IL-25 switch on the IL-17B expression in non-malignant cells which may enhance the proliferation in ER+ cells and promote the metastasis in ER- cells.

209

The relationship between tumor associated neutrophils and tumor progression and the mechanism

Han, M., Liu, H., Bai, R.

Ningxia Medical University, Department of Immunology, Yinchuan, China

Objective: To study the relationship of tumor associated neutrophils (TANs) with the occurrence and progression of

gastric cancer, and its molecular mechanism.

Methods: Collecting gastric tumor tissues and adjacent noncancerous tissues from 48 patients with final diagnosis of gastric cancer. Immunohistochemistry method was used to detect the number of TANs and the levels of NE and CXCL-1. The correlations between TANs and CXCL-1, NE, MMP-9, LOX, angiogenesis in gastric cancer tissues were evaluated with Pearson correlation analysis. Peripheral blood neutrophils of normal person were separated, and induced through IFN- β antibody with concentration of 5ug/ml (IFN- β antibody group) and 50% tumor cultivation mediums (tumor cultivation mediums group). The RNA and proteins of LOX MMP-2 MMP-9 generating from neutrophils were detected using real-time PCR and ELISA. And enzymatic activity of MMP-2 and MMP-9 were analyzed with gelatin zymography assay.

Results: The number of TANs was more in gastric cancer tissue than that in adjacent noncancerous tissues; the number of TANs were positively correlated with the expression levels of NE, CXCL-1, LOX, VEGF and tumor angiogenesis; when the neutrophils from normal person were induced to N2 type, the amounts of MMP-9, MMP-2 and LOX secreting by neutrophils were increased significantly.

Conclusions: The most of tumor associated neutrophils in gastric cancer were N2 type, they adjust the angiogenesis and occurrence of gastric cancer through NE, CXCL-1, LOX, MMP-2, MMP-9 and VEGF.

Immune biomarkers of response to chemoradiotherapy in locally advanced rectal cancer

McCoy, M.J.^{1,2}, Hemmings, C.^{3,4}, Anyaegbu, C.C.¹, Lee-Pullen, T.F.^{1,4}, Austin, S.J.¹, Miller, T.J.^{1,4}, Bulsara, M.K.⁵, Zeps, N.^{1,4}, Nowak, A.K.^{2,6}, Lake, R.A.², Platell, C.F.^{1,4}

¹St John of God Subiaco Hospital, Perth, Australia, ²The University of Western Australia, School of Medicine and Pharmacology, Perth, Australia, ³St John of God Pathology, Perth, Australia, ⁴The University of Western Australia, School of Surgery, Perth, Australia, ⁵The University of Notre Dame, Institute for Health Research, Fremantle, Australia, ⁶Sir Charles Gairdner Hospital, Medical Oncology, Perth, Australia

Background: Chemoradiotherapy prior to surgery (neoadjuvant CRT) is recommended for locally advanced rectal cancer. Individual response to CRT varies considerably with ~20% of patients achieving a pathologic complete response (pCR), which is associated with improved long-term outcome. Factors associated with response are poorly understood. This study aims to identify immunological markers of response to CRT.

Methods: Foxp3+, CD3+, CD8+, CD4+, and IL-17+ cell density was assessed by standard immunohistochemistry in post-CRT surgical samples from 128 patients with advanced rectal cancer. Pre-CRT biopsy samples were obtained from 114 (89%) of cases and infiltrating Foxp3+, CD3+ and CD8+ cells identified using the same methods. Cell densities were quantified using digital image analysis software and correlated with clinical outcome (tumour regression grade and survival).

Results: Low stromal Foxp3+ Treg density post-CRT was strongly associated with pCR (OR: 5.27 (95% CI 1.62 - 17.16), P

= 0.006, after adjustment for pre-surgery clinical factors) and improved recurrence-free survival (HR: 0.46 (95% CI: 0.23 - 0.92), P = 0.03). However, density of Treg, total T cells, or CD8+ T cells in pre-CRT biopsy samples was not predictive of subsequent response to CRT or long-term outcome. Peripheral blood T cell subsets pre- and post-CRT are currently being assessed in a second patient cohort for correlation with CRT response and tumour-infiltrating T cell subset densities.

Conclusions: Pretreatment density of T cell subsets in the local tumour environment does not predict response to neoadjuvant CRT in rectal cancer. However, depletion of Treg during CRT may contribute to treatment efficacy.

212

***P. gingivalis*-induced inflammation and immunoregulation promote the progression of pancreatic cancer**

Jan, M.-S.^{1,2,3}, Lin, C.-W.¹, Lin, Y.-C.¹, Chen, W.-T.¹, Chen, Y.-J.¹, Tsai, C.-H.⁴, Lee, H.-L.⁵, Hsu, L.-J.⁶

¹Chung-Shan Medical University, Institute of Biochemistry, Microbiology and Immunology, Taichung, Taiwan, Republic of China, ²Chung Shan Medical University Hospital, Division of Allergy, Immunology, and Rheumatology, Taichung, Taiwan, Republic of China, ³Chung-Shan Medical University, Immunology Research Center, Taichung, Taiwan, Republic of China, ⁴Chung-Shan Medical University, Institute of Medicine, Medical College, Taichung, Taiwan, Republic of China, ⁵Chung Shan Medical University Hospital, Division of Surgery, Taichung, Taiwan, Republic of China, ⁶National Cheng Kung University, Department of Medical Laboratory Science and Biotechnology, Tainan, Taiwan, Republic of China

Pancreatic cancer is one of the most malignant cancers, with a very low five-year relative survival rate. It is noteworthy that recently a few epidemiological research studies have suggested an association between periodontitis and pancreatic cancer. Our studies demonstrated that inoculation of periodontal pathogen *Porphyromonas gingivalis* (*P. gingivalis*) could promote pancreatic cancer (PC) progression in *LSL-Kras^{G12D/w}Pdx-1-Cre^{+/-}* transgenic mice. Significant rapid pancreatic intraepithelial neoplasias (PanINs) progression, which was not found among the *vehicle group mice*, was discovered in *pancreata* of six-week-old *LSL-Kras^{G12D/w}Pdx-1-Cre^{+/-}* mice one month following *P. gingivalis* inoculation episodes. The levels of epithelial-mesenchymal-transition increased in *P. gingivalis*-treated group as well. On the other hand, in vitro treatments of *P. gingivalis* or *P. gingivalis*-cultured broth could induce inflammatory responses including IL-1b, TNF-a, and COX-2 expression of PC and macrophage cell lines. These findings significantly support that periodontitis can accelerate pancreatic cancer progression through induction of inflammation, which, in turn can provide guidance for future research into prophylactic strategy for pancreatic cancer development.

213

Anti-proliferation effects of *Scrophularia oxypepala* medicinal plant extract on the prostate cancer cell line (PC3)

Baradaran Gavvani, M.¹, Nasirzonouzi, M.², Nasirzonouzi, P.³, Baradaran, M.⁴

¹Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, ²Azad Islamic University of Tabriz, Biomedical Engineering, Tabriz, Iran, Islamic Republic of, ³Azad Islamic University of Tabriz, Tabriz, Iran, Islamic Republic of, ⁴Technical University of Sahand, Tabriz, Iran, Islamic Republic of

Introduction: Medical plants have been intensively studied as a source of antitumor compounds and immunomodulatory effect. The antitumor effects of the *Scrophularia oxypepala* medicinal plant extract is not studied on the PC3 prostate cancer cell lines. In the present study, cytotoxic effects of the *Scrophularia oxypepala* extract were investigated on viability of PC3 prostate cancer cell lines.

Material & methods: The cytotoxic effects of *Scrophularia oxypepala* on PC3 prostate cancer cell lines were studied using MTT assay, Trypan blue staining, and DNA fragmentation assay were done at selected concentrations of the plant extract.

Results: According to the findings, the *Scrophularia oxypepala* medicinal plant extract (stems and leaves) altered cells morphology. The *Scrophularia oxypepala* extract inhibited cell growth albeit in a time and dose dependent manner and resulted in degradation of chromosomal DNA.

Conclusion: Our data well established the anti-proliferative effect of *Scrophularia oxypepala* extract, and clearly showed that the plant extract can induce apoptosis in vitro, but the mechanism of its activities remained unclear.

214

Pre-clinical development of a first-in-class heat shock protein-based personalized cancer vaccine

Khattar, M., Morin, B., Uduman, M., Zelin, J., Stein, R., Exley, M., Castle, J., Levey, D.

Agenus Inc., Lexington, United States

Tumors accumulate mutations which can give rise to neo-epitopes recognizable as non-self by T-cells. Advances in next-generation sequencing and bioinformatics make it possible to analyze individual patients' tumor genomes and predict immunogenic mutations, which can be synthesized as short peptides, RNA or DNA for use in personalized cancer vaccines. However, these approaches need optimization for safe and effective induction of anti-tumor T-cell responses. We addressed this challenge by complexing synthetic long peptides comprising predicted tumor neo-epitopes to recombinant Hsc70, creating personalized vaccine candidates, AutoSynVax™ (ASV™), administered with QS-21 Stimulon® adjuvant. The same platform comprising Hsc70 plus synthetic long viral peptides was previously validated in a Phase-2 trial, demonstrating effective T-cell responses and reduced viral shedding in HSV-2+ subjects. ASV immunization is designed to facilitate antigen-processing and presentation of neo-epitopes to T-cells, resulting in robust immune responses. Therapy with ASV comprising two previously validated neo-epitopes in B16.F10 melanomas

resulted in significantly lower tumor burden and prolonged survival in mice in a dose-dependent manner. The relationship between tumor protection conferred by ASV and T-cell response to neo-epitopes is under investigation. In addition, novel B16.F10 neo-epitopes have been identified using our proprietary algorithm, AIM™ v1.1, which analyzes whole-exome and RNA-sequencing data to identify immunogenic mutations. We continue to optimize ASV to facilitate complexing of larger pools of peptides to Hsc70. With a positive record of Hsc70 and QS-21 Stimulon exposure in humans and demonstrated preclinical anti-tumor activity of ASV, we are poised to begin a first-in-human clinical trial in second half of 2016.

215

Cytokine/chemokine pattern in cutaneous melanoma

Neagu, M.^{1,2}, Constantin, C.¹, Surcel, M.¹, Zurac, S.^{3,4}

¹Victor Babes National Institute of Pathology, Immunology, Bucharest, Romania, ²University of Bucharest, Bucharest, Romania, ³Colentina University Hospital, Pathology, Bucharest, Romania, ⁴University of Medicine and Pharmacy, Pathology, Bucharest, Romania

Circulatory cyto/chemokines pinpoint inflammation processes enabling melanoma cells metastasis through blood/lymphatic systems to other tissues. Patterns of these immune-related molecules and their secretory immune cells can be useful in immune-therapy monitoring of cutaneous melanoma patients. Hence, the aim of our study was the identification in melanoma patients' peripheral blood the cyto/chemokines and the percentage of immune cells that can secrete them, as an outline of the disease stage and clinical outcome.

50 patients (AJCC stages) were included and followed for 36 months. Pre and post-surgery/therapy immune parameters evaluation was performed for all patients including peripheral immune cell populations (*Intracellular Cytokine Staining Kit - Human (BD Pharmingen)*) and circulating cytokines / chemokines using xMAP technology; 170 normal subjects (matching gender and age) represented the control group. All enrolled subjects gave their written consent and the study was approved by the Ethical Committees.

We have found different circulatory cyto/chemokines patterns matching disease stages. Out of the studied cyto/chemokines, IL-6, TNF-alpha, IL-10 and IL-8 were found statistically increased with advanced stages. In the follow-up study, IL-6 correlated with survival, while IL-8, IL-10 and IL-12 did not correlate with overall survival or relapse free survival. Regarding circulatory immune cells capable of secreting the studied cyto/chemokines we found that there is a significant proportion of lymphocytes that can be induced to secrete IFN-γ or TNF-α, while no differences compared to controls for IL-2 secreting cells.

Circulatory immune markers can complete the immune status of the patient.

Study funded through PN-II-PT-PCCA-2013-4-1407(MELTAG 190/2014).

Roles of CD11c⁺ T cells in anti-tumor immune responses

Chiba, M., Nakano, N.

Tokyo University of Science, Research Institute for Biomedical Sciences, Noda, Japan

Immune responses against tumor cells are suppressed as tumor microenvironment changes during tumor progression. T cells that attack tumor cells are energized by various mechanisms including signals induced through PD-1 and CTLA-4. In order to find out the molecules that control T cell activation and suppression in tumor microenvironment, we analyzed infiltrating cells in the grafted tumors from early time point (day 10~15) to later stages (day 20~30). Tumor microenvironment was clearly shifted from the M1 macrophage-dominant stage (early phase) to the M2 macrophage stage. Among T cells infiltrating in an early phase, there were T cells expressing CD11c, however, these T cells were rare in the later stage. CD11c⁺ T cells in tumor tissues were CD44^{high}, CCR2⁺, Foxp3⁻, expressing lower levels of PD-1 than CD11c⁻ T cells. In normal mice, T cells with CD11c expression were also found in the spleen, lymph nodes and the thymus although the frequency was low. CD11c⁺ T cells were frequently found within the intestinal epithelial lymphocytes, most of which were expressing CD8aa.

In vitro activation of T cells with anti-CD3+CD28, PMA+ionomycin failed to induce CD11c expression while T cells stimulated with Concanavalin A (Con A) became CD11c⁺. Interestingly, these CD11c⁺ T cells were always PD-1 negative. These results suggested that Con A could activate a distinct signaling pathway, which induced CD11c expression and suppressed PD-1 induction.

The prognosis of a variety of human malignancies including melanoma is dictated by the abundance, spatial trafficking and quality of intratumoral T cell infiltrates (Erdag G, Cancer Res, 2012). Salerno *and al.* recently studied chemokine receptors (CC/CXCR) expression on Tumor-Infiltrating T cells (TILs) from several metastasis localizations and suggest a limited tissue-specific homing to human melanoma (Salerno EP, Int J Cancer, 2014). We studied the expression of these CC/CXCR on peripheral T cells from 57 metastatic melanoma (MM) patients, during Ipilimumab therapy (47 patients) and healthy volunteers (HV). Firstly, correlation matrices indicated similar chemokine receptor expression on CD4 and CD8 T cells, except for CXCR4 and CD103, and concordant patterns in naïve, effector and memory T cells. After classification of patients based on their metastasis localizations with skin and lymph node, lung or other distant organs with or without lung involvement, 62 parameters were found to differ significantly (FDR < 0.1) according to distinct localizations metastasis. Expression level normalized with respect to HV indicated that specific signatures could identify preferential metastasis localizations. Loss of CCR6 or CXCR3 (but not CLA) on circulating T cell subsets was associated with skin or lymph node metastases, loss of CXCR4, CXCR5 and CCR9 with lung involvement, and a raise in CCR10 or CD103 with widespread dissemination. High frequencies of CD8⁺CCR9⁺ TN correlated with prolonged OS, while neutralizing the CCR9/CCL25 axis in mice stimulated tumor progression. Effector memory CLA⁺CD8⁺TEM cells increased upon CTLA4 blockade, predicting disease control at 3 months of therapy.

Trastuzumab is a humanized antibody to the human epidermal growth factor receptor-2 (HER2/neu) and mainstay therapy for HER-2-positive breast cancer. However, many patients on Trastuzumab develop resistance. Here we demonstrate the unique and potent ability of the histone deacetylase inhibitor, panobinostat to augment the therapeutic efficacy of anti-HER2 therapy in models of trastuzumab sensitive and resistant HER2⁺ cancer. Against human BT474 tumors that are intrinsically sensitive to the cytostatic effects of trastuzumab, the combination therapy caused tumor regression in both NOD SCID IL-2 receptor gamma^{-/-} (NSG) and SCID mice. Rejection of the BT474 tumors in response to trastuzumab and panobinostat co-treatment was dependent on therapy-induced inactivation of AKT in the BT474 tumor cells. Most striking and clinically important however, was the combined ability of panobinostat and trastuzumab to eradicate trastuzumab-resistant HER2⁺ tumors. An intact host innate immune system was critical to the curative activity of the combination therapy in trastuzumab resistant AU565 xenografts and BT474 tumors, expressing constitutively active myristoylated AKT (MyrATK). Against these tumors, therapy-induced recruitment of NK cells and antibody dependent cell mediated cytotoxicity underpinned the combined curative effects of panobinostat and trastuzumab. Importantly these findings highlight the novel immune enhancing effects of panobinostat. They also provide compelling evidence that this HDACi can effectively cooperate with the tumor-extrinsic actions of trastuzumab to evoke durable therapeutic responses in settings of relapsed refractory HER2⁺ breast cancer.

Blockade of interleukin-6 signaling reduces regulatory T cells in ascites of advanced epithelial ovarian cancer

Kampan, N.C.^{1,2}, Madondo, M.T.¹, Quinn, M.A.^{3,4}, McNally, O.M.^{3,4}, Plebanski, M.¹

¹Monash University, Immunology, Melbourne, Australia, ²University Kebangsaan Malaysia, Obstetrics & Gynaecology, Kuala Lumpur, Malaysia, ³Royal Women Hospital, Gynae-oncology Unit, Melbourne, Australia, ⁴Melbourne University, Obstetrics & Gynaecology, Melbourne, Australia

Epithelial ovarian cancer (EOC) has the highest gynaecologic mortality rate globally, as up to two-thirds are diagnosed at an advanced-stage. Ascites, an accumulation of peritoneal fluid is linked to poor prognosis and chemo-resistance. Malignant ascites may aid tumour persistence by harboring immunosuppressive regulatory T cells (Tregs) that render effector T cells (Teff) dysfunctional, as well as soluble factors such as interleukin 6 (IL-6) that promote an inflammatory niche. Upregulation of Tregs and IL-6 have been correlated separately with tumour progression and reduced survival in advanced EOC, however their relationship is not well understood. We studied the immunomodulatory effect of IL-6 on Tregs within malignant ascites *in-vitro*. Peripheral blood mononuclear cells (PBMC) from healthy donors were incubated in two conditions with controls- media with exogenous IL-6 or cell-free malignant ascites from advanced EOC patients for 48 hours. Exogenous IL-6 was used at 50ng/ml to mimic the natural level in ascites.

Bioactive IL-6 within the ascites was neutralized with human monoclonal antibody to IL-6. The frequency and phenotype of Tregs as well as Teff were then evaluated. The results from this study show for the first time that a blockade of IL-6 activity in ascites decreases the frequency of Treg, otherwise induced by exogenous IL-6 in media and ascites, and increases the ratio of Teff/Tregs. Antibody blockade of IL-6 specifically within ascites may offer a novel, clinically translatable strategy to increase immunocompetence in the local tumour microenvironment, and combined with other treatments, may offer more effective modalities of management for advanced EOC.

Adenosine receptor A_{2A} blockade increases the efficacy of anti-PD-1 through enhanced anti-tumor T cell responses

Beavis, P.¹, Milenkovski, N.¹, Henderson, M.¹, John, L.¹, Allard, B.², Loi, S.¹, Kershaw, M.¹, Stagg, J.², Darcy, P.¹

¹University of Melbourne, Peter MacCallum Cancer Centre, Melbourne, Australia, ²Centre Hospitalier de l'Université de Montréal, Montreal, Canada

Immunotherapy is rapidly emerging as a cancer treatment with high potential. Recent clinical trials with anti-CTLA-4 and anti-PD-1/PD-L1 antibodies (mAbs) suggest that targeting multiple immunosuppressive pathways may significantly improve patient survival. The generation of adenosine by CD73 also suppresses anti-tumor immune responses through the activation of A_{2A} receptors on T cells and natural killer (NK) cells. We sought to determine whether blockade of A_{2A} receptors could enhance the efficacy of anti-PD-1 mAb. The expression of CD73 by tumor cells limited the efficacy of anti-PD-1 mAb in two tumor models, and this was alleviated with concomitant treatment with an A_{2A} adenosine receptor antagonist. The blockade of PD-1 enhanced A_{2A} receptor expression on tumor-infiltrating CD8(+) T cells, making them more susceptible to A_{2A} -mediated suppression. Thus, dual blockade of PD-1 and A_{2A} significantly enhanced the expression of IFN γ and Granzyme B by tumor-infiltrating CD8(+) T cells and, accordingly, increased growth inhibition of CD73(+) tumors and survival of mice.

The results of our study (1) indicate that CD73 expression may constitute a potential biomarker for the efficacy of anti-PD-1 mAb in patients with cancer and that the efficacy of anti-PD-1 mAb can be significantly enhanced by A_{2A} antagonists. We have therefore revealed a potentially novel biomarker for the efficacy of anti-PD-1 that warrants further investigation in patients. Because our studies used SYN-115, a drug that has already undergone phase IIb testing in Parkinson disease, our findings have immediate translational relevance for patients with cancer.

Comparison of the distribution of ERAP1 single nucleotide polymorphisms in non-small cell lung cancer patients and healthy controls in Poland and China

Yao, Y.¹, Wiśniewski, A.², Ma, Q.³, Kowal, A.⁴, Porębska, I.⁴, Pawełczyk, K.⁵, Yu, J.¹, Dubis, J.⁶, Żuk, N.⁶, Li, Y.⁷, Shi, L.¹, Kuśnierczyk, P.⁸

¹Institute of Medical Biology, Chinese Academy of Medical Sciences

& Peking Union Medical College, Kunming, China, ²Ludwik Hirsfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Laboratory of Immunogenetics and Tissue Immunology, Wrocław, Poland, ³No.3 Ailiated Hospital of Kunming Medical University, Thoracic Surgery, Kunming, China, ⁴Wrocław Medical University, Pulmonology and Lung Cancer, Wrocław, Poland, ⁵Wrocław Medical University, Thoracic Surgery, Wrocław, Poland, ⁶Regional Specialist Hospital in Wrocław, Research and Development Centre, Wrocław, Poland, ⁷No.1 Ailiated Hospital of Kunming Medical University, Geriatrics, Kunming, China, ⁸Ludwik Hirsfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Laboratory of Immunogenetics and Tissue Immunology, Wrocław, Poland

HLA-I-bound peptide antigen presentation depends on antigen-processing machinery molecules. Aminopeptidase residing in endoplasmic reticulum 1 (ERAP1) trims peptides to optimal length for HLA-I binding. Single nucleotide polymorphisms (SNPs) in the ERAP1 gene result in changes in aminopeptidase activity and specificity, which may affect susceptibility to cancer. However, non-small cell lung carcinoma (NSCLC), the most frequent type of lung cancer, has not been studied in this respect yet. Here, we present results of our study of genotype and haplotype frequencies of four coding and nonsynonymous ERAP1 SNPs, rs26653G>C [R127P], rs26618T>C [I276M], rs30187C>T [K528R], rs27044C>G [Q730E], in NSCLC in two genetically distant populations, Chinese Han and Poles. We tested 420 cases and 385 healthy control individuals in China as well as 317 cases and 506 controls in Poland. We found associations of all four SNPs with NSCLC in Chinese but not in Poles. No differences in SNP frequencies between squamous cell carcinoma and adenocarcinoma were found, although a weak trend in Poles for two SNPs (rs26653 and rs30187) was observed. The differences between Chinese and Poles might be explained by highly significant differences in SNP genotype frequencies between Chinese and Poles (except for rs26618). In accord with this, most frequent ERAP1 haplotypes were distributed differently in cases versus controls in Chinese, but not in Poles. Our findings add to differences between Orientals and Caucasians in genetics of disease susceptibility.

222

p16 overexpression and high levels of Treg cells in smokers young patients with oropharyngeal cancer

Faxas, M.E.¹, Hernández, D.¹, Carballoso, E.¹, Jiménez, J.¹, González, N.², Arango, M.¹

¹Institute of Oncology and Radiobiology, Immunology, Havana, Cuba, ²Institute of Oncology and Radiobiology, Havana, Cuba

Introduction: Head and neck cancers are malignancies virally mediated and tobacco and alcohol associated. In these diseases, tumor development is close related to the host immune system. Material and methods: Twenty-two young patients (Median age: 30 years, range, 20-37 years), heavily smokers, with locally advanced oropharyngeal carcinoma were studied. Pretreatment peripheral blood lymphocytes were analyzed by flow cytometry (CD3, CD4, CD8, CD16, CD20, and CD4+CD25+Foxp3+ Treg cells). All patients were subjected to immunochemistry assays

for p16 and lymphocyte subsets.

Results: Seventeen tumors (80%) were p16-positive. The tissue samples from p16 positive patients showed an infiltration by intratumoral CD20 B cells and FoxP3 Treg cells. In peripheral blood, high levels of Tregs, NK and of CD8 cells were detected. On the contrary, low values of CD3 and CD4 cells were detected. In assessing conventional prognostic factors, there were no correlations of lymphocyte subsets with tumor grade or nodal status.

Conclusions: In young patients with oropharyngeal carcinoma an immunosuppressive status could favor the carcinogenic effects of tobacco and virus.

Blockade of inhibitory receptor TIGIT prevents tumor-induced NK cell exhaustion

Zhang, Q., Bi, J., Zheng, X., Sun, R., Tian, Z.

University of Science and Technology of China, Hefei, China

Checkpoint immunotherapy against tumor has drawn extensive attentions. Emerging studies showed that TIGIT might be a potential checkpoint supplementary for existing ones inducing CTL exhaustion. Since TIGIT expressed on both CTL and NK cells, we want know whether TIGIT is involved in NK cell exhaustion and its blockade improves NK cell-based immunotherapy. Here, we found that TIGIT expression is strongly associated with exhaustion of NK cells during tumor progression while NK cells barely expressed CTLA-4 or PD-1, two well-recognized checkpoints on CTL. TIGIT blockade reversed exhaustion of tumor-infiltrating NK cells, independent of adaptive immune system, and improved adaptive recall response against tumor reloading. Absence of NK cells more significantly diminished the therapeutic effects from TIGIT blockade if compared with CTL. Thus, our findings indicate that TIGIT might be critical checkpoint for reversing exhaustion of not only CTL but also NK cells, implying more promising application.

The molecular and immunological mechanism of hepatoma development promoted by HBV-SALL4

Han, Q.

Shan Dong University, Jinan, China

HBV infection and liver cancer are closely related, but the mechanism of HBV-induced liver cancer has not been fully elucidated. Recent research demonstrated that the SALL4 is highly expressed in patients with hepatoma, but the relationship between HBV infection and SALL4 is not clear, also the effect of SALL4 on hepatic immune tolerance remains unclear. In our study, DEN-induced liver cancer was established in HBV transgenic mice. Dynamic SALL4 up-regulation expression was observed during HCC development. Using the bioinformatics and molecular biology methods, we confirmed the molecular mechanism that HBV regulate of SALL4 expression by STAT3 signal pathway. And luciferase reporter assay validated several target genes of SALL4. When SALL4 is overexpressed or silenced, liver immune tolerance state was assayed, and we found MDSC

accumulation when SALL4 is high expressed in liver. This study revealed the relationship between HBV infection and SALL4 expression, and reveal the molecular and immunological mechanism how SALL4 promotes hepatoma. Thus, our study will finally provide more precise evidence for diagnosis and treatment of liver cancer.

225

PEG10 promotes human breast cancer cells proliferation, migration and invasion

Zhang, Q., Li, X.

School of Basic Medical Sciences, Wuhan University, Department of Immunology, Wuhan, China

Paternally expressed imprinted gene 10 (PEG10), derived from the Ty3/Gypsy family of retrotransposons, has been implicated as a genetic imprinted gene. Accumulating evidence suggests that PEG10 plays an important role in tumor growth in several cancers, including hepatocellular carcinoma, lung cancer and prostate cancer. However, the correlation between PEG10 and breast cancer remains unclear. In the present study, we evaluated and characterized the role of PEG10 in human breast cancer proliferation, cell cycle, clone formation migration and invasion. The expression level of PEG10 was significantly elevated in breast cancer tissues and associated with distant metastasis and poor clinical outcome. Gene set enrichment analysis indicated that high expression of PEG10 could enrich cell-cycle related processes in breast cancer tissues. Ectopic overexpression of PEG10 in breast cancer cells enhanced cell proliferation, cell cycle, clone formation along with migration and invasion. Cell-to-cell junction molecule E-cadherin was downregulated and matrix degradation proteases MMP-1, MMP-2, MMP-9 were upregulated after PEG10 overexpressed. Our results demonstrated that PEG10 is a crucial oncogene and has prognostic value for breast cancer, which could be applied in breast cancer diagnosis and targeting therapy in future.

226

HER-2⁺ breast cancer cells expressing GPI-anchored cytokines induce long lasting anti-tumor memory response

Bommireddy, R., Margaroli, C., Shafizadeh, Y., Bozeman, E., Munoz, L., Menon, A., Selvaraj, P.

Emory University School of Medicine, Department of Pathology, Atlanta, United States

Breast cancer is the second leading cause of death among female cancer patients. Human epidermal growth factor receptor 2 (HER-2) overexpression is associated with poor prognosis in 15-20% of breast cancer patients. Anti-HER-2 antibody (Herceptin) prolongs the survival of the HER-2⁺ breast cancer patients. However, resistance to Herceptin is a cause for relapse of aggressive, metastatic cancer in these patients. Our earlier studies have demonstrated that PD-L1 blockade enhances the efficacy of HER-2⁺ breast cancer whole cell vaccine by increasing the infiltration of T cells into the tumor. The goal of the present study is to determine the duration of protective anti-tumor memory responses to HER-2⁺ breast cancer. In this

study, we demonstrate the beneficial effect of GPI-anchored cytokine molecules as adjuvants for generating long lasting memory response against HER-2⁺ as well as HER-2 negative breast cancer in syngeneic tumor models. Female BALB/c mice were challenged with D2F2/E2 (HER-2 positive) cells or D2F2/E2 transfected with GPI-IL-12 or GPI-GM-CSF. While the wild-type challenged mice developed tumors, the mice challenged with GPI-cytokine expressing D2F2/E2 cells were protected. Protected mice were re-challenged with D2F2/E2 cells 3 months later and D2F2 cells 4 months later. All of the mice challenged with D2F2 (HER-2 negative) or D2F2/E2 were protected. We have observed strong antibody responses against HER-2 and D2F2 tumor specific antigens in these mice. Our results show that long lasting protective anti-tumor memory response against D2F2 and D2F2/E2 is generated by vaccination with D2F2/E2 cells expressing GPI-anchored cytokine molecules.

227

Galectin-3 in prostate cancer proliferation and metastasis

Aalinkel, R., Abou-Jaoude, E., Parikh, N., Reynolds, J., Sykes, D., Mammen, M., Mahajan, S., Schwartz, S.
University at Buffalo, Medicine, Buffalo, United States

Bone metastasis occurs in >90% of patients in advanced, metastatic prostate cancer (CaP). Development of therapies to prevent bone metastases are a high priority in CaP research. In CaP, factors released from infiltrating CaP cells can alter the equilibrium between the host's bone-degrading cells, osteoclasts and osteoblasts, facilitating the process of bone metastases. Galectin-3 (Gal-3) is implicated in apoptosis, angiogenesis, and tumor progression. We hypothesized that silencing of Gal-3 expression using RNAi technology would suppress the progression of CaP. Our goal was to investigate how Gal-3 suppression would affect osteoclast and osteoblasts within the microenvironment of metastasis and identify the molecular mechanisms underlying the role of Gal-3 in CaP metastasis. Gal-3 may regulate the expression of osteopontin (OPN), which regulates osteoclast motility and osteoclast-mediated bone resorption. We evaluated if Gal-3 knockdown in PC-3 CaP cells was associated with reduced proliferation, invasion and colony formation, and if Gal-3 potentiates the transcription of OPN in ST2 human osteoblasts. Our results show a significant decrease in cell proliferation (62% decrease; $p < 0.01$), colony formation (77% decrease; $p < 0.01$), and decreased expression of VEGF (41% decrease; $p < 0.05$), IL-8 (56% decrease; $p < 0.05$) and MMP-9 (69% decrease; $p < 0.01$) in PC-3 CaP cells treated with Gal-3 siRNA, additionally, we observed a significant decrease in OPN expression (73% decrease; $p < 0.01$), indicating that Gal-3 plays a role in progression of CaP metastasis. Our results suggest that Gal-3 may be a therapeutic target to prevent bone metastases in advanced CaP.

228

IL-23, an inflammatory cytokine, decreased by shark cartilage and vitamin A oral treatment in patient with gastric cancer

Zarei, R.

Azad Islamic University, Faculty of Medical Science-Immunology Department, Sari, Iran, Islamic Republic of

Introduction: IL-23 is responsible for the differentiation and expansion of Th17/ThIL-17 cells from naive CD4⁺ T cells. TGF- β is also share for the differentiation Th17 producing IL-17 and CD4⁺CD25⁺Foxp3^{hi}T regulatory cells from naive CD4⁺ T cells which are involved in the regulation of immune response,..... Vitamin A and it's derivatives inhibit or reverse the carcinogenic process in some types of cancers . Shark cartilage has antitumor peptides to prevent angiogenesis, in vitro. Our purpose is whether simultaneous oral treatment vitamin A and shark cartilage can modulate IL-23/IL-17 and CD4⁺CD25⁺Foxp3 T regulatory cell/TGF- β pathways and Th1/Th2 immunity in patients with gastric cancer or not.

Materials and methods: The first investigated an imbalanced supernatant of cytokines in patients with gastric cancer existing was measured by ELISA. Associated with cytokines measuring such as IL-23,IL-17,TGF- β ,IL-4 and γ -IFN, then flow cytometry was employed to determine whether the peripheral blood mononuclear cells such as CD4⁺CD25⁺Foxp3^{high}T regulatory cells in patients with gastric cancer were changed correspondingly.

Results: An imbalance between IL-17 secretion and TGF- β /Foxp3 t regulatory cell pathway and so, Th1 immunity (γ -IFN production) and TH2 immunity (IL-4 secretion) was not seen in patients with gastric cancer treated by vitamin A and shark cartilage. But, the simultaneous oral treatment of shark and vitamin A indicated a down-regulation of IL-23, at least cytokine level.

Conclusion: IL-23, as a pro-angiogenesis cytokine, probably, helps with tumor growth. Hence, it is suggested that down-regulation of IL-23, at least cytokine level, is useful for anti-tumor immune responses in patients with gastric cancer.

229

MPL adjuvant encapsulated in liposome coated with P5 HER2/neu peptide: a potent prophylactic vaccine for breast cancer

Shariat, S.¹, Jalali, S.A.², Jafari, M.R.³, Alimohammadi, R.²

¹School of Pharmacy, Shahid Beheshti University of Medical Sciences, Department of Pharmaceutics, Tehran, Iran, Islamic Republic of, ²Medical School, Shahid Beheshti University of Medical Sciences, Department of Immunology, Tehran, Iran, Islamic Republic of, ³Mashhad University of Medical Sciences, Biotechnology Research Center, Nanotechnology Research Center, Mashhad, Iran, Islamic Republic of

Vaccines containing synthetic peptides derived from tumor-associated antigens (TAA) can elicit potent cytotoxic T lymphocyte (CTL) response if they are formulated in an optimal vaccine delivery system. The aim of this study was to develop a simple and effective lipid-based vaccine delivery system

using P5 HER2/ neu-derived peptide conjugated to Maleimide-PEG2000-DSPE. The conjugated lipid was then incorporated into liposomes composed of DMPC:DMPG:Chol:DOPE containing Monophosphoryl lipid A (MPL) (LipDOPE-P5-MPL). Different liposome formulations were prepared and characterized for their physicochemical properties. To evaluate anti-tumoral efficacy, BALB/c mice were immunized subcutaneously 3 times in two-week intervals and the generated immune response was studied. The results demonstrated that LipDOPE-P5-MPL induced a significantly higher IFN- γ production by CD8+ T cells intracellularly which represents higher CTL response in comparison with other control formulations. CTL response induced by this formulation caused the lowest tumor size and the longest survival time in a mice model of TUBO tumor. The encouraging results achieved by Lip-DOPE-P5-MPL formulation could make it a promising candidate in developing effective vaccines against Her2 positive breast cancers.

Targeting tumor hypoxia improves Immunotherapy based on peptide vaccination and immune-checkpoint blockade

Noman, M.Z., Chouaib, S.

INSERM U1186, Equipe Labellisée Ligue Contre le Cancer, Gustave Roussy Campus, Villejuif, France

Immune checkpoint blockade has shown impressive results in treating previously untreatable cancers, however a significant proportion of patients still do not respond to treatment. Understanding the influence of microenvironmental hypoxia on the peptide/ immune-checkpoint blockade combination induced tumor regression could provide insight into how to improve cancer immunotherapy. We have previously shown that hypoxia is an essential driver of tumor resistance and immune suppression. In this study, our aim was to investigate whether targeting tumor hypoxia will improve the outcome of immunotherapy based on peptide-based vaccination and immune-checkpoint blockade. Using B16-F10 xenograft tumor model, we examined the effect of simultaneous *in vivo* inhibition of hypoxia and peptide-based vaccination and immune-checkpoint blockade. We observed that targeting tumor hypoxia along with peptide-based vaccination and immune-checkpoint blockade significantly decreased tumor growth as compared to targeting tumor hypoxia alone or peptide-based vaccination or immune-checkpoint blockade. More interestingly, triple combination treatment (targeting tumor hypoxia along with peptide-based vaccination and immune-checkpoint blockade) improved significantly the double combination treatment (targeting tumor hypoxia and peptide-based vaccination or peptide-based vaccination and immune-checkpoint blockade). The impact of triple combination treatment (targeting tumor hypoxia along with peptide-based vaccination and immune-checkpoint blockade) as compared to double combination treatment (targeting tumor hypoxia and peptide-based vaccination or peptide-based vaccination and immune-checkpoint blockade) on tumor immune infiltration will be discussed.

231

The induction of autophagy in tumor cells by hypoxic stress and the acquisition to CTL resistance involves the stemness transcription factor NANOG

Hasmim, M.¹, Noman, M.Z.¹, Janji, B.², Chouaib, S.¹

¹INSERM U1186, Equipe Labellisée Ligue Contre le Cancer, Gustave Roussy Campus, Villejuif, France, ²Luxembourg Institute of Health, Luxembourg, Luxembourg

Both experimental and clinical studies have shown that hypoxia plays an important role in tumor progression, affecting both metastatic spread and selection of cells with more resistant phenotypes. Nanog is an essential transcription factor maintaining the self-renewal and pluripotency of embryonic stem cells. Our laboratory reported that, under hypoxic stress, NANOG was upregulated in non small cell lung carcinoma cells and involved in hypoxia-induced tumor cell resistance to autologous specific cytotoxic T lymphocytes. We are now investigating the molecular mechanisms underlying NANOG-mediated tumor cell resistance to specific lysis. We have obtained evidence of a link between upregulation of NANOG and autophagy activation under hypoxic stress. Autophagy is a mechanism of tumor cell resistance to CTL-mediated killing. The inhibition of NANOG expression by siRNA under hypoxic stress led to a significant reduction of the number of autophagosomes formed inside tumor cells and a decrease in the expression of genes regulating autophagy. Furthermore, overexpression of NANOG in tumor cells significantly increased the number of autophagosomes per cell and the autophagic flux. Several NANOG-binding sites were found in the promoter region of genes regulating autophagy, and we are performing chromatin immunoprecipitation (ChIP) and luciferase assays to confirm the functional link between NANOG and autophagy activation under hypoxia. The relationship between the expression of this stemness transcription factor and the activation of autophagy under hypoxia will be discussed.

232

Specific targeting of the RAS/MAPK pathway in combination with immunotherapy promotes anti-tumor immune responses against triple negative breast cancers

Dushyanthen, S.¹, Henderson, M.¹, Virassamy, B.¹, Mintoff, C.¹, Zhou, C.¹, Savas, P.¹, Caramia, F.¹, Teo, Z.L.¹, Beavis, P.¹, Darcy, P.^{1,2}, Loi, S.^{1,2}

¹Peter MacCallum Cancer Centre, Melbourne, Australia, ²University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia

Tumor infiltrating lymphocytes (TILs) are an important prognostic factor in triple negative breast cancer (TNBC); where their presence is associated with improved survival. Research involving a genomically and clinically characterized cohort of TNBCs suggests an association between activation of the RAS/MAPK pathway with lower levels of TILs and poorer outcomes in patients. However, insight into the cell intrinsic molecular pathways behind the host anti-tumor immune response is lacking. Our studies have demonstrated that the MEK targeted inhibitor (trametinib) increased immunogenicity (MHCII/II₁) of tumors and reduced tumor growth. However, whilst MEK

inhibition effectively inhibited tumor growth, blockade of this pathway triggered adverse inhibitory effects on crucial ERK signaling in immune cells, thus reducing their functional activity and overall efficacy of this treatment. We have previously shown that combining anti PD-1 with trametinib can enhance anti-tumor effects [1]. In the current study immune agonists anti-4-1BB or anti-OX-40 were combined with trametinib in order to recover immune cell function independently of the MEK1/2 pathway. These agonists restored T cell proliferation (Ki67), cytokine production (IFN γ) and redirected signaling through p38 activation following trametinib treatment, leading to enhanced TIL function and more effective anti-tumor immune responses in vivo. Accordingly, this data suggests that immune agonists with anti-PD-1 checkpoint blockade may be an effective strategy, as the combination can directly overcome T cell suppression induced by MEK inhibition. As such, we propose that combining trametinib with agonist/checkpoint immunotherapy could be a promising strategy in the clinic for TNBC patients.

Combination immune checkpoint blockade as an effective therapy for mesothelioma

Fisher, S.^{1,2}, Solin, J.^{1,2}, Casey, T.^{1,2}, Lesterhuis, W.J.^{1,2}, Lansley, S.³, Robinson, B.W.S.^{1,2}, Lake, R.^{1,2}

¹National Centre for Asbestos Related Diseases, Perth, Australia, ²University of Western Australia, School of Medicine & Pharmacology, Perth, Australia, ³Institute for Respiratory Health, Perth, Australia

Immune checkpoint blockade (ICPB) offers great promise for treating cancer, including mesothelioma. Most ICPB therapies are focused on CTLA4 and PD1 with dual blockade appearing superior. However, at least 22 other checkpoint molecules have been identified and the best combinations for each cancer have yet to be defined. We used an established preclinical mesothelioma tumour models to characterise the expression profile of checkpoint molecules on tumour resident immune cells to identify likely combinations for effective checkpoint blockade therapy.

Flow cytometry was used to characterise expression of immune checkpoint molecules CTLA-4, OX40, TIM-3, GITR and PD-1 on tumour resident immune cells. Tumour bearing mice were then treated with ICPB antibodies to identify the best combinations for inducing anti-mesothelioma immunity.

OX40 and CTLA-4 are highly expressed on tumour resident regulatory T cells compared to tumour infiltrating lymphocytes (CD4 and CD8 TILs). PD-1 expression was observed on non-Treg CD4 and CD8 TILs, while broad TIM-3 expression was observed on both effector and regulatory T cells.

Treatment with either α CTLA-4 or α GITR, but not α TIM-3, α PD-1 or α OX40, significantly delayed tumour growth and improved overall survival. Combining α CTLA4 with α OX40 provided no additional benefit in tumour growth delay over CTLA-4 alone. Conversely, a small delay was observed when PD-1 and TIM-3 were combined. These combinations are currently being tested

in an orthotopic (intrapleural) mesothelioma mouse model. These data suggest that immune checkpoint molecules are highly expressed on tumour infiltrating immune cells and that immunotherapies targeting these molecules can delay mesothelioma development and improve survival.

234

Targeted depletion of regulatory T cells in solid cancers

Fisher, S.^{1,2}, Solin, J.^{1,2}, Aston, W.^{1,2}, Cleaver, A.^{1,2}, Lesterhuis, W.J.^{1,2}, Khong, A.^{1,3}, Robinson, B.W.S.^{1,2}, Lake, R.^{1,2}

¹National Centre for Asbestos Related Diseases, Perth, Australia, ²University of Western Australia, School of Medicine & Pharmacology, Perth, Australia, ³University of Western Australia, Perth, Australia

Regulatory T cells (Treg) play an important role in suppressing anti-tumour immunity and their depletion has been linked to improved outcomes. To better understand the role of Treg in limiting the efficacy of anti-cancer immunity, we used diphtheria toxin (DTX) to specifically deplete Treg from tumour bearing BALB/c FoxP3.dtr transgenic mice.

Mice bearing solid tumours were subject to different treatment protocols, with or without Treg depletion and tumour growth and survival monitored. Flow cytometry was used to confirm Treg depletion, immune cell phenotyping and assess immune correlates with treatment outcomes.

DTX administration specifically depleted Treg in a transient, dose dependent manner. Treg depletion correlated with delayed tumour growth, increased effector T cell activation and enhanced survival. Tumour regression was dependent on effector T cells as the depletion of both CD4 and CD8 T cells completely abrogated any survival benefit. Severe morbidity following Treg depletion was only observed when consecutive doses of DTX were given during peak CD8 T cell activation, demonstrating that Treg can be depleted on multiple occasions, but only when CD8 T cell activation has returned to base line levels.

Clinical translation of targeted Treg depletion as a cancer immunotherapy is currently limited by the lack of Tregs specific reagents. However, Treg express high levels of the immune checkpoint molecules CTLA-4, GITR and OX40, while tumour infiltrating effector cells express PD-1 and TIM-3, suggesting that specific combinations of checkpoint immunotherapies could be designed to specifically target Treg and simultaneously enhance effector T cell function to generate effective cancer immunity.

235

Impaired signalling in T cells from patients with colorectal cancer in response to IL-2 and IL-7

Shen, S.¹, Taylor, E.¹, Ward-Hartstonge, K.¹, Mccall, J.², Kemp, R.¹

¹University of Otago, Department of Microbiology and Immunology, Dunedin, New Zealand, ²University of Otago, Department of Surgical Sciences, Dunedin, New Zealand

T cells are key components of the antitumour response, particularly in mediating an effector function against colorectal cancer (CRC) to prevent tumour progression. The survival and

proliferation of T cells are dependent on signals from IL-2 and IL-7; these cytokines are therefore important for initiating and maintaining an immune response against colorectal tumours. The aim of this study was to measure the phosphorylation of signalling molecules downstream of IL-2 and IL-7 receptor binding in T cells isolated from patients with CRC. This was achieved by using phosphoflow cytometry to measure STAT5 phosphorylation in T cells after IL-2 or IL-7 stimulation. We hypothesised that patients with CRC would have a dysregulation in T cell signalling in response to IL-2 and IL-7 when compared to healthy subjects.

Preliminary results indicate an increase in STAT5 phosphorylation in T cells from CRC patients after IL-7 stimulation when compared to healthy controls; however this increase was not due to an increased expression of IL-7Ra. Conversely, no aberrant phosphorylation of STAT5 was observed in T cells from CRC patients that were stimulated with IL-2. Results from this study will contribute to understanding the functionality of tumour-infiltrating T cells in patients with CRC.

Anti-tumor CTL effect targeting the ASB4 gene-derived natural peptide presented by HLA-A24 of human colon cancer stem cells

Miyamoto, S., Kanaseki, T., Takahashi, A., Kochin, V., Hongo, A., Hirohashi, Y., Torigoe, T., Sato, N.
Sapporo Medical University School of Medicine, Department of Pathology, Sapporo, Japan

Cancer stem cells (CSC) are the small cell population that is responsible for cancer growth in vivo as well as resistant to chemo/radiotherapies. We enriched a highly tumorigenic CSC population from the human colon cancer SW480 line based on their elevated transporter activities of ATP-binding cassette, followed by screening peptides that were naturally presented by HLA-A24 of the cells. Large-scale MS/MS sequencing following affinity purification with an HLA-A24-specific antibody allowed us to identify the natural peptide, which source gene, ASB4, was specifically expressed in the CSC population. We found the gene was expressed in a variety of cancer cell lines as well as primary colon cancer tissues, but not in a panel of normal tissues. Moreover, the identified peptide was immunogenic to elicit CTL responses from healthy donor and cancer patient PBMC. In immunodeficient mice, intravenous injection of the induced CTL clone successfully prevented growth of the original SW480 cells that consist of CSC and non-CSC populations. Thus, the CTL induced by the ASB4 gene-derived peptide is specific to CSC and is effectively able to inhibit cancer growth in vivo.

237

Prognostic relevance of tumor infiltrating immune populations and of circulating miRNAs and cytokines/chemokines in Breast Cancer (BC)

Fortis, S.¹, Mahaira, L.¹, Sotiriadou, N.², Sofopoulos, M.², Haritos, C.¹, Anastasopoulos, N.¹, Arnogiannaki, N.², Ardavanis, A.³, Perez, S.¹, Baxevas, C.¹

¹Saint Savas Cancer Hospital, Cancer Immunology and

Immunotherapy Center, Athens, Greece, ²Saint Savas Cancer Hospital, Pathology Department, Athens, Greece, ³Saint Savas Cancer Hospital, Oncology Department, Athens, Greece

There is accumulating evidence supporting the pivotal role of miRNAs and cytokines/chemokines for cancer progression and therefore it is reasonable to suggest that they could be potential biomarkers predicting cancer progress. Moreover, tumor infiltrating lymphocytes (TILs) shape an efficient immune microenvironment with favorable clinical outcome. Here, we profile the composition of TILs, from a retrospective BC patient cohort (n=100) and correlate with clinical outcome, depending on TILs spatial distribution (Tumor Invasive Margin, TIM vs Tumor Center, TC). We also, investigate possible correlations between TILs at TIM vs TC and circulating biomarkers in a prospective cohort of BC patients (n=50).

Peripheral blood from women diagnosed with invasive breast carcinoma (IBC) (prospective cohort), without neoadjuvant therapy, was obtained one day before surgery. Selected circulating miRNAs (e.g. miR-21, miR-23a, miR-146a, miR-155, miR-181a), were measured in the serum. The levels of cytokines/chemokines (e.g. TGF- β 1, Rantes, IL-9, IL-10, IL-1Ra), were also evaluated. The infiltration analysis of immune subpopulations (CD4, CD8, FoxP3 and CD163) was performed by IHC in FFPE tissues of patients with histologically-confirmed IBC in both cohorts.

We have identified strong correlations between systemic parameters (circulating miRNAs & cytokines/chemokines) and tumor microenvironment (density & localization of TILs) in the prospective cohort. Additionally, we observed favorable outcome (longer DFS/OS) with certain TILs patterns in the retrospective cohort. We report for the first time that (i) the spatial distribution of TILs plays a significant role in clinical outcome in IBC and (ii) peripheral immune-signatures may predict density and the localization of TILs in IBC. Thus, the combination of peripheral with intratumoral immune-signatures may more precisely predict clinical outcome.

238

Altered expression and function of NK receptors in pediatric acute lymphoblastic leukemia (ALL)

Mathew, S.¹, Powers, S.¹, Bowman, W.P.^{2,3}, Aldy, K.¹, Mathew, P.¹
¹UNT Health Science Center, Cell Biology & Immunology, Fort Worth, United States, ²UNT Health Science Center, Pediatrics, Fort Worth, United States, ³Cook Children's Medical Center, Oncology & Hematology, Fort Worth, United States

Acute lymphoblastic leukemia (ALL) is the most common pediatric cancer in the developed world with peak prevalence between the ages of 2 and 5 years. Despite current treatment protocols achieving significant improvement in survival of ALL patients, serious acute and late complications are frequent and resistance to chemotherapy often develops. Although NK cells have long been known to mediate antigen independent tumor killing, the therapeutic potential of NK cell-based immunotherapy has yet to be realized. NK cells have the capacity to kill virus-infected or tumor-transformed cells and they express several surface molecules that regulate NK cell

function both positively and negatively. We have previously identified 2B4 (CD244) and CS1 (CRACC) playing a major role in NK activation. In this study, we evaluated the expression and function of NK cell receptors in 12 ALL subjects and 11 healthy subjects both male and female in the age range of 3 - 18 yrs. The peripheral blood samples were collected and analyzed by flow cytometry and real-time PCR for expression and cytotoxicity assays were done for functional analysis. A significant increase in the expression of CS1 and NKp30 in B cells and 2B4 and CS1 in the CD14+ monocytes was observed in ALL subjects as compared to healthy controls. NK cells from 3 ALL subjects also showed impaired cytotoxic function as they demonstrated lower killing of K562 cells compared to a healthy control subject. These results implicate that 2B4, CS1 and NKp30 may play a role in NK-mediated surveillance of childhood ALL.

Manipulation of tumor microenvironment by cytokine gene transfection enhances dendritic cell-based immunotherapy

Wijesekera, D.P.H.¹, Sugiura, K.¹, Ichida, C.¹, Yuba, E.², Kono, K.², Yamate, J.³, Kanegi, R.¹, Nishimura, T.¹, De Silva, N.H.¹, Hatoya, S.¹, Inaba, T.¹

¹Osaka Prefecture University, Department of Advanced Pathobiology, Osaka, Japan, ²Osaka Prefecture University, Department of Applied Chemistry, Sakai, Japan, ³Osaka Prefecture University, Department of Integrated Structural Biosciences, Osaka, Japan

The tumor microenvironment strongly influences the clinical outcome of immunotherapy. By using intratumoral (i.t.) injection of interferon (IFN) γ , a cytokine which induces Th1 polarization and dendritic cell (DC) -maturation, we obtained satisfactory clinical results in dog tumor therapy. This manipulation is expected to be more effective and persistent by transfecting genes of the relevant cytokine into tumor cells *in vivo*. To verify this hypothesis, we transfected genes of the cytokine into tumor cells growing in mice, and examined the effect on DC therapy. For the transfection we used a novel synthetic vector composed of a cationic lipid bound with pH-sensitive liposomes, which effuses enclosed DNAs from endosomes into the cytoplasm. The efficiency of transfection into the LM8 osteosarcoma growing in syngeneic C3H mice was approximately 10% by i.t. even with intravenous (i.v.) injection of the vector enclosing the plasmid containing GFP-cDNA (GFP-vector). Therapeutic experiments were performed to inhibit LM8 growth by i.t. or i.v. injection of the IFN γ -vector or the CD40L-vector, followed by i.t. injection of the DCs presenting the LM8 antigens. This treatment was performed four times at 7-day intervals. Growth of the tumor was significantly suppressed by the i.v. treatment of the IFN γ -vector and the i.t. and i.v. treatment of the CD40L-vector, relative to untreated mice. The CD40L-vector treatment led to significantly improved survival. These results indicate that gene transfection of the cytokine genes manipulate the tumor microenvironment effectively and significantly improve DC-based tumor immunotherapy.

240

Targeting endosomal receptor of immune cells by multivalent polymer nanocomplex for enhanced immunostimulation and anti-tumor response

Kim, S.-Y., Phuengkham, H., Lim, Y.T.

Sungkyunkwan University, Suwon-Si, Korea, Republic of

In this work, we designed and developed a multivalent polymer nanocomplex for the effective intracellular delivery and subsequent multivalent display of stimulating epitope through the combination of multivalent immune adjuvants with CpG ODNs (as a TLR9 ligands) and cationic PLL (for the enhancement of cellular uptake) in antigen presenting cells such as dendritic cell and macrophage cells.

Cytosine-Guanine (CpG) oligodeoxynucleotides can be recognized by Toll-like receptor 9 (TLR9) and induce powerful immune response via cell signaling pathways including NF κ B. Hyaluronic acid is a biocompatible, biodegradable, non-toxic polysaccharide, which has been applied for various drug delivery systems.

Finally, the multivalent polymer nanocomplex caused the enhanced cellular uptake efficiency and modulation of the continuous stimulation of endosomal TLR9. We show that multivalent polymer nanocomplex exhibit a potent immunostimulatory activity *in vitro*. Inspired by the *ex vivo* immunostimulating capacity of the nanocomplex, we investigated the *in vivo* tumor therapeutic effect. Mice vaccinated with the nanocomplex exhibited tumor growth inhibition as well as a strong anti-tumor memory response.

We demonstrated that multivalent polymer nanocomplex exhibited potent immunostimulatory activity both *in vitro* and *in vivo*. The future, these studies could be used to develop programmed immune-cells for effective cancer immunotherapy.

241

Adjuvanticity and chemo-therapeutic potential of novel Phytol-derived immunoadjuvants

Ghosh, S.¹, Johnson, D.¹, Steding, C.¹, Fitch, R.²

¹Indiana State University, Biology, Terre Haute, United States,

²Indiana State University, Chemistry, Terre Haute, United States

This study was initiated on the premise that surgery and radiotherapy often fail to eliminate cancer. The residual cancer portends danger, but also provides antigenic stimuli exploitable for development of immunotherapy using immuno-adjuvants. If the latter also exhibits chemotherapeutic properties, the treatment would boost immunity and destroy cancer. This led us to test lipophilic terpenoid adjuvants, PHIS01 (phytanol) and squalene, and an amphiphilic adjuvant phytanyl sulphate. We have been systematically investigating adjuvanticity of long-chain acyclic diterpenoid phytol of photosynthetic green pigment chlorophyll and several of its derivatives (Ghosh: USA Patent 8088395). We observed that some derivatives, e.g. PHIS01 and PHIS03 (phytanyl mannose) are excellent immunoadjuvants for different cancer cells (Front Immunol. 2012; 3:49). Moreover, there are reports highlighting cancer-killing properties of some terpenoids. In this study, we addressed:

(a) Could an oil-in-water micro-emulsion of PHIS01 be an

effective immune-stimulator comparable to squalene as in commercial MF59?

(b) Could phytol-based adjuvants be chemotherapeutic causing tumor regression?

Our results demonstrated effective adjuvanticity of PHIS01 formulated as in MF59 even at low doses. Also, its direct administration into murine lymphomas A20, and 2C3 caused tumor regression. Studies *in vitro* with mammary tumor 4T1 demonstrated cytotoxic effects with both PHIS01 and phytanyl sulphate. The latter, being more surfactant-like, was effective at lower doses than PHIS-01. Based on ongoing studies, we speculate that necrosis induced by isoprenoid micro-emulsion help recruit and activate dendritic cells and induce anti-tumor immunity. Supported by the Fraternal Order of Eagles, and the University Research Committee (URC319).

242

Diagnostic and prognostic immunobiological markers of bladder cancer

Avdonkina, N.¹, Slavyanskaya, T.¹, Salnikova, S.²

¹People's Friendship University of Russia, Moscow, Russian Federation, ²Institute of Immunophysiology, Moscow, Russian Federation

Bladder cancer (BC) is the second most common urinary tract malignancy. Early diagnosis and prognosis monitoring are very important for the survival of patients with bladder cancer. To find current immunological and biological markers (IBM) for BC. Search results revealed, that the expression levels of proteins p53, p63 и p16; EGFR, VEGF, HER2/neu; Ki 67, PCNA; bcl-2, bcl-x, CD 95; cytokeratin profile had no prognostic significance and connection with disease state. At the same time it is determined, that the levels of expression of Cyclin D1, antiadhesive glycoprotein tenascin, matrix metalloproteinases and their tissue inhibitors; the reduced expression of adhesion molecules EpCAM E-cadherin and b-catenin were correlated with disease prognosis. The importance of determining the levels of inflammatory markers was shown: IL-6, IL-8, CRP; thrombomodulin, expression of chemokine receptor CXCR7 for assessment of the disease state and prediction of its course. A promising marker of tumor progression survivin was installed, which may be a potential target with immunotherapy. The possibility of using overexpression of cancer-testicular antigen MAGEA and oncofetal protein IMP3 is considered as independent predictors of progression and recurring of urothelial carcinoma. Worth noticing is the definition of circulating tumor cells in the blood and microRNAs involved in transcriptional and posttranscriptional regulation of gene expression. The heterogeneity of the IBM, moderate level of evidence of their clinical and diagnostic significance, and also insufficient quantity of works demands further experimentations for their selection and accurate significance in cases of BC.

243

Polyporus alveolaris extract (PAE) induces anti-tumor activity of RAW264.7 macrophage

Kanai, H.¹, Matsuzaki, T.¹, Sasajima, Y.¹, Kawamura, M.¹, Aradate, T.², Katagiri, T.¹

¹University of Toyama, Dept. Biology (Faculty of Pharmaceutical Sciences), Toyama-shi, Japan, ²University of Toyama, Dept. Biology (Faculty of Medical Sciences), Toyama-shi, Japan

From the screening results of a number of hot-water extract, finally we revealed the extract from Hachinosutake (*Polyporus alveolaris*), PAE, is the good activator for macrophages to anti-tumor. PAE stimulated growth inhibitory activity against tumor cells by RAW264.7 was approximately equal to high concentration of LPS. However, unlike LPS, anti-tumor effect of PAE induced in RAW264.7 was not affected under Polymyxin B coexist. We examined the effects of PAE to the production of anti-tumor effector molecules, TNF- α and NO production, from RAW264.7. As a result, it was confirmed to induce TNF- α production and NO production in a concentration dependent manner in RAW267.4. Moreover, it was not affected to these activity under Polymyxin B coexist. To examine these production mechanism, it analyzes the intracellular signaling were examined for phosphorylation of tyrosine phosphorylation and MAP kinase ERK, JNK, p38. As a result, the phosphorylation time course pattern with PAE was quite unique which compared from LPS pattern. From the result of the analysis of the receptor necessary for effect of PAE, with neutralizing antibodies, at least a portion of the anti-tumor effect induction revealed that from Dectin-1 is a receptor for β -glucan. Moreover, fractionated molecular weight with cutting filters by molecular size contained in PAE using molecular weight, were studied active ingredient. As a result, components of molecular weight of 100~1,000kDa has induced the highest activity to the macrophages. These results are characteristic β -glucan contained in PAE are believed to indicate that the beneficial anti-tumor activity induction of macrophages.

244

Understanding the anti-tumour immune response to melanoma in the brain

George, T.^{1,2}, Endersby, R.¹, Brizard, G.¹, Kuchibhotla, M.¹, Waithman, J.¹

¹Telethon Kids Institute, The University of Western Australia, Subiaco, Australia, ²Curtin University, Bentley, Australia

Up to 75% of patients suffering from malignant melanoma develop brain metastases. Treatment options are currently limited for these patients. While immunotherapy has shown success in treating melanoma, patients with brain involvement have traditionally not been considered for immunotherapies. This is due to the long-standing concept that the brain is immune privileged. Recently, however, it was reported that the brain is not immune privileged, and possesses lymphatic-like vessels that provide a connection between the immune system and the central nervous system (CNS).

To understand the coordination of brain tumour immunity, B16 melanoma cells expressing ovalbumin (OVA) were intracranially implanted into C57BL/6 mice. OVA-specific T cells

were transferred into tumour-bearing mice to assess antigen presentation. CD69 upregulation, used as a marker of T cell activation, was observed on OVA-specific T cells in both deep and superficial cervical lymph nodes (LNs). This indicated that antigen presentation occurred in these LNs. To further assess whether migratory antigen presenting cells (APCs) coordinate this CD8 T cell response, T cell activation was investigated in CCR7^{-/-} mice. In these mice, migration of APCs is compromised. CD8 T cell activation in deep and superficial cervical LNs was impaired in tumour-bearing CCR7^{-/-} mice, suggesting that activation of brain tumour-specific CD8 T cells is dependent on CCR7⁺ migratory APCs.

Future studies will aim to elucidate which APCs drive this immune response to brain tumours, which may provide insight for the design of better treatment strategies against this disease and potentially other cancers involving the CNS.

245

Difference in proinflammatory response induced by Newcastle disease virus in tumor and normal cells contributes to tumor-specific cytotoxicity

Ginting, T., Suryatenggara, J., Christian, S., Mathew, G. Mochtar Riady Institute for Nanotechnology - Universitas Pelita Harapan, Immunology, Tangerang, Indonesia

Newcastle disease virus (NDV) has been clinically proven to activate immune responses that are harmful to tumor cell but not to normal cell. In order to investigate the actual role of immune responses induced by lentogenic NDV for its antitumor effect, we infected NDV LaSota strain into human cells i.e. small lung carcinoma (A549), glioblastoma (U87MG), lung fibroblast (HF19), skin fibroblast (NB1RGB), transformed embryonic kidney (HEK293) and monocyte cells at low (0.0001) and high (0.01) MOI (multiplicity of infection); and observed the cytotoxicity and expression of proinflammatory cytokines. Both A549 and U87MG cell lines showed viability of less than 20%, while normal cell lines NB1RGB, HEK293, and monocyte showed more than 50% viability 72 hours post infection. Proinflammatory cytokines profiling showed that NDV mainly induced the secretion of interferon alpha (IFN- α), beta (β) and lambda (λ) in tumor cells and only IFN- λ in normal cells.

We found that NDV infection stimulated apoptosis in both tumor and normal cells and this effect is reduced with the addition of type I IFN-blocker in tumor cells but not in normal cells. The cumulative effect of IFN- α , β , and λ expression in tumor cells enhances tumor cells cytotoxicity when compared to that observed in normal cells after NDV LaSota infection. This finding introduces a new perspective on the role of IFN- λ in NDV-mediated oncolysis.

The regulatory effects of NKT and MAIT cells in cancer

Meredith, T.^{1,2}, Minoda, Y.^{1,2}, Toohey, B.², Kannourakis, G.², Berzins, S.^{1,2,3}

¹Federation University Australia, Ballarat, Australia, ²Fiona Eley Cancer Research Institute, Ballarat, Australia, ³Melbourne University, Melbourne, Australia

Natural killer T (NKT) cells and mucosal associated invariant T (MAIT) cells contribute to immune regulation in several settings, including cancer. NKT cells in particular have a strong association with cancer in mice, but less is known about their role in humans. We seek to understand whether NKT and MAIT cells have a regulatory effect on cells such as natural killer (NK) cells, dendritic cells and conventional T cells that are known to have important anti-tumour effects.

Our approach is to measure the effector functions of these cells in the presence or absence of NKT and MAIT cells, and their ligands. Our preliminary data suggests that altering NKT/MAIT cell concentrations can cause a decrease in T and NK cell cytokine production, as well as T cell proliferation.

We are also investigating the impact of NKT and MAIT cells on the tumour lysing abilities of NK cells using primary and established tumour cell lines as targets or as sources of stimulation. Preliminary data suggests that NK cells lysing ability is unaffected by MAIT cell levels.

These experiments will seek to determine the importance of NKT and MAIT cells in anti-cancer immunity and if these cells could be useful targets in new immune therapies.

247

TCR beta sequencing to determine clonal T-cell populations in melanoma patients undergoing immunotherapy

Witkowski, T.¹, Behren, A.², Woods, K.², Fritz, B.³, Wong, S.Q.⁴, Colebatch, A.⁴, McArthur, G.⁴, Cebon, J.², Dobrovic, A.¹

¹Olivia Newton-John Cancer Research Institute, Translational Genomics & Epigenomics, Heidelberg, Australia, ²Olivia Newton-John Cancer Research Institute, CIBL, Heidelberg, Australia, ³Adaptive Biotechnologies Corp, Seattle, United States, ⁴Peter MacCallum Cancer Centre, Department of Cancer Research, Melbourne, Australia

The adaptive immune system elicits clonal expansion of tumour-infiltrating lymphocytes (TILs) in melanoma¹. Immunotherapeutics targeting immune suppressive receptors such as CTLA-4 and PD-1 have been shown to influence prognosis with a correlated increase in TILs^{2,3}. However, immune-checkpoint inhibition can also prompt immune-related adverse events such as rare instances of acute inflammation including complications like cytomegalovirus (CMV) pneumonia⁴. Assessing clonality and TIL numbers is therefore of interest in solid tumours. Next Generation Sequencing (NGS) assays designed across the V, D and J regions of the *TCRB* gene can be used to infer T-cell clonality. The immunoSEQ hsTCRB kit from Adaptive Biotechnologies utilizes an initial VDJ gene-specific amplification with a proprietary set of primers, followed by adapter ligation and sequencing on an Illumina platform. The sensitivity of the assay was assessed by spiking in a single

clone population, isolated using NY-ESO-1 derived peptides in proportions with healthy donor peripheral blood mononuclear cell (PBMC) DNA. It was shown that genomes derived from healthy donor PBMCs contain 85% unique clones of TCR, and we were able to detect our clone spiked at 0.01%. This ability to detect specific clones of lymphocytic DNA indicates that the immunoSEQ NGS assay is readily adapted to the study of clonal T-cell populations and will be sensitive enough to target limited lymphocytic DNA in FFPE from tumour tissues including serial studies of patients undergoing immunotherapy. Following sequencing individual clones can also be monitored using uniquely designed qPCR assays utilising rearrangement specific primers.

248

Vascular endothelial growth factor-A and placental growth factor regulate tumor progression via increased vasculature in cutaneous T cell lymphoma

Miyagaki, T., Sugaya, M., Oka, T., Takahashi, N., Kawaguchi, M., Suga, H., Fujita, H., Yoshizaki, A., Asano, Y., Sato, S.
Faculty of Medicine, University of Tokyo, Department of Dermatology, Tokyo, Japan

Angiogenesis and lymphangiogenesis are regarded as essential steps to support tumor growth and metastasis. Also in hematological malignancies including cutaneous T cell lymphoma (CTCL), angiogenesis and lymphangiogenesis are increased and serum levels of some proangiogenic and prolymphangiogenic markers are elevated. In this study, we investigated expression levels of vascular endothelial growth factor (VEGF) family members in lesional skin and sera in CTCL patients and assessed their association with CTCL development. We found that mRNA and protein expression of VEGF-A and placental growth factor (PIGF) but not VEGF-C was significantly elevated in lesional skin of CTCL. Tumor cells expressed VEGF-A in most cases and PIGF in some cases. Moreover, serum VEGF-A and PIGF levels were elevated in patients with advanced CTCL and both of them decreased after treatment. Increased serum VEGF-A levels were associated with pruritus, while serum PIGF levels reflected disease severity. Remarkably, local administration of PIGF enhanced tumor growth of lymphoma cells through increasing vasculature in vivo. These findings suggest that VEGF-A and PIGF play important roles in angiogenesis during progression of CTCL. In addition, considering the correlations of expression of VEGF-A and PIGF with pruritus and disease severity, inhibitors of those proangiogenic factors, such as bevacizumab, or VEGF receptor inhibitors could be promising therapies in CTCL.

249

High expression of Ecto-nucleotidases CD39-CD73, A2A-A2B adenosine receptors and IL-10 is associated with HLA class I downregulation in advanced cervical cancer

Gutierrez, V.^{1,2}, Mora, M.D.L.¹, García, R.², Weiss, B.¹, Monroy, A.²
¹UNAM, FES Zaragoza, Laboratory of Immunobiology, UIDCC, UMIÉZ, Ciudad de México, Mexico, ²IMSS, CMN SXXI, Laboratory of Immunology and Cancer, UIMEO, H. Oncology, Ciudad de México, Mexico

Development of Cervical cancer (CC) is strongly associated with high-risk HPV infection and several factors involved in the tumor microenvironment, including immunosuppressive cytokines, such as IL-10, that inhibit cellular immune response and favor HLA class I downregulation. On the other hand, the co-expression of the ectonucleotidases CD39 and CD73 in malignant tumors is also associated with immunosuppression, via adenosine production and high expression of IL-10. The aim of this study was to analyze the co-expression of molecules involved in the adenosinergic pathway such as the CD39 and CD73 ecto-nucleotidases, and A2A-A2B adenosine receptors, as well as the expression of IL-10 and HLA-Class I molecules in tissue samples derived from different stages of the development of CC. The expression of these cell markers was analyzed in immunohistochemical samples from normal cervix (20), LSIL (20), HSIL(20) and CC(20) by using the Image-pro Plus 6.0 program. We found that the expression of CD39 and CD73, as well as, A2A and A2B was strongly associated with an increase of the IL-10 expression and HLA-Class I downregulation in relation to the degree of disease progression. These results suggest that the expression of molecules participating in the adenosinergic pathway, can be a favorable condition to generate IL-10, providing a possible mechanism for immunosuppression and immune evasion during the development of CC. This work was supported by DGAPA-PAPIIT (IN226516), FIS/IMSS/PROT (1314 and 1383) and CONACYT (240635) grants.

Cancer chemo immunotherapy - exploiting the immunogenic potential of cytotoxic chemotherapy

Aston, W.J.^{1,2}, Rinaldi, C.^{1,2}, Fisher, S.A.^{1,2}, Nowak, A.K.^{1,2,3}, Lake, R.A.^{1,2}, Lesterhuis, W.J.^{1,2}

¹National Centre for Asbestos Related Diseases, Perth, Australia, ²University of Western Australia, School of Medicine & Pharmacology, Perth, Australia, ³Sir Charles Gairdner Hospital, Medical Oncology, Perth, Australia

Background: Cytotoxic chemotherapy is the primary treatment for many cancers however is often not curative. Recently, a number of novel immunotherapeutic treatments have shown promising clinical results including the checkpoint blocking antibodies. It has long been believed that these could not be combined with chemotherapy due to the latter largely exhibiting myelosuppressive effects. However, it has recently been shown that selected chemotherapeutics may be immunestimulating and so this research aimed to investigate the antitumour immune responses of cyclophosphamide specifically focusing on lymphoid and myeloid subsets.

Methods: BALB/c mice were inoculated subcutaneously with 5x10⁵ AB1 mesothelioma cells. On day 12 they were given 250 mg/kg cyclophosphamide intraperitoneally. Tumours were harvested at various times after chemotherapy and analysed using H&E histology and flow cytometry to characterise immune cell infiltrates.

Results: AB1 tumours treated with cyclophosphamide regressed, appeared to regrow then regressed completely over a 20 day period. Based on this four time points were selected for histology and flow cytometry analysis: growth before treatment,

growth after treatment, regrowth phase and final regression phase. The most notable finding was in the final regression phase in which the resected tumour section showed large leukocytic infiltrates. Gross changes to immune cell populations included a decrease in FoxP3+ Tregs and a significant increase in both CD4+ and CD8+ T lymphocytes. Functional studies showed that CD8+ T cells were necessary for the curative effect of cyclophosphamide.

Conclusion: Cyclophosphamide treatment of mesothelioma *in vivo* results in leukocytic infiltrates that mediate regression, particularly CD8+ T cells.

IL-15 derived from gastric cancer mesenchymal stem cell involved in the progression of gastric cancer

Li, S.¹, Chen, B.¹, Sun, X.¹, Xu, R.¹, Han, Y.¹, Zhao, Y.¹, Wang, M.², Zhu, W.²
¹Jiangsu University, Zhenjiang, China, ²Jiangsu University, School of Medicine, Zhenjiang, China

Objective: In previous study has shown that interleukin 15 (IL-15) involved in the progression of leukemia, but the role of IL-15 in solid tumor was unclear. In the present study we aims to investigate the role of IL-15 derived from gastric cancer-derived MSCs (GC-MSCs) in the progression of gastric cancer (GC).

Methods: The expression of IL-15 was assessed using ELISA and immunohistochemical (IHC). The GC cell lines were treated with culture media of GC-MSCs (GC-MSC-CM) and their proliferation and migration ability was detected using colony formation assay and transwell migration assay, respectively. The stemness and epithelial-mesenchymal transition (EMT) of GC cell lines were detected by western blot.

Results: We found that the level of IL-15 was higher in GC patients compared with that in healthy individuals, which were associated with lymph node metastasis. The results of IHC showed that there was no IL-15 expression in gastric epithelial cells in healthy individuals. However, the tumor tissues of GC patients expressed different intensities of IL-15 and were also associated with lymph node metastasis. We also discovered that IL-15 derived from GC-MSC enhance proliferation, migration and stemness and promote EMT of GC cell lines. We found that IL-15 derived from GC-MSC promote proliferation of regulatory T cells and inhibit proliferation of regulatory Th17 cells.

Conclusion: IL-15 is involved in the occurrence and progression of gastric cancer. IL-15 may be a novel marker for GC diagnosis and treatment.

Molecular mechanisms of DUSP22 ablation in enhancing EGFR-mediated lung tumor development: potential involvement of immunosuppression

Lin, H.-P., Ho, H.-M., Chang, C.-W., Tan, T.-H., Lin, W.-J.
 National Health Research Institutes, Immunology Research Center, Miaoli County, Taiwan, Republic of China

DUSP22, a member of the dual-specificity phosphatases (DUSPs) family, is a key phosphatase controlling the activity of protein kinases and transcription factors through the dephosphorylation

(serine/threonine or tyrosine) process, such as MAPKs, FAK, Lck, and STAT3. Many members of DUSP22-targeted proteins are important for tumorigenesis, and DUSP22 downregulation has been reported in some cancers. Importantly, DUSP22^{-/-} mice manifest multi-organ inflammation, supporting a role for DUSP22 in maintaining immune homeostasis. However, little is known about the *in vivo* role of DUSP22 during tumor development. Here, utilizing a murine lung tumor model driven by the combination of mutated EGFR amplification (exon 19 deletion) and the loss of DUSP22, we found genetic ablation of DUSP22 promoted aggressive EGFR-mediated lung tumor development at early age, and identified MDSCs and exhausted T cells as the two main tumor-infiltrating immune cell types. Our cytokine array profiling found a significant increase of IL-1 and CXCL1 in EGFR/DUSP22 KO lung tumors, suggesting these two cytokines may potentially serve as EGFR/DUSP22 KO tumor-derived factors to attract immunosuppressive cells and promote tumor development. Consistently, GEO data analysis shows that lung adenocarcinoma patients with low DUSP22 expression have poor survival. Collectively, our current data indicate that DUSP22 underexpression may facilitate the recruitment of MDSCs and dysfunctional T cells and establish an immunosuppressive tumor microenvironment for tumor development. Currently, we are using pharmacological and immune approach to elucidate molecular mechanisms of DUSP22 ablation for enhancing lung tumor development.

T-cells in the anal mucosa of men with high-grade squamous intraepithelial lesions

Tong, W.W.Y.^{1,2}, Turville, S.³, Roberts, J.⁴, Zaunders, J.^{1,3}, Jin, F.³, Poynten, I.M.³, Hillman, R.^{1,5,6}, Grulich, A.³, Kelleher, A.^{1,3}, Carr, A.^{1,2}, for the SPANC Study Team

¹St Vincent's Centre for Applied Medical Research, HIV, Immunology & Infectious Diseases, Darlinghurst, Australia, ²University of New South Wales, Sydney, Australia, ³The Kirby Institute for Infection and Immunity in Society, University of New South Wales, Sydney, Australia, ⁴Douglas Hanly Moir Pathology, Sydney, Australia, ⁵Western Sydney Sexual Health Centre, Sydney, Australia, ⁶University of Sydney, Sydney, Australia

Introduction: Anal mucosal cellular immune responses and their role in controlling human papilloma virus (HPV)-induced precancerous lesions have not been previously studied.

Methods: The Study of the Prevention of Anal Cancer (SPANC) is a longitudinal natural history study of anal HPV infection in men ≥35 years who have sex with men. 26 participants with anal high-grade squamous intraepithelial lesions (HSIL) had 44 anal biopsies. Lymphoid aggregates were detected by inspection of haematoxylin & eosin-stained sections. Additional sections were immunofluorescently stained to enumerate stromal and intra-epithelial CD4+ and CD8+ T-cell counts. Whole slide imaging of full tissue architecture (x600) was used. Student's t-test of log10-transformed T-cell density was used to compare means; a generalized, linear model was used to determine factors associated with total T-cell density (biopsy-based analysis with intra-subject adjustment).

Results: Of 26 men (mean age 53 years, SD 10.5), 7 (27%) were HIV-infected. Seventeen (68%) had concurrent anal HPV16 detected. Of 44 biopsies, 26 (59%) revealed HSIL. Twenty-four (55%) had lymphoid aggregates localised in the stroma adjacent to the epithelium. Lymphoid aggregate presence was associated with higher CD4+ T-cell density (mean 192 vs. 69 cells/mm², $P < 0.001$), but not higher CD8+ T-cell density (106 vs. 62 cells/mm², $P = 0.077$). A biopsy with HSIL was significantly associated with higher total T-cell density (OR 11.80, 95%CI 1.51 - 92.08, $P = 0.02$), as was having anal HPV16 detected (OR 14.08, 95%CI 1.15 - 172.71, $P = 0.04$).

Conclusion: CD4+ T-cell enriched lymphoid aggregates in the anal mucosa were associated with anal HSIL and HPV16.

Effects of upregulation of Id3 in human lung adenocarcinoma Q1 cells on proliferation, apoptosis, mobility and tumorigenicity

Li, X.-J.^{1,2}, Chen, F.-F.¹, Liu, Y.¹, Wang, F.¹, Pang, X.-J.¹, Zhu, C.-D.¹, Xu, M.¹, Yu, W.¹

¹Center of Clinical Laboratory Science, Jinling Hospital, School of Medicine, Nanjing University, Nanjing, China, Nanjing, China,

²State Key Laboratory of Analytical Chemistry for Life Science, Nanjing University, Department of Chemistry, Nanjing, China

The inhibitor of DNA-binding/differentiation 3 (Id3) protein is a helix-loop-helix transcription factor and may have an important role in cell proliferation and differentiation. This study was to evaluate the effects of upregulation of Id3 in human lung adenocarcinoma cells on proliferation, apoptosis, mobility and tumorigenicity. Short interference RNA suppression of Id3 (miRId3) in A549 cells was used to investigate the functional role(s) of Id3. Next, we used in vitro wound-healing assay and trans-well assay to study the effects of overexpressed Id3 on migration and invasion of A549 cells. Furthermore, to explore the influence of overexpressed Id3 on in vivo tumorigenesis, adenoviruses containing Id3 gene (Ad-Id3) and empty vector (Ad-LacZ) were generated. Co-transfection of pcDNA/miRId3 and pEGFP/Id3 into A549 cells reversed the Id3-induced cell proliferation inhibition and apoptosis. Upon Id3 transfection, A549 cells displayed decreased migratory and invasive capabilities, however, co-transfection of miRId3 and Id3 into A549 cells reversed the Id3-induced inhibitions of migratory and invasive capabilities. Three groups of nude mice were inoculated with Ad-LacZ, Ad-Id3 transfectants and untransfected A549 cells, respectively. Twenty-eight days after inoculation, tumors induced by Ad-Id3 transfectants grew much more slowly compared with Ad-LacZ transfectants and control group. This study provides for the first time both in vitro and in vivo proofs that forced expression of Id3 in lung adenocarcinoma cells reduces tumor growth rate and may be a potential target for tumor suppression.

255

Hepatocyte growth factor activates stromal fibroblasts to promote tumorigenesis in gastric cancer

Chen, X.

Shanghai Jiaotong University, Ruijin Hospital, Shanghai, China

Cancer-associated fibroblasts (CAF), as the activated fibroblasts in the tumor stroma are important modifiers of tumor progression. However, the mechanisms underlying stromal fibroblast activation and their promotion of tumor growth remain largely unknown in gastric cancer. In this study, we show that normal fibroblasts (NFs) from non-cancerous regions of gastric cancer exhibit the traits of CAFs when grown together with gastric cancer cells in vivo. Activation of NFs can be induced by co-culture with gastric cancer cells. while deprivation of hepatocyte growth factor (HGF) using a neutralizing antibody inhibits the activation of NFs. Moreover, we identify HGF as an important factor from CAFs that acts in a paracrine manner to promote tumorigenesis in vitro and in vivo

Preclinical modeling of EGFR-specific mAb and immune pathways that impact immunotherapeutics for squamous cell carcinoma

He, X.^{1,2}, Gonzalez Cruz, J.¹, Simpson, F.¹, Wells, J.¹

¹The University of Queensland Diamantina Institute, Brisbane, Australia, ²The University of Queensland, Brisbane, Australia

Non-melanoma skin cancers (NMSCs) are the most common skin cancer within the caucasian population. Basal cell carcinoma (BCC) and squamous cell carcinoma (SCC) are the most frequent NMSCs, and it has been shown that UV irradiation and immunosuppression are two of the main triggers of these pathologies. While BCCs typically react positively to topical treatments, SCC does not and is especially prone to local recurrence. This problem highlights the need for new and more effective treatments. However, in order to develop new treatments we first need to develop a reliable pre-clinical model. It has been previously reported that 95% of UV-induced SCC over-express the epidermal growth factor receptor (EGFR) on their surface, making EGFR an attractive target for anti-SCC therapies. In fact, the use of anti-EGFR antibody therapy has been demonstrated to mediate tumour regression by interrupting oncogenic signals and by inducing Fc-mediated innate mechanisms.

In our laboratory we have recently developed a UV-induced SCC mouse model with arising tumours that over-express EGFR. In this project we will use this mouse model to investigate the efficacy of monoclonal antibody therapies that target the EGFR using one of the two anti-murine EGFR antibodies (7A7) available worldwide, in order to investigate the impact that these therapies have on immune system activation.

The insights derived from our study will benefit the development of successful combination therapies for the treatment of EGFR-positive cancers, such as SCC and head and neck cancer.

257

Overview of T cells populations in human colorectal cancer by single cells analysis*Simoni, Y.¹, Koo, S.-L.², Tan, I.², Newell, E.²**¹A*STAR, SigN, Singapore, Singapore, ²A*STAR, Singapore, Singapore*

T lymphocytes are one of main cell subsets infiltrating colorectal tumor (CRC), however technical and inherent experimental limitations have hampered a clear profiling of these cells in humans tumors. By using mass spectrometric analysis (CyTOF), we optimized two panels of 38 markers each, that allowed us to simultaneously assess all T cells subsets (CD4, CD8, T γ δ , MAIT cells) and their phenotypes (exhaustion/activation), transcription factor expression profiles (FoxP3, T-bet, EOMES, Ki67) and tumors antigen specificity of CD8 T cells using combinatorial peptide-MHC tetramer staining. With t-Distributed Stochastic Neighbor Embedding (t-SNE) to display phenotypic diversity, our data showed much greater complexity in the CD4⁺ and CD8⁺ tumor-infiltrating T cell population than previously appreciated, including distinct niches occupied by tumor specific CD8 T cells. We also observed a non-uniform pattern of variation across patients tested, highlighting diversity as previously described. In addition, we observed striking variation in T cell composition between different sectors of the same tumor. Overall, the large degree of diversity we observe, and particularly with respect to markers of T cells exhaustion, may help to explain heterogeneity in clinical outcome during various forms of immunotherapy.

258

Caspase-1 is involved in drug resistance to triterpenoid anticancer drug in adult T-cell leukemia*Nakanishi, T., He, C., Wang, D., Song, Y., Morita, K., Kanazawa, T., Yoshida, Y.**University of Occupational and Environmental Health, Kitakyushu, Japan*

We previously reported that the inflammasome inhibitor cucurbitacin D (CuD) induces apoptosis in human leukemia cell lines. Here, we investigated the effects of CuD and a B cell lymphoma extra large (Bcl-xL) inhibitor on autophagy in peripheral blood lymphocytes (PBL) isolated from adult T cell leukemia (ATL) patients. CuD induced PBL death in patients but not in healthy donors. This effect was not significantly inhibited by treatment with rapamycin or 3-methyladenine (3-MA). The Bcl-xL inhibitor Z36 induced death in primary cells from ATL patients including that induced by CuD treatment, effects that were partly inhibited by 3-MA. Similarly, cell death induced by the steroid prednisone was enhanced in the presence of Z36. A western blot analysis revealed that Z36 also promoted CuD-induced poly ADP ribose polymerase cleavage. Interestingly, the effects of CuD and Z36 were attenuated in primary ATL patient cells obtained upon recurrence after umbilical cord blood transplantation, as compare to those obtained before chemotherapy. Furthermore, cells from this patient expressed high level of caspase-1, and treatment with caspase-1 inhibitor enhanced CuD-induced cell death. Taken together, these

results suggest that rescue from resistance to steroid drugs can enhance chemotherapy, and that caspase-1 can serve as a marker of drug resistance in ATL patients.

Identification and quantification of innate like T cells in patients with cancer*Minoda, Y.¹, Godfrey, D.², Kannourakis, G.¹, Toohey, B.¹, Berzins, S.¹**¹Fiona Elsey Cancer Research Institute, Ballarat, Australia, ²The University of Melbourne, Melbourne, Australia*

Innate-like T cells, including invariant natural killer T (iNKT) cells, mucosal associated invariant T (MAIT) cells and gamma delta T (γ δ T) cells, are associated with regulation of anti-tumour responses in humans and mice, although their precise role, particularly within the tumour microenvironment is poorly defined. We have studied innate-like immune cells isolated from tumours, blood and bone marrow of patients undergoing treatment for cancer and compared their phenotypic and functional characteristics with cells from healthy donors. Our results indicate that the frequency of NKT cells and MAIT cells in tissue samples from patients with solid or blood cancer was usually significantly lower than in healthy individuals, and the distribution of their subsets was often abnormal. Interestingly, cytokine productivity by these innate like T cells was relatively similar to healthy individuals, however, MAIT cell proliferation in blood and tumour from patients with solid cancer was significantly reduced compared to healthy individuals. Collectively, our results indicate that innate like T cells in patients with cancer are often abnormal and targeting them in new therapies could a viable option for new treatments.

260

Epac1 knockdown inhibits the proliferation of serous ovarian carcinoma cells by inactivating AKT/CyclinD1/CDK4 pathway in vitro and in vivo*Wang, X.¹, Gao, M.¹, Ma, Y.¹, Bast Jr., R.C.², Wei, Z.³**¹Shandong University School of Medicine, Department of Immunology, Jinan, China, ²Division of Cancer Medicine, University of Texas MD Anderson Cancer Center, Department of Experimental Therapeutics, Houston, United States, ³Shandong University School of Medicine, Department of Gynecology and Obstetrics, Jinan, China*

Ovarian cancer is the leading cause of death among gynecological malignancies, and high grade serous ovarian carcinoma is the most common and most aggressive subtype. Recently, it was demonstrated that cAMP mediates protein kinase A-independent effects through Epac (exchange protein directly activated by cAMP) proteins. Epac proteins, including Epac1 and Epac2, are implicated in several diverse cellular responses, such as insulin secretion. Several reports document that Epac1 could play vital roles in promoting proliferation, invasion and migration of some cancer cells. However, the expression levels and roles of Epac1 in ovarian cancer have not been investigated. In the present study, we detected the expression levels of Epac1 protein in serous ovarian carcinomas and normal ovarian tissues by immunohistochemistry. Furthermore, the effect of Epac1

knockdown on the proliferation and apoptosis of serous ovarian carcinoma cell lines SKOV3 and OVCAR3 were evaluated in vitro and in vivo. The results showed that the expression of Epac1 was significantly upregulated in serous ovarian carcinoma tissues and cells lines. Epac1 knockdown inhibited the proliferation of serous ovarian carcinoma cells in vitro and in vivo. Decreased proliferation may be due to Epac1 downregulation-induced G1 phase arrest by inactivating the AKT/CyclinD1/CDK4 pathway, but not to alterations in the MAPK pathway or to apoptosis of ovarian carcinoma cells. Taken together, our data provide new insight into the essential role of Epac1 in regulating growth of serous ovarian carcinoma cells and suggest that Epac1 might represent an attractive therapeutic target for treatment of serous ovarian carcinomas.

261

N-glycosylation HMGB1 preferentially promoted M-MDSCs expansion via driving differentiation from bone marrow, contributing conversion of monocytes into MDSC-like cells and facilitated breast cancer progression

Su, Z.¹, Ni, P.², Liu, Y.², Lu, H.², Su, X.², Xu, H.²

¹Jiangsu University, Immunology, Zhenjiang, China, ²Jiangsu University, Zhenjiang, China

Myeloid-derived suppressor cells (MDSCs) are major cell populations that regulating immune responses. It is accumulated in tumor progression, chronic inflammatory and autoimmunity. Previous data indicated that high mobility group box 1 (HMGB1) facilitated MDSCs differentiation from bone marrow, and suppressed antigen-driven activation of CD4⁺ and CD8⁺ T cells and involved in cancer development. whereas the potential mechanisms of HMGB1 facilitating MDSCs differentiation from bone marrow are unclear. In the present work, we clearly demonstrated that:

- (i) HMGB1 secreted by MCF-7 cells was glycosylation at Asn37
- (ii) N-glycosylation HMGB1 not normal HMGB1 preferentially driven M-MDSCs differentiation from bone marrow progenitor cells STAT3/Erk1/2/NFκB pathway;
- (iii) N-glycosylation HMGB1 contributed conversion of monocytes into MDSC-like cells;
- (iv) In vivo, HMGB1 blockade by ethyl pyruvate (EP) significantly reduced the accumulation of MDSCs in tumor-bearing mice, thus leading to the delayed tumor growth. Therefore, our results shown that N-glycosylation HMGB1 facilitated MDSCs expansion and contributed cancer progression; which indicated that HMGB1 might be a potential tumor immunotherapy targets.

262

Opposing effects of the adenosine/PGE2/cAMP vs. STAT3 pathways on CD73 expression on human tumour-associated monocytes

Al-Taei, S.¹, Spary, L.¹, Salimu, J.¹, Clayton, A.¹, Lester, J.², Tabi, Z.¹

¹Cardiff University, Division of Cancer and Genetics, Cardiff, United Kingdom, ²Velindre NHS Trust, Velindre Cancer Centre, Cardiff, United Kingdom

ATP, released by damaged or dying cells, represents a danger signal that contributes to the initiation of immune responses. On the other hand, the ATP-metabolite adenosine has extensive immunosuppressive effects and also directly supports tumour growth, differentiation and metastasis. ATP conversion into ADP-5'-AMP-adenosine is catalysed by a highly regulated stepwise activity of ectonucleotidase enzymes CD39 and CD73. Most malignant cells express CD73, while tumour stroma, including immune cells, express CD39. The aim of this study was to reveal if there is a unique expression pattern of CD73 on tumour-associated immune cells in malignant pleural mesothelioma.

We found CD73-expressing CD14⁺ cells in tumour-associated pleural effusion (PF) but not in the peripheral blood of mesothelioma patients. The co-expression of CD39 and CD73 makes tumour-associated myeloid cells uniquely capable of metabolising ATP to adenosine. CD73 was induced on normal CD14⁺ cells, but not on CD3 cells, with PF, adenosine and cAMP-activators forskolin and prostaglandin E₂ (PGE₂). Inhibition of the adenosine A_{2a} receptor or PGE₂ receptors (EP2/EP4) abolished CD73 induction by PF. Monocyte treatment with PF also induced STAT3 phosphorylation; however, STAT3 blocking resulted in enhanced CD73 expression, pointing towards a negative control of the adenosine pathway by STAT3.

Here we demonstrate a link between prostaglandin, cAMP and adenosine pathways under the negative control of STAT3 in human monocytes. The complex control of CD73 expression on myeloid cells points towards the importance and potential therapeutic targeting of the ATP:adenosine balance in the tumour microenvironment.

Human mesothelioma induces defects in dendritic cell numbers and antigen processing function which predict survival outcomes

Cornwall, S.^{1,2}, Wikstrom, M.³, Musk, A.⁴, Alvarez, J.⁵, Nowak, A.^{6,7}, Nelson, D.^{1,2}

¹Curtin University, School of Biomedical Sciences, Immunology and Cancer Group, Bentley, Australia, ²Curtin University, CHIRI Biosciences Research Precinct, Bentley, Australia, ³University of Western Australia, Lions Eye Institute, Nedlands, Australia, ⁴Sir Charles Gairdner Hospital, Department of Respiratory Medicine, Nedlands, Australia, ⁵The Mount Hospital, Perth, Australia, ⁶University of Western Australia, School of Medicine and Pharmacology, Nedlands, Australia, ⁷Sir Charles Gairdner Hospital, Department of Medical Oncology, Nedlands, Australia

Mesothelioma is an almost invariably fatal tumor with chemotherapy extending survival by a few months. One immunotherapeutic strategy is to target dendritic cells (DCs), key antigen presenting cells involved in antigen presentation, to induce antigen-specific T cell responses. However, DC-targeting will only be effective if DCs are fit-for-purpose, and the functional status of DCs in mesothelioma patients was not clear. We found that mesothelioma patients have significantly decreased numbers of circulating myeloid (m)DC1 cells, mDC2 cells and plasmacytoid (p)DCs relative to healthy age and gender-matched controls. Blood monocytes from patients could not

differentiate into immature monocyte-derived DCs (MoDCs), indicated by a significantly reduced ability to process antigen and reduced expression of costimulatory (CD40, CD80 and CD86) and MHC (HLA-DR) molecules, relative to controls. Activation of mesothelioma-derived MoDCs with LPS+/-IFN γ generated partially mature MoDCs, evident by limited up-regulation of the maturation marker, CD83, and the costimulatory markers. Attempts to rescue mesothelioma-derived DC function using CD40Ligand(L) also failed, indicated by maintenance of antigen processing capacity and limited up-regulation of CD40, CD83, CD86 and HLA-DR. These data suggest that mesothelioma patients have significant numerical and functional DC defects and that their reduced capacity to process antigen and reduced expression of costimulatory molecules could induce anergized/tolerized T cells. Nonetheless, survival analyses revealed that individuals with mesothelioma and higher than median levels of mDC1s and/or whose MoDCs matured in response to LPS, IFN γ or CD40L lived longer, implying their selection for DC-targeting therapy could be promising especially if combined with another treatment modality.

Cytokine-driven loss of plasmacytoid dendritic cell function in chronic lymphocytic leukemia

Saulep-Easton, D.¹, Vincent, F.B.¹, Le Page, M.¹, Wei, A.², Ting, S.B.², Croce, C.M.³, Tam, C.⁴, Mackay, F.⁵

¹Monash University Central Clinical School, Department of Immunology, Melbourne, Australia, ²The Alfred Hospital and Monash University, Department of Haematology, Melbourne, Australia, ³The Ohio State University, Department of Molecular Virology, Immunology and Medical Genetics, Columbus, United States, ⁴Peter MacCallum Cancer Institute, Department of Haematology, Melbourne, Australia, ⁵University of Melbourne, School of Biomedical Sciences - Department of Microbiology and Immunology, University of Melbourne, Australia

Chronic lymphocytic leukemia (CLL) is characterized by the accumulation of CD5+CD19+ B cells in the peripheral blood, and in primary and secondary lymphoid organs. A major complication associated with CLL is severe recurrent infections, which are often fatal. Vulnerability to infection is due to a wide variety of immunological defects, yet the initiating events of immunodeficiency in CLL are unclear. Using CLL patient samples and a mouse model of CLL, we have discovered that plasmacytoid dendritic cells (pDCs), which underpin the activity of effector immune cells critical for anti-viral immunity and anti-tumor responses, are reduced in number and functionally impaired in progressive CLL. As a result, the levels of interferon alpha (IFN α) production, a cytokine critical for immunity, are markedly reduced. Lower pDC numbers with impaired IFN α production was due to the decreased expression of FMS-like tyrosine kinase 3 receptor (Flt3) and Toll-like receptor 9 (TLR9), respectively. Reduced Flt3 expression was reversed using inhibitors of TGF- β and TNF, an effect correlating with a reduction in tumor load. Defects in pDC numbers and function offer new insight into mechanisms underpinning the profound immunodeficiency affecting CLL patients and provide a potentially novel avenue for restoring immunocompetency in CLL.

Tumour Immunology

Novel mediators of immune suppression within the tumor microenvironment

Restifo, N.P.

National Cancer Institute, NIH, Bethesda, MD, USA

Tumours progress despite being infiltrated by effector T cells. Tumour necrosis is associated with poor survival in a variety of cancers. Here, we report that that necrosis causes release of an intracellular ion, potassium, into the extracellular fluid of human and mouse tumours. Surprisingly, elevated extracellular potassium [K⁺] was sufficient to profoundly suppress mouse and human T cell anti-tumor function. Elevations in extracellular [K⁺] acted to acutely impair T cell receptor (TCR) dependent Akt-mTOR phosphorylation and effector function. Potassium mediated suppression of Akt-mTOR signaling and T cell effector function required intact activity of PP2A, a serine/threonine phosphatase. The suppressive effect mediated by elevated extracellular [K⁺] required a T cell-intrinsic increase in intracellular potassium [K⁺] and was independent of changes in plasma membrane potential (V_m). Finally, ionic reprogramming of tumour-specific T cells via over-expression of the voltage-gated potassium channel Kv1.3 lowered intracellular [K⁺] and improved effector functions in vitro and in vivo, with this gain of function being dependent on intact channel function. Consequently, Kv1.3 T cell expression enhanced tumour clearance and the survival of melanoma-bearing mice. These results uncover a previously undescribed ionic checkpoint against T cell function within tumors and identify new strategies for cancer immunotherapy.

T Cell Memory

Transcriptional regulation of Memory T cell Formation

Goldrath, A.

University of California San Diego

Long-lived memory T cells mediate protection from reinfection with previously encountered pathogens; keep chronic, opportunistic and latent pathogens at bay; and can serve as endogenous defenders against tumor growth and metastases. The memory T cell population is heterogeneous, typically categorized into central memory cells found in the blood and lymphoid tissues or effector memory cells predominantly located in the blood and non-lymphoid tissues. The recent recognition of a third subset of memory lymphocytes, termed tissue-resident memory cells, that reside strictly within tissues and do not recirculate requires a revision of our understanding of memory T cell differentiation. The goal of our research is to understand how each population of CD8⁺ memory T cells is generated and maintained by identifying the transcriptional, epigenetic and signaling events that regulate the survival and differentiation of T cells as they navigate the immune response and become long-lived memory T cells.

Golden anniversary of IgE: WAO –IUIS session

Hierarchy and molecular properties of house dust mite allergens

Thomas, W.

Telethon Kids Institute

Antiserum produced to the purified major allergen of ragweed was central to the discovery of IgE but largely due to variable allergen extracts the use of IgE to define allergens was slow to develop. Molecular cloning and production of recombinant allergens reshaped the field by providing defined and pure allergen components required for reproducible assays and take confounding reactivities to degradation products, cross-reactivities and isoforms into account. House dust mite allergy can now be clinically and scientifically investigated within the framework that most of the response is caused by sensitization to a small number of immunodominant and mid-tier allergens that show a characteristic hierarchy in their ability to induce IgE antibody making proportionate contributions to the overall response of all responding subjects. The allergen components bound by IgE by children susceptible to recurrent and persistent asthma are the same as those with manageable disease although sensitised subjects without disease have both lower overall IgE titres and detectable antibody to fewer components. Both the likelihood of children developing allergic disease and the likelihood of mite allergens being responsible for extant disease are proportional to the titres of their anti-mite IgE but the probabilities are not significant at the low titres required for positive skin tests and for mite about 40% of subjects with high titre do not develop disease. Anti-mite IgG antibodies that reach titres the same as those of anti-microbial responses are largely confined to sensitised subjects and to the allergens but are in low subjects susceptible to di.

Rational of blockade of IgE in Allergic Airway Disease

Pawankar, R., MD, Ph.D., FRCP, FAAAAI

Department of Pediatrics, Nippon Medical School, Tokyo, Japan

The strategy for the treatment of allergic diseases like allergic rhinitis and asthma lies in its capacity to reduce the severity of symptoms either by interfering with or modulating the allergic inflammatory cascade. IgE plays a crucial role in the pathophysiology of allergic diseases. In view of this pivotal role that IgE has in triggering immediate-type hypersensitivity responses, its capacity to bind to its receptors, IgE represents a potentially important therapeutic target. In addition, the identification of both FcεR1 and FcεR2 on

monocytes, dendritic cells and epithelial cells, suggests important roles for IgE in the regulation of allergic inflammation, including enhanced allergen presentation. Moreover, increase in FcεR1 expressing cells and increased FcεR1 expression in mast cells, basophils, dendritic cells, epithelial cells, its upregulation by IL-4 or IgE is reported in patients with AR and asthma. Targeting IgE is therefore an important strategy in the treatment of allergic diseases. Omalizumab is a humanized anti-IgE monoclonal antibody that binds to free IgE and prevents its binding to specific receptors on the surface of cells, thus preventing the release of immune mediators. Treatment with omalizumab in asthmatics results in a rapid and pronounced decrease in serum IgE levels correlated with improvement in the severity of symptoms and in the quality of life and reduction in asthma exacerbation and emergency visit rates, down-regulation of IgE receptors on basophils and dendritic cells, reductions in tissue eosinophils and IgE+ cells, as well as T cells and B cells. Long term treatment showed disease modifying effects.

Infection

Immune control of chronic malaria

Langhorne, J., Perez-Mazliah, D, Sodenkamp, JC, McLaughlin, S.

Francis Crick Institute

CD4+ T-cells play a central role in immune control of erythrocytic stages of the malaria parasite *Plasmodium*. Classical studies have shown that IFN-γ-producing Th1 cells are important for controlling acute infections, however they also contribute to acute blood-stage pathology. CD4+ T-cell help and antibodies are required for elimination of chronic infection. However, in humans in endemic areas, antibody responses can be slow to develop, and are short lived, and exhausted B and T cells are expanded suggesting some impairment of host responses. We have investigated the requirements for activating a protective B cell response in malaria using a model of *P. chabaudi* in C57bl/6 mice. We show that IL-21 produced by T follicular helper cells, co-expressed with IFN-γ and acting on the IL-21 receptor on B cells is required to resolve chronic infection, and for immunity to re-infection. The absence of IL-21, IL-21R and bcl/6 in T cells resulted in abrogation *P. chabaudi*-specific IgG responses, including memory B cells. The SLAM-associated protein, SAP, which has been shown to regulate T:B cell interactions particularly for long-term immunity was not required in this infection for Tfh activation, IgG responses or control of infection. Our data show that CD4+ T cells and B cells can control parasitemia during chronic blood-stage malaria through a single cytokine produced by Tfh cells. Knowledge of how T-cell help and antibodies are regulated during blood-stage malaria will help us understand how humoral responses can be impaired, and how this impacts on protective immunity.

Neutrophil necroptosis triggers NET release via RIPK3 and MLKL to combat *Staphylococcus aureus* infection

D'Cruz, A.¹, Bliss-Moreau, M.¹, Al-Obeidi, A.¹, Gavillet, M.¹, Williams, D.¹, Ericsson, M.², Croker, B.^{1,2}

¹Boston Children's Hospital, Boston, United States, ²Harvard Medical School, Boston, United States

Neutrophil extracellular traps (NETs) are networks of chromatin and microbicidal proteins released by neutrophils in response to infection and tissue damage. Although classically viewed as a discrete cellular process in neutrophils, the genetic factors controlling NETosis are poorly defined. To investigate the involvement of regulated cell death pathways in NETosis, we examined the consequences of activating positive regulators of necroptosis including receptor-interacting protein kinase-3 (RIPK3) and mixed lineage kinase domain-like (MLKL). The release of hyper-citrullinated histone H3 and double-stranded DNA (dsDNA) from neutrophils was dependent on reactive oxygen species (ROS), RIPK3 and MLKL. Phosphorylated MLKL was identified at the plasma membrane of necroptotic neutrophils, and MLKL colocalized to regions of the membrane releasing DNA. Necroptotic mouse and human neutrophils restricted the growth of *Staphylococcus aureus* (*S.aureus*) but not in the presence of DNaseI. Consistently, mice deficient in RIPK3 or MLKL displayed increased numbers of *S.aureus* in the blood and kidney. Our studies place NET formation in the context of non-apoptotic cell death pathways to prevent bacteremia via regulated DNA release.

Redefining myeloid Cell subsets in murine spleen

Hey, Y.Y., Tan, J.K.H., O'Neill, H.C.

Bond University, Gold Coast, Australia

Spleen is known to contain multiple dendritic and myeloid cell subsets, distinguishable on the basis of phenotype, function and anatomical location. As a result of recent intensive flow cytometric analyses, splenic dendritic cell (DC) subsets are now better characterised than other myeloid subsets. In order to identify and fully characterise a novel splenic subset termed 'L-DC' in relation to other myeloid cells, it was necessary to investigate myeloid subsets in more detail. In terms of cell surface phenotype, L-DC were initially characterised as a CD11b^{hi}CD11c^{lo}MHCII⁻Ly6C⁻Ly6G⁻ subset in murine spleen. Their expression of CD43, lack of MHCII, and a low level of CD11c was shown to best differentiate L-DC by phenotype from conventional DC subsets. A complete analysis of all subsets in spleen led to the classification of CD11b^{hi}CD11c^{lo}MHCII⁻Ly6C^{lo}Ly6G⁻ cells as monocytes expressing CX₃CR1, CD43 and

CD115. Siglec-F expression was used to identify a specific eosinophil population, distinguishable from both Ly6C^{lo} and Ly6C^{hi} monocytes, and other DC subsets. L-DC were characterised as a clear subset of CD11b^{hi}CD11c^{lo}MHCII⁻Ly6C⁻Ly6G⁻ cells, which are CD43⁺, Siglec-F⁻ and CD115⁻. Changes in the prevalence of L-DC compared to other subsets in spleens of mutant mice confirmed the phenotypic distinction between L-DC, cDC and monocyte subsets. L-DC development *in vivo* was shown to occur independently of the BATF3 transcription factor that regulates cDC development, and also independently of the FLT3L and GM-CSF growth factors which drive cDC and monocyte development, so distinguishing L-DC from these commonly defined cell types.

Sugar modification of carrier protein in allergen determines the magnitude of IgE- and basophil-mediated allergic inflammation

Nagao, T., Takahashi, S., Kawawa, M., Miyake, K., Yoshikawa, S., Sato, S., Yamaniishi, Y., Karasuyama, H.

Tokyo Medical and Dental University, Department of Immune Regulation, Tokyo, Japan

In the field of immunological research, ovalbumin (OVA) is commonly used as allergen, but it remains why OVA has strong allergenicity in animals. Recently we have established a basophil-dependent allergy model "IgE-mediated chronic allergic inflammation (IgE-CAI)", in which mice sensitized with hapten-specific IgE are challenged intradermally with hapten-conjugated OVA. In this model, mice show delayed-onset ear swelling with accumulation of inflammatory cells including eosinophils and macrophages. Intriguingly, when challenged with the same hapten-conjugated bovine serum albumin (BSA) instead of OVA, mice showed poorer IgE-CAI response with reduced ear swelling and cellular infiltration, suggesting that the nature of carrier protein is important for the induction of IgE-CAI. Notably, BSA and OVA, when conjugated with the same number of hapten, showed comparable capacity to activate IgE-sensitized basophils *in vitro*. To address the molecular mechanism underlying the functional difference *in vivo* between OVA and BSA, we focused on their post-transcriptional modifications. OVA but not BSA has one sugar chain, giving the hypothesis that the sugar modification in carrier proteins may determine the magnitude of the IgE-CAI response. Consistent with this hypothesis, the addition of sugar moiety conferred the capacity of eliciting the efficient IgE-CAI response on BSA. Collectively, our results indicate that post-transcriptional sugar modification of carrier protein plays a significant role in the induction of IgE-CAI, and this finding may account for the reason why OVA, but not BSA, is preferentially used as allergen to induce allergy.

1961**Engagement of the ITIM receptor CD31 regulates neutrophil adhesion and rolling on activated endothelial cells in vitro and in vivo**

Andreata, F., Ollivier, V., Syvannarath, V., Rasser, C., Loste, A., Procopio, E., Nicoletti, A., Le Borgne, M., Caligiuri, G.
INSERM U 1148, Paris, France

CD31 is an ITIM-bearing transhomophilic receptor highly expressed by both endothelial cells and neutrophils but, intriguingly, nothing is known about the dynamic of CD31 expression and the role of its engagement during neutrophils rolling and adhesion onto activated endothelial cells.

By using flow cytometry and fluorescence microscopy, we found most of the CD31 extracellular portion is rapidly lost, leaving a membrane-proximal extracellular fragment expressed by activated neutrophils. Western Blot analysis revealed that the use of a synthetic peptide able to engage the lingering CD31 extracellular fragment sustains, in a dose-dependent manner, the phosphorylation of the intracellular CD31 ITIMs and the consequent SHP2 activation.

Such CD31 agonist peptide prevents neutrophil rolling and adhesion onto activated endothelial cells in vivo in C57BL/6 mice as detected by intravital videomicroscopy after application of ionomycin onto a mesenteric venule. The administration of the CD31 agonist peptide resulted in a durable 60% inhibition of leukocytes adhesion onto the activated endothelium as compared to control mice (n=4/group). In separate *in vitro* experiments we used a flow system in which purified human neutrophils were let stream with a post-capillary flow rate (5 dynes/cm²) on human coronary artery endothelial cell (HCAEC) previously cultured until confluence under continuous flow on cellix VENAFLUOR® chambers and activated overnight with 10ng/ml of TNF α . As compared to control cells, neutrophils pre-treated with the CD31 agonist peptide rolled weakly and virtually did not arrest onto the activated HCAEC.

We conclude that CD31 signalling modulates neutrophils interactions with activated endothelial cells and effectively controls neutrophil extravasation.

588**Lfc regulates the formation of neutrophil extracellular traps**

Weng, C.-M., Chiang, H.-S.

National Taiwan University, Life Science, Taipei, Taiwan, Republic of China

Neutrophils are the most abundant type of white blood cells in most mammals, and play a critical role in innate immunity. Previous studies have shown that neutrophils trap and kill a variety of pathogens by neutrophil extracellular traps (NETs), whose formation depends on dynamic microtubule networks. The guanine nucleotide exchange factor Lfc is crucial in coupling microtubule dynamics to Rho GTPase activation in a variety of normal biological situations. It is also a newly defined component of cellular defenses for the detection of microbial effectors during cell invasion by pathogens. However, it remains unknown whether Lfc regulates NET formation in response to pathogen infection. Here we show that upon activation by

phorbol 12-myristate 13-acetate (PMA), the rate of NET release was reduced in Lfc-deficient neutrophils compared to wild-type neutrophils. The reduced NET formation in Lfc-deficient neutrophils was not due to the impaired granulopoiesis for neutrophils in the bone marrow. We further found that Lfc deficiency lead to impaired NET formation in response to *shigella flexneri* infection. Overall, our results suggested a potential role for Lfc in the regulation of NET formation.

1462**mMCP-8, a basophil specific protease, triggers an inflammatory response by stimulating fibroblasts to produce chemokines**

Tsutsui, H., Yamanishi, Y., Yoshikawa, S., Sato, S., Karasuyama, H.
Tokyo Medical and Dental University (TMDU), Department of Immune Regulation, Tokyo, Japan

Basophils store a variety of bioactive molecules including proteases in the secretory granules and rapidly release them upon degranulation that contributes to allergic response or host defense against pathogens. Mouse mast cell protease-8 (mMCP-8) is specifically expressed in murine basophils and widely accepted as a basophil-specific marker in mice. However, the physiological function of mMCP-8 has not been elucidated. In the present study, we show evidence that basophil-derived mMCP-8 provokes an inflammatory response in the skin lesion. Notably, mMCP-8 was localized to the secretory granules in basophils and released promptly after IgE/antigen-induced degranulation. Subcutaneous injection of recombinant mMCP-8 (rmMCP-8) caused transient skin swelling with local accumulation of neutrophils and macrophages in a dose-dependent manner. Consistent with the leukocyte accumulation, increased expression of chemokines such as CXCL1 and CCL2 was observed in the rmMCP-8-injected skin lesions. To distinguish what cell types are a main source of CXCL1 and CCL2 in rmMCP-8-injected skin lesion, we sorted the skin cells into hematopoietic cells, fibroblasts, and others. Importantly, the chemokine expression was exclusively induced in dermal fibroblasts, suggesting that fibroblasts were a possible target for mMCP-8. To address this possibility, primary-cultured fibroblasts were stimulated with rmMCP-8 *in vitro*. Of note, significant amount of CXCL1 and CCL2 was produced by fibroblasts in response to rmMCP-8 stimulation. Collectively, our results suggest that basophil-specific protease mMCP-8 activates dermal fibroblasts that produce chemokines and attract inflammatory cells at the site, leading to skin inflammation.

310**Functional and metabolic reprogramming drives the development of a pathogenic subset of neutrophils in inflammatory airway diseases**

Forrest, O.¹, Ingersoll, S.¹, Preininger, M.², Laval, J.², Limoli, D.¹, Brown, M.¹, Lee, F.³, Bedi, B.³, Sadikot, R.³, Goldberg, J.¹, Tangpricha, V.³, Tirouvanziam, R.¹

Background: Airway inflammation in cystic fibrosis (CF), chronic obstructive pulmonary disease (COPD), and severe asthma (SA) is characterized by the massive recruitment of polymorphonuclear neutrophils (PMNs) to the lumen. Neutrophil elastase (NE) released from primary granules is a strong predictor of lung function in CF and COPD. However, it remains unclear how NE and other PMN granule mediators are released into the lumen.

Methods: Blood and sputum were collected from CF, COPD, SA, and healthy control subjects, and PMNs were analyzed for viability, degranulation, and other changes. In a transepithelial migration assay, airway fluid from the same four cohorts of subjects was used to induce blood PMN recruitment into the airway lumen. In vitro migrated PMNs were analyzed for survival, degranulation, and metabolic and bacterial killing activities.

Results: CF, COPD, and SA airway fluid induced rapid transepithelial migration and survival of PMNs in vitro; (ii) CF, COPD and SA, but not HC, airway PMNs release their primary granules actively, both in vivo and in vitro; and (iii) migration into CF airway fluid reprograms PMNs to upregulate glycolysis while paradoxically dampening their ability to kill the CF pathogen *P. aeruginosa*, which is consistent with prior in vivo observations.

Conclusions: Together, these data suggest a primary role for the inflammatory airway milieu in promoting survival, functional and metabolic reprogramming of recruited PMNs.

Pathological manifestations in lymphatic filariasis correlate with lack of inhibitory properties of IgG4 molecules on IgE-armed granulocytes

Prodjinotho, U.F., von Horn, C., Hoerauf, A., Adjobimey, T. Institute for Medical Microbiology, Immunology and Parasitology (IMMIP), University Hospital Bonn, Germany, Bonn, Germany

Background: Helminth parasites are renowned for their capacity to dampen inflammation to support their own survival, thus generating a modified Th2 immune response characterized by the presence of regulatory cytokines and high plasma levels of the non-cytolytic antibody IgG4. This particular isotype is described in both helminth and allergy models to inhibit diverse effector cells. How IgG4 molecules affect granulocyte activation and functions is still not well characterized.

Methods: Using isolated granulocytes and affinity purified IgG and IgG4 fractions from plasma of endemic normals (EN), lymphatic filariasis pathology patients (CP), asymptomatic microfilaraemic (MF+) and amicrofilaraemic (MF-) infected individuals, we analyzed the impact of bulk plasma and IgG positive or negative fractions on IgE/IL-3 stimulated granulocytes by flow-cytometric analysis of CD66b/CD63/HLADR expression and ELISA assessment of histamine, eosinophil cationic protein and neutrophil elastase in culture supernatants. In addition, the granulocyte modulation pathways were investigated by FcγRs blocking, immunofluorescence and western blot.

Results: Granulocytes activation and granules content release were significantly inhibited by plasma of EN and MF+ individuals. This inhibitory capacity was abrogated upon depletion of IgGs

from the plasma of MF+ individuals but persisted in EN plasma. Interestingly, affinity-purified IgG4 molecules from EN, MF+ and MF-, but not those of CP, interact with FcγRI and FcγRII while significantly inhibiting granulocytes activation in a Src, AKT and MEK dependent mechanism.

Conclusion: Our data indicate that, during helminth infections, MF+ individuals display IgG4 antibodies with potent inhibitory activities on granulocytes. In addition, we have identified possible functional differences between IgG4 molecules.

Advances in practical clinical blood analysis for eosinophilic disorders using high throughput table top imaging flow cytometry

Piasecka, J.¹, Summers, H.D.², Thornton, C.A.¹

¹Institute of Life Science, Swansea University Medical School, Swansea, United Kingdom, ²Swansea University, College of Engineering, Swansea, United Kingdom

Autofluorescence that localizes to cytoplasmic granules can be used during flow cytometry to identify eosinophils within mixed leukocyte preparations such as blood. A wider range of cellular features can be captured using imaging flow cytometry to provide more detail about cell phenotype including, potentially, the activation status of the cells. We have developed a simple, sensitive and rapid imaging cytometry technique for identifying activated and non-activated eosinophils in clinical whole blood samples.

Whole human peripheral blood and isolated blood eosinophils from healthy volunteers were exposed to various stimuli responsible for eosinophil recruitment, growth, survival, and for inducing selective protein release from eosinophilic granules (IL-3, IL-5, GM-CSF, Eotaxin, and RANTES) for different time points. Results from imaging flow cytometry were compared by treatment, and for isolated eosinophils, with images from electron microscopy.

Eosinophils were readily identified in whole peripheral blood by imaging cytometry in a label-free manner and populations analysed from spatial metrics (size, shape, granularity) obtained from light scatter (dark field), light transmission (bright field) or autofluorescence images. Texture information relating to intra-cellular granules can be extracted from bright field images and this reports on eosinophil activation status. Thus we demonstrate a label-free method, allowing continuous and harmless monitoring of both eosinophil number and cellular state.

This project provides early validation that eosinophil images captured through imaging cytometry have potential as a clinical tool for monitoring of various eosinophilic diseases.

Invariant and $\gamma\delta$ T cells

The protective role of $\gamma\delta$ T cells in neonatal influenza

Guo, X.^{1,2}, Dash, P.¹, Thomas, P.^{1,2}

¹St. Jude Children's Research Hospital, Immunology, Memphis, United States, ²University of Tennessee Health Science Center, Microbiology, Immunology and Biochemistry, Memphis, United States

Influenza virus infection is a continuing worldwide health threat, especially in infants and the elderly. Neonates are highly susceptible to influenza infection. $\gamma\delta$ T cells are the first T cells to develop during embryogenesis and are a significant component of the neonatal immune system. In the neonatal period, conventional $\alpha\beta$ T cell responses are functionally less prominent. Hence, $\gamma\delta$ T cells are poised to play a critical role in neonatal infections, however, the specific role of $\gamma\delta$ T cells in neonatal influenza infection remains to be elucidated. Using a neonatal mouse model of intranasal influenza infection, we observed the activation and proliferation of $\gamma\delta$ T cells within two days after infection. By utilizing *Nur77*-GFP reporter mice, we demonstrated the activation of these $\gamma\delta$ T cells was via the TCR and its downstream signaling. IL-17-producing $\gamma\delta$ T cells, rather than IFN- γ -producing cells, dominated in this response. A comparison between wild-type and *TCR δ* -deficient neonates identified a protective function of $\gamma\delta$ T cells in neonates, as an increased survival rate were observed in the wild-type compared to *TCR δ* -deficient animals. In infected lungs, wild-type neonates also had increased IFN- β and inflammatory cytokine production, especially among the Th2-relevant cytokines. Consistent with this observation, more eosinophils infiltrated into the lungs of wild-type neonates. Our findings demonstrate a vital role for $\gamma\delta$ T cells in mediating protection during neonatal influenza virus infection via a mechanism which appears to include promotion of a Type 2 immune environment that may provide a new therapeutic target for pediatric influenza treatment.

Australia, ⁸Australian Research Council Centre of Excellence in Advanced Molecular Imaging, Monash University, Clayton, Australia, ⁹Institute of Infection and Immunity, Cardiff University, School of Medicine, Heath Park, United Kingdom

Studies on the biology of Mucosal-Associated Invariant T (MAIT) cells in mice have been hampered by a lack of specific reagents. Using MR1-antigen (Ag) tetramers that specifically bind to the MR1-restricted MAIT cell receptors (TCRs), we demonstrate that MAIT cells are detectable in a broad range of tissues in C57BL/6 and BALB/c mice. These cells include CD4-CD8-, CD4-CD8+, and CD4+CD8- subsets and their frequency varies in a tissue- and strain-specific manner. MAIT cells are relatively rare in spleen and thymus, but more abundant in liver, lymph nodes and lungs, where they represent up to 3% of T cells. Mouse MAIT cells have a CD44^{hi}CD62L^{lo} memory phenotype and produced high levels of IL-17A, and other cytokines including IFN- γ , IL-4, IL-10, IL-13, GM-CSF at moderate levels. Consistent with high IL-17A production, most MAIT cells expressed high levels of retinoic-acid-related orphan receptor (ROR) γ t, whereas (ROR) γ t^{lo} MAIT cells predominantly expressed T-bet and produced IFN- γ . Most MAIT cells expressed the promyelocytic leukaemia zinc finger (PLZF) transcription factor and their development was largely PLZF-dependent. Residual MAIT cells in PLZF deficient mice had an immature, CD4+ phenotype and failed to produce cytokines upon stimulation, indicating a key role for this transcription factor in MAIT cell biology. Thus, MAIT cells can be readily identified in mice using MR1 tetramers, as soon as they emerge in the thymus in a PLZF dependent manner, functionally diverse subpopulations can be detected. These studies represent a key component in understanding the function of MAIT cells in the immune system.

4122

New pathways regulating immunosurveillance by tissue-resident gd T cells

Iannitto, M.L.^{1,2}, Nussbaumer, O.¹, Woolf, R.¹, Hayday, A.^{1,2}

¹King's College London, London, United Kingdom, ²Francis Crick Institute, London, United Kingdom

gd-T cells are unique unconventional lymphocytes, mostly tissue-resident, and able to mount rapid "lymphoid stress-surveillance responses" to sentinels of tissue dysregulation. We ignore the molecules regulating these potentially potent responses. The importance of the PVR-TIGIT-DNAM1 axis is emerging in conventional T cell activation and tumour immunology, but its relevance to tissue-resident T cell populations, particularly gd-T cells, is unknown. PVR, expressed in cell-cell junctions and over-expressed in tumours, can switch from a DNAM1-dependent activator to a TIGIT-dependent suppressor.

We found that human peripheral blood Vd2⁺ cells and human skin-resident Vd1⁺ cells both express DNAM1, but Vd1⁺ cells constitutively express TIGIT whereas Vd2⁺ cells express TIGIT only transiently post-activation. These data suggest that human tissue-resident gd-T cells are pre-activated cells regulated by TIGIT that relays inhibitory signals in response to PVR engagement. Indeed, rhPVR inhibited TCR-induced cytokine production by Vd1⁺ cells, whereas Vd2⁺ cells were unaffected.

Constitutive TIGIT expression was likewise displayed by murine, tissue-resident, epidermal Vg5⁺Vd1⁺ cells. TIGIT expression commenced during their *Skint1*-dependent developmental checkpoint, suggesting that TIGIT is switched on to regulate the cells' innate-like immune-surveillance potentials. Under physiological conditions, PVR is expressed primarily by Langerhans Cells, the other large epidermal immune population, and only by a fraction of the CD45⁺ compartment. This argues that the PVR-TIGIT-DNAM1 axis is utilised by local DCs to suppress local T cell activation, until a threshold of immunogenicity is exceeded. These findings have profound implications and clinical relevance to tissue-mediated regulation of anti-tumour responses and of local T cell regulation in inflammatory diseases.

4133

HEB plays a critical role in the installation of IL-17 program in $\gamma\delta$ T cells

In, T.^{1,2}, Trotman-Grant, A.¹, Anderson, M.K.^{1,2}

¹Sunnybrook Research Institute, Biological Sciences, Toronto, Canada, ²University of Toronto, Immunology, Toronto, Canada

IL-17 producing $\gamma\delta$ T cells that arise during fetal development form an integral part of the immune system of various lymphoid and mucosal tissues in mice. Here, we aim to better understand the transcriptional network that drives functional programming of the IL-17 producing $\gamma\delta$ T cells. Specifically, we characterized the role of HEB in this process by utilizing fetal thymic organ culture (FTOC) from mouse embryos at E14. First, we observed that the HEB-deficient fetal $\gamma\delta$ T cells lacked the ability to upregulate SOX13, a hallmark transcription factor of IL-17 producing $\gamma\delta$ T cells, at the immature stage, leading to an inability to express IL-17 upon maturation, marked by downregulation of CD24 and upregulation of CD73. These differences in the gene expression profile of developing fetal thymic $\gamma\delta$ T cells in the absence of HEB were also met by a significant reduction in the frequency of ROR γ t⁺ $\gamma\delta$ T cells and a profound deficiency in their ability to produce IL-17 in response to stimulation with IL-1 β , IL-23 and IL-21 as determined by intracellular flow cytometry analysis and ELISA. Reflecting the deficiency in IL-17 producing $\gamma\delta$ T cells in HEB-deficient fetal thymus, HEB conditional knockout mice on a *vav*-Cre background had significantly lower frequencies of ROR γ t⁺ IL-17 producing $\gamma\delta$ T cells in the spleen, lymph nodes and lungs. Collectively, our work shows for the first time that HEB plays an indispensable role in the transcriptional network that drives the installation of IL-17 program in $\gamma\delta$ T cells.

742

$\gamma\delta$ T cells and the regulation of immune responses at epithelial surfaces

Havran, W.¹, Johnson, M.¹, Borkowski, A.¹, Tekkam, S.², Crooke, S.², Finn, M.G.², Witherden, D.¹

¹Scripps Research Institute, Immunology and Microbial Science, La Jolla, United States, ²Georgia Institute of Technology, Chemistry and Biochemistry, Atlanta, United States

Intraepithelial $\gamma\delta$ T cells play unique roles in homeostasis, tissue repair, inflammation and protection from malignancy in mice

and man. Human epidermal T cells contribute to wound healing and are defective in patients with chronic wounds. Increasing numbers of elderly and diabetic patients have defects in tissue repair leading to chronic, non-healing wounds. We have identified key regulators of intraepithelial $\gamma\delta$ T cell recognition of damaged epithelial cells leading to activation and participation in local immune responses, including the JAML and CAR costimulatory molecules. Expression of the CAR costimulatory ligand is upregulated on epithelial cells around human healing wounds but not in chronic wounds. Surgical debridement to remove non-healing tissue can create a new acute wound, lead to upregulated CAR expression, and result in improved healing. Since expression of CAR correlates with effective wound healing, we hypothesize that defective costimulation due to lack of CAR expression is responsible for the T cell dysfunction in chronic wounds. We are utilizing biodegradable hydrogels to deliver costimulatory ligands directly into non-healing wounds as a new therapeutic strategy targeting the dysfunctional T cells. Further characterization of the molecules and mechanisms that regulate interactions between tissue-resident T lymphocytes and neighboring epithelial cells may allow for the development of this and other new therapeutic strategies to treat chronic wounds and other epithelial disorders.

Hybrid $\alpha\beta$ - $\gamma\delta$ T cells, novel T cell populations with a critical pathogenic role in CNS autoimmunity

Edwards, S.C.¹, Sutton, C.E.¹, McLaren, J.E.², Ladell, K.², Ribot, J.C.³, Baik, S.⁴, Moran, B.¹, Anderson, G.⁴, Silva-Santos, B.³, Price, D.A.², Mills, K.H.G.¹

¹School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland, ²Institute of Infection and Immunity, Cardiff University, School of Medicine, Cardiff, United Kingdom, ³Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal, ⁴MRC Centre for Immune Regulation, Institute for Biomedical Research, Medical School, University of Birmingham, Birmingham, United Kingdom

$\gamma\delta$ T cells and CD4 T cells are the main sources of IL-17 during inflammation and host immunity. V γ 4⁺ $\gamma\delta$ T cells are found at high frequency in the central nervous system (CNS) of mice with experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis. Here, we describe novel populations of T cells, hybrid $\alpha\beta$ - $\gamma\delta$ T cells distinct from conventional $\alpha\beta$ or $\gamma\delta$ T cells which play a critical pathogenic role in CNS autoimmunity. Hybrid $\alpha\beta$ - $\gamma\delta$ T cells which express V γ 4⁺ cells arise in the foetal thymus on day 16 of ontogeny, where they constitute around 10% of V γ 4⁺ cells in the peripheral lymphoid organs. Hybrid $\alpha\beta$ - $\gamma\delta$ T cells are present in WT but absent in TCR α ^{-/-} and TCR β ^{-/-} mice, however hybrid $\alpha\beta$ - γ T cells were identified in TCR δ ^{-/-} mice. Co-expression of α , β , γ and δ chains was confirmed at the molecular level, revealing a restricted V γ repertoire with more heterogeneous V α and V β usage. Hybrid $\alpha\beta$ - $\gamma\delta$ T cells express the master transcription factor, ROR γ t, and IL-1R, IL-23R, CD44, CCR6 and α 4 β 1. Furthermore, these cells secrete IL-17A, IFN- γ and IL-22, following stimulation with IL-1 β and IL-23 and respond to autoantigens when purified from mice

with EAE. Depletion of V γ 4⁺ cells from either WT or TCR δ ^{-/-} mice dramatically attenuated EAE, and this effect was associated with a significant reduction in CNS-infiltrating Th17 cells. These data identify novel populations of T cells, hybrid $\alpha\beta$ - $\gamma\delta$ T cells which play a critical role in autoimmunity via the activation of Th17 cells.

3871

Thymic precursors to the mucosal-associated invariant T cell lineage

Mucosal-associated invariant T (MAIT) cells, are activated by microbial vitamin B2 (riboflavin) derivatives presented by the major histocompatibility complex (MHC) class I related protein, MR1. In humans, MAIT cells represent between 5 and 50% of T cells in different human tissues. The number of MAIT cells varies widely between individuals and the factors that govern the development of these cells are unclear. Using MR1 tetramers to detect MAIT cells in mice and humans, we have now identified thymic precursors to the MAIT cell lineage and delineated three distinct stages in MAIT cell development. In mice, the least mature, stage 1 (CD24⁺CD44⁻) cells progress to an intermediate stage 2 (CD24⁻CD44⁻) before maturing into stage 3 (CD24⁻CD44⁺) MAIT cells. Progression through each of these checkpoints is MR1 dependent, while the final maturation checkpoint that gives rise to functional MAIT cells requires the transcription factor, promyelocytic leukemia zinc finger (PLZF). In humans, stage 1 (CD161⁻CD27⁻) and stage 2 MAIT cells (CD161⁻CD27⁺) predominate in the thymus, while stage 3 cells (CD161⁺) progressively increase in percentage in umbilical cord blood, young peripheral blood and adult peripheral blood. MAIT cell maturation can also occur after thymic emigration of immature MAIT cells in both humans and mice. Accordingly, this study maps the intrathymic developmental pathway and identifies key checkpoints that control the maturation of functional MAIT cells in mice and humans.

Mucosal associated invariant T lymphocytes (MAIT) are a class of innate like T cells, which use their semi-invariant T-cell receptors (TCRs) to detect small molecules presented by the monomorphic MHC Class-I related protein (MR1). Ubiquitously expressed, MR1 captures compounds associated with folic acid degradation and riboflavin biosynthesis - the latter being indicative of bacterial infection, stimulating MAIT cells into producing an array of cytokines in an innate-like response.

Considering the monomorphic nature of MR1, its ability to bind small molecules and the relatively high abundance of MAIT cells in humans; two fundamental questions are whether MR1 will capture drugs or other naturally derived compounds, and importantly, do these molecules then modulate MAIT cell activity. We have addressed these fundamental questions. Using an *in silico* approach followed by *in vitro* screening, we identified a panel of small molecules that are captured by MR1. These include; the degradation products of methotrexate and sirtinol, formyl-salicylates, as well as the non-steroidal anti-inflammatory drug diclofenac, and its metabolite 5-OH-diclofenac. Moreover, we have shown that they can inhibit or activate MAIT cell activity *in vitro* and *ex vivo*. Finally, we solved the X-ray crystal structures of MR1-Ag-TCR of six of these compounds, revealing the mechanisms used by these diverse chemical scaffolds to modulate MAIT cell activity.

These findings show how heterogeneous chemical scaffolds, including FDA-approved drugs, are sequestered within MR1 and can modulate MAIT cell activity. Another crucial chapter in understanding the immunological repercussions of the current pharmacological age is beginning to be realised.

Obesity is associated with a state of chronic, low-grade inflammation in adipose tissue. It has been found that

altered ratios of Tregs to activated T cells augment the enhanced cytokine and chemokine output of macrophages and adipocytes to generate this inflammatory environment. However, whether obesity alters the balance of immune cells in lymphoid tissues has remained largely unexplored. We placed mice on a high fat diet (HFD) for 15 weeks, after which time we examined T cell populations in the spleen and lymph nodes (LN). We did not observe any significant changes in proportions of Tregs or cytokine-producing CD4⁺ or CD8⁺ T cells. However, we did observe an increase in IL-17-producing cells in the peripheral, but not mesenteric, LN. These cells were identified as ROR γ t⁺ γ δ T cells, and we subsequently found an increased proportion of dermal IL-17-producing γ δ T (γ δ T-17) cells in the skin. Surprisingly, we not only found these cells in the dermis, but also found a significant proportion had migrated into the epidermis. Upon further analysis of HFD mice we found that cells in the epidermis, most likely keratinocytes, had upregulated chemokines and cytokines key to γ δ T-17 cells. Furthermore, we found that this transepidermal migration of γ δ T-17 cells coincided with an increased disease severity in the IMQ model of psoriasis. These data suggest that excess adiposity has distinct consequences for immune cells in the skin.

The critical roles of IRF1 and BATF during differentiation of Tr1 cells

Karwacz, K.¹, Miraldi, E.^{2,3}, Pokrovskii, M.³, Asaf, M.⁴, Bonneau, R.^{2,5,6}, Dan, L.^{7,8}, Kuchroo, V.⁹

¹University College London, London, United Kingdom, ²Simons Center for Data Analysis, Simons Foundation, New York, United States, ³New York University School of Medicine, New York, United States, ⁴Evergrande Center for Immunologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, United States, ⁵Center for Genomics and Systems Biology, Department of Biology, New York University, New York, United States, ⁶Courant Institute of Mathematical Sciences, Computer Science Department, New York University, New York, United States, ⁷Molecular Pathogenesis Program, The Kimmel Center for Biology and Medicine of the Skirball Institute, New York University School of Medicine, New York, United States, ⁸The Howard Hughes Medical Institute, New York University School of Medicine, New York, United States, ⁹Evergrande Center for Immunologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, United States

Tr1 cells are IL-27-induced IL-10 producing cells crucial for the control of autoimmunity. We show that IL-27 induces IRF1 and BATF transcription factors (TFs), which are critical for Tr1 differentiation and their suppressive function *in vitro*.

In vivo, *Irf1*^{-/-} and *Batf*^{-/-} mice fail to induce Tr1 cells when treated with an anti-CD3 monoclonal antibody and during autoimmune disease (EAE). Furthermore, transfer of *in vitro* IL-27-treated *Irf1*^{-/-} and *Batf*^{-/-} CD4⁺ T cells into MOG₃₅₋₅₅/CFA immunized mice fails to suppress EAE progression, while transfer of WT control cells does suppress it. *Irf1*^{-/-} cells develop more severe disease, characterized by impaired recovery and increased numbers of

IL17A⁺IFN γ ⁺ double producing cells as well as decreased IL10 in the central nervous system.

We further show that both IRF1 and BATF bind to the IL-10 promoter in overlapping sites and require each other for this binding. Moreover, cMaf and AhR, which also bind to and induce IL10, cannot bind to IL10 in the absence of IRF1 or BATF. While IRF1 can directly transactivate IL10, while BATF cannot.

We have analyzed chromatin changes in *Irf1*^{-/-} and *Batf*^{-/-} IL-27 primed cells using ATAC-seq and found that both TFs influence chromatin accessibility. IRF1-induced chromatin changes are local, while BATF-dependent changes are global and drastically alter the transcriptional state of the knockout cells, suggesting a role for BATF as a Tr1 pioneer factor. Finally, by coupling chromatin accessibility data with RNA sequencing of *Irf1*^{-/-} and *Batf*^{-/-} cells, we constructed a network of IRF1 and BATF interactions during Tr1 differentiation.

Novel role for heparan sulfate in intrathymic T cell development

Simon Davis, D.A., Parish, C.R.

John Curtin School of Medical Research, The Australian National University, Cancer Biology & Therapeutics, Canberra, Australia

The thymic stromal microenvironment is crucial for MHC-restricted positive and negative selection of T cells in the thymus to generate functional and self-tolerant α β T cells. Our recent studies have provided new insights into this important process. We found that CD8 β on CD4⁺CD8⁺ double positive (DP) thymocytes strongly interacts with highly sulfated heparan sulfate (HS) carrying 6-O sulfate groups. Furthermore, we discovered that a HS mimetic (dextran sulfate 500-kDa) can trigger a sustained Ca²⁺ flux in DP thymocytes that is CD8 β and Slp76, but not Zap70 dependent, and results in a lowering of the TCR activation threshold in DP thymocytes. In contrast, α 2-3 sialylation of CD8 β on single positive thymocytes and peripheral CD8⁺ T cells blocks HS binding and prevents the HS-induced Ca²⁺ flux, an inhibitory effect that is reversed by enzymatic desialylation. Moreover, cortical thymic epithelial cells (cTEC) express high levels of highly sulfated HS and readily form 'rosettes' with thymocytes, rosettes formation being accompanied by a sustained Ca²⁺ flux in TEC-bound thymocytes, that is substantially blocked by HS mimetics and is markedly reduced in CD8-deficient thymocytes. Additionally, MHC on cTEC synergises with HS to enhance thymocyte rosetting capacity and the extent of the rosette-induced Ca²⁺ flux in cTEC-bound thymocytes. Collectively, the data imply that the CD8-HS interaction

- (1) enhances the interaction of DP thymocytes with cTEC expressing self-peptide/MHC complexes and
- (2) triggers unique CD8-dependent accessory signals, additional to TCR signals, that lower the threshold required for positive selection of TCR clones for self-peptide/MHC complexes.

4114**Notch/RBPJ signaling in a conditional inducible state in vivo**

Zuniga-Pflucker, J.

University of Toronto, Department of Immunology, Toronto, Canada

T-lymphopoiesis depends on temporally- and spatially-regulated settling of the thymic niches by bone marrow-derived progenitors. Thymocyte differentiation and progressive restriction to the T-lineage is contingent on Notch signaling together with other transcriptional networks. However, how exactly Notch modulates these activities during T cell development is still largely unresolved. A clear understanding of these processes has been limited by the unavailability of appropriate assays, which would permit regulation of Notch responsiveness within the same cellular microenvironment, thus making precise assessments regarding the role of Notch at various stages of T-lymphopoiesis possible. In order to more precisely and extensively address the role of Notch signaling throughout T cell development, we have developed an inducible mouse model system, in which Notch responsiveness can be temporally regulated in bone marrow stem/progenitor cells, developing lymphocytes. This mouse model will allow us to address the many Notch signaling requirements at various stages of lymphocyte development, such as thymic settling by progenitors, T-lineage commitment, b-selection checkpoint, ab versus gd or CD4 versus CD8 lineage decisions.

236**The linear ubiquitin chain assembly complex: a new function in thymic T cell differentiation and regulatory T cell homeostasis**

Teh, C.^{1,2}, Lalaoui, N.^{1,2}, Jain, R.^{1,2}, Policheni, A.^{1,2}, Heinlein, M.^{1,2}, Alvarez-Diaz, S.^{1,2}, Rieser, E.³, Deuser, S.³, Koay, H.-F.^{4,5}, Hu, Y.^{1,2}, Kupresanin, F.¹, O'Reilly, L.^{1,2}, Godfrey, D.^{4,5}, Smyth, G.^{1,2}, Bouillet, P.^{1,2}, Strasser, A.^{1,2}, Walczak, H.³, Silke, J.^{1,2}, Gray, D.^{1,2}

T cell differentiation involves the integration of diverse inputs, including signals from the TCR, cytokine and TNF receptors. The linear ubiquitin assembly complex (LUBAC) is a signalling hub composed of three proteins, HOIL-1, HOIP and SHARPIN, that post-translationally modifies substrates via the addition of linear ubiquitin chains. Although LUBAC has essential roles in regulating innate immunity, its role in adaptive immunity is less clear. T cell deficiency observed in patients with loss-of-function mutations in LUBAC proteins prompted us to examine a role for this complex in T cell differentiation.

We show that mice lacking the LUBAC proteins, HOIL-1 or HOIP, in the T cell lineage were almost devoid of peripheral T cells, Foxp3+ regulatory T cells (Treg) and non-conventional T cell

subsets, due to a block late in thymic differentiation. By contrast, mice deficient in a third LUBAC component, SHARPIN, had normal conventional T cell development, but selective loss of thymic Foxp3+ regulatory (Treg) cells. Treg cell-specific ablation of HOIP led to severe Treg cell deficiency in the periphery and lethal immune pathology, revealing a requirement for ongoing LUBAC activity for Treg cell homeostasis. Genetic or pharmacologic blockade of cell death pathways did not rescue these defects. SHARPIN, HOIL-1 or HOIP were required in thymocytes to propagate NFκB and MAP kinase signals, but not ERK phosphorylation, downstream of TCR or TNFR ligation. These data reveal a novel differential, stage-specific requirement for LUBAC components in coordinating the signals required for T cell differentiation.

1631**Specific requirement of C-terminal Zn finger motifs in Bcl11b transcription factor for lineage dissection upon receiving positive selection signals in the thymus**

Kojima, S., Seo, W., Muroi, S., Taniuchi, I.

RIKEN Center for Integrative Medical Sciences, Laboratory for Transcriptional Regulation, Yokohama, Japan

Several T cell subsets with distinct functionality arise from CD4⁺CD8⁺ DP precursors according to TCR signals through induction lineage specifying transcription factor, ThPOK, Runx3 and FoxP3 for helper, cytotoxic and regulatory T cells, respectively. However, it remains elusive how differences in TCR signals are linked with transcriptional regulation that control expression of above key molecules. In order to address this question, we have used a *Thpok* as a model locus and identified a transcriptional silencer as a key cis-regulatory element that control helper-lineage specific expression of *Thpok* gene. Our biochemical approach identified Bcl11b transcription factor, known as a commitment factor for T-lineage, as relevant regulator for silencer function. In addition, Bcl11b turned out to play essential role to regulate lineage specificity of *Runx3* gene. Another Bcl11b mutation that get rid of the last Zn-finger motif at C-terminal-end of Bcl11b protein also failed to control expression of *Thpok*, *Runx3* and *FoxP3* genes, while it could support commitment to T-lineage. Analyses of promoter and enhancers usage in *Thpok* locus in the absence of Bcl11b suggested that *Thpok* locus behaves like as it was in non-T cells. Our results thus provide a novel insight that pre-priming of lineage specifying genes by Bcl11b through its C-terminal Zn finger motifs upon T-lineage is essential to couple TCR signals with lineage dissection in the thymus.

3632**The TCR signalosome specifies thymic selection outcome by a quantitative network mechanism that sums activity across a single protein-interaction signature**Schrum, A.¹, Neier, S.¹, Smith, S.¹, Ferrer, A.¹, Wilton, K.¹, Chen, Z.², McCluskey, J.², Burrows, S.³, Rossjohn, J.⁴, Gil, D.¹

Medical Research Institute, Brisbane, Australia, ⁴Monash University, Biochemistry & Molecular Biology, Clayton, Australia

During conventional alpha-beta T cell selection, TCR engagement initiates biochemical signals based on protein-protein interactions (PPI). Still unclear is the network mechanism by which the TCR signalosome transmits signal specificity to program the cellular response for positive- versus negative-selection. This could occur by signatures differing *qualitatively* (customized, unique PPI combinations for each signal), *quantitatively* (graded amounts of a single PPI combination), or *kinetically* (speed of PPI pathway progression). To gain insight, we mounted an adaptable multiplex matrix system applicable to physiologic network signaling protein complexes, with >200 pairwise measurements of proteins in shared complexes detected by exposed surface epitopes (PiSCES). Upon stimulation with peptide/MHC ligands on APCs, we found that pre-selection OT1.b2m-/-RAG2-/- thymocytes produced PiSCES network signatures that differed quantitatively between positive versus negative selection conditions, but did not differ qualitatively or kinetically. This was also true when overall signaling activity was amplified by using hyper-responsive genetically engineered Jurkat cells expressing either murine OT1 or human LC13 TCRs. To test whether this quantitative difference in the network was deterministic for signaling outcome, we found peptide doses of classic negative-selection ligands that produced network signatures with intensity equal to that of positive-selection ligands, and discovered that when used in FTOC these specially-low-dosed negative-selection ligands now produced positive selection of conventional T cells. We confirmed this concept a second way, observing that in reduced-TCR-expressing thymocytes from OT1.b2m-/-RAG2-/-CD3d+/- mice, some classic negative-selection peptides induced positive selection. These data indicate that a quantitative network signaling mechanism through the TCR signalosome specifies thymic selection outcome.

3641

The unique features of pTa mediate pre-TCR down-regulation rather than constitutive signalling

Call, M., Krshnan, L., Call, M.

The Walter and Eliza Hall Institute, Parkville, Australia

The T cell receptor (TCR) is formed by the step-wise rearrangement of the TCR loci. To ensure rearrangement leads to a functional TCR β chain prior to TCR α rearrangement, TCR β assembles with pTa and CD3 signalling dimers to form the constitutively active pre-TCR, which initiates β -selection. Knockout of pTa stalls thymocyte development at this checkpoint resulting in the accumulation of DN3a cells (CD4⁺CD8⁺CD44⁺CD25⁺CD28⁻). We hypothesised that a structural understanding of how pre-TCR maintains constitutive activity would lead to mechanistic insights into ligand-induced TCR triggering, an unresolved problem in T cell biology. We developed a retrogenic approach where pTa or TCR α chains could be introduced into pTa knockout foetal liver cells to reconstitute lethally irradiated mice. Our results showed TCR α and pTa could both mediate transition from DN3a to DN3b (CD4⁺CD8⁺CD44⁺CD25⁺CD28⁺)

but OT-I TCR α was inefficient at transitioning past DN4 (CD4⁺CD8⁺CD44⁺CD25⁺CD28⁺). A second TCR α chain raised in a different MHC background however, could match wild-type pTa function suggesting that DN4 cells are highly sensitive to MHC-induced signalling. Like TCR α , pTa has two basic residues in the transmembrane domain that mediate stable recruitment of CD3. Mutation of both these residues resulted in pTa chains that were unable to pass β -selection, however pTa chains carrying single mutations were better than wild-type at reconstituting host thymi. These data support a model where pre-TCR signalling is not a special property of the pre-TCR, but instead suggests a role for the unique features of pTa in destabilising receptor after β -selection initiation to allow efficient transition through DN4.

2673

Cooperative TCR-pMHC-CD8 catch bond distinguishes thymocyte positive versus negative selection

Hong, J., Zhu, C.

Georgia Institute of Technology, Atlanta, United States

For a developing thymocyte to mature into a functional peripheral T cell, the T cell receptor (TCR) must recognize self-peptide-major histocompatibility complex (pMHC) well enough to signal survival while remaining below the activation threshold that would induce clonal deletion. Thus, the binding propensity for self pMHC provides the selection criteria to separate thymocyte positive from negative selection. Although this process is well known, the biophysical measurements to date cannot easily explain thymocyte fate. Using mechanical-based assays, we show that the quality, not quantity, of binding determines thymocyte fates. Force regulates selection outcomes through the induction of cooperative binding to convert two TCR-pMHC and MHC-CD8 slip bonds into a TCR-pMHC-CD8 trimolecular catch bond for negative but not positive selecting ligands. Thymocytes exert more sustained tension on TCR and CD8 that form higher quality catch bonds with negative selecting ligands compared to lower quality slip bonds with positive selecting ligands, resulting in their differential engagement times. Our results reveal a novel mechanism driving thymocyte selection, highlighting the roles of force and CD8 coreceptor.

Search for substrates of protein kinase D during thymocyte development

Ishikawa, E.¹, Kosako, H.², Yasuda, T.³, Kurosaki, T.^{3,4}, Saito, T.^{5,6}, Yamasaki, S.¹

¹Division of Molecular Immunology, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan, ²Division of Cell Signaling, Fujii Memorial Institute of Medical Sciences, Tokushima University, Tokushima, Japan, ³Laboratory for Lymphocyte Differentiation, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan, ⁴Laboratory for Lymphocyte Differentiation, WPI Immunology Frontier Research Center (iFReC), Osaka University, Suita, Japan, ⁵Laboratory for Cell Signaling, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan, ⁶Laboratory for Cell Signaling, WPI Immunology Frontier Research Center (iFReC), Osaka University, Suita, Japan

Thymic selection shapes an appropriate T cell antigen receptor (TCR) repertoire during T cell development. In contrast to tyrosine phosphorylation events through protein tyrosine kinases, the role of serine/threonine kinases in this process is not fully understood.

We found that a serine/threonine kinase PKD (protein kinase D) is phosphorylated upon stimulation with antigen peptides in preselection CD4⁺CD8⁺ double positive (DP) thymocytes. We then established T cell-specific PKD-deficient mice (PKD^{ΔT} mice) to investigate a role of PKD in T cell development. In PKD^{ΔT} mice, the generation of CD4 single positive (SP) thymocytes was abrogated. By crossing with OT-II TCR Tg mice, we found that positive selection of CD4 SP thymocytes was severely impaired in PKD^{ΔT} mice. The generation of CD4⁺CD8^{int} population was also significantly impaired and the CD5 expression was low, suggesting that TCR signaling during positive selection is attenuated in PKD^{ΔT} mice.

TCR-induced proximal tyrosine phosphorylation events and Ca²⁺ influx were not affected in the absence of PKD. We thus searched for cellular substrates for PKD using phosphoproteomic analyses. Two-dimensional fluorescence difference gel electrophoresis (2D-DIGE) followed by LC-MS/MS identified several proteins that are selectively phosphorylated in wild-type but not PKD-deficient thymocytes upon TCR engagement. *In vitro* kinase assay revealed that these proteins are direct substrates for PKD. These results suggest that PKD enhances TCR signaling to promote CD4⁺ T cell development through a novel signaling pathway.

¹Institut Pasteur, Viral Pathogenesis Unit, Department of Virology, Paris, France, ²AP-HP, Department of Internal Medicine and Clinical Immunology, University Hospital Paris Sud, Le Kremlin Bicêtre, France, ³Monash University, Department of Biochemistry and Molecular Biology, School of Biomedical Sciences, Melbourne, Australia, ⁴Institut Pasteur, Department of Immunology, Paris, France, ⁵INSERM U 1018, Centre de Recherche en Epidémiologie et Santé des Populations, Le Kremlin Bicêtre, France, ⁶Institut Pasteur, Genomic Bioanalysis Group, Paris, France, ⁷Raymond Poincaré University Hospital, AP-HP, Infectious and Tropical Diseases Department, Garches, France

Rare patients termed HIV Controllers are able to spontaneously control HIV replication to undetectable levels and maintain normal CD4⁺ T cell counts in the absence of anti-retroviral therapy. Accumulating evidence suggests that control of viral replication in these patients is mediated by a particularly efficient cellular immune response. To identify the molecular determinants underlying this response, we characterized the

TCR repertoire directed at the most immunoprevalent CD4 epitope in HIV-1 capsid, Gag293. HIV Controllers from the ANRS CODEX cohort showed a highly skewed TCR repertoire characterized by a predominance of TRAV24 and TRBV2 variable gene families, the presence of conserved motifs in both CDR3 regions, and a high frequency of public clonotypes (n=18 for each TCR chain). The most prevalent public clonotypes generated TCRs with affinities in the micromolar range, at the higher end of values reported for naturally occurring TCRs. These high-affinity Gag293-specific TCRs were cross-restricted by up to 5 distinct HLA-DR alleles, accounting for their expression in HIV Controllers of diverse genetic backgrounds. Transfer of these TCRs to healthy donor CD4⁺ T cells conferred high antigen sensitivity and polyfunctional cytokine responses, thus recapitulating key features of the Controller CD4 response. Transfer of a high-affinity Gag293-specific TCR could also redirect

CD8⁺ T cells to target HIV-1 capsid via nonconventional MHC II restriction. These findings indicate that TCR clonotypes with superior functions are associated with HIV control. Amplifying or transferring such clonotypes may contribute to immunotherapeutic approaches that aim at a functional HIV cure.

2032

Association of the G801A polymorphism in chemokine cxc ligand 12 (CXCL12) gene with liver complication in HIV-infected Thais

Chiraunyanann, T.¹, Changsri, K.², Sretapanya, W.¹, Yuenyongchaiwat, K.³, Akekawatchai, C.²

¹Graduate Program in Medical Technology, Faculty of Allied Health Sciences, Thammasat University, Pathumthani, Thailand, ²Faculty of Allied Health Sciences, Thammasat University, Department of Medical Technology, Pathumthani, Thailand, ³Faculty of Allied Health Sciences, Thammasat University, Department of Physical Therapy, Pathumthani, Thailand

Our previous study has reported high prevalence of elevated liver enzymes in Thai HIV patients receiving combined anti-retroviral therapy (cART) and risk of liver disease in the patients requires more investigation. CXCL12 participates in immune cell homing to the liver and hepatic inflammation. This study aimed to examine an impact of 3'UTR G801A polymorphism in CXCL12 gene on liver complication in the patients ongoing cART. A cross-sectional study was conducted in 164 HIV-infected Thais. cART was received by 71.3% of the patients with median ART duration of 39 (16-55) months. Prevalence of coinfection with hepatitis B (HBV), hepatitis C virus (HCV) and HBV/HCV were 9.1%, 8.3% and 0.8% respectively. The rates of transaminitis, defined as increased levels of aspartate aminotransferase (AST) and/or alanine aminotransferase (ALT), was 28% while there were 14% of the patients with higher baseline levels of the hepatic fibrosis marker AST to platelet ratio index (APRI). The G801A polymorphism was studied by tetra-primer PCR. In this study group, frequencies of AA/GA and GG genotypes were 25.6% and 74.4% consequently. Analysis demonstrated a significant association of the genetic polymorphism with transaminitis ($p=0.014$) and APRI ($p=0.045$). Univariate and

multivariate analyses indicated that the AA/GA genotypes were significant predictive factors for the higher baseline APRI levels (OR: 4.1, 95% CI: 1.1-14.5, $p=0.030$), together with being male, CD4⁺ cell count less than 350 cells/ul and HCV coinfection. Our data suggested a contribution of the CXCL12 G801A polymorphism in progression of chronic liver disease in Thai HIV patients ongoing cART.

1574

Fc effector polyfunctionality in individuals that develop HIV-specific broadly neutralizing antibodies

Richardson, S.^{1,2}, Chung, A.³, Lassauniere, R.¹, Lambson, B.¹, Abdool Karim, S.⁴, Tiemessen, C.^{1,2}, Moore, P.^{1,2,4}, Mkhize, N.^{1,2}, Alter, G.³, Morris, L.^{1,2,4}

¹Centre for HIV and STIs, National Institute for Communicable Diseases, Johannesburg, South Africa, ²Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, ³Ragon Institute of MGH, MIT and Harvard, Boston, United States, ⁴Centre for the AIDS Programme of Research in South Africa (CAPRISA), University of KwaZulu-Natal, Durban, South Africa

The finding that antibody-dependent cell-mediated cytotoxicity (ADCC) was a correlate of protection in the RV144 HIV-1 vaccine trial, has suggested that a vaccine should elicit antibodies with both neutralizing and effector functions. However, it is unknown if individuals who develop broadly cross-neutralizing antibodies (BCN) also have antibodies with increased Fc effector polyfunctionality. We therefore assessed the gp41, gp120 and gp140-targeted ADCC, antibody-dependent complement deposition (ADCD), antibody-dependent cellular phagocytosis (ADCP), NK degranulation and measured HIV-specific IgG1-4 levels of polyclonal IgG isolated from 14 BCN and 11 non-BCN individuals at 6, 12 and 36 post-infection (p.i.) from the CAPRISA cohort. Gp120 and gp140 but not gp41- specific ADCP and ADCD responses were significantly higher ($p = 0.01$) in the BCN group at 6 months p.i. indicating that HIV epitopes may be targeted differently by antibodies bound to Fc-receptors. Gp120-specific IFN- γ secretion following NK degranulation was significantly higher in the BCN group ($p = 0.03$) at all three time points. Since IFN- γ enhances IgG3 (the most polyfunctional of all isotypes) class-switching, we also noted that IgG3 levels were higher in the BCN group ($p = 0.04$). Overall our study shows that there are differences in Fc-mediated effector function between BCN and non-BCN individuals in early infection and that this is likely to be antigen specific. Regardless, while elicitation of broadly neutralizing antibodies remains a focus, vaccination strategies should also aim to enhance Fc effector function of the overall HIV immune response which may be easier to achieve than neutralization.

HIV-1 infection depletes CD4⁺ T-cells, but induces chronic follicular hyperplasia. HIV infection in humans and SIV infection in macaques is characterized by accumulation of CXCR5⁺PD-1^{high}Bcl-6⁺ Tfh cells in lymphoid tissues (LT). In both infections Tfh are infected at similar or higher rates to other memory CD4⁺ T-cells. Further, despite Tfh being characterised as CCR5⁻, the envelopes of viruses found in these cells are phylogenetically indistinguishable from viruses infecting other memory CD4⁺ T-cells and are CCR5 tropic. We confirm that in both infected and uninfected macaques, Tfh cells are CCR5⁻, but a subset of their precursors are either CCR5⁺ or transiently become CCR5⁺ as they differentiate into Tfh. We show that in macaques, SIV infection of Tfh is indirect, occurring at this precursor stage. In humans the same route of infection of Tfh is available, but we have also found a small subset of Tfh, isolated directly from tissue, that expresses CCR5. This population exists regardless of HIV status. Fusion assays show these cells are susceptible to infection by CCR5 tropic virus, with viral entry blocked by CCR5 inhibitors. CXCR5, PD-1 and Bcl-6 expression in these cells is indistinguishable from the CCR5⁻ Tfh. Intriguingly, fine needle biopsies of LT, show that increases in Tfh in HIV infection are not normalised by antiretroviral therapy, suggesting ongoing follicular hyperplasia, and a long lasting reservoir of infected Tfh despite aviremia. Although we have uncovered mechanisms for the establishment of this viral reservoir, the mechanisms of survival and expansion of infected Tfh require further investigation.

Introduction: We have previously demonstrated that myeloid DC (mDC), but not plasmacytoid DC (pDC), induce HIV latency in T-cells in vitro. pDC produce high levels of type-I IFN so we asked whether different IFNs have an effect on the establishment, maintenance and reversal of HIV latency.

Methods: Resting CD4⁺ T-cells from blood were labelled with the proliferation dye eFluor670, cultured with SEB and autologous mDC or pDC for 24h and infected with an eGFP-expressing-CCR5-tropic virus. At day 5 post-infection, non-productively-infected, non-proliferating (eGFP-eFluor670hi) and proliferating (eGFP-eFluor670lo) T-cells were sorted and inducible latent

infection quantified by measuring eGFP expression in sorted subsets after activation with anti-CD3/CD28+IL-7+IL-2 in the presence of Raltegravir.

Results: Using qPCR, type-I and type-III IFN mRNA could be detected in T+pDC co-cultures. When IFN α was added to T+mDC prior to infection, there was a reduction in productive infection, with a percentage mean inhibition (MI) of 60% at 1000U/ml, compared to untreated controls. Similar results were obtained with IFN β and IFN ω but not with IFN λ 1 and IFN λ 3. Latent infection was significantly reduced in non-proliferating T-cells in the presence of 100U/ml IFN α (MI=62%, p=0.014, n=4). When IFN α was added after latency was established, eGFP expression significantly increased compared to unstimulated controls in non-proliferating cells (mean fold change (MFC) eGFP=1.3, p=0.015, n=8).

Conclusion: Multiple type-I interferons can inhibit productive infection and the establishment of HIV latency in vitro, however, once latency is established IFN α can reverse latency in non-proliferating T-cells. IFN α should be explored as a potential therapeutic intervention to perturb latency.

Variability in HIV-1 envelope glycan shield vulnerability: implications for immune escape from anti-glycan neutralising antibodies

Moyo, T.^{1,2}, Ferreira, R.³, Davids, R.^{1,2}, Sondag, Z.¹, Moore, P.L.^{4,5}, Travers, S.³, Wood, N.⁶, Dorfman, J.R.^{1,2}

¹International Centre for Genetic Engineering and Biotechnology, Cape Town, South Africa, ²University of Cape Town, Pathology, Cape Town, South Africa, ³South African National Bioinformatics Institute, South African Medical Research Council Bioinformatics Unit, University of the Western Cape, Cape Town, South Africa, ⁴University of the Witwatersrand, Johannesburg, South Africa, ⁵National Institute for Communicable Disease, Johannesburg, South Africa, ⁶University of Cape Town, Integrative Biomedical Sciences, Cape Town, South Africa

The HIV-1 envelope protein is heavily glycosylated. These glycans serve multiple functions including shielding epitopes from antibodies. This is particularly important for the gp120 V3 loop because it is targeted by very common, narrowly-neutralizing antibodies. However, some broadly neutralizing antibodies directly target the V3/glycans, i.e those at amino acid positions 301, 332 and 334, making these glycans important in vaccine immunogens. We show that removal of the potential N-linked glycosylation site (PNG) at position 301 has substantially different effects in two subtype C viruses with similar sequences. In virus Du156.12, removal of the 301 PNG reveals epitopes recognized by 18/64 sera from chronically HIV-1-infected individuals. In contrast, removal of the 301 PNG in CAP45.2 only revealed epitopes recognized by 3/64 sera. This suggests that removing PNG 301 had less of an effect on the integrity of the glycan shield in CAP45.2 than Du156.12. This difference was not substantially affected by whether the nearby V3/glycan was at position 332 or 334. Molecular modeling of fully glycosylated Envelope trimers predicted that the absence of PNG 301 would likely result in greater exposure of portions of the V3 and C4 regions in Du156.12 compared to CAP45.2.

Our data indicate that the contribution of PNG 301 to resistance to common neutralizing antibodies is variable. Thus, certain viruses may be subject to less antibody-mediated pressure to maintain the 301 PNG, allowing them to more easily evade broadly neutralizing anti-V3/glycan antibodies. This may impair the efficacy of passively-infused anti-V3/glycan antibodies or those induced by a vaccine.

Comparison of the antigen sensitivity of Gag-specific CD4+ T cell responses in controlled HIV infection and HIV vaccination

Mukhopadhyay, M.¹, Galperin, M.¹, Nouël, A.¹, Vasan, S.², Ho, D.D.³, Lambotte, O.⁴, Benati, D.¹, Chakrabarti, L.¹

¹Institut Pasteur, Department of Virology, Viral Pathogenesis Unit, Paris, France, ²Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, ³Aaron Diamond AIDS Research Center, New York, United States, ⁴Hôpital de Bicêtre, AP-HP, Médecine Interne et Maladies Infectieuses, Le Kremlin-Bicêtre, France

Spontaneous control of HIV infection is characterized by a highly efficient cellular immune response. We showed in particular that HIV Controllers from the ANRS CO21 CODEX cohort harbor a population of specific CD4⁺ T cells that detect the immunodominant CD4 epitope Gag293 with high antigen sensitivity. To determine whether candidate vaccines can induce the high sensitivity responses seen in Controllers, we analyzed Gag293-specific responses in healthy volunteers who received the ADVAX DNA vaccine administered by electroporation. Comparison of Gag293-specific responses in primary CD4⁺ T cell lines via IFN- γ ELISpot revealed that the median antigen sensitivity in vaccinees was similar to that observed for Controllers (5×10^{-8} M) but higher than that in treated patients (5×10^{-7} M). However, antigen sensitivity remained higher in a subset of Controllers compared to vaccinees. TCR repertoire analysis of Gag293-specific CD4⁺ T cells from vaccinees revealed a preferential amplification of TCR β family chain TRBV2, which also predominates in Controllers. However, TRAV family gene usage appeared more diverse in vaccinees compared to Controllers. Sequence analysis of the TCR chains amplified in 4 vaccinees revealed a biased TCR repertoire with the presence of public clonotypes (3 TRAV24 and 2 TRBV2) shared with HIV Controllers. In conclusion, DNA vaccination administered by electroporation has the potential to induce Gag-specific CD4⁺ T cells responses with a high antigen sensitivity and partial TCR repertoire overlap with that of Controllers. Monitoring the amplification of public TCR clonotypes could provide a novel approach to evaluate the quality of HIV vaccine responses.

Immunity, Microbiology and Immunology, Melbourne, Australia,
²*Reef Pharmaceuticals Pty Ltd, Melbourne, Australia*

HIV-patient serum with elite virus-neutralizing breadth has led to preparation of monoclonal antibodies (mAb) with long and highly mutated CDRH3 domains that can neutralize a broad array of viral strains and prevent transmission in animal models. Primate vaccination has not matched these broad neutralizing antibody responses, but vaccination of cows before then during pregnancy with four 100µg doses of purified HIV-1_{AD8} Env-gp140 trimers in Montanide adjuvant yields vast quantities, up to 1kg, of polyclonal IgG in colostrum that binds HIV Env-gp140 with titres of 1x10⁵ and neutralise all 27 Env (24-strongly, 3-moderately) from clade A, B and C reference panels. We assessed this potent bovine IgG by preparing mAbs with matched chimeric bovine-VH and -VL with human C-regions from HIV gp140-binding IgG+ CD21+ circulating memory B-cells present at 0.66%. The 33 mAbs had long CDRH3 sizes ranging from 12 - 64 aa's with a high Cys and aromatic-aa frequency. Two mAbs, 6A and 8C, displayed strong binding to HIV-1_{AD8} Env-gp140 uncleaved trimers, but not monomer, and bound cleaved covalently-stabilized HIV-1_{AD8} SOSIP gp140 trimers. The VH somatic mutation rate for 6A and 8C was 27% and 25% respectively and their 21 and 14aa CDRH3 domains were 57% and 93% mutated from germline. Mutation of CDRH3 Cys or Trp eliminated the HIV-specific binding characteristics. Despite strong trimer-specific binding, these mAbs didn't match the broad neutralizing activity of the polyclonal IgG. We have now produced large quantities of HIV-1 hyperimmune colostrum polyclonal antibodies for further evaluation as a microbicide to block HIV transmission.

Characterization of gut tissue resident memory CD8⁺ T-cells in HIV infection

Kiniry, B.¹, Ganesh, A.¹, Hunt, P.², Somsouk, M.², Deeks, S.², Shacklett, B.¹

¹*University of California, Davis, Davis, United States,* ²*University of California, San Francisco (UCSF), San Francisco, United States*

The gastrointestinal tract (GIT) is an important site of HIV transmission and pathogenesis. Combating HIV will likely require maintenance of cells capable of protective anti-HIV immune responses in the GIT. Tissue resident memory T-cells (T_{RM}) are long-lived, non-recirculating memory T-cells localized in tissues like the GIT. Positioned near sites of infection, T_{RM} are a first line of defense against pathogens. A knowledge gap exists regarding CD8⁺ T_{RM} in the human GIT and their role in HIV infection. We used flow cytometry to characterize T_{RM} in blood and rectal biopsies. CD8⁺ T-cells from HIV+ and HIV- adults were phenotyped using CD45RO, CD69, CD103, S1PR1, T-bet, and Eomesodermin (Eomes). Functionality was assessed in a 6-hour *ex vivo* stimulation assay. Cells were stimulated with DMSO, Gag or CMV-EBV-Flu (CEF) peptides, or Staphylococcal Enterotoxin B, and stained for CD107a, IFNγ, Mip-1β, TNFα, IL-2, and Granzymes A and B. Most rectal CD8⁺ T-cells were CD103⁺CD69⁺S1PR1⁺, indicative of tissue residency. This subset was significantly more abundant in gut than blood (P=0.005). CD45RO⁺ cells in this subset were classified as T_{RM}⁺. Consistent with murine studies, CD8⁺ T_{RM} were mainly T-bet^{Low}Eomes^{Neg}. The rectal mucosa has

an expanded population of GrzA^{High} CD8⁺ T-cells compared to blood; these were predominantly CD69⁺CD103⁺S1PR1⁺. Participants who control HIV without drug therapy displayed stronger polyfunctional and cytotoxic (CD107a⁺GrzA⁺GrzB⁺) Gag-specific CD8⁺ T_{RM} responses compared to antiretroviral-treated subjects. In summary, a large subset of CD8⁺ T-cells in rectal mucosa are T_{RM} and likely play an important role in HIV containment. *Supported by NIH/NIAD R01 AI057020.*

Implications of Spns2-deficiency on S1P-driven lymphocyte egress, HEV-integrity and immunity

Simmons, S.¹, Sasaki, N.², Umemoto, E.³, Yoshizumi, N.², Fukuhara, S.⁴, Kitazawa, Y.⁵, Okudaira, M.⁶, Inoue, A.⁶, Motooka, D.⁷, Nakamura, S.⁷, Iida, T.⁷, Aoki, J.⁶, Mochizuki, N.⁴, Matsuno, K.⁵, Takeda, K.³, Miyasaka, M.², Ishii, M.¹

¹*Osaka University, WPI Immunology Frontier Research Center and Graduate School of Medicine & Frontier Biosciences, Department of Immunology & Cell Biology, Osaka, Japan,* ²*Osaka University, Graduate School of Medicine, Laboratory of Immunodynamics, Osaka, Japan,* ³*Osaka University, WPI-Immunology Frontier Research Center and Graduate School of Medicine, Laboratory of Mucosal Immunology, Osaka, Japan,* ⁴*National Cerebral and Cardiovascular Center Research Institute, Department of Cell Biology, Osaka, Japan,* ⁵*Dokkyo Medical University, Department of Anatomy (Makro), Tochigi, Japan,* ⁶*Tohoku University, Graduate School of Pharmaceutical Sciences, Laboratory of Molecular and Cellular Biochemistry, Sendai, Japan,* ⁷*Osaka University, Research Institute for Microbial Diseases, Department of Infection Metagenomics, Osaka, Japan*

In order to reveal the role of the S1P-specific transporter Spinster-homologue-2 (Spns2) in controlling S1P-mediated lymphocyte egress from secondary lymphoid organs into the lymphatic system we conditionally deleted Spns2 in Lyve1+ lymphatic endothelial cells (LECs).

We detected a strong reduction of S1P in the lymph of Lyve1-Spns2^{Δ/Δ} (KO) mice, leading to a strong accumulation of lymphocytes in Peyer's patches (PPs) and the development of hypotrophic lymph nodes (LNs). The difference between lymphocyte immigration and egress in pLN and PPs caught our particular attention. We could show that total WT congenic splenocytes transplanted *i.v.* showed reduced immigration into pLNs of KO mice in comparison to Spns2^{fl/fl} (WT) mice, whereas the appearance of B/T-cells in PPs was not affected. Importantly, we detected severe impairment in morphology and size of high-endothelial venules (HEVs) in pLNs of KO mice. We observed that DCs which enter pLNs by afferent lymphatics were absent in close proximity to the HEVs. Interestingly, DCs, which co-localize in WT animals with HEVs in order to provide lymphotoxin-β for proper development and function, are unable to overcome a restricted area around HEVs of KO mice. Impaired micro-anatomical co-localization of DCs and HEVs in LNs was also observed if mice were treated with several S1PR-specific antagonists. Furthermore, S1PR1-signalling was reduced in HEVs of KO mice.

Taken together all these studies reveal the importance of Spns2 to control S1P-driven lymphocyte egress from lymphoid organs and uncovers new insights in the role of LEC-derived S1P in controlling micro-anatomical migration of immune cells in LNs.

Boosting migration and function of tumor-specific T cells using integrin transregulation

Cantor, J.¹, Ginsberg, M.²

¹University of California San Diego, Medicine, La Jolla, United States, ²University of California San Diego, La Jolla, United States

Poor homing and tumor-mediated suppression of T cells are barriers to adoptive ex vivo-modified T-cell immunotherapy for solid tumors. Inhibiting Protein Kinase A(PKA)-mediated phosphorylation of $\alpha 4$ integrin in human T cells results in an increase in $\alpha \text{L}\beta 2$ -mediated migration on mixed ICAM-1-VCAM-1 substrates *in vitro*, a phenomenon termed "integrin trans-regulation." We have created an $\alpha 4$ (S988A)-bearing mouse, a mutation which precludes PKA-mediated $\alpha 4$ phosphorylation, to examine the effect of integrin trans-regulation *in vivo*. The $\alpha 4$ (S988A) mouse exhibits selectively increased migration of lymphocytes but not myeloid cells to an inflammatory site, strikingly reduced growth of B16 melanoma tumors, and increased tumor-infiltrating T cells with lower expression of exhaustion markers. Boosting $\alpha 4$ trans-regulation of $\alpha \text{L}\beta 2$ integrin function thus increases migration and function of tumor-specific T cells. This novel mechanism could enhance adoptive immunotherapy using modified T cells for solid tumor cancers.

Exocrine gland surveillance by tissue resident memory T cells depends on cell contractility and Cdc42-mediated polarity but not integrin and chemokine signaling

Ficht, X.¹, Stolp, B.², Thelen, F.¹, Kreuzfeldt, M.³, Page, N.³, Fukui, Y.⁴, Merkler, D.³, Stein, J.V.¹

¹University Bern, Theodor-Kocher-Institute, Bern, Switzerland, ²University Clinic Heidelberg, Department of Virology, Heidelberg, Germany, ³University of Geneva, Institute for Pathology and Immunology, Geneva, Switzerland, ⁴Kyushu University, Department of Immunobiology and Neuroscience, Fukuoka, Japan

Distinct CD8⁺ memory T cell populations persist after infection to ensure host efficient protection upon pathogen re-encounter and actively migrate in their target tissues for immunosurveillance. T cell motility is presumed to be driven by chemokine-induced F-actin treadmilling while force transmission is mediated by specific binding of integrins to extracellular matrix. This canonical view is largely built on 2D *in vitro* findings, which do not take into account the complex architecture of tissues and organs, nor cell intrinsic properties of memory T cell subsets. Here, we used multiphoton intravital imaging to dissect the cellular requirements for *in vivo* migration of central memory T cells (T_{CM}) in lymph nodes and tissue resident memory T cells (T_{RM}) in salivary and lacrimal glands. We found that inhibition of αE -, αL -, $\alpha 4$ - and $\beta 1$ - integrins or G_{ai} does impair

the migration of T_{CM} but not T_{RM} cells. Rather, T_{RM} migration required ROCK-mediated contractility and pseudopodia formation mediated by the Cdc42 activator DOCK8. In sum, our findings show that T_{RM} cell migration in exocrine glands doesn't rely on specific adhesion of integrins nor on signaling of G_{ai} -coupled chemokine receptors. Instead, we propose a novel model of resident memory T cell migration: Intrinsically active pseudopodia formation and myosin contractility use confinement-induced friction to generate momentum. Our findings imply that memory T cell migration is less dependent on specific molecular interactions than previously anticipated and may instead be influenced to a greater extent by physical tissue properties such as confinement and extracellular matrix architecture.

CXCR4 mediates homeostatic compartmentalization of monocytes and pulmonary inflammatory responses

Chong, S.Z.¹, Evrard, M.¹, Devi, S.¹, Balabanian, K.², Chen, Q.³, Renia, L.¹, Wang, C.-I.¹, Looney, M.R.⁴, Krummel, M.F.⁴, Randolph, G.J.⁵, Biswas, S.K.¹, Ginhoux, F.¹, Hidalgo, A.⁶, Bachelier, F.², Ng, L.G.¹

¹Singapore Immunology Network (SiGN), A*STAR, Singapore, Singapore, ²INSERM UMR-S 996, Université Paris-Sud, Clamart, France, ³Institute of Molecular and Cell Biology (IMCB), A*STAR, Singapore, Singapore, ⁴University of California (UCSF), Department of Medicine and Pathology, San Francisco, United States, ⁵Washington University, Division of Immunobiology, St. Louis, United States, ⁶Fundación Centro Nacional de Investigaciones Cardiovasculares (CNIC), Area of Cell and Developmental Biology, Madrid, Spain

The migration of monocytes between tissue compartments represents a critical aspect of their immune surveillance function. However, mechanisms that regulate their distribution between tissue compartments remain unclear. Using *in vivo* assays in transgenic mice with either loss- or gain-of-function in CXCR4-signaling, we show that CXCR4 is a key regulator in maintaining circulating monocyte numbers by controlling their shuttling between the circulation, bone marrow (BM) and lung marginal pool. We show through BrdU pulse-chase assays and parabiosis that CXCR4-signalling not only regulated the bi-directional trafficking of monocytes between the blood and BM compartments, but fluctuations in its expression levels regulated the circadian rhythmic oscillation of monocyte numbers. In addition, we observed that BM Ly6C^{hi} monocytes that have differentiated from the common monocyte progenitor (cMoP) consists of a heterogenous population with distinct maturity and ability to respond to mobilization cues. Specifically, CXCR4 expression delineates this functional heterogeneity, with "immature" monocytes being CXCR4^{hi} and "mature" monocytes being CXCR4^{lo}. Importantly, our intravital imaging revealed that CXCR4 orchestrates monocyte margination in the pulmonary vasculature and this process was augmented upon exposure to endotoxins. In particular, CXCR4 inhibition reduced monocyte margination, which resulted in decreased occurrence of lung injury and mortality in mouse models of sepsis. Together, our data identify CXCR4 as a key regulator of monocyte compartmentalization and homeostasis in both steady and inflammatory states.

L-selectin controls trafficking of chronic lymphocytic leukemia cells in lymph node high endothelial venules *in vivo*Lafouresse, F.^{1,2,3}, Bellard, E.^{1,2}, Laurent, C.^{4,5,6}, Moussion, C.^{1,2}, Fournié, J.-J.^{2,4,5}, Ysebaert, L.^{4,5}, Girard, J.-P.^{1,2}¹CNRS, IPBS (Institut de Pharmacologie et de Biologie Structurale), Toulouse, France, ²Université de Toulouse, UPS, Toulouse, France, ³Swinburne University of Technology, Melbourne, Hawthorn, Australia, ⁴IUCT (Institut Universitaire du Cancer Toulouse)-Oncopôle, Toulouse, France, ⁵INSERM, U 1037, CRCT (Centre de Recherches en Cancérologie de Toulouse), Toulouse, France, ⁶INSERM, U 563, Centre de Physiopathologie de Toulouse Purpan, Toulouse, France

Chronic Lymphocytic Leukemia (CLL) is characterized by the progressive accumulation of CLL cells in the blood and lymph nodes (LN). Although chemotherapy and immunotherapy are effective at targeting circulating CLL cells, LN resident CLL cells are resistant to treatment and are often source of relapse. We studied the first step of CLL migration to LN, their interaction with high endothelial venules (HEV), specialized blood vessels for lymphocyte recruitment (Moussion & Girard, *Nature* 2011; Girard et al., *Nature Rev Immunol*, 2012).

We observed the frequent presence of CLL cells within HEV pockets in human CLL LN, indicating intense trafficking of CLL cells through HEV. Using *in vivo* imaging, we visualized for the first time, the behavior of human CLL cells within murine LN microcirculation. We found that CLL cells roll, stick and crawl on HEV endothelium. Functional analyses revealed that the lymphocyte homing receptor L-selectin (CD62L) is the key factor controlling the binding of CLL cells to HEV walls *in vivo*. Interestingly, L-selectin expression was decreased on CLL cells from patients treated with idelalisib, a phosphoinositide 3-kinase delta inhibitor recently approved for treatment of CLL patients. Reduced rolling and sticking of CLL cells to HEV was observed after treatment with idelalisib, correlating with L-selectin downregulation.

Together, our findings indicate that interference with L-selectin-mediated trafficking in HEV could be useful to limit the entry of circulating CLL cells into LN in order to increase the efficacy of conventional therapy (Lafouresse et al., *Blood*, 2015, Cover page and Highlighted in commentaries).

3293

Platelets direct leukocytes to their sites of extravasationZuchtriegel, G.^{1,2}, Uhl, B.², Pühr-Westerheide, D.², Pörnbacher, M.², Lauber, K.³, Krombach, F.², Reichel, C.A.^{1,2}¹Ludwig Maximilians University Munich, Department of Otorhinolaryngology, Head and Neck Surgery, Munich, Germany, ²Ludwig Maximilians University Munich, Walter Brendel Centre of Experimental Medicine, Munich, Germany, ³Ludwig Maximilians University Munich, Department of Radiation Oncology, Munich, Germany

Leukocyte recruitment from the microvasculature to the site of injury or infection is a key event in the inflammatory response. Whereas the principles of this highly complex process have been

elucidated in the past decades, it remained poorly understood how these immune cells 'find' their site of extravasation.

Interactions of platelets, neutrophils, inflammatory monocytes, and endothelial cells were analyzed by multi-color *in vivo* microscopy in the cremaster muscle of male CX₃CR-1^{GFP/+} mice (exhibiting fluorescence-labeled monocytes) upon stimulation with CCL2. Expression profiles of adhesion and signaling molecules in the microvasculature were assessed *ex vivo* by confocal microscopy in cremasteric tissue whole mounts. Different *in vitro* assays were used to further characterize the underlying mechanisms.

Upon onset of inflammation, circulating platelets immediately adhered at distinct sites in venular microvessels enabling these cellular blood components to capture neutrophils and, in turn, inflammatory monocytes via CD40-CD40L-dependent interactions. In this cellular crosstalk, ligation of leukocyte PSGL-1 by P-selectin initiates conformational changes in surface-expressed leukocyte integrins via ERK1/2 MAPK which subsequently promote the successive extravasation of neutrophils and inflammatory monocytes to the perivascular tissue. Conversely, blockade of this cellular partnership resulted in misguided, inefficient leukocyte responses.

Here, we report a previously unrecognized role of platelets as pathfinders navigating neutrophils and inflammatory monocytes to their exit points in the inflamed microvasculature. This platelet-directed guidance enhances the efficacy of the leukocyte transmigration process and is essential for effective leukocytes responses.

3163

Real-time intravital longitudinal imaging of osteoclast formation, function and fate during bone remodelingMcDonald, M.^{1,2}, Butt, D.^{1,2}, Terry, R.^{1,2}, Quinn, J.^{1,2}, Rogers, M.^{1,2}, Brink, R.^{1,2}, Croucher, P.^{1,2}, Phan, T.^{1,2}¹Garvan Institute of Medical Research, Sydney, Australia, ²UNSW Australia, Faculty of Medicine, Sydney, Australia

Osteoclasts are large multinucleated cells derived from the recruitment and fusion of cells of the monocyte/macrophage lineage in response to signals provided by bone lining stromal cells and osteoblasts, such as M-CSF and RANKL. Bone resorption by osteoclasts and bone formation by osteoblasts is tightly coupled in the basic multicellular unit (BMU). By resorbing bone and remodeling the endosteal bone niche, osteoclasts also control the mobilisation of hemopoietic stem cells, and the activation of dormant cancer cells that metastasise to bone. Thus, in addition to their role in skeletal homeostasis, osteoclasts also play key roles in hematopoiesis, and in controlling bone metastasis. However, because of the inaccessibility of the bone to real-time interrogation in live animals, little is known about the dynamic cellular and molecular events that regulate osteoclast formation, function and fate during physiological and pathological bone remodeling. To address this, we have developed a novel method for intravital two-photon microscopy that enables longitudinal deep tissue imaging of intact long bones at high resolution. This has allowed us to image these processes using lineage reporters and fluorescent probes in the steady state and following perturbation with osteoclast

inhibitors and activators. Our data reveals a previously unappreciated dynamic equilibrium between osteoclasts and macrophages under homeostatic conditions in the BMU that can be shifted in favour of osteoclasts during bone resorption and against them during bone formation. Thus, manipulating osteoclasts to alter this equilibrium may provide novel strategies to treat metabolic bone disease, control hematopoiesis and regulate cancers in bone.

MST1 dependent vesicle trafficking regulates neutrophil transmigration through the vascular basement membrane

Kurz, A.R.M.¹, Pruenster, M.¹, Rohwedder, I.¹, Schäfer, K.², Breithaupt, U.³, Gouveia, G.^{1,4}, Nussbaum, C.^{1,5}, Immler, R.¹, Wiessner, J.R.¹, Margraf, A.¹, Lim, D.-S.⁶, Walzog, B.¹, Dietzel, S.¹, Moser, M.¹, Klein, C.⁵, Vestweber, D.², Haas, R.³, Sperandio, M.¹

¹Ludwig Maximilians University, Walter Brendel Center of Experimental Medicine, Munich, Germany, ²Max Planck Institute for Molecular Biomedicine, Department of Vascular Cell Biology, Münster, Germany, ³Ludwig Maximilians University, Max von Pettenkofer-Institute for Hygiene and Medical Microbiology, Munich, Germany, ⁴Ministry of Education of Brazil, CAPES Foundation, Brasilia, Brazil, ⁵Ludwig Maximilians University, Dr. Von Hauner Children's Hospital, Munich, Germany, ⁶Korea Advanced Institute of Science and Technology, Department of Biological Sciences, Biomedical Research Center, Daejeon, Korea, Republic of

Extravasation of neutrophils from postcapillary venules into inflamed tissue is a crucial step during the inflammatory response. Within this process, neutrophils migrate across the endothelium and subsequently need to penetrate the perivascular basement membrane. The precise regulation of both steps is not fully understood, yet. By using multiphoton intravital microscopy and immunofluorescence staining we identified mammalian sterile 20-like kinase 1 (MST1) as a key player for the migration of neutrophils through the perivascular basement membrane. *Mst1* knock out neutrophils (*Mst1*^{-/-}) persist between the endothelium and the basement membrane of inflamed murine cremaster muscle venules and fail to migrate into inflamed tissue. *Mst1*^{-/-} neutrophils also fail to extravasate from gastric submucosal vessels in a murine *Helicobacter pylori* infection model. Mechanistically, impaired extravasation of *Mst1*^{-/-} neutrophils was accompanied by defective translocation of VLA-3, VLA-6, and neutrophil elastase from intracellular vesicles to the neutrophil surface, a requirement for neutrophils to penetrate the basement membrane. Taken together, our findings identify MST1 as a critical regulator of neutrophil transmigration and emphasize the importance of MST1-dependent vesicle trafficking for the recruitment process.

Tc17 cells: a non-cytotoxic pro-inflammatory effector CD8⁺ T cell subset?

McCull, S.¹, Fenix, K.¹, Gregor, C.¹, Kara, E.¹, McKenzie, D.¹, Bastow, C.¹, Sutton, V.², Trapani, J.², Gartlan, K.³, MacDonald, K.³, Hill, G.³, Comerford, I.¹

¹The University of Adelaide, Molecular and Cell Biology, Adelaide, Australia, ²Peter MacCallum Cancer Centre, Cancer Immunology Program, Melbourne, Australia, ³Queensland Institute of Medical Research, Immunology, Brisbane, Australia

Tc17 cells are a subset of effector CD8⁺ T cells that develop similarly to their CD4⁺ T cell counterpart Th17 and have emerging functional significance. Both Tc17 and Th17 cells share developmental characteristics and cytokine expression profiles with Tc17 cells thought to fulfil a pro-inflammatory role in response to MHC class-I restricted antigens. However, their reported function as cytotoxic cells is controversial and the trafficking mechanisms used by these cells are not well understood. We have detected Tc17 cells in a number of model immune responses and shown an important functional role for these cells in experimental graft versus host disease through pro-inflammatory cytokine production. Our investigation of the migratory properties of Tc17 cells reveals that the chemokine receptor CCR6 is important for their recruitment. Regarding their cytotoxic potential, we show that Tc17 cells have only very limited capacity to kill targets and this property derives from their reliance on TGFβ for development, which also inhibits expression of granzymes and perforin. Highly cytotoxic Tc17 cells, dependent on granzymes A and B, develop in conditions where TGFβ signalling is limited, indicating additional complexity within the Tc17 cell subset to encompass both cytotoxic and non-cytotoxic cell types.

Dendritic cell development is dependent on Drosha-mediated cleavage of mRNAs

Johanson, T.^{1,2,3}, Keown, A.³, Cmero, M.³, Yeo, J.^{1,2,3}, Kumar, A.³, Lew, A.^{2,4,5}, Zhan, Y.^{1,2}, Chong, M.^{6,7}

¹The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ²The University of Melbourne, Department of Medical Biology, Melbourne, Australia, ³St. Vincent's Institute of Medical Research, Melbourne, Australia, ⁴The Walter and Eliza Hall Institute of Medical Research, Immunology Division, Melbourne, Australia, ⁵The University of Melbourne, Department of Microbiology & Immunology, Melbourne, Australia, ⁶St. Vincent's Institute of Medical Research, Melbourne, Australia, ⁷The University of Melbourne, Department of Medicine (St. Vincent's), Melbourne, Australia

Drosha and Dicer are enzymes required for microRNA biogenesis. By genetic ablation in mice, we found that Drosha is critical for the development of dendritic cells (DCs) and other myeloid lineages. Drosha deficiency resulted in a block early in DC development, leading to an accumulation of early haematopoietic progenitors in the bone marrow, and a near

total absence of mature DCs in the periphery. In contrast, Dicer deficiency only partially affected DC numbers. This suggests that the impact of Drosha deficiency on DC development is largely independent of the microRNA pathway.

In addition to the cleavage of microRNA precursors, our lab and others discovered that Drosha is capable of directly degrading specific messenger RNAs (mRNAs). This occurs via the recognition and cleavage of stem loop structures within the target mRNA. Transcriptional profiling of haematopoietic progenitors revealed a series of transcripts that accumulated upon Drosha, but not Dicer deletion, suggesting microRNA independent regulation. We showed that the derepression of two of these transcripts, Myl9 and the previously unannotated Target Of Drosha 1 (Todr1) are responsible for the block in DC development in the absence of Drosha. Furthermore, knockdown of Myl9 or Todr1 via shRNA in Drosha deficient haematopoietic progenitors restores DC development. We also demonstrated that these two transcripts are specific targets of, and are directly cleaved by, Drosha in haematopoietic progenitors. Thus, Drosha is required for DC development through degrading inhibitors of myelopoiesis. This is the first demonstration of a microRNA independent function for Drosha in the haematopoietic system.

Clec9A-mediated induction of Tfh and B cell responses

Kato, Y.¹, Lahoud, M.², Kaisho, T.³, Shortman, K.^{4,5}, Mueller, S.¹, Caminschi, I.², Heath, W.¹

¹The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Parkville, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia, ³Wakayama Medical University, Department of Immunology, Institute of Advanced Medicine, Wakayama, Japan, ⁴The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ⁵The University of Melbourne, Department of Medical Biology, Parkville, Australia

Clec9A is a surface molecule expressed by CD8⁺ DCs. We have previously shown that targeting Ag to this receptor induces a potent humoral immunity without adjuvant. Here we demonstrate that Clec9A targeting promotes antibody responses by two distinct mechanisms. Upon Clec9A-targeted priming, CD8⁺ DCs induced Tfh expressing CXCR5, PD1, Bcl6 and IL-21 that localized within GCs. Furthermore, targeting gD peptide derived from HSV-1 to Clec9A induced memory CXCR5⁺ PD1⁺ CD4⁺ T cells that proliferated extensively upon secondary challenge with the virus and rapidly developed into effector Tfh. This was associated with an enhanced GC B cell response and accelerated antibody production. Strikingly, Clec9A targeted antigens also mediated direct interaction between CD8⁺ DCs and Ag-specific B cells. Ag captured via Clec9A was efficiently retained in the native form on the surface of CD8⁺ DCs. CD8⁺ DCs induced rapid activation of Ag-specific B cells, resulting in their accumulation at the T-B border in the spleen and lymph nodes within 12h. Intravital two-photon imaging showed Ag-specific B cells physically interacted with CD8⁺ DCs prior to their accumulation at the T-B border. The B cells activated by CD8⁺ DCs readily acquired help from cognate T cells and underwent divisions, resulting in generation of strong antibody responses. These findings collectively show that a Clec9A targeted

vaccination strategy harnesses the ability of steady-state CD8⁺ DCs to prime Tfh and to share intact antigens with cognate B cells, facilitating their rapid activation. These findings have important implications for development of novel vaccination strategies.

Dendritic cells, division of labour during peripheral herpes simplex virus-1

Whitney, P., Tebartz, C., Macleod, B., Bachem, A., Turner, A., Bedoui, S.

University of Melbourne, Microbiology and Immunology, Melbourne, Australia

Dendritic cells (DC) continually patrol peripheral tissues and transport antigen to draining lymph nodes (LN) to drive antigen-specific T cell responses. The ever-expanding knowledge of different DC subsets provides ever-expanding questions; such as what is each DC subsets actual contribution during infections. Skin-draining LN consists of both migratory DCs (Langerhans cells, dermal DC and CD103⁺ DC) and lymph node-resident DCs. In this study, we utilised a localised cutaneous HSV-1 infection model to assess the relative *in vivo* contributions for the different DCs subsets involved in priming HSV-specific CD8⁺ T cells. Using mouse models with complete or conditional depletion of various DC subsets (eg. *irf8*^{-/-} and Langerin-DTR) we could confirm importantly *in vivo*, that CD8α⁺ DC and/or CD103⁺ DCs are the main antigen-presenting subsets priming HSV-1-specific CD8⁺ T cells. These findings were further expanded utilising mice expressing diphtheria toxin under the control of the ROSA26 locus in combination with HSV-1 expressing Cre recombinase. This allowed for the selective killing of HSV-1-infected cells and thereby eliminated direct antigen-presentation by infected DC. This approach showed convincingly that the majority of antigen presentation driving HSV-1-specific CD8⁺ T cells occurs via cross presentation. These findings are consistent with skin-resident DCs, either directly infected or containing virally infected material migrating to the draining lymph nodes and handing over their cargo to LN-resident CD8α⁺ DC for priming of CD8⁺ T cells. This work highlights that not all DCs are contributing equally and that indeed a division of labour exists allowing unique tailoring to fit different situations.

BCAP regulates DC homeostasis in response to immune stimulus through bi-switch NF-κB and PI3K/Akt pathway

Fang, E.^{1,2}, Jiang, M.^{1,2}, Miao, Y.^{1,2}, Qi, L.^{1,2}, Xiao, W.^{1,2}

¹University of Science and Technology of China, Hefei, China, ²Key Laboratory of Innate Immunity and Chronic Disease, Chinese Academy of Sciences, Hefei, China

B cell adapter protein (BCAP) is a transduction adapter protein expressed only in B cell, NK cell, macrophage and dendritic cell (DC). Notably, BCAP regulates distinct signaling pathways in different cell types, suggesting that it exerts a cell-specific feature. The function of BCAP in DC was still unknown. Our study demonstrated that bone marrow-derived DC (BMDC)

and spleen conventional-DC from BCAP gene knockout mice showed diverse characteristics with increased expression of co-stimulation molecules, cytokine production, specific antigen presentation, but decreased migration compare to the control DC. The activities of NF- κ B and PI3K/Akt showed distinct status, where NF- κ B pathway was prolonged and PI3K/Akt was reduced during LPS-induced maturation in BCAP-KO BMDC compare to the control BMDC. Further study showed that, in the steady state, BCAP associated with MyD88 to inhibit the activation of downstream NF- κ B signaling; when induced with LPS, BCAP dissociated from MyD88 and interacted with p85 α , which freed MyD88 from the MyD88/BCAP complex and activated NF- κ B. At the same time, BCAP bound to p85 α and promoted PI3K/Akt activation. Short after the response, BCAP dissociated with p85 α and interacted with MyD88 again. Thus, the BCAP served as a bi-switch of MyD88 and PI3K pathways in response to LPS stimulation. Additionally, the similar results were observed in DC stimulated with TLR2 agonist Pam3CK, but not TLR3 agonist poly:I:C. These observations clearly suggested that BCAP plays a critical role in maintaining homeostasis through bi-switch of NF- κ B and PI3K/Akt pathways in MyD88-dependent manner in DC response to immune stimulus.

The dendritic cells that prime Th2 immune responses in vivo are transcriptionally heterogeneous

Connor, L.¹, Cognard, E.¹, Ochiai, S.¹, Tang, S.C.¹, Hilligan, K.¹, Old, S.¹, Pellefigues, C.¹, Smith, A.T.¹, Eccles, D.¹, McConnell, M.², Ronchese, F.¹

¹Malaghan Institute of Medical Research, Wellington, New Zealand, ²Victoria University of Wellington, Wellington, New Zealand

Dendritic cells (DC) acquire the capacity to prime immune responses by undergoing a coordinated programme of transcriptional changes where they upregulate expression of costimulatory signals and soluble mediators to induce CD4⁺ T cells proliferation and differentiation into the appropriate effector cell type. To gain an understanding of the signals involved in the differentiation of IL4-producing Th2 cells in vivo, we used RNAseq to carry out a transcriptional characterization of skin-derived DC subsets in the lymph nodes of mice exposed to two different Th2 stimuli, the TSLP-independent nematode parasite *Nippostrongylus brasiliensis* (Nb), and the TSLP-dependent contact sensitizer DBP-FITC. We find that both stimuli induced extensive but distinct transcriptional changes in the CD11b⁺CD103⁻CD326⁻ (CD11b⁺) and CD11b⁻CD103⁻CD326⁻ (TN) DC subsets. Pathway analysis revealed a clear cytokine signature that was specific to DC subsets from Nb-injected mice. This signature was functionally important as treatment with cytokine receptor blocking antibodies at the time of immunization suppressed the development of IL4-producing T cells in Nb-primed, but not DBP-FITC-primed, mice. Surprisingly, comparison of the DC transcriptional changes in Nb-primed and DBP-FITC-primed mice revealed only a small number of similarly regulated genes, mostly consisting of well-known molecules associated with DC migration, activation, and Th2 immunity. Thus the priming of Th2 immune responses

does not appear to be associated with a unique DC signature, a finding that may be consistent with a model where incomplete or insufficient signals from DC result in a "default" development of Th2 responses.

1467

Activation of plasmacytoid dendritic cells in colon-draining lymph nodes during *C. rodentium* infection involves pathogen-sensing and inflammatory pathways distinct from CD103⁺ DC

Toivonen, R.¹, Kong, L.², Rasool, O.², Lund, R.², Lahesmaa, R.², Hänninen, A.¹

¹University of Turku, Medical Microbiology and Immunology, Turku, Finland, ²Turku Centre for Biotechnology, Turku, Finland

Dendritic cells (DC) bear the main responsibility for initiation of adaptive immune responses necessary for antimicrobial immunity. In the gut, CD103⁺ migratory DC traffic from small intestinal lamina propria to small intestinal mesenteric lymph nodes (siMLN) and induce regulatory and antimicrobial immunity there. Immune surveillance of the large intestine and the role of CD103⁺DC therewith are less well characterized. We identified three small mesenteric lymph nodes, distinct from small intestinal lymph nodes, which drain lymph specifically from the colon, and studied DC responses to the attaching and effacing pathogen *C. rodentium* in these. Transcriptional profiling of CD103⁺ DC and the lymph-node resident pDC populations during steady-state conditions revealed activity of distinct sets of genes in these two DC subsets, both in small intestinal and colon-draining lymph nodes. *C. rodentium* activated DC especially in colon-draining lymph nodes, and gene expression changed in pDC more profoundly than in CD103⁺DC. Among the genes most upregulated in pDC were C-type receptor CLEC4E, IL-1-receptors (IL1R1-2), proinflammatory cytokines (IL1a, IL-6) and TLR6. The coMLN and siMLN also showed differential lymphocyte response to bacterial signals as seen with increased IFN γ production by CD4⁺ cells in the coMLN, but not in the siMLN.

Our results indicate that colon immune surveillance is distinct from that of the small intestine in terms of draining lymph nodes, and identify pDC as active sentinels of colonic inflammation and/or microbial dysbiosis.

Human plasmacytoid dendritic cells diversify into specialized innate and adaptive subsets after viral activation

Alculumbre, S.G.¹, Vargas, P.², Di Domizio, J.³, Maiuri, P.², San Roman, M.¹, Terrier, B.⁴, Saadoun, D.⁵, Gilliet, M.³, Soumelis, V.¹

¹Institut Curie, INSERM U932, Paris, France, ²Institut Curie, CNRS UMR144, Paris, France, ³University Hospital CHUV, Department of Dermatology, Lausanne, Switzerland, ⁴Cochin Hospital, APHP, Department of Internal Medicine, Paris, France, ⁵Groupe Hospitalier Pitié Salpêtrière, APHP, Department of Internal Medicine, Paris, France

Microbial activation stimulates plasmacytoid pre-dendritic cells (pDC) to secrete large amounts of type I interferon (IFN) and

differentiate into mature dendritic cells capable of modulating the adaptive immune response. Here, we show that peripheral innate activation of steady state human pDC induced their differentiation into three phenotypically, morphologically, and functionally distinct subsets, in the absence of cell proliferation: P1 (PD-L1⁺CD80⁻), P2 (PD-L1⁺CD80⁺) and P3 (PD-L1⁻CD80⁺). The innate and adaptive functions previously associated to pDC biology were differentially linked to each of the subsets. P1-pDCs display a plasmacytoid morphology and innate immune functions, comprising IFN production, whereas P3-pDCs adopt a dendritic morphology and adaptive immune functions, including T cell activation and proliferation. P2-pDCs had an intermediate functional profile. Different stimuli induced variable proportions of the subsets, suggesting that steady state pDC are multipotent. We found distinct pDC subsets associated with human autoimmune and inflammatory diseases, supporting their pathophysiological relevance. We propose that peripheral innate activation induces pDC subset diversification with reciprocal exclusion of innate and adaptive functions.

1438

Inflammation induces two types of inflammatory dendritic cell in lymph nodes

Min, J.¹, Yang, D.¹, Kim, M.², Haam, K.², Kim, Y.S.², Kim, D.¹, Kang, S.J.¹

¹Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, ²Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of

The spatio-temporal regulation of immune cells in lymph nodes (LNs) is crucial to mount protective T cell responses, which are orchestrated by dendritic cells (DCs). However, it is unclear how the DC subsets are altered by the inflammatory milieu of LNs. Here, we show that the inflamed LNs of *Listeria*-infected mice are characterized by the clustering of neutrophils and monocytes, and IFN- γ production. Significantly, the early inflammatory responses are coupled to the differentiation of not one, but two types of inflammatory DCs. Through assessment of chemokine receptor dependency and gene expression profiles, we herein unveiled a novel inflammatory DC population that arises from conventional DCs (cDCs), contrary to the current consensus on the single monocytic origin of inflammatory DCs (moDCs). The cDC-originated inflammatory DCs had a higher potential to stimulate T cell proliferation and Th1 differentiation than moDCs, whereas the latter displayed more robust expression of inflammatory genes. These findings reveal the role of early inflammatory responses for driving the differentiation of two inflammatory DC subsets with distinct competencies. Further our study delineates unprecedented regulatory mechanisms that are set by the early innate immune responses for orchestrating the following adaptive immunity.

The non-canonical Wnt pathway negatively regulates the differentiation of dendritic cell by inhibiting the expansion of Flt3⁺ lymphocyte-primed multipotent precursors

Xiao, J., Zhou, H., Wu, N., Wu, L.

Tsinghua University School of Medicine, Beijing, China

The differentiation of dendritic cells (DC) altered during the process of aging. However, the molecular mechanisms for the alteration of DC development in aged mice are far from clarified. Recently, Wnt5a has been reported as an important aging related molecule in hematopoietic system. Here, we suggest that the increased expression of Wnt5a in aged hematopoietic precursors led to deficient differentiation of DC in aged mice. Compared with young mice, the percentages and cell numbers of plasmacytoid DC (pDC) and CD172aCD8 α ⁺ conventional DC (cDC) decreased in aged mice. Further analysis indicated that the hematopoietic precursors that can give rise to DC, including Flt3⁺ lymphocyte-primed multipotent precursors (LMPP), common lymphoid progenitors (CLP) and common DC precursors (CDP) all decreased in the bone marrow of aged mice. Overexpression of Wnt5a in hematopoietic precursors strongly affected the differentiation of cDC and pDC in vivo. Treatment of hematopoietic stem cells (HSC) with Wnt5a led to a significant decrease in the differentiation of LMPP, CLP and CDP populations, which was similar to that of the HSC in BM of aged mice. Molecular studies demonstrated that Wnt5a negatively regulated the expression of an array of genes important for DC differentiation, including Flt3, Gfi-1, Ikaros, Bcl11a and IL-7R by activating Wnt5a-Cdc42 pathway. Finally, we rejuvenated DC differentiation from aged precursors by blocking the non-canonical Wnt pathway. Therefore, our study identified the key roles of non-canonical Wnt pathway in DC differentiation and DC aging.

Profiling immunogenic bacteria within the microbiota of SKG mice associated with spondyloarthritis and ileitis using IgA-SEQ

Rehaume, L.M.¹, Kang, A.¹, Zbarskaya, O.¹, Mullaney, J.A.¹, Kim, M.¹, Ó Cuív, P.¹, Angel, N.², Lachner, N.², Daly, J.², Morrison, M.¹, Hugenholtz, P.², Thomas, R.¹

¹The University of Queensland Diamantina Institute, Brisbane, Australia, ²Australian Centre for Ecogenomics, Brisbane, Australia

IgA is the main barrier mechanism of mucosal surfaces. High affinity IgA binds to pathogenic bacteria, whereas low affinity IgA binds commensal bacteria. Next-generation sequencing of IgA-coated bacteria (IgA-SEQ) identified a consortia of bacteria from human gut microbiota that exacerbates murine colitis, including a *Prevotella* species. *Prevotella copri* was associated with new-onset rheumatoid arthritis. BALB/c ZAP-70^{W163C} (SKG) mutant mice housed in specific pathogen-free (SPF) conditions treated with beta-glucan develop spondyloarthritis, in which ileitis is microbiota-dependent. Our aim was to define bacteria driving ileitis development in a genetically susceptible host.

Fecal samples were collected from germ-free (GF) SKG and GF-BALB/c mice recolonized with altered Shaedler flora (ASF), and the microbiota composition determined by real-time PCR. Fecal samples were collected from naive SPF-SKG mice, and IgA-coated bacteria enriched by magnetic- and fluorescence-activated cell sorting. IgA⁻, IgA⁺, IgA^{dim} and IgA^{bright} bacteria were identified by deep sequencing.

Four bacterial strains were detected in ASF-SKG and ASF-BALB/c mice: *Clostridium* sp., *Lactobacillus murinus*, *Mucispirillum schaedleri*, *Parabacteroides* sp. Whilst the *Clostridium* sp. and *Parabacteroides* sp. were decreased in SKG, the dominant bacteria in both strains of mice was the *Parabacteroides* sp. *Prevotellaceae* were enriched among IgA^{bright} bacteria, while *Lactobacillaceae* were diminished.

Interaction of the microbiota and immune system of SKG mice alters the composition of the bacterial community. The immunogenic IgA^{bright} bacteria within the microbiota of SKG mice are enriched in *Prevotellaceae*, which has been associated with rheumatoid arthritis and inflammatory bowel disease. IgA-SEQ is a powerful tool to identify immunogenic bacteria from a highly diverse microbiota.

Epithelial HVEM regulates intestinal homeostasis of microbiota and immune cells

Takahashi, D.¹, Geo, G.², Lu, H.-H.³, Kronenberg, M.², Shui, J.-W.³

¹Keio University, Division of Biochemistry, Tokyo, Japan, ²La Jolla Institute for Allergy and Immunology (LIAI), La Jolla, United States,

³Academia Sinica, Institute of Biomedical Sciences, Taipei, Taiwan, Republic of China

Blocking TNF has been proven effective in treating inflammatory disorders including inflammatory bowel disease (IBD). HVEM (herpes virus entry mediator), also called TNF receptor superfamily 14, has been recently reported as an IBD risk gene. We found HVEM is highly expressed in intestinal epithelium and HVEM can regulate epithelial innate function by inducing epithelial Stat3 activation. Furthermore, we showed epithelial HVEM provides indispensable host defense against bacterial infection in the gut and lung (*Nature* 488:222, 2012), suggesting epithelial HVEM serves as an important surface receptor for intestinal homeostasis.

To further understand whether epithelial HVEM regulates intestinal immunity at the steady state, we generated epithelium-specific HVEM conditional knockout mouse. Epithelial scrape samples from small intestines of co-housed littermates were prepared and subjected to RNAseq analysis. Significantly, Paneth cell-derived anti-microbial products (defensin, lysozyme and phospholipase A2), commensal bacteria SFB-associated host defense mediators (Reg3g, Mmp7, Saa1, Nos2), and pro-inflammatory products (IL18bp, Ceacam1, Socs3, Dmbt1) were up-regulated in HVEM conditional knockout mice. Correlated to this, co-housed aged (7-month old) HVEM conditional knockout mice had increased SFB, which likely led to over-activation of immune cells (Th17 and ILC3) in the lamina propria of ileum (SFB has tropism to ileum). Furthermore, vancomycin treatment of co-housed littermates wiped out SFB and restored over-activation of immune cells in HVEM knockout mice. Together,

our data indicate that epithelial HVEM is important for intestinal homeostasis of microbiota and mucosal immune cells. Our findings will also provide insights into how HVEM could be targeted for treating intestinal inflammatory conditions.

TGF- β signaling in ILC3 prevents spontaneous microbiota-induced colorectal cancer

Bauché, D.¹, Lélu, K.¹, Noiret, J.¹, Ferreira, C.², Deceneux, C.¹, Guibert, P.³, Treilleux, I.⁴, Veldhoen, M.², Marie, J.^{1,5}

¹Cancer Research Center of Lyon, Immunology Virology and Inflammation Dpt, Lyon Cedex, France, ²Babraham Institute, Cambridge, United Kingdom, ³Centre Léon Berard, Gastroenterology, Lyon, France, ⁴Centre Léon Berard, Anapathology, Lyon, France, ⁵DKFZ, Tumor Immunology, Heidelberg, Germany

The incidence of intestinal cancer is particularly high in the colorectal region, coinciding with a high microbial load. Whether microbiota contributes to spontaneous induction of colorectal cancers (CRC) and which mechanisms are in place to prevent CRC are unknown. Here, we show that the TIF-1 γ and SMAD4-dependent branches of (transforming growth factor β) TGF- β signaling maintain the expression of AhR (arylhydrocarbon receptor) in type 3 innate lymphoid cells (ILC3), sustain their IL-22 production and thereby the intestinal barrier-integrity. The concomitant deprivation of both SMAD4 and TIF-1 γ results in microbial translocation responsible for excessive TH17 cell-response, and subsequent CRC- induction. Antibiotics, neutralization of IL-17, recombinant IL-22 or the reconstitution of an AhR-sufficient ILC3-compartment are adequate to prevent CRC induction. Furthermore, we confirm that CRC patient-derived colonic ILC3 are unable to sustain high levels of AhR upon TGF- β stimulation. This work reveals an unsuspected role for TGF- β in the maintenance of the host-intestinal barrier integrity, keeping in check the ability of the microbiota to induce an IL-17 environment responsible for spontaneous CRC development.

636

Hyper inflammasome signaling in *Nlrp3* mutant mice alters gut microbiota and confers resistance to colitis and colorectal cancer

Yao, X.¹, Xing, Y.¹, Zhang, C.², Zhao, L.³, Meng, G.⁴

¹Institut Pasteur of Shanghai, Chinese Academy of Sciences, Shanghai, China, ²State Key Laboratory of Microbial Metabolism, Shanghai Jiao Tong University, Shanghai, China, ³State Key Laboratory of Microbial Metabolism, Shanghai Jiao Tong University, Department of Biological Sciences, School of Life Sciences and Biotechnology, Shanghai, China, ⁴Institut Pasteur of Shanghai, Chinese Academy of Sciences, Unit of Innate Immunity, Shanghai, China

Inflammatory bowel disease (IBD) is a prominent threat to human health. Moreover, uncontrolled progression of IBD leads to increased risk for colorectal cancer. Dysbiosis in the gut microbiota has long been recognized as a key factor mediating IBD pathogenesis. As an important gene in the innate immune

system, NLRP3 has been linked with IBD and colorectal cancer. But whether and how gut microbiota is involved in NLRP3 function in IBD remains obscure. Here we report that mice carrying the R258W mutation which acquires an autoactivation of the Nlrp3 inflammasome remains gut homeostasis through remodeling their gut microbiota. During DSS colitis induction, this reshaped microbiota responds differently compared to that of wildtype, which is revealed by the internal microbial networks. Strikingly, this special microbiota composition confer Nlrp3^{R258W} mice protection against DSS induced acute colitis as well as AOM plus DSS induced colorectal cancer. Mechanistically, we found the mutated Nlrp3^{R258W} protein mainly acts in lamina propria CD11C+ macrophages. Interestingly, it was IL-1 but not IL-18 mediating the microbiota change and resistance to colitis. In summary, we demonstrate that the Nlrp3^{R258W} mutation led to a shift in the gut microbiota of the mice, which turned out to be a key causative factor to mediate the resistance to colitis and colorectal cancer.

High-affinity, poly-reactive IgA is required for gut homeostatic maintenance to prevent colitis in mice

Okai, S.¹, Usui, F.¹, Hasegawa, M.², Nakamura, T.³, Yamamoto, K.⁴, Nishiyama, E.⁴, Mori, H.⁴, Yamada, T.⁴, Kurokawa, K.⁵, Matsumoto, S.⁶, Nanno, M.⁶, Naito, T.⁶, Kato, T.⁷, Miyauchi, E.⁷, Ohno, H.^{7,8,9}, Shinkura, R.¹
¹Nagahama Institute of Bio-Science and Technology, Immunology, Shiga, Japan, ²Nagahama Institute of Bio-Science and Technology, Protein Function Analysis, Shiga, Japan, ³Nagahama Institute of Bio-Science and Technology, Epigenetics, Shiga, Japan, ⁴Tokyo Institute of Technology, Graduate School of Bioscience and Biotechnology, Tokyo, Japan, ⁵Tokyo Institute of Technology, Earth-Life Science Institute, Tokyo, Japan, ⁶Yakult Central Institute, Tokyo, Japan, ⁷RIKEN Center for Integrative Medical Sciences, Kanagawa, Japan, ⁸Chiba University, Graduate School of Medicine, Chiba, Japan, ⁹Yokohama City University, Graduate School of Medical Life Science, Kanagawa, Japan

Growing evidence suggests that dysbiosis resulting from compromised immune responses has a role in the pathogenesis of inflammatory bowel disease (IBD). Immunoglobulin A (IgA) is the main antibody isotype secreted into the intestinal lumen. It plays a critical role in the defense against pathogens and in the maintenance of intestinal homeostasis. However, the molecular mechanisms of how secreted IgA (SIgA) regulates intestinal microbiota are not completely understood but a plausible explanation is that it selectively coats disease-associated bacterial taxa. In this study, we isolated a monoclonal IgA antibody (clone W27), which had high-affinities to a variety of commensal bacteria. Activation-induced cytidine deaminase mutant (AID^{G235}; glycine to serine at the 23rd amino acid) mice produce only low-affinity Igs due to somatic hypermutation (SHM) defect and develop lymph proliferative disease associated with of dysbiosis. Oral administration of the W27 IgA modulated gut microbiota composition and prevented lymph proliferative disease in AID^{G235} mice. Identical beneficial effects of W27 were observed in different models of colitis. Thus a high-affinity, poly-reactive IgA oral treatment is a potential remedy for IBD, acting through restoration of the host-microbial symbiosis.

1284

Microbiota of the small intestine are selectively engulfed by phagocytes of the lamina propria and Peyer's patches

Morikawa, M., Tsujibe, S., Shibata, J., Watanabe, Y., Nagaoka, N., Shida, K., Matsumoto, S.

Yakult Central Institute, Kunitachi, Japan

Phagocytes, such as dendritic cells and macrophages that are distributed in the small intestinal mucosa, play a crucial role in maintaining mucosal homeostasis by sampling the luminal gut microbiota. However, there is limited information regarding the microbial uptake in steady state. We investigated the composition of gut microbiota that is engulfed by the phagocyte subsets in the small intestinal lamina propria (SILP) and Peyer's patches (PP) from C57BL/6 mice.

On the basis of CD11b/CD11c expression patterns, SILP and PP cells were divided into four and three subsets, respectively. Each phagocyte subset exhibited distinct immune properties, such as cytokine gene expression and abilities to induce helper T cell subsets from naïve T cells. Interestingly, phagocytes that had engulfed bacteria were observed in every subset using FISH. Analysis of bacterial 16S rRNA gene amplicon sequencing revealed 1) all the phagocyte subsets in the SILP mostly engulfed *Lactobacillus* (the most abundant microbe in the small intestine), whereas CD11b^{hi} and CD11b^{hi}CD11c^{hi} cell subsets in PP mostly engulfed segmented filamentous bacteria (indigenous gut bacteria in rodents), and 2) among the *Lactobacillus* species engulfed by the SILP cell subsets, *L. murinus* were engulfed more often than *L. taiwanensis*, although both these *Lactobacillus* species were abundant in the small intestine.

These results suggest that small intestinal microbiota is selectively engulfed by phagocytes that localize in the adjacent intestinal mucosa under a steady state. These observations may provide insight into the crucial role of phagocytes in immune surveillance of the small intestinal mucosa.

Zymosan induces Th17 cell differentiation by promoting IL-6 secretion from small intestinal lamina propria dendritic cells

Park, A.¹, Jin, S.², Yang, B.-G.³, Hong, C.-P.¹, You, D.-J.², Jang, M.H.³, Kim, Y.-M.^{1,4}

¹Pohang University of Science and Technology, Division of Integrative Biosciences and Biotechnology, Pohang, Korea, Republic of, ²Osaka University, World Premier International Research Center Initiative-Immunology Frontier Research Center, Suita, Japan, ³Academy of Immunology and Microbiology, Institute for Basic Science, Pohang, Korea, Republic of, ⁴Pohang University of Science and Technology, Department of Life Sciences, Pohang, Korea, Republic of

The homeostasis of small intestinal immune system is regulated by food antigens and molecules derived from commensal microorganisms. Certain commensal bacteria control CD4+ T cell differentiation and specifically induce Th17 or Treg cells. Commensal microorganisms also include fungi such as *Saccharomyces cerevisiae* and *Candida albicans*, however much less is known on the regulation of intestinal immune system

by these commensal fungi. To understand how fungi affect the intestinal immune system, we first investigated the effects of zymosan, a cell wall derivative of *Saccharomyces cerevisiae*, on lamina propria dendritic cells (LP-DCs). We found that zymosan specifically induced IL-6 in LP-DCs but not in splenic dendritic cells (SP-DCs) whereas both cell types produced IL-12p40 and TNF- α upon zymosan stimulation. Zymosan can signal via TLR-2 and dectin-1. By using TLR-deficient mice and dectin-1-blocking antibodies, we found that IL-6 induction by zymosan in LP-DCs is exclusively mediated by dectin-1. Correlated with production of IL-6, zymosan-activated LP-DCs, but not SP-DCs, induced differentiation of naive CD4⁺ T cells into Th17 cells and concomitantly inhibited Treg differentiation in the presence of TGF- β *in vitro*. We confirmed that these effects by zymosan depends on IL-6 by using dendritic cells from the IL-6-deficient mice. Furthermore, oral delivery of zymosan significantly increased small intestinal Th17 cell population. These findings suggest that zymosan from commensal fungi may provide a Th17-promoting condition in the small intestine via the induction of IL-6 in LP-DCs.

Oral immunization induces an effective mucosal immune response that protects mice against intravaginal HSV-2 challenge

Mulvey, P.¹, Aaskov, J.¹, Aldwell, F.², Beagley, K.¹

¹Queensland University of Technology, Brisbane, Australia,

²University of Otago, Otago, New Zealand

Immunity against genital Herpes Simplex Virus 2 (HSV-2) infection is dependent on local memory immune responses in the genital tract. Oral immunisation can induce mucosal immune responses in the genital tract but has not been tested against viral STIs. Here we describe the mucosal immune responses elicited by an oral vaccine that protects mice against intravaginal challenge from lethal HSV-2 infection. Control of HSV-2 was attributed to HSV-2-specific IgG and IgA in the genital mucosa together with CD4 and CD8 T cells recruited to the genital epithelia. Furthermore, combining this vaccine with vaginal application of non-specific inflammatory or chemoattractants, CXCL9 and CXCL10, led to the recruitment of CD8 tissue resident memory cells in the genital epithelia that controlled new infection with HSV-2. Thus, this represents the first oral vaccine that can protect mice against lethal intravaginal HSV challenge.

Interferon- ϵ -regulated gene expression patterns in protection against female reproductive tract infection

Mayall, J.¹, Mangan, N.², Chevalier, A.¹, Kim, R.¹, Rae, B.¹, Hertzog, P.², Horvat, J.¹, Hansbro, P.¹

¹Hunter Medical Research Institute & The University of Newcastle, New Lambton Heights, Australia, ²Hudson Institute of Medical Research and Monash University, Clayton, Australia

Chlamydia trachomatis is the most common sexually transmitted bacterial infection and frequently causes female reproductive tract (FRT) sequelae such as infertility. However, the processes

involved in clearance and immunopathology of *Chlamydia* infection are not well understood. In previous studies, we showed that interferon (IFN)- ϵ is constitutively expressed in the FRT and plays an important role in protecting against *Chlamydia* infections from the earliest stages of infection. To elucidate the mechanisms of IFN- ϵ -mediated protection, we examined the effects of IFN- ϵ on the expression of genes in the FRT in *Chlamydia muridarum* and sham-infected, wild type and IFN- ϵ deficient ($\epsilon^{-/-}$) C57BL/6 mice using whole-genome microarray-based analyses. IFN- ϵ uniquely regulated the expression of 744 genes at baseline and 802 genes during *Chlamydia* infection, and universally regulated the transcription of 61 genes, regardless of infection status. The majority of these transcripts were down-regulated in IFN- $\epsilon^{-/-}$ mice, particularly during infection, and pathway analysis revealed that many of these genes are involved in immune processes. Transcripts associated with leukocyte haematopoiesis, infiltration, and communication were down-regulated in IFN- $\epsilon^{-/-}$ mice at baseline. In *Chlamydia*-infected IFN- $\epsilon^{-/-}$ mice, pathways associated with innate responses, such as IFN regulatory factor activation and pattern recognition receptor signalling were down-regulated. Interestingly, several metabolic pathways were also dysregulated during IFN- ϵ deficiency, highlighting the intimate relationship between host metabolism and defence. These data demonstrate that IFN- ϵ both regulates baseline expression of a wide variety of genes and primes for the rapid expression of factors involved in the host response to *Chlamydia* infections in the FRT.

Mitochondrial stress contributes to differential type I interferon induction by *Mycobacterium tuberculosis* and *Mycobacterium africanum*

Wiens, K.¹, Ernst, J.²

¹NYU School of Medicine, Pathology, New York, United States, ²NYU School of Medicine, Medicine, New York, United States

Type I interferon (IFN $\alpha\beta$) induction varies by *Mycobacterium tuberculosis* (Mtb) strain and by patient disease state, and may contribute to Mtb pathogenesis. The mechanism for variation in IFN $\alpha\beta$ induction is thought to lie in the cytosolic signaling pathway upstream of IFN β transcription. In this pathway Mtb gains access to the cytosol and then triggers STING signaling, either directly or through DNA binding to cGAS in the cytosol. In order to examine this mechanism we infected bone marrow derived macrophages with two Mtb strains and a *Mycobacterium africanum* (Maf) strain. We found that Maf induced less IFN β than either Mtb strain induced. Differences in IFN β were not due to differences in bacterial numbers and were entirely dependent on STING and cGAS. We found that Maf accessed the host cytosol to the same extent as Mtb. We also found that Maf shed similar amounts of bacterial DNA as Mtb. Intriguingly, Maf infection was associated with reduced mitochondrial DNA in the cytosol. Correspondingly, Maf infection was associated with reduced mitochondrial stress as measured by ATP and superoxide production. Finally, we found that treating macrophages with a mitochondria-specific antioxidant reduced

the differences in IFN β induction between the strains. Our results indicate that Maf induces less mitochondrial stress, which results in the accumulation of less mitochondrial DNA in the cytosol and lower IFN β induction. This suggests that mitochondrial dynamics contribute to IFN β induction by Mtb and may also contribute to mycobacterial virulence.

3445

Infection of mice by *Trypanosoma brucei* ameliorates host immune response against *Brucella melitensis*

Machelart, A.¹, Potemberg, G.¹, Truyens, C.², Romano, M.³, Pays, E.⁴, De Trez, C.⁵, Magez, S.⁵, Letesson, J.J.¹, Muraille, E.²

¹University of Namur, Namur, Belgium, ²Université libre de Bruxelles, Laboratory of Parasitology, Bruxelles, Belgium, ³Scientific Institute for Public Health, Bruxelles, Belgium, ⁴Université libre de Bruxelles, Laboratory of Molecular Parasitology, Bruxelles, Belgium, ⁵Vrije Universiteit Brussel, Bruxelles, Belgium

Brucella spp. are facultative intracellular bacterial pathogens responsible for brucellosis, a worldwide zoonosis that causes abortion in domestic animals and chronic febrile disease associated with serious complications in humans. There is currently no approved vaccine against human brucellosis, and antibiotic therapy is long and costly.

Identification of key factors regulating host resistance to brucellosis or other pathogens is classically performed in immunologically naive animals. This approach is highly reductionist and ignores that host contract frequently several pathologies at the same time. In order to characterize the impact of parasitic infection on the course of *Brucella* infection, we administrate *Trypanosoma brucei*, an extracellular protozoan responsible for African trypanosomiasis, in *Brucella melitensis* infected mice.

Surprisingly, our results demonstrate that *T. brucei* infection facilitates the control and the elimination of *B. melitensis* by the host immune system. A large proportion of coinfecting mice display no detectable bacteria in spleen at the time where *Brucella* is always detected in control mice. Higher control of *Brucella* infection appears correlated with a boost of IFN- γ producing CD4⁺ T cells induced by *T. brucei* infection. The importance of CD4⁺ T cells in the *T. brucei*-mediated control of infection is confirmed by the absence of *Brucella* clearing in spleen of CD4 genetically deficient mice.

Brahma complex modulates immune signalling in *Drosophila melanogaster*

Valanne, S.¹, Järvelä-Stöltzing, M.¹, Vanha-aho, L.-M.¹, Vesala, L.¹, Myllymäki, H.¹, Harjula, S.-K.¹, Rämetsä, M.^{1,2,3}

¹University of Tampere / BioMediTech, Laboratory of Experimental Immunology, Tampere, Finland, ²University of Oulu, PEDEGO Research Unit, and Medical Research Center Oulu, Oulu, Finland, ³Oulu University Hospital, Department of Children and Adolescents, Oulu, Finland

Drosophila melanogaster is a widely used model in immunology. *Drosophila* defence against yeast and bacteria is mainly

mediated by two evolutionarily conserved NF-kappaB signalling pathways, the Toll and the Immune deficiency (Imd) pathway. Although the core Toll signalling is well-known, the negative regulation of Toll signalling is poorly understood. In our genome-wide RNAi *in vitro* screen in S2 cells, we identified 14 genes that negatively regulate Toll pathway activity. Among these genes there were four components of the so-called Brahma complex that is involved in chromatin remodelling. We studied the *in vivo* significance of the Brahma complex in immune signalling using the UAS-GAL4 method in *D. melanogaster*. The RNAi flies were crossed to the C564-GAL4 driver, to silence the expression of two members of the Brahma complex (*brahma* and *osa*) in the fat body (equivalent to mammalian liver). The progeny flies were infected first with Gram-positive bacteria, *Micrococcus luteus*, to activate the Toll pathway. 24h post infection, the flies were further infected with more virulent Gram-positive bacteria, *Enterococcus faecalis*. The infection experiments demonstrate that silencing of components of the chromatin remodelling Brahma complex increases survival of the flies against *E. faecalis*. Quantitative PCR analysis of antimicrobial peptide gene expression further suggested that the Brahma complex negatively regulates the Toll pathway. These results indicate that DNA modification may play a role in the regulation of *Drosophila* Toll signalling. Further studies will elucidate the more specific function of the Brahma complex in *Drosophila* immune response.

TLR2/1 orchestrate human pDC response to Gram+ bacteria

Rajeli, S., Soumelis, V.

Institute Curie, U 932, Paris, France

Tuberculosis is worldwide life-threatening disease. Moreover, infections by Gram+, multi-drug resistant bacteria are emerging as a cause of mortality. In both cases new studies are highlighting the pathological role of Type I interferon (IFN-I). Plasmacytoid dendritic cells (pDCs) produce high amounts of IFN-I following viral sensing. Recent evidence suggests that human pDCs might sense bacteria. However, human pDCs are reported to express only few pathogen pattern recognition receptors, namely Toll like receptor (TLR)-7 and TLR9. The receptors mediating bacterial sensing in pDCs are not known.

We show here that pDCs respond to Gram+ bacteria *Mycobacterium tuberculosis*, *Staphylococcus aureus* and *Listeria monocytogenes* by upregulating costimulatory molecules and secreting IFN-I. pDCs activation in these settings was blocked by a TLR2/1 competitive antagonist (CU-CPT22). Our work showed that human primary pDCs express TLR1 at the mRNA and protein level. We demonstrated that pDCs respond to TLR2/1 synthetic ligand (Pam3CSK4) with the up-regulation of costimulatory molecules (as MHCII, CD80 and CD86) and cytokines secretion (IL-6, TNF- α , IFN-I). In human primary pDC we found that in response to bacterial lipoproteins up-regulation of costimulatory molecules is TLR1-dependent while IFN-I secretion is TLR2-dependent. TLR2/1 ligand-stimulated pDCs primed naïve CD4+ T-cells, inducing proliferation and differentiation to TH1/TH2 subsets.

Overall, we showed the pDCs sense Gram+ bacteria through

the TLR2/1 pathway, and suggest a differential role for TLR1 and TLR2 in the induction of IFN- λ . This work provides the rationale to explore pDCs in human bacterial infection.

Functional and structural insights into a unique SEIXy staphylococcal superantigen

Langley, R.¹, Ting, Y.T.², Radcliff, F.¹, Clow, F.¹, Young, P.², Choi, J.¹, Baker, H.², Fraser, J.¹

¹The University of Auckland, Faculty of Medical and Health Sciences and The Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand, ²The University of Auckland, The School of Biological Sciences and The Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand

Staphylococcus aureus is a serious human pathogen. It causes higher rates of disease in New Zealand than other developed countries and is a major cause of skin and soft tissue infections, bacteraemia, and endocarditis. Its success as a pathogen can be attributed to the large number of diverse virulence factors it produces. The superantigen (SAg) family of toxins is a major class of virulence factors with twenty four distinct members identified to date. SAGs are infamously known for causing staphylococcal toxic shock syndrome and have been shown to be important for bacterial persistence and immune evasion during infection. By concurrently binding and activating major histocompatibility complex (MHC) class II molecules on antigen-presenting cells and T-cell receptors (TCRs) on T lymphocytes bearing susceptible V β regions SAGs promote massive activation of immune cells, leading to the release of inflammatory mediators that can ultimately result in hypotension, shock, organ failure, and death. The most recently discovered SAg, Staphylococcal Enterotoxin-Like X (SEIX), is unique in several respects. In contrast to other SAGs, it is chromosomally located and thus present in over 95% of *S. aureus*. SEIX lacks homology with the known MHC class II binding sites of SAGs. It possesses a unique N-terminal domain and its C-terminal domain shows greater homology to the Staphylococcal Superantigen-Like (SSL) family of immune evasion molecules than the SAGs.

Here we present functional and structural evidence that SEIX is an SSL-like SAg with features of both related families and additional features that are unique to SEIX.

PD-1 blockade rescues *Mycobacterium tuberculosis* specific polyfunctional T cell responses

Kamboj, D.¹, Thakral, D.¹, Mitra, D.K.¹, Mohan, A.², Basil, M.V.³

¹All India Institute of Medical Sciences, Department of Transplant Immunology and Immunogenetics, New Delhi, India, ²All India Institute of Medical Sciences, Department of Pulmonary Medicine and Sleep Disorders, New Delhi, India, ³V.P. Chest Institute, Department of Microbiology, New Delhi, India

Tuberculosis remains one of the leading causes of death worldwide. Th1 cytokines, particularly IFN- γ and TNF- α , are known to play a crucial role in protection against tuberculosis. IFN- γ is protective but not sufficient, whereas TNF- α alone can

lead to self tissue damage by causing necrosis. Therefore, the role of polyfunctional T cells is emerging in immunity against *Mycobacterium tuberculosis*. In this study, we found that polyfunctional T cell response was diminished in tuberculosis patients, which could be rejuvenated by blocking PD-1. PBMCs from tuberculosis patients were stimulated with *Mycobacterium tuberculosis* whole cell lysate in presence or absence of PD-1 blocking antibody and cytokine producing antigen specific T cells were determined using polychromatic flow cytometry. We demonstrated reduced frequency of *Mycobacterium tuberculosis* specific polyfunctional (CD4+IFN- γ +TNF- α) T cell responses in tuberculosis patients as compared to healthy controls. Blocking of PD-1 showed increased percentage rescue of polyfunctional response. This was because of higher expression of PD-1 on IFN- γ + TNF- α (dual positive) CD4 T cells as compared to the single cytokine producing T cells.

Further, we wanted to investigate the effect of cytokine milieu in altering the death pattern (apoptosis versus necrosis) of infected macrophages. The effect of cytokines (IFN- γ and TNF- α) either individually or in combination, was tested *in vitro* on MDM (monocyte derived macrophages) infected with *Mycobacterium tuberculosis* H37Rv strain. Our results suggest a critical role of IFN- γ and TNF- α in shifting the death of infected macrophages from necrosis towards apoptosis. This may have implications in the containment of infection.

Understanding antigen specificity of CD4⁺ T cell responses in *Salmonella* infection is key to vaccine design

Wang, N.¹, Schittenhelm, R.B.², Purcell, A.W.², Scott, T.A.³, Kupz, A.⁴, Bedoui, S.¹, Strugnell, R.A.¹

¹Peter Doherty Institute for Infection and Immunity at The University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia, ³Institute of Structural and Molecular Biology, University College of London, London, United Kingdom, ⁴Max Planck Institute for Infection Biology, Berlin, Germany

Pathogenic serovars of *Salmonella enterica* is one of the leading causes of gastroenteritis and febrile diarrhoeal diseases including typhoid fever invasive non-typhoidal *Salmonella* (NTS) infections. Despite the disease burden and rising prevalence of antibiotic resistance, a highly efficacious vaccine against *Salmonella* is still lacking. Elucidating immunogenic *Salmonella* antigens is critical to rational vaccine design, but it has not been successfully resolved to date.

We have recently generated a novel live-attenuated vaccine (LAV) strain of *Salmonella*, denoted TAS2010. We observed that vaccination with TAS2010 conferred superior protection against lethal infection with wild-type *Salmonella* compared to vaccination with the benchmark LAV strain, BRD509. In contrast to BRD509, vaccination with TAS2010 elicited significantly increased activation of CD4⁺ T cells, alongside with increased inflammation as marked by increased neutrophil recruitment and elevated production of cytokines such as IFN- γ , TNF- α and IL-6. The magnitude of immune activation is positively correlated with net bacterial load during the first two weeks

post-vaccination, suggesting a fundamental tension between immunogenicity and safety in *Salmonella* LAV design. Ongoing studies utilise the TAS2010 LAV to elucidate *Salmonella* antigens that are key to optimal vaccine efficacy. Our results suggest that the population of antigen-specific CD4⁺ T cells lack apparent structure of immunodominance but is most likely polyclonal, with each specificity contributing incrementally to overall protection, highlighting the importance of antigen diversity in effective immunity mediated by CD4⁺ T cells during *Salmonella* infection. We anticipate this work will provide critical information relevant for future development of efficacious *Salmonella* vaccines.

The plasmacytoid dendritic cells exert a tolerogenic function during a pulmonary model of fungal infection

Calich, V., Araújo, E., Medeiros, D., Araújo, V., Loures, F.
Institute of Biomedical Science, University of São Paulo,
Department of Immunology, São Paulo, Brazil

Paracoccidioidomycosis (PCM) is a systemic mycosis with the highest incidence in Latin America. A previous study has demonstrated that the resistance and susceptibility to *Paracoccidioides brasiliensis* were associated with diverse dendritic cell (DC) subpopulations. Furthermore, plasmacytoid DCs (pDCs), originally described as the main regulators of viral infections, was shown to promote an effective growth control of *Aspergillus fumigatus* hyphae. The purpose of this study was to evaluate the role of pDC during *P. brasiliensis* infection. pDCs were depleted in 129 mice with 250 µg of the anti-pDC antibody (BX44). The control group received equivalent doses of the GL113 antibody. After 72h, 2 and 8 weeks of infection with one million yeasts, the mice were sacrificed and several aspects of infection evaluated. The depletion resulted in a less severe disease. A higher frequency of activated T CD4⁺ and CD8⁺ lymphocytes was detected in the lungs of pDC-depleted mice when compared with control mice. In addition, the depletion resulted in a prominent expansion of Th1 cells and elevated numbers of activated macrophages and neutrophils to the lungs. The analysis of lung homogenates showed diminished levels of type I IFN as well as reduced levels of anti-inflammatory cytokines such as TGF-β and IL-10. Besides, reduced expression of Foxp3 (Treg) and indoleamine 2,3-dioxygenase (IDO) mRNA was found in the lungs of pDC-depleted mice. Taken together, our results suggest a non-redundant role of pDCs during *P. brasiliensis* infection, and demonstrate a tolerogenic function of these cells associated with Treg cells activation and IDO-mediated mechanisms.

Cross-talk between DNA break repair and chromosome conformation in developing lymphocytes

Collins, P.¹, Porter, S.¹, Purman, C.¹, Bednarski, J.¹, Sleckman, B.², Oltz, E.¹
¹Washington University, Pathology and Immunology, Saint Louis, United States, ²Cornell University, Department of Pathology and Laboratory Medicine, New York, United States

To maintain genomic stability, developing lymphocytes must deal with physiologic double strand breaks (DSBs) that are continually generated by the processes of V(D)J recombination. These genomic lesions must be repaired with high fidelity, minimizing oncogenic alterations such as chromosomal translocations. The DSB response leads to extensive revision of flanking chromatin, including phosphorylation of the histone variant H2AX (termed γ-H2AX), which spreads for 100s of kb from a DSB. In non-cycling cells, the γ-H2AX domain serves as a chromatin-based platform to facilitate repair by the non-homologous end joining (NHEJ) machinery. In this regard, mechanistic links between DNA repair and epigenetic landscapes around DSBs are beginning to emerge. A feature that may bridge these processes is the 3D conformation of chromatin flanking a DSB. However, the impact of DSBs on locus conformation and, conversely, the role of its reconfiguration in stabilizing DNA ends for repair, remain unexplored. We have used ChIP followed by sequencing to finely map and characterize γ-H2AX domains following persistent DSBs at antigen receptor (AgR) loci. We have discovered that DSBs in precursor lymphocytes induce compaction of chromatin over 100s of kb flanking DSB sites, paralleling the spread of γ-H2AX. This compaction of chromatin at broken Ig loci in pre-B cells is dependent upon a transducer of NHEJ signaling, 53BP1, which is recruited to the γ-H2AX domain. We provide evidence that conformational mechanisms are important to generate compact platforms for repair complexes and to spatially restrict DSBs from other regions of the genome.

1763

TLR4 plays a critical role in allowing the persistent, asymptomatic infection with a new commensal *Neisseria*

Powell, D.¹, Ma, I.^{1,2}, So, M.^{1,2}, Frelinger, J.^{1,2}
¹University of Arizona College of Medicine, Immunobiology, Tucson, United States, ²University of Arizona, BIO5 Institute, Tucson, United States

Bacteria of the *Neisseria* genus are part of the normal flora of many animals and humans. Two species, *Neisseria gonorrhoeae* and *Neisseria meningitidis*, are important human pathogens. A major limitation of studying *Neisseria* biology is the lack of a mouse model. Our group has isolated a new species of *Neisseria*, *N. musculi*, from a wild mouse that is able to colonize inbred CAST mice and persists in them at high levels for at least one year. Only CAST mice (among the 8 tested) are colonized and maintain high carriage levels indefinitely. B6 and B6-*rag*^{-/-} mice are relatively resistant to colonization. In contrast, B6 MyD88 deficient mice are colonized at high frequency and

high levels.

We compared the sequences of MyD88, CD14, TLR4, and MD2 in the 8 strains tested. The only unique coding polymorphism in CAST was found in the TLR4 gene. We hypothesized CAST mice might not recognize *N. musculi* lipopolysaccharide (LPS).

Splenocytes from CAST and C57BL/6 (B6) mice were stimulated with a variety of TLR ligands and secreted IL-1, IL-6 and TNF α were measured. Both strains of mice responded equally well to TLR9 ligand ODN, which requires functional MyD88; however, the response of CAST mice to purified *E. coli* LPS and intact *N. musculii* was diminished compared to B6. Thus, the diminished cytokine response was likely due to TLR4. To account for other differences in mouse strains we are currently expressing the TLR4s from both mouse strains in the same genetic background.

2028

Neuroinflammatory pathways and risk genes associated with Alzheimer's disease

Hodges, A.¹, Lim, Y.M.¹, Lupton, M.K.², Dumas, A.¹, King, A.³, Troakes, C.³, Murray, C.⁴, Lin, K.¹, Al-Sarraj, S.³, Kazakoff, S.², Waddell, N.², Pearson, J.V.², Sivakumar, L.¹, Papouli, E.⁵, Mirza, G.⁵, Saxena, A.⁵, Lashley, T.⁴, Powell, J.³

¹King's College London, Old Age Psychiatry, London, United Kingdom, ²QIMR Berghofer Medical Research Institute, Royal Brisbane Hospital, Brisbane, Australia, ³King's College London, Basic & Clinical Neuroscience, London, United Kingdom, ⁴University College London, Institute of Neurology, London, United Kingdom, ⁵NIHR Biomedical Research Centre, Genomics Core Facility, Guy's Hospital, London, United Kingdom

Growing evidence suggests inflammation contributes to Alzheimer's disease (AD). Activated microglia cluster around amyloid and correlate with disease symptoms. Inflammatory genes including TREM2 contribute to AD risk. We investigated whether additional rare variants in 112 genes from a TREM2 containing brain co-expression module may also contribute to AD risk. We also investigated the effects of TREM2 variants on microglia activation in post-mortem human brain to establish whether microglia behave similarly in AD patients regardless of their TREM2 genotype. We sequenced the exons of 144 genes (including controls) in 950 DNA samples from AD, MCI and control individuals. After de-multiplexing, alignment and quality control, we tested for variant association with AD. 80% of bases were covered at $\geq 12 \times$ read depth in the majority of samples. A number of rare variants were found to be associated with AD, suggesting multiple linked pathways may lead to AD vulnerability. Validation of these findings in independent cohorts is underway. We investigated microglia activation using the established markers CD68, Iba-1 and HLA in CA1 and CA4 hippocampal regions. AD/TREM2+ cases were found to have significantly fewer HLA and CD68-stained microglia compared to AD and control TREM2- cases, while Iba-1-stained microglia numbers were similar between groups. It appears having a TREM2 risk variant attenuates microglial activation in AD patients and there may be multiple points of vulnerability in microglia which can together contribute to AD pathology. These results have implications for strategies which target neuroinflammation to treat AD.

Immunogenetic traits of a heritable CD56+ cell population dysregulated in Multiple sclerosis: clinical utility and implications for pathogenesis

Booth, D.¹, McKay, F.¹, Gatt, P.¹, Fewings, N.¹, Parnell, G.¹, Schibeci, S.¹, Barnett, M.¹, Slee, M.², Kermode, A.³, McCauley, J.⁴, Stewart, G.¹, Vucic, S.¹

¹University of Sydney, Westmead Institute for Medical Research, Sydney, Australia, ²Flinders University, Neurology, Adelaide, Australia, ³University of Western Australia, Medicine, Perth, Australia, ⁴University of Miami, John P. Hussman Institute for Human Genomics, Miami, Australia

Multiple Sclerosis (MS) is a common neurological disease driven, in part, by an autoimmune response. Genes affecting susceptibility have been identified and indicate many immune cell subsets contribute to pathogenesis. Recent studies have identified that the proportion of some immune cell subsets in peripheral blood is highly heritable, such that environmental factors have limited effect on their relative populations in individuals over time. We recently identified that a population of CD56+ cells are under-represented in MS from studies of multiple cohorts. In whole blood this dysregulation is tagged by expression of the MS genetic risk factors EOMES and TBX21. From transcriptomic studies a module of genes co-regulated with these two has been identified. This module was confirmed in independent cohorts from Sydney, Perth, and Adelaide in Australia; and Miami in USA; and the correlated gene set is present in controls and people with MS. MS risk factor genes are over-represented in the module genes. The downregulated genes in MS control cytolytic activity and immune cell trafficking. Expression of the module genes is tightly associated with Vitamin D activation, suggesting an interaction of these environmental and genetic risk factors which may be tractable to therapeutic intervention. MS therapies fingolimod and tysabri affect this cell population. The clinical utility of this phenotype is discussed.

Diversity of Killer cell immunoglobulin-like receptors (KIRs) and HLA ligands in susceptibility to dengue infections in northeastern Thais

Chaisri, S.^{1,2}, Jumniansong, A.^{2,3}, Romphruk, A.V.^{2,4}, Leelayuwat, C.^{2,3}

¹Chulabhorn International College of Medicine (CICM), Thammasat University, Pathum Thani, Thailand, ²Khon Kaen University, Centre for Research and Development of Medical Diagnostic Laboratories (CMDL), Faculty of Associated Medical Sciences, Khon Kaen, Thailand, ³Khon Kaen University, Department of Clinical Immunology and Transfusion Sciences, Faculty of Associated Medical Sciences, Khon Kaen, Thailand, ⁴Khon Kaen University, Blood Transfusion Center, Faculty of Medicine, Khon Kaen, Thailand

Killer cell immunoglobulin-like receptors (KIRs) are cell surface receptors on natural killer (NK) cells and subsets of T cells. The interactions between KIRs and human leukocyte antigen (HLA) class I molecules on target cells can modulate function of NK cells in responses to infected or transformed cells. In order to study

genetic variations of *KIRs* and *HLA* ligands relevant to dengue infections, a case-control study was investigated in 253 dengue infections and 235 healthy controls in northeastern Thais (NETs) using polymerase chain reaction with sequence specific primer (PCR-SSP) technique. *KIR2DS1* was significantly increased in healthy control (47.2% vs 37.6%, $p = 0.030$), whereas *KIR2DL3* and *2DS4F* were significantly increased in dengue infections with 96.4% vs 90.2%, $p = 0.005$ and 61.7% vs 52.8.2%, $p = 0.028$, respectively. For analysis of *HLA* ligands, the frequencies of *HLA-C1* were significantly higher in the control group (97% vs, 92.1% $p = 0.017$), but *HLA-A11* was significantly lower in dengue infections (60.4% vs 78.7% $p < 0.001$). *KIR+HLA* combinations in dengue infections were analyzed. Consequently, a *KIR2DS4F+A11* combination was positively associated with dengue infections (49% vs 30.2%, $p < 0.001$), whereas a negative association of *KIR2DL2+ C1* was found (24.8% vs 38%, $p = 0.026$). Moreover, B haplotype showed a possible protective factor against dengue infections. This study indicates that the diversity of *KIR* and *HLA* ligands is associated with dengue infections. *KIR-HLA* interactions would play an important role in immune responses and susceptibility to dengue infections.

Identification of differentially methylated genes in purified disease relevant blood cell populations in patients with spondyloarthritis

Miceli-Richard, C.^{1,2}, Bugge Tinggaard, A.³, Wang-Renault, S.-F.³, Busato, F.³, Dougados, M.¹, Tost, J.³

¹Université Paris Descartes (Paris V), Rheumatology - Hôpital Cochin, Paris, France, ²Pasteur Institute of Paris, Immunoregulation, Paris, France, ³Institut de Génomique - Centre National de Génotypage - CEA, Epigenetics, Evry, France

Background: Spondyloarthritis (SpA) is a complex disease involving genetic, epigenetic and environmental contributions to disease risk.

Objective: This study aimed to perform a genome-wide DNA methylation analysis in sorted CD4 and monocytes from SpA patients compared with controls.

Methods: Genome-wide DNA methylation patterns were analyzed in cell-sorted (MACS) monocytes and CD4 T-lymphocyte populations from 24 SpA patients and 16 controls using the Illumina 450K Infinium Human Methylation 450K BeadChip allowing the simultaneous quantitative monitoring of more than 480,000 CpG positions.

Results: In CD4 cells 122 CpGs in 82 promoter regions of genes were found to be differentially methylated using stringent quality thresholds including several genes involved in disease-relevant signaling cascades such as Wnt-signaling and genes in which genetic polymorphisms have previously been associated with susceptibility to SpA. With 158 CpGs located in 86 promoter regions, slightly more genes were found to be differentially methylated in monocytes. Differentially methylated loci included again genes in Wnt signaling and bone metabolism, osteoblast or chondrocyte-specific genes as well as genes that have previously been shown to be implicated in related diseases such as psoriasis. A single gene was found differentially methylated in both monocytes and T-lymphocytes underlining

the importance to perform these epigenetic analyses in purified cell populations.

Conclusions: This study is the first to analyze genome-wide DNA methylation in purified disease-relevant blood cell populations in SpA bringing into evidence a moderate number of promoters whose deregulation might contribute to the pathogenesis of SpA.

4717

Association study involving polymorphisms in IL-6, IL1-RA, and CTLA4 genes and rheumatic heart disease in New Zealand population of Māori and Pacific ancestry

Azevedo, P.¹, Merriman, T.², Topless, R.², Sika-Paotonu, D.³, Crengle, S.⁴, Wilson, N.⁵, Percival, T.⁶, Lennon, D.⁷

¹Hospital Israelita Albert Einstein, Rheumatology, Sao Paulo, Brazil, ²University of Otago, Biochemistry, Dunedin, New Zealand, ³Victoria University of Wellington, GSNMH, Wellington, New Zealand, ⁴University of Auckland, Tomaiora Māori Health Research Centre, Auckland, New Zealand, ⁵Starship Children's Hospital, Paediatric Cardiology, Auckland, New Zealand, ⁶University of Auckland, Pacific Health, Auckland, New Zealand, ⁷University of Auckland, Paediatrics, Auckland, New Zealand

Introduction: Rheumatic Fever (RF) incidence among New Zealand (NZ) individuals of Māori and Pacific ancestry remains among the highest in the world. Polymorphisms in the IL-6, IL1RN, and CTLA4 genes have been associated with RF, and their products are modulated by new medications. Confirmation of these previous associations could help guide clinical approaches.

Objective: To test IL-6, IL1-RA (IL1RN), and CTLA4 functional SNPs in 204 rheumatic heart disease (RHD) patients and 116 controls of Māori /Pacific ancestry.

Method: Self-reported ancestry of the eight great-grandparents defined ancestry of participants. Severity of carditis was classified according to the 2012 World Heart Federation guideline for the echocardiographic diagnosis of RHD. The IL-6 promoter rs1800797, IL1RN rs447713 and CTLA4 rs3087243 SNPs were genotyped by Taqman. Correlations were assessed by logistic regression analysis adjusting for gender and ancestry.

Results: The IL-6 rs1800797 variant was significantly associated with RHD, being the carriers of the GG genotype 6.09 (CI 1.23; 30.23) times more likely to develop RHD than the carriers of the AA genotype ($p = 0.027$). No significant associations with RHD were found for IL1RN rs447713 and CTLA4 rs3087243. Patients carrying the G allele (GG plus AG genotype) for the IL1RN rs447713 SNP had 2.36 times (CI 1.00; 5.56) more severe carditis than those without this allele (the AA genotype) ($p = 0.049$).

Conclusion: The IL-6 promoter rs1800797 (-597G/A) SNP may influence susceptibility to RHD of people of Māori and Pacific ancestry living in NZ, and that the IL1RN rs447713 SNP may influence the severity of carditis in this population.

4193**Regulation of CD4 commitment is conserved between marsupial and placental mammals***Kappes, D.J., Hua, X., Mookerjee-Basu, J.**Fox Chase Cancer Center, Philadelphia, United States*

Lineage- and stage-specific transcriptional silencers play critical roles in control of gene expression and development. The ThPOK transcription factor acts as master regulator of CD4/CD8 lineage choice, which is necessary and sufficient for CD4 commitment. In mice, a silencer element (Sil^{ThPOK}) restricts ThPOK expression to MHC class II-restricted thymocytes. The Sil^{ThPOK} element is highly conserved at the DNA level between placental and marsupial mammals, raising the question of whether its function has also been preserved across this evolutionary span. To test this, we generated knockin mice, in which the murine Sil^{ThPOK} is replaced by the homologous marsupial (*Monodelphis domestica*) element. Remarkably, knockin mice display normal control of ThPOK transcription and lineage choice, indistinguishable from wt mice, as verified by crossing to MHC class I- and II-restricted TCR transgenes. Next we compared inherent functional properties of the ThPOK silencer with the CD4 silencer, another T lymphoid silencer, by carrying out reciprocal inter-chromosomal silencer swaps. Importantly, knockin mouse lines in which the Sil^{ThPOK} was replaced by the Sil^{CD4}, or vice versa, exhibited severe defects in CD4 expression and lineage-specification, indicating important inherent differences in their regulatory capacities. We show that the Sil^{ThPOK} encodes the unique capacity to discriminate between MHC class I- and class II-restricted TCR signals. Our data indicate that the function of the ThPOK silencer has been subject to severe evolutionary constraints, since at least the time of marsupial/placental divergence 165 million years ago, including the ability to respond selectively to MHC class II-restricted TCR signals.

Intestinal interleukin-17 receptor signaling mediates reciprocal control of the commensal microbiota and autoimmune inflammation

Kumar, P., Castillo, P., Kolls, J.

University of Pittsburgh, Department of Pediatric, Pittsburgh, United States

Despite recent advances in understanding the role of IL-17 in host immunity, its role in regulating enteric and systemic immune responses as well as its impact on the commensal microbiome has not been well studied. To further understand this, we have generated intestinal epithelial cells specific IL-17R knockout mice.

Our data shows that global (*Il17ra*^{-/-}) and intestinal epithelial cell specific (*Il17ra*^{fl/fl} *x villin* cre+) mice have overgrowth of segmented filamentous bacteria (SFB), suggesting a critical role of IL-17 signaling in SFB colonization. Higher SFB colonization in *Il17ra*^{fl/fl} *x villin* cre+ mice results in expansion of IL-17A and IL-22 producing Th17 cells. 16S microbial analysis demonstrated that the overall microbial community remained largely unchanged, however, a detailed analysis of operational taxonomic units (OTUs) revealed differential abundance of SFB, S24-7 and the *Clostridiales* family in *Il17ra*^{fl/fl} *x villin* cre+ mice. RNA sequencing data from mouse primary intestinal organoid and terminal ileum of SFB-colonized *Il17ra*^{fl/fl} *x villin* cre+ mice revealed a direct role of IL-17 in regulating *Nox1* (an apical NADPH oxidase) and *Pigr* expression. Furthermore, *Nox1*^{-/-} and *IgA*^{-/-} mice showed a higher degree of SFB colonization as compared to cohoused control WT mice. When subjected to experimental autoimmune encephalomyelitis, *Il17ra*^{fl/fl} *x villin* cre+ mice demonstrated earlier disease onset and worsened severity that was associated with increased intestinal *Csf2* expression and elevated systemic GM-CSF cytokine concentrations.

Our study highlights the importance of intestinal IL-17R signaling in the host-microbiome interaction and its impact on intestinal and peripheral autoimmune inflammation.

Changes of microbiota, and their metabolites, in the development of T1D

McLeod, K.H.¹, Stanley, D.², Richards, J.L.¹, Yap, Y.A.¹, Moore, R.³, Mackay, C.R.¹, Marino, E.¹

¹Monash University, Biochemistry, Clayton, Australia, ²Central Queensland University, School of Medical and Applied Sciences, Rockhampton, Australia, ³MIT University, School of Applied Sciences, Bundoora, Australia

The rise of autoimmune diseases, such as type 1 diabetes (T1D) in the western world over the last 60 years has been of concern. The leading hypothesis for the increased prevalence of autoimmune illnesses is due to changes in diet. Understanding the microbiota and its metabolites is important to understand the link between diet and the development of T1D. Studies in twins suggested that differences in diabetes progression in identical twins could be due to altered microbiota. Here we use diets rich in resistant starches to target colonic bacteria in the non-obese diabetic (NOD) mice. We found that high acetate-yielding diets induced protection in the NOD mice towards increased abundance of *Bacteroides* genus and increased production of microbial short chain fatty acid (SCFAs) acetate. Similarly, germ free (GF) NOD mice were re-colonized with fecal acetate-modified microbiota showed delayed onset of T1D and higher abundance *Clostridium* and reduced *Parabacteroides*. This is consistent with one study, abundance of bacterial species that either produce acetate, such as *Bifidobacterium adolescentis*, or *Clostridium cluster XIVa* or *IV* species (which produce butyrate from acetate), correlated inversely with a number of B-cell autoantibody specificities. Interestingly, protected GF NOD mice re-colonized with acetate-shaped microbiota showed increased CD4⁺Foxp3⁺ Treg cells in the PLN. This is consistent with bacterially-derived butyrate directly promoting Treg cell differentiation. Our study highlights an alternative approach for the treatment or prevention of T1D in humans- use of specialized diets that operate at many levels to correct defects in gut microbiota and immune homeostasis.

Anticancer probiotics: a novel tool of the oncological armamentarium

Daillère, R.¹, Vétizou, M.¹, Waldschmitt, N.², Chamaillard, M.², Plebanski, M.³, Cattoir, V.⁴, Gomperts Boneca, I.⁵, Zitvogel, L.¹

¹Gustave Roussy Cancer Campus, Villejuif, France, ²Institut Pasteur, Lille, France, ³Monash University, Melbourne, Australia, ⁴CHU de Caen, Caen, France, ⁵Institut Pasteur, Paris, France

The tumor microenvironment is influenced by anticancer therapies, and even more so by those affecting the gut homeostasis. We reported that a deviated repertoire of the intestinal microbiome called « dysbiosis », caused by broad spectrum antibiotics compromised the efficacy of

cyclophosphamide (CTX), an immunomodulatory alkylating agent exerting cytotoxic effects against cancer (Viaud, Science, 2013). Lately, we reported the importance of the gut microbiota in the efficacy of ipilimumab, a human monoclonal antibody targeting CTLA-4 (Vétizou, Science, 2015). Mechanisms underlying this gut-cancer axis in these two therapeutic contexts are different.

CTX is responsible for disrupting the gut barrier integrity as well as the intestinal homeostasis, allowing a NOD1/2-dependent translocation of several Gram-positive bacteria into secondary lymphoid organs. CTX breaks the intestinal tolerance towards the intestinal microbiota and leads to the immunization of the host against some bacterial strains. We identified a Gram positive bacteria, *Enterococcus hirae*, which markedly modulates the intestinal and systemic immunity through the elicitation of bacterial-specific Th1 and pathogenic Th17 cells. Moreover, we have shown that *E. hirae* is capable of enhancing tumor-specific CD4⁺ and CD8⁺ T cell responses against candidate tumor antigens. Finally, *E. hirae* specific-memory Th1 immune responses selectively predicted longer progression-free survival in advanced lung or ovarian cancer patients treated with immunotherapy and chemotherapy (platinum salts- or CTX-based chemotherapy).

Altogether, *E. hirae* represents a valuable probiotic against cancer, an oncobiotic ameliorating the efficacy of the most common alkylating immunomodulatory compound. Other oncobiotics discovered in the context of CTX will be presented at this meeting.

Early life host-microbiota interactions have lifelong consequences for humoral immunity

Poyntz, H.¹, Robinson, M.¹, Pitt, L.¹, Everitt, C.¹, Jones, A.¹, Plunkett, C.¹, van den Elsen, L.¹, Naidoo, K.¹, Jones, J.¹, Geuking, M.², McCoy, K.², Weyrich, L.³, Le Gros, G.¹, Forbes-Blom, E.¹

¹Malaghan Institute of Medical Research, Gut Inflammation, Wellington, New Zealand, ²University of Bern, Bern, Switzerland, ³University of Adelaide, Adelaide, Australia

The infant immune system co-evolves with the developing gut microbiota in a mutualistic relationship, providing signals that imprint immune health for life. Recent studies have demonstrated the immunomodulatory effects the microbiota exert on humoral immune development using germ-free mice and antibiotic treatment. However, examining the impact that naturally divergent gut microbial communities have on the development of humoral immunity remains to be elucidated.

We have developed a model system whereby two lines of BALB/c mice harbour naturally and prominently divergent gut microbiota compositions. These two lines of mice demonstrate disparate levels of immune activation, resulting in markedly different antibody responses. In turn, protective immunity to infectious disease and susceptibility to allergic disease is affected. Microbial transfer has identified a critical window in early life during which microbial imprinting of immune capability occurs and elucidated the key associated microbes. Taken together, we have established a critical window during the ontogeny of the immune system in which gut microbial composition may be therapeutically manipulated to promote optimal humoral immunity.

Depletion of gut microbiota protects against renal ischemia reperfusion injury by reducing bone-marrow derived monocyte and renal resident macrophage maturation status and function

Emal, D.¹, Stroo, I.¹, Rampanelli, E.¹, Butter, L.M.¹, Teske, G.J.¹, Claessen, N.¹, Stokman, G.¹, Florquin, S.^{1,2}, Leemans, J.C.¹, Dessing, M.C.¹

¹Academic Medical Center, University of Amsterdam, Department of Pathology, Amsterdam, Netherlands, ²Radboud University Nijmegen Medical Center, Department of Pathology, Nijmegen, Netherlands

Background: An accumulating body of evidence shows that gut microbiota play an important role in health and disease by modulating local and systemic immunity. The importance of the microbiome in the development of kidney disease is however largely unknown.

Methods: To study this, we depleted gut microbiota with broad-spectrum antibiotics and performed renal ischemia reperfusion injury (IRI) in mice. In addition, we analysed the function and phenotype of bone-marrow derived (BMD)-monocytes and renal resident macrophages from antibiotic-treated mice.

Results: Our results reveal that depletion of microbiota significantly attenuates renal damage, dysfunction, tubular integrity and remote organ injury after renal IRI. We found a significant reduction in expression levels of F480, chemokine receptors CX3CR1 and CCR2 in renal resident macrophages and BMD-monocytes from antibiotic-treated mice. In addition, our data present that BMD-monocytes from gut flora depleted mice are less responsive to TLR2 but not TLR4 ligands and have a decreased migration capacity compared to control mice. To study whether observed phenotype/effects were driven by depletion of microbiota, we performed fecal transplantation in antibiotic-treated mice and show that fecal transplantation restores the expression level of F480/CX3CR1/CCR2 and reverses the protective effect against renal IRI.

Conclusions: In conclusion, our data strongly indicate that signals from the gut microbiota are essential for priming of renal resident macrophages and BMD-monocytes. Therefore, renal resident macrophages from gut flora depleted mice are less responsiveness to ischemic insult, resulting in protection against renal IRI.

Molecular characterization of alpha-galactosylceramides from commensal Bacteroidales and their immunomodulatory functions to the host

Oh, S.F.^{1,2}, Zheng, W.¹, Iyer, S.², Gensollen, T.², Blumberg, R.S.², Kasper, D.L.¹

¹Harvard Medical School, Boston, United States, ²Brigham and Women's Hospital, Boston, United States

Education of the immune system by commensal microbiota is recognized as critical to host development. The basic molecular mechanisms and effectors of these such processes are of considerable interests. Recently, we have identified alpha-galactosylceramides (aGCs) from gut commensal *Bacteroides fragilis*, as having an immunomodulatory impact on host natural

killer T (NKT) cells in the early stage of life. We have carried out multi-pronged (microbiological, chemical and immunological) approaches to understand the biological relevance of these symbiotic factors. Untargeted lipidomic profiling of related commensal Bacteroidales and non-Bacteroidales revealed that the aGCs are unique and limited to only two of more than 20 gut commensal species studied, as opposed to the most of commensals in genera *Bacteroides*, *Prevotella* and *Porphyromonas* can synthesize ceramides. Genome-wide metabolomic screening of *B. fragilis* transposon library with high-throughput MALDI-TOF/TOF mass spectrometry has identified multiple responsible target loci for aGC biosynthesis and further genetic characterization is under way, along with the *in vivo* functional analysis with monoclonized mice model.

1273

Targeting gut microbial composition to enhance protective immunity against influenza

van den Elsen, L., Poyntz, H., Jones, A., Plunkett, C., Forbes-Blom, E. Malaghan Institute of Medical Research, Wellington, New Zealand

Influenza remains a substantial public health burden with significant rates of morbidity, mortality and economic loss. The efficacy of influenza vaccination could be improved. Toll like receptors (TLR) play an important role in promoting antibody responses and can also adjuvant vaccine-induced antibody responses. It has recently been demonstrated that TLR-mediated sensing of gut microbiota is required for antibody responses induced by influenza vaccine. We investigated the effect of gut microbial composition on protective immunity in two lines of BALB/c mice with divergent gut microbiota (BALB/c A versus B). BALB/c A showed significantly increased serum concentrations of IFN- γ , MCP-1 and IL-12p70 compared to BALB/c B, especially 6h following systemic LPS or CpG administration. Body weight loss after intranasal influenza infection with HKx31 (H3N2) was lower in BALB/c A. On the contrary, systemic immunization with influenza only protected BALB/c B mice from secondary intranasal influenza infection as a result of higher antibody production in this line of mice. Vaccination with trivalent inactivated influenza vaccine (TIV) resulted in higher primary and secondary (5 days post boost) immune responses in BALB/c B mice, as measured as TIV-specific antibody titers. In conclusion, the innate versus adaptive immune responses to influenza are differentially altered in these two lines of mice with divergent gut microbiota.

The effect of microbiome/Toll-like receptor interactions on susceptibility to type 1 diabetes

Jordan, M.A.¹, Stanley, D.², Moore, R.³, Crowley, B.¹, Baxter, A.G.¹

¹James Cook University, Comparative Genomics Centre, Townsville, Australia, ²Central Queensland University, School of Medical and Applied Sciences, Rockhampton, Australia, ³MIT University, Applied Sciences, Melbourne, Australia

Changes in microbiome, mucosal immunity and intestinal integrity have been associated with the onset of Type 1 Diabetes

(T1D) in children. Toll-like Receptors (TLR) have been associated all three factors. The role of TLR and their effects on microbiome in autoimmunity were studied by crossing TLR1,2,4,6,9 and MyD88 targeted deficiency mutations to the type 1 diabetes (T1D)-prone NOD mouse strain. While NOD.*Tlr9*^{-/-} and NOD.*Tlr6*^{-/-} mice were unaffected, T1D in NOD.*Tlr4*^{-/-} and NOD.*Tlr1*^{-/-} mice was exacerbated and that in NOD.*Myd88*^{-/-} and NOD.*Tlr2*^{-/-} mice ameliorated. Physical parameters of the intestines were compared; ileal weight was reduced in NOD.*Tlr1*^{-/-} mice. Similarly, by histology, these mice had reduced villus length and width. The intestinal microbiomes of NOD wild-type (WT), NOD.*Tlr1*^{-/-}, NOD.*Tlr2*^{-/-} and NOD.*Tlr4*^{-/-} mice were compared by high throughput sequencing of 16S ribosomal DNA (rDNA), in two cohorts, 18 months apart. Analysis of caecal 16S sequences clearly resolved the mouse lines and there were significant differences in beta diversity between the strains, with individual bacterial species contributing greatly to the differences in the microbiota of individual TLR-deficient strains. To test the relationship between microbiome and T1D, all strains were re-derived onto the parental NOD/Lt line and the incidence of T1D re-assessed within two generations. All rederived lines expressed an incidence of disease similar to that of the parental line. TLR deficiencies are associated with changes in microbiome; changes of microbiome are associated with T1D; the effects of TLR deficiencies on T1D appear to be mediated by their effects on gut flora.

An expansion of rare lineage intestinal microbes characterizes rheumatoid arthritis

Taneja, V.

Mayo Clinic, Rochester, United States

Genetic and environmental factors are involved in predisposition to develop rheumatoid arthritis (RA). Although the etiology of RA is unknown, recent studies on the role of gut microbiota in adaptive immune response have led to the concept that interaction between the host microbiome and genetic factors influences autoimmunity. In this study, we characterized intestinal microbiome signatures in patients with RA. 16S ribosomal DNA from fecal samples of RA patients and healthy non-RA comparator subjects were sequenced and analyzed for an association between variables of interest and the overall microbiota composition. The machine learning algorithm 'Random Forest' was used to build a predictive model, and identify the most discriminatory taxa between patients and controls. Patients with RA exhibited decreased gut microbial diversity compared to controls. Increased rheumatoid factor levels and disease duration were associated with decreased species richness and diversity ($P < 0.05$ and $P < 0.1$ respectively). PERMANOVA based on Bray-Curtis distance showed that the structure of the microbiota of patients with RA differed significantly from control subjects. A taxon-level analysis suggested an expansion of the rare taxa, Actinobacteria, with a decrease in abundant taxa in patients with RA compared to controls. Prediction models based on the Random Forests algorithm suggested that 3 genera segregated with RA. These observations suggest dysbiosis in patients with RA resulting

from the abundance of certain rare bacterial lineages. A correlation between the intestinal microbiota and metabolic signatures could determine a predictive profile for disease causation, progression, and drug efficacy.

Association of differential microbiota profile and cytokines expression levels at cervical level in the different stages of cervical cancer

Torres Poveda, K.J.¹, Audirac Chalifour, A.¹, Bahena Román, M.¹, Téllez Sosa, J.¹, Martínez Barnetche, J.¹, Delgado Romero, K.², Burguete García, A.¹, García Carrancá, A.³, Madrid-Marina, V.¹
¹Instituto Nacional de Salud Pública, Chronic Infections and Cancer Division, Cuernavaca, Mexico, ²Health Services of the State of Morelos, Capasam, Cuernavaca, Mexico, ³Instituto Nacional de Cancerología, Division of Basic Research, Cuernavaca, Mexico

The cervical cancer (CC) is given by HPV persistence due to the immunosuppressive tumor microenvironment generated by immunosuppressive cytokines such as IL-10. It is known that the vaginal microbiota determines the presence of certain cytokines locally. We assessed the association between cervical microbiota diversity and the histopathological diagnosis of each stage of CC, and evaluated IL-4, IL-6, IL-10, TGF- β 1, TNF- α and IFN-gmRNA expression levels in cervix across histopathological diagnosis and specific bacterial clusters. We determined cervical microbiota by High-throughput sequencing of 16S rDNA amplicons and classified it in community state types (CST). Mean difference analyses between alpha-diversity and histopathological diagnosis were evaluated. β -diversity analysis within histological diagnosis was carried out. Cytokine mRNA expression at the cervix level was analyzed across CST and histopathological diagnosis. We found a significant difference of microbiota diversity between NCL-HPV negative vs SIL and CC ($p=0.006$, $p=0.036$). When β -diversity was evaluated, the CC samples had the highest variation within groups ($p < 0.0006$) and largest distance compared to NCL-HPV negative ($p < 0.00001$). Predominant bacteria in women with normal cytology are *L. crispatus* and *L. iners*; *Sneathia* spp. in SIL and *Fusobacterium* spp. in CC. We found higher median levels of IL-4 and TGF- β 1 mRNA at the cervix level, in CST dominated by *Fusobacterium* spp. These results show that cervical microbiota may play a role in cervical cancer pathology.

The immune pathogenesis of neonatal infection: relevant to digestive health

Kent, P., Merani, S., Xu, G., Elahi, S.

University of Alberta, Edmonton, Canada

Neonates are highly susceptible to disseminated infections, which are often fatal. The mechanisms underlying the susceptibility of neonates to infections and the molecular basis for the transition of immunologic function from fetal to postnatal life has remained a mystery. While most vaccines do induce protective immunity in older children and adults, their efficacy in the very young often requires further manipulation

and optimization. Recently, we have reported that CD71⁺ erythroid cells are physiologically enriched in neonatal mice and human cord blood with distinctive immune suppressive properties. Our most recent data indicate that CD71⁺ cells impair neonatal adaptive immune responses by suppressing T cell functions *in vitro* and *in vivo*. In addition, CD71⁺ erythroid cells by expression of PD-1 ligands (PDL-1 and PDL-2) and production of TGF- β could play an essential role in immune regulation. More interestingly, CD71⁺ cell mediated susceptibility to infection is counterbalanced by protection against aberrant immune cell activation in the intestine where brisk postnatal colonization with commensal microbes occurs. CD71⁺ cells quench excessive upregulation of TLRs induced by abrupt commensal colonization after parturition. Our data provide new insight into the role of this novel subset of "suppressor cells" in immunopathogenesis of neonatal infections and immune regulation early in life.

The transcription factor Myb plays an important role in eosinophil development

Fairfax, K., Bolden, J., Lucas, E., Hilton, D.

Walter and Eliza Hall Inst, Parkville, Australia

Eosinophils are important immune modulators, involved in the early innate inflammatory response to many pathogens, the most studied of which is the helminth. They function by engulfing small pathogens and secreting many proteins including peroxidases, RNases and enzymes, that destroy large pathogens (and host tissue). They also secrete chemokines and cytokines that heighten subsequent immune responses. However, the genetic control of the development of eosinophils is poorly understood (in contrast to innate lymphocytes). Myb is an important transcription factor involved in both erythroid and lymphocyte lineage specification, and our expression data shows it is highly expressed in eosinophil precursors, and present in eosinophils. Published data suggests Myb hypomorphs are eosinophil deficient, therefore we set out to examine the role of Myb in eosinophil development. In contrast to published reports, we show that Myb hypomorphic (Myb^{Plt4/Plt4}) mice do have eosinophils, however, these eosinophils have substantially altered side scatter properties (and thus are not detected using differential blood analysis). RNAseq and ELISA data suggests these eosinophils have reduced expression of a number of genes important for eosinophil function, such as eosinophil peroxidase. The eosinophils from Myb^{Plt4/Plt4} mice still resemble eosinophils by cyto-spin and TEM, however, preliminary experiments show a reduction in the number of crystalloid granules. Thus these cells resemble something that may represent an immature eosinophil. *In vitro* differentiation and *in vivo* challenge experiments show Myb^{Plt4/Plt4} eosinophils develop and recruit normally up to a certain stage, but are unable to mature into fully functional mature eosinophils *in vivo*.

The use of *ex vivo* expanded human invariant natural killer T cells as a novel cell therapy to modulate graft versus host disease

Im, J.S.¹, He, H.², Besra, G.³, Shpall, E.J.², Porcelli, S.⁴, Molldrem, J.M.²

¹The University of Texas MD Anderson Cancer Center, Stem Cell Transplantation and Cellular Therapy, Houston, United States,

²The University of Texas MD Anderson Cancer Center, Houston,

United States, ³The University of Birmingham, Birmingham, United Kingdom, ⁴Albert Einstein College of Medicine, Bronx, United States

CD1d-restricted invariant Natural Killer (iNK) T cells are innate cells that can influence adaptive immunity toward inflammation or immune-suppression via production of Th1-type or Th2-type cytokines, respectively. Several studies suggest that iNK T cells may play a role in preventing graft versus host disease (GVHD) in allogeneic stem cell transplantation (ASCT), thus can become novel therapy to prevent GVHD in ASCT. Here, we sought to compare phenotypic and functional differences of expanded iNK T cells from cord blood (CB) and adult PBMC, and evaluated the modulatory property in a murine xenograft GVHD model. We successfully expanded polyclonal iNK T cells from CB or adult PBMC to a greater than 90% purity via co-culturing enriched iNK T cells with dendritic cells in the presence of α -GalCer and IL-2. Expanded CB iNK T cells were mostly CD4⁺CD25⁺Foxp3⁺ and preferentially produced Th2-type cytokines, while adult iNK T cells contained a varying degree of CD4⁺ and preferentially produced Th1 type cytokines. Despite preferential Th1 type responses, adult iNK T cells showed a trend towards decreased GVHD-related mortality in murine xenograft GVHD model (HR 0.3921, $p=0.0712$). In summary, we demonstrated it is feasible to selectively expand iNK T cells from CB and adult PBMC, and that expanded CB iNK T cells maintained regulatory phenotype and function, suggesting that CB might be a preferred source for iNK T cell therapy to modulate GVHD in ASCT. Further investigation is needed to delineate unique regulator-effector function of CD4⁺ vs CD4⁻ iNK T cells in modulating GVHD.

Regulation of T cell receptor signaling by lipid metabolites

Wang, F.¹, Beck-García, K.², Zorzín, C.², Schamel, W.², Davis, M.¹

¹Stanford University, Stanford, United States, ²University of

Freiburg, Freiburg, Germany

Most adaptive immune responses require the activation of specific T cells through the T cell receptor/CD3 complex (TCR). Here we show that cholesterol sulfate (CS), a naturally occurring cholesterol metabolite, inhibits CD3 ITAM phosphorylation, a crucial first step in T cell activation. Biochemical studies show that CS disrupts TCR multimers, apparently by displacing cholesterol, known to bind TCR β . Moreover, CS deficient mice show a heightened sensitivity to a self-antigen, whereas increasing CS levels by intrathymic injection inhibits thymic selection, indicating that this molecule is an intrinsic regulator of thymocyte development. These results show a novel regulatory role for sterol metabolism in TCR signaling and thymic selection, highlighting the importance of the membrane microenvironment in modulating cell surface receptor activation.

4633**Antigen-linked rather than T_{FH} cell-derived signals select high affinity germinal centre B cells for plasma cell differentiation**

Suan, D.¹, Krautler, N.^{1,2}, Butt, D.¹, Bourne, K.¹, Hermes, J.¹, Schofield, P.¹, Jackson, J.¹, Phan, T.G.¹, Christ, D.¹, Brink, R.¹

¹Garvan Institute, Darlinghurst, Australia, ²ETH Zurich, Zurich, Switzerland

Preferential activation of high affinity germinal centre (GC) B cells provides the basis for serological immune protection and vaccine efficacy. Within GCs, B cells undergo somatic hypermutation (SHM) to modify the specificity of their clonally-defined B cell antigen receptor (BCR). Rare clones developing increased antigen affinity are either retained in the GC (positive selection) or differentiate into plasma cells (PCs) that secrete high-affinity antibodies. The key stimuli for GC B cells reside in the light zone (LZ) in the form of intact antigen held on follicular dendritic cells (FDCs) and T follicular helper (T_{FH}) cells that bind to processed antigenic peptides presented on the B cell surface. Whilst preferential provision of T_{FH}-derived help is thought to mediate the selective activation of high-affinity B cells, direct validation of this is lacking. To resolve this issue, we developed the capability to directly identify and compare high and low affinity GC B cells. High affinity LZ B cells (LZhi) showed greater cell cycle activation compared to low affinity cells (LZlo) but did not possess a gene expression signature consistent with preferential reception of T_{FH} cell help. Indeed, initiation of PC differentiation within the LZhi compartment did not require T_{FH}-cell help but was instead dependent on signals derived from direct engagement of intact antigen. T_{FH}-cell derived signals were subsequently required for the progression of PC differentiation and the migration of mature PCs out of the GC.

4450**Identification of broadly conserved cross-species protective Leishmania antigen and its responding CD4⁺ T cells**

Mou, Z., Okwor, I., Uzonna, J.

University of Manitoba, Immunology, Winnipeg, Canada

Recovery from natural or experimental infection with *Leishmania major* induces long-term protection to reinfection collectively known as infection-induced resistance. However, it is not known what antigens induce and maintain this resistance and whether these antigens preferentially favor the development of memory T cells. To identify protective *Leishmania* antigens, we eluted and identified naturally processed *L. major* peptides were from I-A^b MHC II molecules on infected BMDCs and by immunoproteomics approach. One of the peptides activated *Leishmania*-reactive T cells from mice that have healed their primary *L. major* infection *in vitro*. Interestingly, the source protein of this peptide, glycosomal phosphoenolpyruvate carboxykinase (PEPCK), was expressed in both the promastigote and amastigote stages of the parasite. Also, cellular immune responses against PEPCK were detected in *L. major*-infected patients, while antibody responses were detected in infected mice, dogs and human. I-A^b-PEPCK₃₃₅₋₃₅₁ tetramer identified for the first time protective *Leishmania*-specific CD4⁺ T cells at

clonal level, which comprised ~ 20% of all *Leishmania*-reactive CD4⁺ T cells at the peak of infection. PEPCK₃₃₅₋₃₅₁-specific CD4⁺ T cells are oligoclonal in their TCR usage, produce polyfunctional cytokines (IL-2, IFN- γ and TNF) and undergo expansion, effector activities, contraction and stable maintenance following lesion resolution. Vaccination with PEPCK peptide, DNA expressing full length PEPCK or rPEPCK induced strong durable cross-species protection in both resistant and susceptible mice. Given the remarkable effectiveness and durability of protection in vaccinated mice, our study suggests a real possibility for development of a broadly cross-species protective vaccine against different forms leishmaniasis by targeting PEPCK.

4360**LYVE-1 expressing macrophages as gatekeepers of large blood vessel homeostasis**

Angeli, V.¹, Lim, H.Y.¹, Lim, S.Y.¹, Tan, C.K.T.², Goh, C.C.G.³, see, P.³, Tan, N.S.T.², Ng, L.G.³, Ginhoux, F.³

¹National University of Singapore, Singapore, Singapore, ²Nanyang Technological University (NTU), Singapore, Singapore, ³A*STAR, Singapore, Singapore

Although lymphatic vessel endothelial hyaluronic acid receptor-1 (LYVE-1) is a specific marker for lymphatic vessels, it has also been reported on some tissue macrophages. However, the function of these macrophages has been largely overlooked and limited to embryonic development. Unexpectedly, imaging of adult skin, trachea and aorta revealed that LYVE-1 expressing macrophages are lining the outer layer of vessels exhibiting smooth muscle cells (e.g veins, arteries/arterioles) but not those displaying pericytes (capillaries). Parabiosis, bone marrow transplantation and fate-mapping revealed that these tissue-resident macrophages derive from fetal monocyte and mainly sustain in adulthood through self-renewal. Comparative gene-expression analysis showed that LYVE-1+ macrophages exert homeostatic rather than immune functions. Consistent with this, we found that severe depletion of LYVE-1+ macrophage in aorta following colony stimulating factor receptor-1 inhibition leads to arterial wall remodeling and arterial stiffness characterized by changes in collagen and elastin and decreased smooth muscle cell contractility. We have evidence that LYVE-1+ macrophages mediate this homeostatic function by acting in part on smooth muscle cells. Altogether, our data reveals LYVE-1+ macrophages as a previously unrecognized perivascular population of macrophages that are essential for maintaining large blood vessel integrity and function.

4728**Tissue-resident ILC2 and inflammatory ILC2: two distinct ILC populations**

Huang, Y.¹, Mao, K.², Chen, X.¹, Kawabe, T.¹, Zhu, J.¹, Urban Jr., J.F.³, Germain, R.N.², Paul, W.E.¹

¹National Institute of Allergy and Infectious Diseases, National Institutes of Health, Laboratory of Immunology, Bethesda, United States, ²National Institutes of Health, Laboratory of System Biology, National Institute of Allergy and Infectious Diseases, Bethesda, United States, ³Beltsville Human Nutrition Research

Center, Agricultural Research Service, USDA, Diet, Genomics, and Immunology Laboratory, Beltsville, United States

Innate lymphoid cells (ILCs) have important functions not only in immune defense against pathogens but also in allergy, inflammation, tissue remodeling and metabolic homeostasis. ILCs are generally considered as tissue-resident cells in the intestine, lung, skin and other mucosal surfaces, but ILC subsets have been also identified in non-mucosal sites, such as lymphoid organs and adipose tissues. We have reported the existence of a distinct ILC population, which is not present in these tissues under steady state conditions but appears in high numbers in lung, liver, mesenteric lymph nodes and spleen upon systemic administration of the cytokine IL-25 or *Nippostrongylus brasiliensis* infection. This cell population has been termed "inflammatory ILC2", as it only appears in diverse tissues under inflammatory circumstances (*Nat Immunol.* 2015 Feb; 16(2): 161-9). Inflammatory ILC2 cells develop into natural ILC2-like cells *in vitro* and *in vivo* and contribute to the expulsion of *N. brasiliensis*. They can also acquire IL-17-producing ability and provide partial protection against *Candida albicans*, indicating their multipotentiality or plasticity. Very recent experiments reveal that inflammatory ILC2 cells are not generated in peripheral, non-gut tissues *in situ*; they are circulating cells and are well exchanged in parabiosis mice in contrast to natural ILC2 cells that are tissue-resident in the steady state and barely exchange in parabiotic mice. Thus, inflammatory ILC2 cells are a unique circulating ILC population that is distinguishable from tissue-resident ILC subsets and that plays an important role in peripheral tissue host defense.

This research was supported by the Intramural Research Program of NIAID, NIH.

Bile acids control inflammation and metabolic disorder through inhibition of NLRP3 inflammasome

Guo, C., Xie, S., Chi, Z., Wang, D.

Institute of Immunology, School of Medicine, Zhejiang University, Hangzhou, China

Reciprocal interactions between the metabolic system and immune cells play pivotal roles in the pathogenesis of a variety of inflammatory diseases, but the underlying mechanisms are still unclear. The activation of bile acid-mediated signaling has been linked to improvement in metabolic syndromes and enhanced control of inflammation. Here, we demonstrate that bile acids inhibit NLRP3 inflammasome activation via the TGR5 signaling. TGR5 signaling induces the phosphorylation of NLRP3 on a single, evolutionarily conserved residue. Importantly, the TGR5-induced phosphorylation leads to the ubiquitination of NLRP3, and this serves as a critical brake on NLRP3 inflammasome activation. Several gain-of-function mutations in *Nlrp3* that cause cryopyrin-associated periodic fever syndromes (CAPS) disrupt the phosphorylation and ubiquitination of NLRP3 *in vitro*, potentially allowing the uncontrolled CAPS-associated activation of the NLRP3 inflammasome. In addition, *in vivo* results indicate that TGR5 activation blocks NLRP3 inflammasome-dependent inflammation, including

lipopolysaccharide-induced systemic inflammation, alum-induced peritoneal inflammation, and type-2 diabetes-related inflammation. Altogether, our study unveils a novel mechanism with combinational post-translational modifications of the NLRP3 protein through which bile acids endogenously constrain NLRP3-related inflammation. Thus, pharmacological targeting of TGR5 may be a potential strategy for the treatment of NLRP3 inflammasome-related diseases.

²Research Institute for Sustainable Humanosphere, Kyoto University, Kyoto, Japan, ³Department of Life Science, Gakushuin University, Tokyo, Japan, ⁴Osaka City Institute of Public Health and Environmental Sciences, Osaka, Japan, ⁵Medical Mycology Research Center, Chiba University, Chiba, Japan, ⁶Graduate School of Biostudies, Kyoto University, Kyoto, Japan

RIG-I-like receptor (RLR) plays a pivotal role in the detection of invading pathogens to activate type I interferon (IFN) gene transcription. Since aberrant IFN production is harmful to the host, RLR signaling is strictly regulated. However, the regulatory mechanisms are not fully understood. By expression cloning, we identified Pumilio proteins, PUM1 and PUM2, as candidate positive regulators of type I IFN induction. Overexpression of Pumilio proteins and their knockdown augmented and diminished IFN- β promoter activity induced by Newcastle disease virus (NDV), respectively. Both proteins showed a specific association with LGP2, but not with RIG-I or MDA5. Furthermore, all of these components were recruited to NDV-induced antiviral stress granules. Interestingly, biochemical analyses revealed that Pumilio increased double-stranded (ds) RNA binding affinity of LGP2; however, Pumilio was absent in the dsRNA-LGP2 complex, suggesting that Pumilio facilitates viral RNA recognition by LGP2 through its chaperon-like function. Collectively, our results demonstrate an unknown function of Pumilio in viral recognition by LGP2.

PU.1 and SPI-B transcription factors mediate Ig light chain accessibility during B cell development

Batista, C.R.¹, Solomon, L.A.¹, Xu, L.S.¹, Li, S.K.H.¹, DeKoter, R.P.^{1,2}

¹Western University, Microbiology & Immunology, London, Canada,

²Centre for Human Immunology, London, Canada

PU.1 and Spi-B are members of the E26 transformation-specific family of transcription factors and regulate the transcription of genes important for B-cell development. Mice carrying a conditional deletion of PU.1 in the absence of Spi-B, under the control of the *Cd79a* gene, show a severe block in B cell development in the bone marrow at the stage at which B

cells undergo rearrangement of immunoglobulin light chain genes (IgL). Therefore, we hypothesized that PU.1 and Spi-B are pioneer transcription factors mediating accessibility and rearrangement of IgL chain genes. In order to test this, we reintroduced PU.1 expression using a doxycycline-inducible system in an IL-7-dependent PU.1 and Spi-B knockout pro-B cell line lacking IgL rearrangements. We performed RNA and chromatin immunoprecipitation (ChIP) sequencing analysis to determine differential gene expression and the PU.1 binding profile in pro-B cells. We found that PU.1 changed the expression of 4528 genes, and bound to approximately 49,000 regions in the mouse genome. PU.1 peaks were identified at several sites in the immunoglobulin kappa (Igκ) and lambda (Igλ) chain loci, including in the Igκ3' and Igλenhancers. PU.1 bound to *Rag1* and *Rag2* genes and induced their transcription. PCR analysis confirmed that PU.1 induced transcription of unarranged Vκ regions, as well as rearrangement of the Igκ locus, indicating a role for PU.1 and Spi-B in controlling IgL accessibility for RAG-mediated rearrangement. Our findings point out a key role for PU.1 and Spi-B as pioneer factors mediating the pre-B cell checkpoint during bone marrow B cell development.

Complete degradation of CD74-invariant chain by the endopeptidase SPPL2A is necessary for B cell survival

Bergmann, H.¹, Vega-Ramos, J.², Yabas, M.¹, Barthel, N.¹, Young, C.¹, Goodnow, C.C.³, Villadangos, J.², Enders, A.¹

¹John Curtin School of Medical Research, Department of Immunology and Infectious Disease, Canberra, Australia, ²The University of Melbourne, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ³Garvan Institute of Medical Research, Immunology Division, Sydney, Australia

Mice lacking the intramembrane protease SPPL2A exhibited profound humoral immunodeficiency and specifically lack most mature B cells. Surviving B cells are characterized by low surface expression of the B-Cell Receptor (BCR) and BAFF-Receptor (BAFFR) and do not produce specific antibodies in response to immunizations. Mature B cell accumulation, but not expression of the BCR and BAFFR could be rescued by over-expression of the pro-apoptotic protein BCL2, indicating a survival defect of mature B cells.

On a molecular level we identified SPPL2A as the long sought-after, final enzyme in the sequence of CD74 (MHC II invariant chain) cleaving proteases. In the absence of SPPL2A the ultimate step of CD74 degradation is blocked. This causes a dramatic build-up of short N-terminal CD74 peptide fragments including the p8 product of Cathepsin S processing in the MHCII antigen presenting compartment. Accumulation of CD74 fragments was responsible for the cellular phenotype as deletion of CD74 in SPPL2A deficient animals reconstituted mature B cell numbers to levels seen in mice solely deficient in CD74, and also restored surface BCR and BAFFR expression. Despite a very similar accumulation of CD74 fragments, the observed cellular phenotype in SPPL2A^{-/-} mice strongly contrasts with the phenotype observed in Cathepsin S^{-/-} mice. Furthermore, block of CD74 egress from the ER through loss of MHCII did not prevent accumulation of CD74 N-terminal fragments. Taken together,

these results show a novel mechanism of CD74 degradation in B cells that is essential for B cell survival and function.

Defining antigen specific plasmablast and memory B cell subsets in blood following viral infection and vaccination of humans

Ellebedy, A.¹, Jackson, K.², Boyd, S.², Ahmed, R.³

¹Emory University, Atlanta, United States, ²Stanford University, Stanford, United States, ³School of Medicine, Emory University, Atlanta, United States

Upon antigen exposure B cells eventually bifurcate into two functionally and phenotypically distinct subsets, plasmablasts and memory B cells. We previously reported that plasmablasts or antibody-secreting cells (ASCs) are transiently detected in blood shortly after infection or vaccination of humans. Here, we define the phenotype and the transcriptional program of a novel human antigen-specific B cell subset, referred to as activated B cells (ABCs). ABCs do not spontaneously secrete antibodies and possess a unique transcriptional profile that distinguishes them from ASCs and resting memory B cells. The clonal lineages of ABCs and ASCs are partially overlapping, and both show elevations in frequency among day 90 memory B cell pool compared to pre-vaccination levels, suggesting that they both contribute to longer-term B cell memory. ABCs and ASCs are clearly distinguishable in blood following influenza and Ebola virus infections in humans. Our data clearly suggest that ABCs could potentially be precursors for long-term memory B cells. Defining and studying ABCs along with ASCs in humans will reveal the intrinsic differences between B cells constituting the two compartments of humoral immune memory, which in turn could enhance our understanding of how to make better vaccines.

Blimp1 controls plasma cell function through regulation of immunoglobulin secretion and the unfolded protein response

Tellier, J.^{1,2}, Shi, W.^{3,4}, Minnich, M.⁵, Liao, Y.^{2,3}, Crawford, S.⁶, Smith, G.K.^{3,7}, Kallies, A.^{1,2}, Busslinger, M.⁵, Nutt, S.L.^{1,2}

¹Walter & Eliza Hall Institute, Molecular Immunology, Parkville, Australia, ²The University of Melbourne, Medical Biology, Parkville, Australia, ³Walter & Eliza Hall Institute, Parkville, Australia, ⁴The University of Melbourne, Computing and Information Systems, Parkville, Australia, ⁵Research Institute of Molecular Pathology (IMP), Vienna, Austria, ⁶The University of Melbourne, School of BioSciences, Parkville, Australia, ⁷The University of Melbourne, Mathematics and Statistics, Parkville, Australia

The differentiation of plasma cells requires resetting of gene expression to silence B-cell transcription, whilst establishing antibody-secretory function and long-term survival. The transcription factors Blimp1 and Irf4 are essential for the initial differentiation of plasma cells, however their function in mature plasma cells has remained elusive. We have found that while Irf4 was essential for plasma-cell survival, Blimp1 was dispensable.

Blimp1-deficient cells retained the plasma-cell transcriptional signature, but lost the ability to secrete antibody. Blimp1 regulated many components of the unfolded protein response (UPR), including Xbp1 and Atf6. The overlap of Blimp1 and Xbp1 function was restricted to the UPR, with Blimp1 uniquely regulating mTOR activity and plasma cell size. Thus, Blimp1 is required for the unique physiological capacity of plasma cells that enables the secretion of protective antibody.

844 miRNAs are critical for the regulation of RAG expression and secondary Ig rearrangement in peripheral B lymphocytes

Coffre, M.¹, Benhamou, D.², Riess, D.³, Blumenberg, L.¹, Snetkova, V.¹, Chakraborty, T.³, Jensen, K.³, Chong, M.¹, Blleloch, R.⁴, Littman, D.¹, Skok, J.¹, Melamed, D.², Rajewsky, K.⁵, Korolov, S.¹

¹NYU School of Medicine, Dept of Pathology, New York, United States, ²Technion, Haifa, Israel, ³Harvard Medical School, Children's Hospital Boston, Boston, United States, ⁴UCSF, Urology, San Francisco, United States, ⁵Max Delbruck Center, Berlin, Germany

The differential expression of miRNAs throughout B cell development suggests that these ncRNAs contribute to stage-specific regulation of the intricate transcriptional program during B cell differentiation. Conditional ablation of Dicer or deletion of the miR-17~92 cluster in pro-B cells, revealed a critical role of miRNAs in B cell differentiation.

In the present study we analyzed mice in which enzymes critical for miRNA biogenesis, Dicer, Drosha and DGCR8 are conditionally ablated in B lymphocytes. Global ablation of miRNAs in B lymphocytes lead to an early block in B cell development. Rescue of B cell survival by overexpression of the anti-apoptotic factor Bcl2 revealed that in the absence of miRNAs, B cells in the periphery expressed low levels of Ig heavy chain without expressing light chain. We demonstrate that miRNA-deficient B cells fail to regulate recombination machinery in the periphery, resulting in ongoing Ig light chain gene rearrangement. In addition to the upregulation of RAG1/2 in peripheral B cells, we demonstrated ongoing DNA double strand breaks at Ig loci and upregulation of surrogate light chain components. We show that these events occur downstream of deregulated PI3K signaling and we recapitulate many of these defects in wild-type B lymphocytes by targeting individual components of PI3K signaling network. Furthermore, we achieve complete rescue of miRNA deficient B cells when we introduce a pro-survival Bcl2 transgene along with an Ig transgene resistant IgL editing. Our data highlight an important and novel role for miRNAs in the maintenance of a mature phenotype in peripheral B cells.

3644 Differential responsiveness of IgM and IgD B cell receptors regulate early B cell development and the activation of mature B cells

Übelhart, R.¹, Surova, E.², Iype, J.², Reth, M.², Juma, H.¹

¹University Hospital Ulm, Institute of Immunology, Ulm, Germany,

²Albert Ludwigs University Freiburg, Centre for Biological Signaling Studies (BIOSS), Freiburg, Germany

During development, B cells express IgM and IgD variants of their BCR. However, despite possessing similar antigen specificity, it is unclear why B cells shift from IgM to IgD during maturation. We have recently demonstrated that IgM-BCR possess the characteristic property of inducing signaling in response to monovalent antigens, while IgD-BCR required polyvalent antigens for activation.

To further confirm our findings, we addressed the function of IgM and IgD in the context of an autoreactive BCR expressed at the immature B-cell stage. While IgM efficiently supported BCR editing in response to the low-affinity autoantigen, expression of IgD supported editing of the autoreactive idiotype only upon engagement with the high-affinity autoantigen. Retention of the autoreactive IgD-BCR idiotype in the presence of the low-affinity autoantigen is accompanied by the loss of allelic exclusion of the Ig heavy-chain gene. In order to show that these findings also apply for human B cells, we generated a human mature BCR-deficient B-cell line and reconstituted expression of IgM- and IgD-BCRs with defined antigen specificities. We found that human mature B cells behave similar to murine B cells in that monovalent antigen stimulated only IgM-expressing cells, while those expressing IgD required polyvalent antigen for activation.

Taken together, these data demonstrate that the low activation threshold of IgM-BCR is essential for early B cell development and selection, while the increased expression of IgD on mature B cells is important for selective responses towards polyvalent antigens in immune complexes.

22 Effects of neonatal microbial exposure on B cell development and protection against allergic and autoimmune disease

Kearney, J.F.

University of Alabama at Birmingham, Microbiology, Birmingham, United States

Our goals in this project are to identify factors affecting the establishment of the mouse B cell clonal repertoire reactive to polysaccharide (PS)-associated epitopes expressed by a select group of bacteria and also occurring as self neo-epitopes. The antibody response to PS in immunized neonatal mice is delayed and protracted and follows similar kinetics regardless of the age at immunization. These results suggest that the advent of antibody production to PS antigens following neonatal immunization may reflect the maturation of the system more than expansion of antigen specific clones. Neonatal immunization (Day 3 v14) with *Streptococcus pyogenes* (expressing GlcNAc residues on the cell wall PS) results in identical alterations in the repertoire in absence of increased antibody titers convincingly demonstrating that these two effects are decoupled. Detailed examination of the anti-GlcNAc repertoire in single B cells shows a restriction in IGvH usage but includes many different nucleotide CDR3 sequences, however there is a remarkable degree of identical public translated protein sequences indicating a strong role for antigen selection in the development of the anti-GlcNAc B cell repertoire. Our preliminary studies of germ-free mice show that the commensal intestinal flora has a strong influence on

the selection and composition of the peripheral splenic B cell anti-GlcNAc repertoire. Finally we show that neonatal but not adult exposure of mice to bacteria has protective effects against the development of allergic airway disease to multiple allergens and dampens the development of type one diabetes in NOD mice. Supported by NIAID AI100005, AI14782 and JDRF.

Early B cell development requires balanced expression of miR-191

Blume, J., Lyszkiewicz, M., Witzlau, K., Krueger, A.

Hannover Medical School, Institute for Immunology, Hannover, Germany

B cell development is a tightly regulated process yielding cells capable of producing highly diverse antibodies by random rearrangement of the B cell receptor gene loci. MicroRNAs (miRs) have been reported to regulate hematopoiesis by influencing transcription factor networks. However, little is known about individual miRs influencing lineage fate and development in the B cell lineage.

We found that miR-191 is dynamically regulated during B cell development and activation and identified three transcription factors E2A, Foxp1 and Egr-1 as direct targets of miR-191. In consequence, ectopic expression of miR-191 led to an accumulation of preB1 cells at the expense of later developmental stages in bone marrow chimeras. This developmental delay was possibly due to down-regulation of the rearrangement machinery during heavy chain recombination and reduced IL-7R α expression. Furthermore, we detected increased levels of apoptosis during negative selection upon overexpression of miR-191. Forced expression of E2A or FoxP1 was able to rescue the block in B cell development introduced by ectopic expression of miR-191.

Aggressiveness of diffuse large B cell lymphoma (DLBCL) is correlated to high expression of Foxp1. Consequently, overexpression of miR-191 reduced expression of Foxp1 in DLBCL lines and resulted in increased levels of apoptosis in DLBCL and thereby inhibited tumor formation and expansion in immunodeficient mice.

Overall, our results suggest that modulation of miR-191 expression is required to maintain balanced B cell development and differentiation.

AP4 mediates resolution of chronic viral infection through amplification of germinal center B cell responses

Chou, C., Verbaro, D., Tonc, E., Cella, M., Colonna, M., Bhattacharya, D., Egawa, T.

Washington University School of Medicine, Pathology and Immunology, Saint Louis, United States

B cells undergo clonal expansion and somatic hypermutation in the germinal center (GC) in response to survival and proliferation signals provided by follicular helper T (T_{FH}) cells. This interaction with T_{FH} cells induces transient c-MYC expression in non-cycling GC B cells in the light zone (LZ), however, B-cell proliferation

occurs after migration into the dark zone (DZ), paradoxically after their separation from T_{FH} cells in the LZ and the extinction of c-MYC expression. Here, we resolve this paradox by showing that the transcription factor AP4, which functions downstream of c-MYC to control the gene expression programs related to cellular growth and survival, is responsible for expansion of GC B cells in the DZ and for diversification of BCR repertoires required for protective antiviral immunity. AP4 is initially induced by c-MYC in the LZ, but is sustained by IL-21 produced by T_{FH} in a c-MYC-independent manner. These results indicate that AP4 integrates T-cell help signals in response to affinity selection in the LZ to drive GC B cell clonal expansion at a distance in the DZ.

Activation induced cytidine deaminase (AID) expression in human B-cell precursors is essential for central B-cell tolerance

Cantaert, T.¹, Schickel, J.-N.¹, Bannock, J.¹, Ng, Y.-S.¹, Massad, C.¹, Oe, T.¹, Wu, R.¹, Lavoie, A.², Walter, J.³, Notarangelo, L.³, Waleed, A.-H.⁴, Sebnem Kilic, S.⁵, Ochs, H.⁶, Nonoyama, S.⁷, Durandy, A.⁸, Meffre, E.¹

¹Yale University School of Medicine, Immunobiology, New Haven, United States, ²Centre Hospitalier de l'Université Laval, Quebec, Canada, ³Harvard Medical School, Boston, United States, ⁴Kuwait University, Kuwait, Kuwait, ⁵Uludag University Medical Faculty, Bursa, Turkey, ⁶University of Washington, Seattle, United States, ⁷National Defense Medical College, Tokorozawa, Saitama, Japan, ⁸Institut Imagine UMR 1163, Paris, France

Activation-induced cytidine deaminase (AID), the enzyme mediating class switch recombination (CSR) and somatic hypermutation (SHM) of immunoglobulin genes, is essential for the removal of developing autoreactive B cells. How AID mediates central B-cell tolerance remains unknown. By analyzing patients with various types of *AID* mutations, we could show that removal of developing autoreactive B cells in the bone marrow is regulated by gene dosage and AID enzymatic activity. In addition, we report that AID proteins are expressed during early B-cell development in both human fetal liver and adult bone marrow. AID expression was found restricted in to early immature B cells that co-express recombination-activating gene 2 (RAG2), suggesting that they undergo secondary recombination to edit autoreactive antibodies. However, most AID⁺ immature B cells lacked anti-apoptotic MCL-1 and were deleted by apoptosis. Furthermore, we show that AID inhibition by lentiviral-encoded short hairpin (sh) RNA in B cells developing in humanized mice impaired the counterselection of autoreactive clones.

Hence, B-cell intrinsic AID expression mediates central B-cell tolerance potentially through its RAG-coupled genotoxic activity in self-reactive immature B cells.

Identification of two MCMV immunoevasins that modulate NK cell recognition via the NKR-P1B:Clr-b axis

Aguilar, O.A.^{1,2}, Rahim, M.M.³, Reichel, J.⁴, Lau, T.^{1,2}, Samaniego, J.^{1,2}, Sampaio, I.S.^{1,2}, Krmpotić, A.⁴, Jonjić, S.⁴, Makrigiannis, A.P.³, Allan, D.S.J.^{1,2}, Carlyle, J.R.^{1,2}

¹University of Toronto, Department of Immunology, Toronto, Canada, ²Sunnybrook Research Institute, Toronto, Canada, ³University of Ottawa, Department of Biochemistry, Microbiology and Immunology, Ottawa, Canada, ⁴University of Rijeka, Department for Histology and Embryology, Rijeka, Croatia

Natural killer (NK) cells are a subset of innate lymphoid cells (ILC) capable of recognizing pathological target cells through germline-encoded receptor-ligand interactions. Murine cytomegalovirus (MCMV) is a betaherpesvirus that has co-evolved with its natural host, and as such, a significant portion of its genome encodes immunoevasins that directly target NK cell receptor-ligand interactions. Here, we identify two putative immunoevasins that modulate host-pathogen interactions via the inhibitory NKR-P1B:Clr-b recognition system. First, we identify an m145 family member, m153, that actively prevents MCMV infection-mediated Clr-b downregulation. Ectopic expression of m153 in mouse fibroblasts increases Clr-b expression at the cell surface. In contrast, infection with a Δ m153-mutant MCMV shows more substantial Clr-b loss at the cell surface compared to wild-type MCMV. Importantly, enhanced Clr-b loss upon infection using Δ m153-mutant MCMV could be reversed upon m153 complementation by overexpression. Secondly, we have identified an m02 family member, m12, that directly interacts with the NKR-P1B inhibitory receptor in reporter cell assays. Notably, the interaction between NKR-P1B and m12 is Clr-b/ β_2 m-independent, and infection of fibroblasts using Δ m12-mutant MCMV abrogates NKR-P1B ligation of reporter cells. This interaction, suggestive of decoy ligand function, is also MCMV strain-dependent and host NKR-P1B allele-specific, in turn suggesting that polymorphisms have evolved at both the pathogen and host levels that affect NK cell recognition of infected target cells.

Interleukin-1 receptor 8 (IL-1R8) plays a crucial role in NK cell differentiation and function

Molgora, M.¹, Bonavita, E.¹, Ponzetta, A.¹, Barbagallo, M.¹, Polentarutti, N.¹, Jaillon, S.¹, Riva, F.¹, Magrini, E.¹, Benigni, G.², Bernardini, G.², Santoni, A.², Mantovani, A.^{1,3}, Garlanda, C.¹

¹Humanitas Clinical and Research Centre, Rozzano (MI), Italy, ²Istituto Pasteur-Fondazione Cenci Bolognetti, Sapienza University of Rome, Rome, Italy, ³Humanitas University, Rozzano (MI), Italy

IL-1R8 is an Interleukin-1R receptor (ILR) family member and acts as a negative regulator of ILR and Toll-like receptor (TLR) signaling. Although it was demonstrated to be a tumor suppressor able to control cancer-related inflammation, it is also highly expressed by NK cells, which activation contributes to the elimination of tumor cells.

The aim of the study was to characterize its role in modulating ILR and TLR signaling in NK cells. We showed that both murine and human NK cells expressed high levels of IL-1R8 and it was differentially expressed during NK cell maturation. IL-1R8-deficient NK cells displayed a more mature phenotype and enhanced effector functions, in terms of IFN- γ production, FasL expression and cytotoxicity. To investigate the mechanism responsible for this phenotype, we focused on IL-18, which is a key regulator of NK cell activities and may be potentially targeted by IL-1R8. Indeed, IL-1R8 regulated IL-18-MyD88 axis during NK cell differentiation, acting through the inhibition of the mTOR and JNK pathways.

To assess the role of IL-1R8 in NK cells in pathology, we used a model of sarcoma-derived metastasis. The primary tumor similarly grew in IL1R8-competent and deficient mice, whereas the number and dimension of lung metastasis were significantly reduced in Il1r8^{-/-} mice. The depletion of NK cells in this model totally abrogated the protection from lung metastasis in Il1r8^{-/-} mice.

IL-1R8 plays therefore a nonredundant role in the regulation of NK cell biology and it is a crucial regulator of NK cell antitumoral activity.

3688

The IRE1/XBP1 pathway is a critical regulatory hub for human NK-cell mediated lysis and motility that modulates the actin-binding protein XIRP1

Gandhi, M.K.¹, Mujaj, S.¹, Vari, F.¹, Cui, Q.¹, Nourse, J.P.¹, Han, E.¹, Cristino, A.²

¹University of Queensland Diamantina Institute, Blood Cancer Research Laboratory, Brisbane, Australia, ²University of Queensland Diamantina Institute, Systems Biology, Brisbane, Australia

We recently demonstrated NK-cell effector function is impaired in aggressive lymphoma (Keane, Lancet Haem 2015). However, the underlying mechanisms are poorly understood. Using NK-cell-lines and unmanipulated *ex-vivo* primary NK-cells (pNK), and various blood cancer targets, we show the critical role of the inositol-requiring enzyme 1/X-box-binding protein 1 (IRE1/XBP1) signaling pathway, involving non-conventional splicing of XBP1 to its active form XBP1s. Minimal splicing of XBP1 occurred in unstimulated NK-cells, with rapid XBP1s induction following activation. Small molecule blockade resulted in dose-dependent reduced direct cytotoxicity and ADCC whereas activation up-regulated effector function, associated with increased granzymeB/TNFA/FasL/GM-CSF/NKG2D/CD16. XBP1-splicing inhibition reduced pseudopodia, motility and migration implicating altered cytoskeletal function. Transcriptome-array identified candidates associated with the IRE1/XBP1 pathway and its downstream effects on NK-cell cytotoxicity. Overlapping differentially expressed genes (DEG) show significant positive correlation ($r=0.88$ and $r=0.95$; both $P < 0.0001$). One-third of DEG promoter regions were enriched in putative XBP1s-binding sites, indicating a robust/conserved molecular kernel involving both direct lysis and ADCC. The cytoskeletal actin-binding protein gene XIRP1 was a key DEG, and IRE1-inhibitors reduced XIRP1 proteins in a dose-dependent manner. Intriguingly, the

XBP1-target network was enriched with binding sites for the microRNAs which were themselves targeting XBP1 target genes. Highly enriched microRNAs included mir-1234 and mir-4488, for which binding sites have been identified in the 3'UTR of XIRP1 consistent with this gene being under concerted direct/indirect regulation by XBP1s and its targeted microRNAs. These data highlight a hitherto unrecognized and potentially targetable role for IRE1/XBP1s as a master regulator of human NK-cell effector function.

1335

Disarming a killer: novel viral infection of human NK Cells interferes with function and phenotype

Campbell, T.M.¹, McSharry, B.P.¹, Steain, M.¹, Ashhurst, T.M.², Slobedman, B.¹, Abendroth, A.¹

¹University of Sydney, Infectious Diseases & Immunology, Sydney, Australia, ²University of Sydney, Discipline of Pathology, Sydney, Australia

Clinical evidence has revealed that NK cell function is critical to controlling infection with varicella zoster virus (VZV), the alphaherpesvirus responsible for varicella and herpes zoster. Despite the crucial role of NK cells, understanding their interaction with VZV has remained surprisingly overlooked. VZV is an established lymphotropic virus, however our findings are the first to demonstrate VZV infection of human peripheral blood NK cells, with remarkably 40% of cells antigen positive after 48 hours, as detected by flow cytometry and immunofluorescence. Importantly, NK cells were able to pass on infection to surrounding cells, suggesting a possible role for these circulating innate lymphocytes in the dissemination of virus during host infection. Additionally it was found that a marked increase in VZV antigen positive NK cells occurs in the presence of interleukin-2, which is typically elevated during infection. To assess the effect of infection on NK cell function a calcein-release cytotoxicity assay was employed. Analysis revealed that infection dramatically disabled cytolytic function of NK cells. In exploring this effect by multi-parameter flow cytometry, human NK cells were assessed for changes in phenotype following VZV infection, through examining expression of 22 receptors. Analysis revealed that VZV-cultured NK cells showed elevated activation, as detected by CD69 expression, and potent downregulation of the Fc receptor CD16, which regulates antibody-dependent cell-mediated cytotoxicity. Our findings identify a novel infection of NK cells and begin to reveal the complex manipulation and evasion of NK cell anti-viral function by VZV.

2121

Role of the non-classical MHC H2-Q10 in NK cell biology

Goodall, K.¹, Sullivan, L.², Andrews, D.¹

¹Monash University, Immunology, Melbourne, Australia, ²Peter Doherty Institute, University of Melbourne, Melbourne, Australia

As a member of the frontline immune response, natural killer (NK) cells can respond rapidly to pathogens by killing infected cells. NK cells in the mouse express Ly49 receptors that recognise both

classical and non-classical MHC-I receptors. Non classical MHC-I receptors typically display tissue-restricted expression, and a restricted peptide repertoire. H2-Q10, however, is a secreted non-classical MHC-I receptor that is expressed primarily in the liver but binds a classical repertoire of peptides, and therefore has both classical and non-classical properties. Recent work has shown that H2-Q10 interacts with the NK cell via Ly49C^{B6}. However, the 129 mouse does not display Ly49C on NK cells, and has impaired function in several infection models. Here we show that H2-Q10 also recognises Ly49I¹²⁹, however unlike Ly49C^{B6}, H2-Q10 shows peptide specificity. We also showed that H2-Q10 binding is significantly impaired when Ly49I is bound in *cis* with H2-K^b/D^b. Alanine substitution has revealed the binding sites of H2-Q10 to Ly49I. This data aims to determine the nature of H2-Q10 recognition of Ly49 receptors on NK cells in mice, and its potential role in infection.

2832

Orientation of CD56^{dim} NK cells toward IFN- γ production directed by NKG2A/KIR expression upon Fc γ RIIIa engagement

Lajoie, L., Congy-Jolivet, N., Bolzec, A., Sung, H.C., Thibault, G. Université François Rabelais, GICC CNRS UMR 7292, Tours Cedex, France

It is not known which antibody-dependent NK cell function, *i.e.* killing or cytokine production, mediates clinical responses to therapeutic monoclonal antibodies (mAbs). Fc γ RIIIa/CD16a is the sole activating receptor of CD56^{dim} NK cells whose engagement induces substantial degranulation and cytokine synthesis. However, it is currently unclear how NK cells are directed toward these effector functions upon Fc γ RIIIa/CD16a engagement. Degranulation and/or IFN- γ -production and the expression of the inhibitory receptors NKG2A, CD158a and CD158b were simultaneously evaluated after stimulation by plate-bound anti-CD16 3G8 mAb, rituximab or trastuzumab. After 4h of 3G8 stimulation, CD107⁺IFN- γ ⁺, CD107⁺IFN- γ ⁻ and CD107⁻IFN- γ ⁺ cells represented $27.1 \pm 14.2\%$, $61.1 \pm 13.9\%$ and $11.8 \pm 5.9\%$ of responding CD56^{dim} NK cells, respectively. This partial functional segregation persisted for up to 20h of stimulation. No correlation was detected between the percentages of degranulating and IFN- γ -producing NK cells from 26 donors. Importantly, IFN- γ production was positively associated with CD158a and CD158b expression and negatively associated with NKG2A expression after Fc γ RIIIa engagement by 3G8, rituximab or trastuzumab. Conversely, degranulation was positively although weakly associated with NKG2A expression. It was concluded that the individual inhibitory receptors expression of CD56^{dim} NK cells, influences their orientation toward degranulation and IFN- γ production in response to the engagement of Fc γ RIIIa by therapeutic mAbs.

4100**Antigen-specific memory responses of human liver- and skin-derived NK cells**

Stary, V.¹, Strobl, J.², Haegele, S.¹, Pereyra, D.¹, Starlinger, P.¹, Stary, G.²

¹Medical University of Vienna, General Hospital, Department of Surgery, Vienna, Austria, ²Medical University of Vienna, General Hospital, Department of Dermatology, Division of Immunology, Allergy and Infectious Diseases, Vienna, Austria

Until now, vaccine strategies have been exclusively focused on promoting effector activity by the two classical arms of the adaptive immune system, namely B and T cells. Mounting evidence points to an important role for a third lymphocyte subset, natural killer (NK) cells, in host resistance to infections. Murine liver-resident NK cells were discovered with long-lived memory of haptens and viral antigens. Despite phenotypic analysis of human liver NK cells, the existence and consequences of antigen-specific NK cell memory still needs to be proven.

We isolated human liver NK cells from individuals vaccinated against hepatitis A / B and characterized them phenotypically and functionally in killing assays against these viral antigens. Furthermore, we evaluated the distribution of NK cells in epicutaneous patch test reactions, a model for delayed-type hypersensitivity reactions.

In contrast to the peripheral blood, two distinct NK cell populations were found in the liver based on their expression of CD16 and CD49a. CD49a⁺CD16⁻ NK cells (54.6% ± 4.2 of total NK cells) performed antigen-specific killing comparable to CD8 T cells. Blood-derived and CD49a⁺CD16⁺ liver NK cells did not exert antigen-specific cytotoxicity, but recognized MHC-I^{low} target cells. Although absent in healthy human skin, 57,8 ± 5.1 % of total NK cells in hapten-induced epicutaneous patch tests were found to belong to the CD49a⁺CD16^{low} NK cell subset.

These results suggest that memory NK cells in humans can be found in the liver and inflamed skin, which might lead to novel strategies of vaccination by harnessing this NK cell subset.

3003**Adenosine impairs the proliferative capacity of terminally mature NK cells**

Young, A.^{1,2}, Souza-Fonseca-Guimaraes, F.^{1,2,3}, Ngiew, S.F.^{1,2}, Gao, Y.^{1,2}, Linden, J.⁴, Huntington, N.D.³, Smyth, M.J.^{1,2}

Adenosine is a critical immunosuppressive metabolite, necessary for protecting against overzealous immune responses. Group 1 innate lymphoid cells (ILCs), both natural killer (NK) and ILC 1 cells, express high levels of the A2A adenosine receptor (A2AR), but not alternate adenosine receptors. Therefore, we interrogated the role of adenosine signaling via the A2AR in these cellular subsets. At baseline, complete and conditional Nkp46^{cre} deletion of the A2AR significantly enhanced accumulation of terminally mature (CD11b⁺CD27⁻ and CD11b⁺KLRG1⁺) NK cells in lymphoid organs. As terminally mature wild type NK

cells display reduced proliferative potential, we performed competitive 1 to 1 transfers of wild type (CD45.1⁺) and A2AR-deficient (CD45.2⁺) bone marrow or sorted splenic NK cells into sublethally irradiated or lymphocyte-deficient Rag^{-/-}γc^{-/-} mice, respectively, to assess their proliferative ability. Surprisingly, significantly greater expansion of A2AR-deficient NK cells was observed compared to wild type. In addition, following bone marrow reconstitution, A2AR-deficient NK cells maintained an altered maturation profile. By sorting individual NK cell subsets, based on CD11b and CD27, we found that terminally mature A2AR-deficient NK cells, but not wild type, proliferated *in vitro* following IL-15 stimulation. Finally, we assessed whether conditional Nkp46^{cre} deletion of the A2AR modified tumour development. Using the SM1WT1 melanoma and MCA *de novo* tumorigenesis models we identified a significant reduction in primary tumour growth and delayed tumour initiation, respectively. These results indicate that A2AR adenosine signaling limits proliferation and anti-tumour responses of NK cells, which may have therapeutic implications for improved NK cell activity as A2AR antagonists reach clinical utility.

384**TGF-beta inhibits NK cell activation and cytotoxicity through repression of the mTOR pathway**

Souza-Fonseca-Guimaraes, F.^{1,2}, Viel, S.³, Marçais, A.³, Huntington, N.¹, Bartholin, L.⁴, Walzer, T.³, Smyth, M.²

¹Walter & Eliza Hall Institute, Melbourne, Australia, ²QIMR Berghofer Medical Research Institute, Herston, Australia, ³CIRI, Centre International de Recherche en Infectiologie - International Center for Infectiology Research, Lyon, France, ⁴INSERM U 1052, CNRS UMR 5286, Centre de Recherche en Cancérologie de Lyon (CRCL), Centre Léon Bérard, Lyon, France

Deciphering the regulation of natural killer (NK) cell maturation is essential to understanding how NK cells are mobilised to combat cancer and infection. TGF-β is a major immunosuppressive cytokine maintaining immune homeostasis and preventing autoimmunity. TGF-β has anti-proliferative and anti-inflammatory properties in various cell types that remain to be characterized at the molecular level. Here, we provide genetic, pharmacologic and biochemical evidences that a major target of TGF-β in mouse and human Natural Killer (NK) cells is the serine/threonine kinase mTOR. *In vitro* treatment with TGF-β or with rapamycin leads to a rapid blockade of IL-15-induced mTOR activation in mouse or human NK cells. TGF-β and rapamycin also had identical effects on NK cell metabolic activity, proliferation and cytotoxic activity. Constitutive TGF-β signaling or mTOR deletion results in similar developmental arrests in NK cells while reciprocally TGF-βRII deletion unleashes mTOR activity and cytotoxic potential upon IL-15 treatment. Suppression of TGF-β signaling in NK cells does not impact on NK cell development and homeostasis. However, it endows NK cells with a better ability to control metastases in two different tumor models. Altogether, these results establish the mTOR kinase as a crucial signaling integrator of pro and anti-inflammatory cytokines in NK cells. Moreover, they suggest that improving metabolic activity of anti-tumor lymphocytes could be a valid strategy to promote tumor suppression.

High salt driven Th17 response induces stem cell mobilization and accelerates atherosclerosis

Lee, M.K.S.^{1,2}, Dragoljevic, D.^{1,2}, Kraakman, M.J.¹, Shihata, W.^{1,2}, Al-sharea, A.^{1,2}, Whillas, A.^{1,2}, Khan, S.^{1,2}, Nguyen, T.¹, Heywood, S.¹, Masters, S.L.³, Chin-Dusting, J.^{1,2}, Murphy, A.J.^{1,2}

¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Monash University, Melbourne, Australia, ³Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia

Introduction: A high-salt diet (HSD) is linked to increased atherosclerosis. Recently, a HSD has been shown to alter the immune response in both mice and humans, by promoting inflammatory and suppressing anti-inflammatory immune cells. We hypothesized that a HSD would drive Th17 cells to promote hematopoietic stem progenitor cells (HSPCs) mobilization, monocytosis and increased atherosclerosis.

Methods: Atherosclerotic-prone Apoe^{-/-} mice were fed a normal salt (1%) or HSD (8%) for 12wks. Levels of HSPCs and myeloid progenitors, myeloid cells and Th17 cells were measured in the blood, spleen and bone marrow using flow cytometry. CD68 and Oil Red O staining were used to quantify sinus plaques that identify macrophage and lipid abundance.

Results: A HSD significantly promoted rupture-prone atherosclerotic lesion formation with increased macrophage and lipid content in the sinus. These changes were associated with monocytosis and neutrophilia. We found HSPC mobilization from the bone marrow to the spleen where more monocytes were produced, suggesting extramedullary hematopoiesis. HSD-fed mice also had increased levels of circulating Th17s, likely driven by the increased abundance of CD24⁺ (IL-23 producing) dendritic cells in the spleen. Using an IL-1RA (Anakinra) and neutralizing antibodies to IL-17 and IL-23R, we found that this signaling axis was responsible for HSPC mobilization and ultimately unstable lesion formation.

Conclusions: A HSD promotes rupture-prone atherosclerotic lesions by increasing Th17 cells to influence HSPC mobilization to the spleen. This results in extramedullary hematopoiesis, expanding the monocyte population, which enter the atherosclerotic lesion. The IL-1/IL-23/IL-17 signaling axis appeared to be responsible for this process.

Desmoglein 2 (DSG2) is a novel surface marker of endothelial and haematopoietic progenitor cells, and plays a critical role in neoangiogenesis

Ebert, L.^{1,2}, Tan, L.Y.^{1,3}, Min, K.K.M.^{1,3}, Cockshell, M.¹, Johan, M.Z.¹, Parham, K.^{1,3}, Betterman, K.^{1,3}, Ruszkiewicz, A.^{1,2}, Zannettino, A.^{4,5}, Gronthos, S.^{4,5}, Koblar, S.^{4,5}, Harvey, N.^{1,3}, Lopez, A.^{1,2}, Shackleton, M.⁶, Bonder, C.^{1,3}

Endothelial progenitor cells (EPC) are rare but clinically important cells present in blood and bone marrow (BM) which contribute to blood vessel growth and repair. We recently undertook a genome-wide search for new surface markers of EPCs, for the purpose of improving EPC detection and isolation. The top candidate was desmoglein 2 (DSG2), an adhesion molecule belonging to the cadherin family. Flow cytometry revealed that DSG2 is expressed on short-term cultured EPCs derived from umbilical cord blood, and on circulating EPCs (CD34⁺ VEGFR2⁺) in peripheral blood. Interestingly, DSG2 was also expressed on the closely related CD34⁺ CD45^{dim} haematopoietic progenitor cell (HPC) population in peripheral and cord blood. Detailed characterisation of BM subsets revealed uniformly high DSG2 expression on the most primitive HPCs (CD34⁺ CD38⁻ CD90⁺) with progressively lower expression on more committed progenitors, while mature leukocytes lacked DSG2. In contrast, DSG2 was maintained on a subset of mature endothelial cells (EC), suggesting DSG2 may play an important role in this lineage. To address this possibility, a 'knock-out first' approach was used to generate a *Dsg2* loss-of-function strain of mice (*Dsg2*^{0/0}). In response to reduced levels of *Dsg2*, EPCs displayed proliferation and differentiation defects, neoangiogenesis was significantly impaired and ECs in some tissues displayed morphological aberrations. Together, our results define DSG2 as a novel, and potentially useful, surface marker for the identification and isolation of EPCs and HPCs, and show that, independent from its classical function as a component of desmosomes, this cadherin also plays a critical role in the vasculature.

1351

The parasympathetic nervous system is involved in the regulation of hematopoietic stem cell activity

Al-Sharea, A.^{1,2}, Whillas, A.^{1,2}, Shihata, W.^{1,2}, Andrews, K.¹, Purton, L.³, Chin-Dusting, J.¹, Murphy, A.¹

¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Monash University, Melbourne, Australia, ³St Vincent's Institute, Melbourne, Australia

Objective: The sympathetic arm of the autonomic nervous system regulates retention/release of hematopoietic stem cells (HSCs). We studied if the parasympathetic nervous system (PNS) also has a regulatory role.

Methods: Wild-type (C57BL/6) mice were injected with the anticholinergic atropine (2mg/kg, bi-daily for 3days), to inhibit the activity of the PNS under normal conditions. Using flow cytometry, levels of HSCs and their downstream myeloid progenitors were quantified in the blood and bone marrow (BM).

Results: Inhibition of the PNS promoted HSC mobilization, associated with changes in the expression of the key genes involved in HSC mobilization including stromal cell-derived factor 1, matrix metalloproteinase 9 (MMP9) and stem cell factor. PNS inhibition appeared to alter the HSC niche, causing a decrease in endothelial cells and down-regulation of ICAM-1. To determine whether stimulating the PNS prevents HSC mobilization, mice were injected with the mobilizing agent G-CSF (250µg/kg bi-daily x 3days) and treated with pyridostigmine (1mg/kg daily), to increase endogenous PNS ligands. G-CSF caused a robust

mobilization of HSCs, marked neutrophilia and splenomegaly, which was reversed with pyridostigmine. We identified alpha7-nicotinic acetylcholine receptor (alpha7nAChR) subunit to be highly expressed in the BM. This appeared to be the dominant receptor, as the alpha7nAChR specific agonist GTS-21 (4mg/kg bi-daily), also prevented G-CSF-induced HSC mobilization.

Conclusion: The PNS appears to play a role in retaining HSCs in the BM under homeostatic conditions. Stimulating the PNS can inhibit G-CSF-induced HSC mobilization. This occurs via acting on the alpha7nAChR to modulate the HSC niche.

BCAP inhibits myeloid cell development from hematopoietic progenitors

Duggan, J.^{1,2}, Hamerman, J.^{1,2}

¹Benaroya Research Institute, Immunology, Seattle, United States,

²University of Washington, Immunology, Seattle, United States

B cell adaptor for PI3-kinase (BCAP) is a signaling adaptor expressed in hematopoietic cells including macrophages, monocytes, and neutrophils. Here we asked if BCAP plays a role in development of these myeloid cells. We found that BCAP was expressed in bone marrow (BM) hematopoietic progenitors, including LSK (Lin⁻Sca1⁺cKit⁺), CMP (Common Myeloid Progenitor) and GMP (Granulocyte/Macrophage Progenitor) cells, suggesting that BCAP may impact myelopoiesis. BCAP^{-/-} mice had more BM monocytes than WT mice, and in mixed chimeras generated with a 1:1 ratio of WT and BCAP^{-/-} BM, monocytes and neutrophils in the BM, blood and spleen exhibited skewing towards BCAP^{-/-} origin, showing a competitive advantage for BCAP^{-/-} myeloid cells. Thus we hypothesized that BCAP inhibits myeloid development. Consistent with this hypothesis, BCAP-deficient BM LSK, CMP and GMP cells out-competed WT progenitors in mixed chimeras. In an in vitro myeloid colony-forming-unit assay, sorted BCAP^{-/-} progenitors produced more myeloid cells than WT progenitors, supporting a cell-intrinsic role of BCAP in inhibiting myeloid differentiation. Furthermore, BCAP^{-/-} progenitors were more mature than WT progenitors, indicating that BCAP^{-/-} progenitors display accelerated myeloid development. During cyclophosphamide-induced myeloablation or specific monocyte depletion, BCAP^{-/-} mice replenish circulating monocytes earlier than WT mice. Lastly, BCAP^{-/-} progenitors showed increased expression of the myeloid-differentiating transcription factors IRF8 and C/EBPα compared to WT progenitors. Together, these data identify BCAP as an inhibitor of myeloid development from BM hematopoietic progenitors in the steady state and during demand conditions.

Mesenchymal cells expressing Tlx1 serve as an extramedullary niche in the spleen

Oda, A., Kasahara, T., Goitsuka, R.

Tokyo University of Science, Division of Development and Aging, Chiba, Japan

Extramedullary hematopoiesis (EMH) is initiated by the pathological stress responses, through an alteration in a

specific hematopoietic microenvironment (niche) in the bone marrow that support steady-state hematopoiesis from the hematopoietic stem and progenitor cells (HSPCs). The pathological stresses, such as chronic hemolytic anemia and severe bacterial infection, induce to mobilize HSPCs from the bone marrow to the periphery, leading to EMH mainly at the spleen and liver, sites that support embryonic hematopoiesis. However the precise mechanisms and nature including the niche leading to EMH and the source of hematopoietic factors remain poorly understood. Here we show that mesenchymal stromal cells expressing Tlx1 (Tlx1⁺ cells), a transcription factor essential for spleen organogenesis, potentially serve as the HSPCs niche during EMH. We generated the *Tlx1^{creER-Venus}; Rosa26-iDTA* mouse that enables both visualization of Tlx1⁺ cells by Venus and depletion of Tlx1⁺ cells by tamoxifen administration. A majority of Tlx1⁺ cells are localized in the red pulp, particularly a perifollicular region, and display immature mesenchymal stem/progenitor phenotypes on their cell surface. When EMH was induced by phenylhydrazine- or LPS-treatment, depletion of Tlx1⁺ cells by tamoxifen administration drastically reduced splenomegaly as well as EMH. Since CXCL12 and SCF, the key niche factors, is highly expressed in Tlx1⁺ cells among other cells in the spleen, these findings suggest that Tlx1⁺ mesenchymal cells in the splenic red pulp serve as a HSPC niche that supports EMH.

Although the thymus has a remarkable capacity for repair following damage, the mechanisms underlying this regeneration remain poorly understood. Here we reveal that endothelial cells (ECs), which are highly damage-resistant, represent a critical pathway of endogenous thymic regeneration. Analysis revealed that ECs significantly increase their production of BMP4 after thymic damage; and abrogating BMP4 signalling or production leads to worse thymic repair. Recovery of thymic function could be significantly boosted with therapeutic administration of *ex vivo* propagated and expanded ECs (exEC), but intriguingly only if they were derived from thymus, not kidney or heart. Treatment with exECs led to upregulation by thymic epithelial cells (TECs) of *Foxn1*, a key TEC transcription factor, as well as the FOXN1 target gene *Dll4*. *In vitro* co-culture studies revealed that conditioned media from exEC derived from the thymus, but not heart or kidney, induced expression of *Foxn1* by thymic epithelial cells (TECs) and that this was abrogated by Noggin, an inhibitor of BMP signaling. Consistent with these studies, exEC^(Thy) produced

significantly more BMP4 compared to exEC derived from the heart or kidney; and silencing *Bmp4* expression by shRNA within exEC^(Thy) limited their capacity to mediate exogenous thymic regeneration, and failed to induce the expression of *Foxn1* and *Dll4*. These studies not only detail a novel pathway underlying endogenous thymic regeneration, but offer an innovative clinical approach to enhance T cell immunity in individuals with T cell deficiencies due to aging, infectious disease, and common cancer treatments such as chemo- and radiation-therapy.

Menstrual blood stromal stem cells modulate the properties of dendritic cells

Bozorgmehr, M.^{1,2}, Zarnani, A.H.^{2,3}, Sheikhan, A.⁴, Salehnia, M.⁵, Nikoo, S.³, Moazzeni, S.M.¹

¹Faculty of Medical Sciences, Tarbiat Modares University, Immunology Department, Tehran, Iran, Islamic Republic of,

²Nanobiotechnology Research Center, Avicenna Research Institute, ACECR, Tehran, Iran, Islamic Republic of, ³Reproductive Immunology Research Center, Avicenna Research Institute, ACECR, Tehran, Iran, Islamic Republic of, ⁴Faculty of Medicine, Lorestan University of Medical Sciences, Immunology Department, Khorramabad, Iran, Islamic Republic of, ⁵Faculty of Medical Sciences, Tarbiat Modares University, Anatomy Department, Tehran, Iran, Islamic Republic of

Menstrual blood stromal stem cells (MenSCs) share several characteristics with mesenchymal stem cells. Nevertheless, data regarding the potential impacts of MenSC on different arms of the immune system is still scarce. Hence, we sought to explore, whether MenSCs affect the generation and function of dendritic cells (DCs) from human peripheral blood monocytes.

MenSCs were separated from menstrual blood of normal women. Monocytes from unrelated donors were differentiated towards immature DCs (iDCs) and mature DCs (mDCs) using appropriate cytokines. Generation of DCs was performed in the presence or absence of MenSCs. The effect of MenSCs on phenotypic and functional characteristics of DCs was evaluated through immunophenotyping, measuring cytokine concentration and regulatory T cell (Treg) induction.

DCs generated in the presence of MenSCs acquired regulatory properties, as judged by the expression level of surface markers (CD14, CD1a, CD40, CD80, CD86), the amount of typical several immunostimulatory and immunoinhibitory cytokines (IL-6, IL-10, IL-12, and TNF- α), and the ability to induce Tregs. Moreover, our data showed that these impacts were exerted on the first step of DC generation (i.e. monocyte to DC differentiation) rather than the second step (i.e. iDC to mDC differentiation); this impact was shown to be in part related to the presence of IL-6 and IL-10 in the cocultures.

This is the first work addressing the modulatory impacts of MenSCs on generation and function of DCs. Accordingly, since DCs play key roles in regulation of immune responses, MenSCs could be regarded as potential tools to be used in future clinical settings.

Differential TLR activation of murine mesenchymal stem cells generates distinct immunomodulatory effects in EAE

Vega-Letter, A.M., Kurte, M., Fernández-O'Ryan, C., Gauthier-Abeliuk, M., Moya, I., Carrión, F.

Universidad de los Andes, Santiago, Chile

Mesenchymal stem cells (MSCs) are multipotent, nonhematopoietic progenitor cells that exhibit potent anti-inflammatory and immunomodulatory properties. Recently, it has been observed that MSCs can modulate their immunomodulatory capacities depending on the specific *in vitro* activation of different Toll-like receptors (TLR), such as TLR3 and TLR4. In the present study, we evaluated the effect of poly(I:C) and LPS pretreatment on the immunological capacity of murine MSCs *in vitro* and in murine experimental autoimmune encephalomyelitis (EAE). In comparison with untreated MSCs, pretreatment of MSCs with poly(I:C) significantly reduced the proliferation of splenocytes as well as that of Th1 and Th17 cells and increased the levels of the soluble immunosuppressive factor nitric oxide. In contrast, MSCs pretreated with LPS increased splenocytes proliferation, and that of Th1 and Th17 cells, as well as the levels of proinflammatory cytokine IL-6. Finally, we showed that intraperitoneal administration of MSCs pretreated with poly(I:C) significantly reduced the severity of EAE as well as the percentages of Th1 and Th17 proinflammatory subsets, while the pretreatment of MSCs with LPS completely reversed the therapeutic immunosuppressive effect of MSCs. Taken together, these data show that pretreatment of MSCs with poly(I:C) improved their immunosuppressive abilities. This may provide an opportunity to better define strategies for cell-based therapies for autoimmune diseases.

Characterisation of mesenchymal cell subsets in human lymph nodes

Park, S.M.^{1,2}, Eom, J.^{1,2}, Brooks, A.^{1,2}, Feisst, V.^{1,2}, McIntosh, J.¹, Dunbar, P.R.^{1,2}

¹The University of Auckland, School of Biological Sciences, Auckland, New Zealand, ²Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand

Lymph nodes (LN) depend on several subsets of mesenchymal stromal cells to construct and maintain their elaborate architecture, and support immune function. Major stromal cell subsets in LNs include fibroblastic reticular cells (FRCs), follicular dendritic cells (FDCs), and marginal reticular cells (MRCs). All these cell subsets need to participate in LN remodeling during immune responses, yet the relationship between these subsets and any potential precursor populations has remained unclear. A lack of specific markers for mesenchymal cell subsets and their precursors in humans has also prevented full exploration of their potential roles in health and disease.

We have recently characterised mesenchymal subsets in human LNs. We discovered that CD141 uniquely labelled MRCs amongst the stromal cell populations in human LNs, revealing that MRCs line all boundaries between sinuses and the parenchyma. Migration of both T cells and Antigen-Presenting Cells (APCs) between MRCs could be observed in human LNs, and enzymes

that generate the sphingosine-1-phosphate (S1P) gradient within LNs showed striking spatial relationships with MRCs. We also identified Mesenchymal Precursor Cells in a distinctive niche within human LNs, with both phenotypic and functional characteristics similar to those we have previously characterised in human adipose tissue and dermis. We hypothesise that these cells may represent precursors of the other mesenchymal cell subsets present in human LNs, and may help increase the populations of these subsets during the substantial LN expansion that occurs during the early phases of an immune response.

Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease. Twin studies indicate a strong genetic contribution to lupus, yet often the pathogenic variant remains unknown. Using next generation sequencing technologies (WES/WGS) it is now possible to identify rare/novel gene variants that cause disease. We previously used WES to identify a genetic variant in TREX1 as a cause of cerebral SLE; providing proof of principle that rare genetic variants do contribute to complex autoimmunity. It also revealed the patient to be a prime candidate for tailored therapies targeting type-I interferons. Using our validated bioinformatics pipeline and methodology, we have now identified two other cohorts of patients with genetic variants that impair thymic tolerance and toll-like receptor (TLR) 2 signaling, respectively. Biochemical assays on patient PBMCs or overexpression in cell lines confirmed the variants impair protein function. Furthermore, flow cytometry identified endophenotypes in the patients' PBMCs that may explain disease pathogenesis. These endophenotypes and the mechanisms by which they drive SLE pathogenesis are being evaluated in mice with CRISPR/Cas9-engineered patient-specific alleles. Our data suggests the first cohort have defects in thymic epithelial cells and developing thymocytes that combine to affect central tolerance, characterized by impaired regulatory T cells. In contrast, in the second cohort, we identified a pathway that primarily affects myeloid cells and neutrophils to cause SLE through production of type-I interferon. Thus by understanding

the precise genetic mechanisms that contribute to SLE pathogenesis, our data is able to stratify patients and through a personalized approach, identify tailored therapeutic options.

The developing pathway of self-reactive B cells in systemic lupus erythematosus (SLE) has not been firmly defined. To understand how self-reactive B cells are generated in SLE, we investigate antigen specificity, clone size and diversity of disease-associated self-reactive B cells. Among monoclonal antibodies generated from blood plasmablasts by a single cell cloning, we isolated distinct anti-nuclear antibody (ANA) clones that show high reactivity with nuclei of Hep2 cells in an indirect fluorescent assay. We obtained the ANAs only from untreated acute patients, but not from patients in remission or healthy donors. Moreover, their staining patterns resemble those of sera from respective donors, suggesting that the ANA clones we obtained are disease-associated autoantibodies. Most of the ANA clones have a relatively small number of mutations, which are, however, critical for the self-reactivity. For further analyses, we chose the anti-dsDNA ANA clone, 71F12, which exhibits a nano-molar equilibrium dissociation constant (K_D) to both ds and ssDNA. Next-generation sequencing (NGS) analysis revealed that the blood lymphocyte-derived immunoglobulin library contained a substantial frequency of 71F12 lineage sequences, most of which shared three somatic mutations. The crystal structure of the ligand-bound Fab revealed that through the mutated residue 71F12 interacted with nucleobases, suggesting that this antibody may unwind dsDNA to bind to nucleobases unlike a previously proposed model where an anti-dsDNA antibody interacts with the backbone of duplex DNA. Collectively, our results demonstrate that self-reactive B cells diverged from less or non-reactive precursors through rapid affinity maturation in SLE.

Harnessing homeostatic mechanisms to resolve innate-directed neuroinflammation

La Flamme, A.C.^{1,2}, Webster, G.³, Mayo, N.⁴, White, M.¹, Sim, D.⁵

¹Victoria University of Wellington, Wellington, New Zealand, ²Malaghan Institute of Medical Research, Wellington, New Zealand

Zealand, ³Innate Immunotherapeutics, Auckland, New Zealand, ⁴McGill University, Montreal, Canada, ⁵University of Otago, Wellington, New Zealand

In recent years, a key role for the innate immune system in regulating neuroinflammation during secondary progressive multiple sclerosis (SPMS) has been revealed and is supported by the inability of therapeutics that target the peripheral adaptive immune response to reduce disease during SPMS. MIS416 is a novel microparticle that targets innate cells by activating TLR9 and NOD2, and this innate-directed therapy is currently undergoing a phase 2b efficacy trial for use during SPMS. Our preliminary clinical and preclinical studies have indicated that MIS416 is activating an IFN- γ -driven homeostatic mechanism that regulates both the peripheral and CNS-resident innate immune environment. A multidimensional scaling analysis of SPMS patient responses to MIS416 therapy as well as analysis of patient outcomes highlighted concordance between a regulated induction of the IFN- γ axis and improvements in SPMS disease parameters post treatment. Together these studies have begun to dissect the mechanism by which MIS416, a first-ever innate-mediated SPMS therapeutic, may regulate innate-driven neuroinflammatory processes during SPMS.

Type 1 diabetes susceptibility genes impair gut physiology and lead to perturbations in the microbiota

Mullaney, J., Stephens, J., Hamilton-Williams, E.
University of Queensland, UQ Diamantina Institute,
Woolloongabba, Australia

Alterations in the gut microbiota have been associated with many autoimmune and inflammatory diseases including type 1 diabetes (T1D). It is postulated that microbial dysbiosis can perturb normal immune development and increase autoimmune responses. It is not known whether T1D associated microbial alterations are caused by altered environmental exposures or whether genetically driven host factors may also contribute. We have used the T1D susceptible NOD mouse model to test whether the introduction of genetic variants that protect from T1D also lead to changes in the microbiota and whether this may be due to reduced intestinal inflammation. We have observed that NOD mice have a significantly different microbiota and signs of inflammation and perturbations in both the ileum and colon compared with protected C57BL/6 mice. We then tested whether specific genetic loci that are highly associated with T1D susceptibility contribute to these changes. NOD.H-2^b mice have the T1D associated MHC region replaced with the C57BL/10 derived H-2^b locus also had a distinct microbiota to wild-type NOD mice. NOD.H-2^b mice had significantly restored Paneth cell morphology along with increased Paneth cell derived cryptdin expression. T1D protected, NOD congenic *Idd3/5* mice also had a distinct microbiota to NOD mice along with increased goblet cell mucous area in the colon. These findings support the conclusion that T1D associated genetic variants lead to changes in the inflammatory state of the intestine, leading to alterations in the gut microbiota.

Targeting the survival mechanism of plasmacytoid dendritic cells for immune intervention in lupus

Zhan, Y.¹, Carrington, E.¹, Brady, J.¹, Oon, S.¹, Morand, E.², Lew, A.¹
¹The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²Monash University, The Monash Centre for Inflammatory Diseases, Clayton, Australia

Plasmacytoid dendritic cells (pDCs) and their products (eg. IFN- α and BAFF) have a strong association with the pathogenesis of autoimmune B cell-mediated diseases like lupus. We recently showed that pDCs of lupus-prone mice have prolonged survival, leading to increase in IFN- α production. Thus, we suggest that altered lifespan of pDCs might be a pathogenic factor for certain autoimmune diseases. We also showed recently that pDCs but not lymphoid-resident conventional DCs (cDCs) rely chiefly on BCL-2 for survival. Accordingly, BCL-2 antagonists selectively kill mouse and human pDCs. In addition, we found that BCL-2 antagonists have strong synergy with steroids, one of main drugs for lupus treatment, to kill pDCs. Interestingly, we also demonstrated that pDC subsets had differential sensitivity to BCL-2 antagonists. Together, we advocate that BCL-2 antagonists have potential as a treatment for lupus and could lower steroid usage and reduce steroid associated side effects. These strategies are currently being investigated in mouse lupus models and humanized mouse models of lupus.

IL-1 receptor antagonist-deficient mice develop autoimmune arthritis due to intrinsic activation of IL-17-producing CCR2⁺V γ 6⁺ γ δ T cells

Akitsu, A., Iwakura, Y.
Tokyo University of Science, Research Institute for Biomedical Sciences, Chiba, Japan

IL-17-producing γ δ T cells (γ δ 17) cells are implicated in autoimmune diseases, but the pathogenic mechanisms, especially the determination of tissue-specific inflammation by these cells, remain unclear. We found that a high proportion of γ δ 17 cells were detected in joints of IL-1 receptor antagonist (IL-1Ra) KO mice, one of a model for rheumatoid arthritis, which depends on IL-17 and T cells. Furthermore, We demonstrated that only a mixture of γ δ T and CD4⁺ T cells induces both γ δ 17 cell localization in joints and arthritis development by using adoptive transfer experiments, suggesting that activated CD4⁺ T cells are required for the tissue distribution of γ δ T cells. To analyze further detailed mechanism, we generated IL-17-reporter mice. We also found that activated CD4⁺ T cells directed γ δ T cell infiltration, in a CCL2-dependent manner. These mice showed that among the CCR2-expressing γ δ T cells, the cells specifically expressing V γ 6 TCR have a dominant role in IL-17 production in the inflamed joints. IL-1Ra suppressed IL-1R expression on γ δ T cells *in vitro* experiments, and thus IL-1Ra KO mice enhance IL-1R expression on specific V γ 6 subset, which plays a pivotal role in activation of them to produce IL-17. Our findings demonstrate a pathogenic mechanism in which adaptive and innate immunity induce an autoimmune disease in a coordinated manner.

N-terminal additions to the WE14 peptide of Chromogranin A creates strong autoantigen agonists in type I diabetes*Jin, N.^{1,2,3}, Wang, Y.³, Crawford, F.^{2,3}, White, J.^{2,3}, Marrack, P.^{2,3,4}, Dai, S.^{3,4,5}, Kappler, J.W.^{1,2,3,4,5}**¹University of Colorado, Barbara Davis Center for Childhood Diabetes, Aurora, United States, ²Howard Hughes Medical Institute, Denver, United States, ³National Jewish Health, Department of Biomedical Research, Denver, United States, ⁴University of Colorado School of Medicine, Department of Immunology and Microbiology, Aurora, United States, ⁵University of Colorado School of Medicine, Program in Structural Biology and Biochemistry, Aurora, United States*

Chromogranin A (ChgA) is an autoantigen for CD4⁺ T cells in the NOD mouse model of type-1 diabetes (T1D). The natural ChgA processed peptide, WE14, is a weak agonist for the prototypical T cell, BDC-2.5, and other ChgA specific T cell clones. Mimotope peptides with much higher activity share a C-terminal motif, WXR(M/D/E), that is predicted to lie in the p5 to p9 position in the IA^{g7} binding groove. This motif is also present in WE14 (WSRMD), but at its N-terminus. Therefore, to place the WE14 motif into the same position as seen in the mimotopes, we added the amino acids RLGL to its N-terminus. Like the other mimotopes, RLGL-WE14, is much more potent than WE14 in T cell stimulation and activates a diverse population of CD4⁺ T cells, which also respond to WE14 as well as islets from wild type, but not ChgA^{-/-} mice. The crystal structure of the IA^{g7}-RLGL-WE14 complex confirmed the predicted placement of the peptide within the IA^{g7} groove. Florescent IA^{g7}-RLGL-WE14 tetramers bind to ChgA specific T cells clones and easily detect ChgA specific T cells in the pancreas and pancreatic lymph nodes of NOD mice. The prediction that many different N-terminal amino acid extensions to the WXR(M/D/E) motif are sufficient to greatly improve T cells stimulation leads us to propose that such a post-translational modification may occur uniquely in the pancreas or pancreatic lymph nodes, perhaps via the mechanism of transpeptidation. This could account for the escape of these T cells from thymic negative selection.

1026

A role for circulating AIM protein in the pathogenesis of autoimmune type 1 diabetes*Matsumoto, A., Arai, S., Miyazaki, T.**University of Tokyo, Faculty of Medicine, Tokyo, Japan*

Type 1 diabetes (T1D) is an autoimmune disease characterized by the destruction of the insulin producing beta cells in the pancreatic islet, which is caused by self-reactive T cells infiltrating to the islets. The non-obese diabetic (NOD) mouse, the most commonly used animal model for T1D, reveals inefficient macrophage differentiation, resulting in a reduction in various macrophage functions including phagocytosis, which is believed to be one of the causes of disease acceleration. The apoptosis inhibitor of macrophage (AIM, encoded by *cd51* gene; ref. 1) is a circulating protein, produced by tissue macrophages. We found that NOD mice possessed significantly reduced

number of F4/80^{high+} liver Kupffer cells, the major AIM producing macrophage, and thus, the blood AIM level was lower in NOD mice than in non-diabetic C57BL/6 mice. Parallel results were obtained in T1D patients, whose AIM levels were lower than those in healthy individuals. We recently demonstrated that AIM accumulates at dead cells and promotes their removal by phagocytes (ref. 2). This fact suggests that lower AIM levels in NOD mice and T1D patients might contribute to the disease acceleration due to inefficient dead pancreatic beta cell clearance by macrophages. To further assess this hypothesis, we successfully generated AIM-deficient NOD mice using CRISPR/Cas9 system. We will present some results from analysis of the mice. Refs.

Nanoengineered myelin oligodendrocyte glycoprotein peptides suppressed experimental autoimmune encephalomyelitis: Implications in Multiple Sclerosis therapy*Prashant, S.¹, Payne L., N.², Sun, G.², Anusha, A.¹, Wilbin, X.¹, Gowd G., S.¹, Nair V., S.¹, Menon N., K.¹, Bernard, C.C.A.², Koyakutty, M.¹**¹Amrita Vishwa Vidyapeetham University, Amrita Centre for Nanosciences & Molecular Medicine, Kochi, India, ²Australian Regenerative Medicine Institute (ARMI), Monash University, Clayton, Australia*

Multiple sclerosis (MS) is an inflammatory disease of the central nervous system (CNS) and is characterized by the destruction of myelin and axons leading to progressive disability. Peptide epitopes from CNS proteins, such as the myelin oligodendrocyte glycoprotein (MOG), possess promising immunoregulatory potential for treating MS; however their instability and poor bioavailability is a major impediment for their use clinically. To overcome this problem, we have prepared different sized silica nanoparticles (100-500nm in diameter) and conjugated selected MOG peptides onto them in order to test the ability of such nanoengineered particles to prevent and/or treat a model of MS, experimental autoimmune encephalomyelitis (EAE) in mice. Using this approach, we showed that the intravenous injections of nanoparticles coated with MOG peptides could prevent and/or significantly delay the development of the chronic form of EAE in C57BL/6 mice when administered during the priming phase of disease. Decreased clinical scores were associated with reduced T-cell proliferative responses, pro-inflammatory cytokine secretion as well as a reduction in inflammation, demyelination and axonal damage. Significant suppression of the relapsing-remitting form of EAE was also observed in NOD/Lt mice following injections of MOG conjugated nanoparticles. Collectively these data demonstrate the therapeutic effects of nanoengineered myelin peptides in two models of MS and suggest that such an approach may have potential therapeutic value for MS.

¹Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia, ²University of Queensland, Diamantina Institute, Brisbane, Australia, ³Leiden University Medical Center, Leiden, Netherlands, ⁴Technological Educational Institute of Ioanian Islands, Argostoli, Greece, ⁵Epirus Institute of Technology, Arta, Greece, ⁶University of Manitoba, Arthritis Centre, Winnipeg, Canada

TCR recognize foreign peptides to trigger T cell activation and expansion for pathogen control; however TCR are both degenerate and cross-reactive. Polymorphisms in the HLA-DRbeta chain arose out of selection pressure imposed by lethal infections in exposed populations, enriching particular HLA-DRB1 alleles within certain ethnic groups. Rheumatoid arthritis (RA) is linked to specific HLA-DRB1 alleles. In Caucasians, alleles associated with anti-citrullinated peptide antibody (ACPA)-positive RA share a conserved motif at positions 11, 13, 71 and 74 of DRbeta. Indigenous North American Native (INA) tribes have a high risk of early-onset ACPA+ RA, associated with the rare allele HLA-DRB1*1402 association, which unexpectedly has a His13betaSer polymorphism. We determined the molecular mechanism of HLA-DRB1*1402 with ACPA+ RA. Unlike HLA-DRB1*04:01/04 where citrulline, but not positively-charged arginine, was accommodated within the electro-positive P4-pocket, both citrulline and arginine were accommodated in the P4-pocket of HLA-DRB1*14:02. When vimentin-64Cit(59-71) was bound to HLA-DRB1*04:01/04 or HLA-DRB1*14:02, citrulline was upright, solvent-exposed, and potentially accessible to TCR. When bound to HLA-DRB1*14:02, arginine-64 of vimentin(59-71) was buried in P4. The TCR repertoire of peripheral blood vimentin(59-71) and vimentin-64Cit(59-71)-specific CD4+ T cells in HLA-DRB1*14:02+ INA RA patients and at-risk first-degree relatives revealed oligoclonality among TCRalpha and TCRbeta, including a public TRBV/CDR3beta/TRBJ sequence. These data indicate broader presentation of native and citrullinated autoantigen by HLA-DRB1*14:02 than HLA-DRB1*04:01/04, and limited TCR diversity among the HLA-DRB1*14:02-restricted autoreactive CD4+ TCR repertoire. Engagement of a "best-fit" TCR for persistent pathogen control may provide a survival advantage for carriage of HLA-DRB1*1402 at the expense of self-epitope cross-reactivity.

Bypassing STAT3-mediated Id2 inhibition improves the anti-tumor efficacy of dendritic cells

Li, H.¹, Liu, C.², Xiao, Y.¹, Chu, F.³, Liang, X.¹, Peng, W.², Neelapu, S.³, Sun, S.-C.¹, Hwu, P.², Watowich, S.¹

¹MD Anderson Cancer Center, Immunology, Houston, United States, ²MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, United States, ³MD Anderson Cancer Center, Lymphoma and Myeloma, Houston, United States

STAT3, a signal transducer for various cytokines and growth factors, is constitutively activated in numerous cell types in the tumor microenvironment, including tumor-infiltrating immune populations. STAT3 has broad immunosuppressive function in cancer, as evidenced by studies using pan-hematopoietic *Stat3*-deficient animals. Nonetheless, it remains unclear whether and how STAT3 regulates the immunogenic properties of antigen-presenting dendritic cells (DCs) within tumors. Our current work suggests a previously unrecognized STAT3-regulated immunosuppressive mechanism in DCs. Here, we show that introduction of GM-CSF-derived DCs (GM-DCs) to murine melanoma tumors in vivo, or GM-DC exposure to melanoma-secreted cytokines, inhibits DC-intrinsic expression of the transcriptional regulator Id2. Melanoma-infiltrating CD103⁺ DCs also demonstrate reduced Id2 expression relative to their skin-resident counterparts. We found melanoma-associated cytokines inhibit *Id2* transcription via STAT3 signaling in DCs. Using DC-restricted *Stat3*-deficient mice and a tumor vaccination strategy with GM-DCs, we show that blockade of STAT3-mediated Id2 repression significantly improves the outcome with melanoma. Furthermore, we found Id2 expression influences GM-DC production of the pro-inflammatory cytokine TNF- α , GM-DC-mediated naive CD4⁺ T cell polarization, and the proportion of tumor-infiltrating immunoregulatory and immunostimulatory T cell populations upon GM-DC vaccination. In addition, we show the efficacy of the Id2-GM-DC vaccine is improved by combinatorial treatment with anti-PD-1 antibody. Collectively, our data indicate Id2 regulates DC-mediated tumor immunity by modulating tumor-associated CD4⁺ T cell responses. Since DCs have shown relatively modest success in cancer immunotherapy, this information may be useful to enhance the efficiency of DC vaccines in cancer.

The mechanism of pathogenicity of IL-17A in CNS autoimmunity

Mc Ginley, A., Mills, K.H.G.

Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland

IL-17 and IL-17-producing Th17 cells and $\gamma\delta$ T cells are emerging as central players in the pathogenesis of many autoimmune diseases. MS is an inflammatory disorder of the CNS, involving autoreactive T cell responses to myelin antigens. In this study we used a murine model of MS, EAE, to examine the role of IL-17A in CNS inflammation. Compared to WT control mice, IL-17A^{-/-}

mice had significantly attenuated EAE with a delayed onset, indicating a requirement for IL-17A in the initiation of neuronal inflammation. Consistent with this, there were significantly fewer CD4 and $\gamma\delta$ T cells secreting GM-CSF, IL-17F, or IFN γ in the lymph nodes of IL-17A^{-/-} mice during the induction phase of EAE, and in the CNS during the acute phase of disease. Furthermore, WT mice treated with anti-IL-17A antibody only at induction of EAE showed similar attenuation of EAE and reduction in Th17 responses as IL-17A^{-/-} mice, indicating a key role for IL-17A in the priming of autoreactive Th17 cells. Surprisingly, T cells from MOG-immunized IL-17A^{-/-} mice were capable of inducing disease following transfer into WT mice, demonstrating that IL-17A production by autoreactive T cells is not essential for development of EAE. Finally, we found decreased expression of Th17-promoting cytokines IL-1 β , IL-23 and IL-6 in the lymph nodes of IL-17A^{-/-} compared with WT mice early in EAE, providing further evidence that IL-17A may function not only as an effector cytokine in host defence, but also as a pathogenic cytokine in autoimmunity through the induction or the expansion of Th17 cells.

A20 as a master regulator of islet inflammation and diabetes

Zammit, N.¹, Horikawa, K.², Langley, D.¹, Walters, S.¹, Goodnow, C.¹, Grey, S.¹

¹Garvan Institute, Darlinghurst, Australia, ²The Australian National University, The John Curtin School of Medical Research, Canberra, Australia

Aims: Single-nucleotide polymorphisms (SNPs) within tnfaip3 (A20) associate with susceptibility to autoimmune and inflammatory diseases including type-1-diabetes. How polymorphisms within the A20 locus contribute to disease at the tissue level is not understood.

Methods: In a genome-wide ENU-mutagenesis screen of C57BL/6 mice we identified a mouse line harboring a non-synonymous change of an evolutionary conserved isoleucine at amino-acid position 325 within the A20-OTU domain (A20I325N). We tested its effect on islet homeostasis.

Results: When challenged with mild inflammatory stress by syngeneic transplantation, A20I325N/I325N islet grafts show abnormal production of inflammatory factors and immune infiltration with severe glucose intolerance due to impaired beta-cell function. When directly challenged with an immunological insult by allogeneic transplantation, A20I325N/I325N islet grafts were hyper-inflammatory and more rapidly destroyed compared to WT allografts. When stimulated with TNF α , A20I325N cells exhibited exaggerated poly-ubiquitination of RIP1 at TNFR1 with enhanced NF- κ B and JNK/AP1. Conversely, ectopic expression of WT-A20 rescued the hyperinflammatory phenotype of A20I325N islets; suggesting that A20 may be used therapeutically to suppress tissue inflammation. Indeed, forced expression of A20 allowed permanent survival of ~50% of islet grafts across a full MHC-mismatch where control grafts are destroyed. The A20-expressing grafts at >100 days showed normal morphology, high frequencies of intra-graft antigen-specific regulatory T-cells with high expression of IL-10 & TGF-beta.

Conclusion: Human GWAS associate polymorphisms within the A20-OTU domain to inflammatory disease. Our data show how SNP's within this domain uncouple A20's protective effect, and provide a model for understanding how subtle A20 polymorphisms contribute to human disease.

Regulation of IL-10 expression in human T-cells in response to TNF blockade

Roberts, C.A.¹, Durham, L.¹, Fleskens, V.¹, Rajasekhar, M.¹, Frederiksen, K.S.², Evans, H.G.¹, Taams, L.S.¹

¹King's College London, Division of Immunology, Infection and Inflammatory Diseases, Centre for Molecular and Cellular Biology of Inflammation, London, United Kingdom, ²Novo Nordisk A/S, Biopharmaceuticals Research Unit, Inflammation Biology, Måløv, Denmark

It is well established that CD4⁺ effector T-cell subpopulations expressing pro-inflammatory cytokines such as interleukin-17 (IL-17) and interferon- γ (IFN γ) can acquire regulatory potential characterised by IL-10 expression. However, the underlying cellular and molecular mechanisms in these subpopulations are not yet fully elucidated. We recently showed that TNF blocking drugs increase IL-10 expression in human IL-17⁺ CD4⁺ T-cells. Here we further characterised the regulation of IL-10 expression via blockade of TNF α signalling, or other cytokine/co-stimulatory pathways, in human T-cell subpopulations.

Addition of the anti-TNF drug adalimumab to anti-CD3-stimulated human CD4⁺ T-cell/monocyte co-cultures promoted IL-10 expression in pro-inflammatory IL-17⁺, IFN γ ⁺, TNF α ⁺ and GM-CSF⁺ CD4⁺ T-cell subpopulations. Conversely, exogenous TNF α suppressed IL-10 expression. TNF α signalling similarly regulated IL-10 expression in CD8⁺ T-cells in anti-CD3-stimulated PBMC. IL-1R1 blockade, but not blockade of IL-17 or IFN γ (using neutralising antibodies), IL-6R (using tocilizumab) or co-stimulation (using abatacept), significantly increased IL-10 expression in CD4⁺ T-cell subpopulations. We found that TNF blockade directly promoted IL-10 in effector CD4⁺ T-cells activated by anti-CD3/CD28, in the absence of monocytes or regulatory T cells and independently of IL-27.

Gene expression profiling revealed 220 genes commonly regulated by TNF blockade in both IFN γ ⁺ and IL-17⁺ T-cells; these genes were enriched for cell cycle-associated functional annotations. Addition of TNF blocking drugs impaired CD4⁺ T-cell proliferative responses; however, elevated IL-10 expression and reduced CD4⁺ T-cell proliferation were not interdependent. Current experiments seek to characterise phenotypic changes induced by TNF blockade in CD4⁺ T-cell subpopulations, which may identify further mechanistic pathways relevant to IL-10 regulation.

1401

Co-expression of receptors type 1 and 2 to TNF-alpha on immunocompetent cells

Alshevskaya, A., Lopatnikova, J., Belomestnova, I., Sennikov, S. Federal State Budgetary Scientific Institution 'Research Institute of Fundamental and Clinical Immunology', Novosibirsk, Russian Federation

Background: Changes in number of membrane-bound receptors type 1 and 2 to pleiotropic cytokine TNF-alpha were shown in pathological conditions, and ratio of different type membrane receptors could be critical to switch type of cell response to mediator.

Aims: To estimate ratio of cells with different combinations of membrane-bound receptors to TNF-alpha in immunocompetent cell subsets (ICS) and assess the stability of their presence on cell membrane.

Methods: Optimization of flow cytometry sorting protocol of ICS with different expression level of TNFR1/2 allowed to allocate among T-lymphocytes, B-lymphocytes and monocytes in four subsets: TNFR1+TNFR2-, TNFR1+TNFR2+, TNFR1-TNFR2+, TNFR1-TNFR2-. Cultivation of sorted fractions over 72 hours was conducted to assess the spontaneous change in the receptor representation on cell membrane.

Results: The average percentages of allocated subpopulations among intact cells were, respectively: 20.8%:4.95%:9.35%:64.9% (for T-cells), 10.8%:11.9%:22.5%:54.75% (for B-cells), 16.3%:47.1%:17.5%:19.2% (for monocytes). Sorted T-lymphocytes with initially high level of TNFR2 expression retained it after 72h cultivation. Among TNFR2- T-lymphocyte fraction not more than 2% of the cells began to express TNFR2 after cultivation.

Conclusion: Immune cells differ in the co-expression of TNFR1 and TNFR2. For T-lymphocyte sorted fractions the expression level of TNFR2 remained stable during 72 hours. Further research of apoptosis level and proliferation activity of cells with different expression levels and different combinations of membrane-bound receptors to TNF-alpha are needed to enhance understanding of the relationship between the number of receptors and functional activity of cells.

Augmented vascular T-cell levels promote vascular dysfunction in the stroke prone spontaneously hypertensive rat via prostanoid pathways

Khan, S.L.¹, Andrews, K.L.¹, Vinh, A.², Jefferis, A.-M.¹, Memon, B.¹, Jennings, G.L.¹, Sampson, A.K.¹, Murphy, A.J.¹, Chin-Dusting, J.P.F.¹
¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia,
²Monash University, Department of Pharmacology, Melbourne, Australia

Vascular dysfunction is a hallmark of hypertension and is associated with vascular T-cell infiltration. The direct effect of T-cells on vascular function is undefined. We aimed to determine how aortic T-cells effect vascular function in the stroke-prone spontaneously hypertensive rat (SHRSP) compared to

normotensive Wistar Kyoto (WKY) rats. We found impaired endothelium-dependent relaxation in the SHRSP aorta, due to a combination of reduced basal nitric oxide (NO) levels, enhanced constrictor prostanoid activity and vasodilatory prostacyclin receptor dysfunction. This was accompanied by increased aortic T-cell levels in the SHRSP compared with the WKY. Isolated T-cells from the aorta, displayed a T-helper-1 cytokine skewing in the SHRSP compared with the WKY, indicated by a higher ratio of IFN γ to IL-4 production. Interestingly, *in situ* stimulation of the aortic T-cells with anti-CD3⁺ and anti-CD28⁺ antibodies worsened endothelial function only in the SHRSP aorta. Importantly, we found that basal NO levels were compromised in both strains after stimulating the T-cells, suggesting that this was not the mechanism responsible for T-cell-mediated vascular dysfunction. Instead, we found that T-cell-mediated vascular dysfunction in the SHRSP was associated with enhanced constrictor prostanoid production that was reversed with cyclo-oxygenase (COX) inhibition. Scavenging of reactive oxygen species (ROS) also abrogated vascular dysfunction and prevented elevated constrictor prostanoid production in T-cell-stimulated SHRSP aortae, highlighting a close interaction between ROS and COX activity. In conclusion, perivascular T-cells appear to contribute to vascular dysfunction in the SHRSP through the elevated production of ROS which in turn stimulates COX to increase constrictor prostanoids.

IL-13-dependent biomarkers with liver inflammatory differentiation after pneumococcal sepsis during rapid inflammatory phase

Yamamoto, N.^{1,2}, Nakamura, K.¹, Arai, K.³, Dela Cruz, C.², Machida, T.⁴, Suzuki, Y.⁵, Ogura, Y.⁶, Abe, Y.⁷, Sekine, H.⁴, Iseki, K.⁷, Askenase, P.², Kanemitsu, K.¹

¹Fukushima Medical University, Department of Infectin Control, Fukushima, Japan, ²Yale University School of Medicine, Section of Allergy and Clinical Immunology, New Haven, United States, ³Kitasato University School of Medicine, Laboratory of Infectious Diseases Science, Tokyo, Japan, ⁴Fukushima Medical University, Department of Immunology, Fukushima, Japan, ⁵Fukushima Medical University, Department of Blood Transfusion and Transplantation Immunology, Fukushima, Japan, ⁶Nara Women's University, Division of Human Life and Environmental Sciences, Nara, Japan, ⁷Fukushima Medical University, Department of Emergency and Critical Care Medicine, Fukushima, Japan

Recently, we demonstrated that single IL-13-gene-dysrupted rodents (BALB/c mice) had a clear defective immune response as highly sustained lung colony-forming units (CFU) to *S. pneumoniae* infection via trachea (*Immunology*, doi:10.1111/imm.12544). The IL-13^{-/-} hosts exhibited a more distinct defect as a shortened survival duration compared to control BALB/c hosts when using an intravenously-injected sepsis model of the *S. pneumoniae*. To elucidate the responsible reason of the severe mortality, serum IgM, and several biomarkers via mRNA, that include CD14, TNF α , IL-6, HMGB1, CXCL2, NLRP3, and 4, IL-1 β , IL-18, caspase1, were investigated for the peripheral mononuclear cells (PBMC), the liver tissue, and blimp-1 for splenocytes in short time of 2.5 hours up to 48 hours after induction of intravenous

infection with *S. pneumoniae*.

The significant and distinct differences were observed with a decreased TNF α and an increased NLRP3 mRNA level within 10 hours post sepsis in the liver tissue in *IL-13*^{-/-} hosts compared with control BALB/c hosts. An averaged serum anti-polysaccharide IgM level, which was measured by ELISA, was lower in *IL-13* mice compared to that of control BALB/c before sepsis, but this was inverted within 48 hours post infection.

We hypothesized that *IL-13*^{-/-} hosts bear yet unknown immunological defects in liver inflammatory differentiation and splenic natural IgM-secretory systems, and both systems affect to the poor prognosis in an acute septic condition with *S. pneumoniae*.

Regulation of immune cell function by short chain fatty acids

*Xu, Y.*¹, *Naselli, G.*¹, *Bandala-Sanchez, E.*¹, *Thomas, T.*¹, *Harrison, L.C.*¹, *Zhang, Y.*^{1,2}

¹Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia, ²Guangzhou Institute of Pediatrics, Guangzhou Women and Children's Medical Center, Guangzhou, China

Short chain fatty acids (SCFAs) including acetate, propionate and butyrate are produced by bacterial fermentation in the colon of dietary fibre and undigested carbohydrate. They have been shown to modulate immune cell function by inhibiting histone deacetylases and activating G-protein coupled receptors. We studied the contribution of SCFAs to cytokine expression in adult human T cells. In the presence of IL-2, SCFAs promoted IFN- γ expression in both CD4⁺ and CD8⁺ T cells upon T cell activation. This was abrogated by either IL-2 neutralization or inhibition of glycolysis or fatty acid synthesis (FAS). SCFAs also promoted the expression of IL-4, most strikingly in CD8⁺T cells activated in the absence of IL-2, or when FAS was inhibited following CD4⁺T cell activation. This correlated with increased expression of carnitine palmitoyltransferase I (CPT1), which is critical in mitochondrial fatty acid oxidation (FAO), and decreased phosphorylation of ribosome protein S6, a target molecule of mTOR pathway in CD8⁺T cells. Thus, SCFAs may promote both IFN- γ and IL-4 expression, either by promoting glycolysis and FAS in the presence of IL-2 or by promoting FAO in the absence of IL-2. Our findings highlight the complexity of immune modulation by SCFAs and caution in their clinical application.

Regulation of myeloid cell differentiation by S100A8 and S100A9

Defrene, J., Laouedj, M., Cesaro, A., Pagé, N., Barabé, F., Tessier, P.
Université Laval, Quebec, Canada

S100A8 and S100A9 are calcium-binding proteins highly expressed by myeloid cells. These damage-associated molecular patterns are found at high concentrations in the serum of patients suffering from inflammatory diseases and myeloid leukemia. S100A8 and S100A9 are secreted by a mechanism presumed to be linked to inflammasome activation,

and once secreted stimulate cytokine secretion by neutrophils and monocytes by binding to TLR receptors. Recent reports suggest that S100A8 and S100A9 modulate dendritic cell maturation. In this study, we examined the roles of S100A8 and S100A9 on myeloid cell differentiation. Deletion of the *S100a8* gene led to an increase of myeloid (CD11b⁺) cells in the blood and bone marrow, including granulocyte (Ly6C⁺Ly6G^{high}) and monocyte/macrophage (Ly6C⁺Ly6G⁻CD115⁻) precursors. Similarly, expression of myeloid markers (CD11c, Gr1, and 7/4) was increased in the tissues of *S100a8*^{-/-} mice. Blocking S100A8 using antibodies induced the differentiation of acute myeloid leukemia cells in granulocytes and monocyte/macrophages, indicating that S100A8 was acting as an extracellular factor. While anti-S100A9 had no effect on myeloid cell differentiation, S100A9 protein increased expression of the neutrophil marker 7/4 in bone marrow cells, and induced the differentiation of AML cells in granulocytes and monocyte/macrophages. We conclude that S100A8 and S100A9 are differential regulators of myeloid cell differentiation. While S100A8 inhibits differentiation, S100A9 promotes differentiation of myeloid precursors/progenitors in granulocytes and monocyte/macrophages.

Introduction: People with asthma and COPD are more susceptible to viral infections, which in turn are major causes of exacerbations. However, the immunological mechanisms underpinning these associations are poorly understood.

Methods: Mice were subjected to Ovalbumin (Ova)-, house dust mite (HDM)- or recombinant IL-13 (rIL-13)-induced models of allergic airway disease (AAD), or cigarette smoke-induced experimental COPD and infected with influenza (A/PR/8/34). Some groups were treated with anti-IL-13 neutralizing antibody, miRNA-21-specific antagomirs, PI3K inhibitors, steroids or relevant vehicle controls during influenza infection. Complimentary in vitro studies using bronchial epithelial cells (pBECs) from asthmatics and COPD patients were performed. The cellular source of IL-13 was determined using IL-13-reporter mice.

Results: Influenza infection enhanced the severity of Ova-, HDM- and rIL-13-induced AAD by increasing lung eosinophils, mucus

and airway hyperresponsiveness (AHR). Importantly, anti-IL-13 treatment during AAD suppressed eosinophils, mucus and AHR. Influenza virus infection also exacerbated experimental COPD. All models resulted in increased viral load, which correlated with suppressed interferon's and increased miR-21 and PI3K levels in the lung. Anti-IL-13 treatment also improved anti-viral responses and reduced viral load. IL-13 increased both miR-21 and PI3K, and inhibition of these molecules protected against infection in both mice and human pBECs. Steroids were ineffective and actually increased viral load. Influenza infection increased IL-13-production by NKT cells, ILC2 and Th2 cells.

Conclusion: IL-13 responses during asthma and COPD lead to impaired anti-viral immune responses resulting in more severe influenza infection that exacerbates the underlying disease. These studies identify anti-IL-13 as a potential therapy in influenza infections.

Off-target effects of a live attenuated pertussis vaccine

Locht, C.

Inserm U 1019, Institut Pasteur de Lille, Center for Infection and Immunity of Lille, Lille, France

Pertussis, caused by *Bordetella pertussis*, is a severe respiratory disease that can be fatal, especially in young infants. Despite high vaccination coverage, pertussis is still not under control in any country and its incidence is even increasing in several industrialized countries. Although protective against pertussis disease, none of the current vaccines provide protection against infection by *B. pertussis*, which may be the main reason for its resurgence. We have developed a live attenuated pertussis vaccine, named BPZE1 that can be administered nasally. BPZE1 was constructed by the genetic alteration or removal of three toxins. It was found to be safe and efficacious in animal models and has now successfully completed a first-in-man phase I safety trial. During its pre-clinical evaluation, BPZE1 was found to possess interesting off-target properties. A single nasal administration provided protection against experimental asthma in mice. BZE1 also protected against Influenza virus-induced inflammatory pathology in mice, without significantly affecting the viral load. No T- or B-cell cross-reactivity between influenza virus and *B. pertussis* was detected, suggesting that the protection involves innate immune mechanisms. Interestingly, two administrations of BPZE1 increased the protective effect, suggesting innate immune memory. A comparison of the transcriptomic profiles of mice infected with anti-inflammatory BPZE1 compared to pro-inflammatory virulent *B. pertussis* revealed that most genes specifically activated by BPZE1 within the first days after administration code for several cytochrome P450 polypeptides, glutathione S-transferases and enzymes involved in lipid metabolism. These findings establish a link between lipid metabolism, detoxification mechanisms and boostable anti-inflammatory effects of BPZE1.

Vaccine-induced, antigen-specific T_H9 immune response blocks tumor cell engraftment

Garipey, J., Abdul-Wahid, A., Cydzik, M., Prodeus, A., Alwash, M., Stanojic, M., Huang, E., Thompson, M.

Sunnybrook Research Institute, Toronto, Canada

Ninety percent of all cancer-related deaths are associated with the occurrence of metastases. The development of a vaccine that would prevent the implantation of circulating cancer cells or the expansion of micrometastases would represent an ideal strategy for averting the recurrence of disease (relapse) in cancer patients. We now report that a vaccination strategy yielding an antigen-specific T_H9 response can induce long term host immune surveillance that prevents the engraftment of circulating cancer cells. Specifically, the vaccination of immunocompetent CEA transgenic mice with an altered-self form of the CEA IgV-like N domain, formulated with the TLR3 agonist poly I:C, elicits a CEA N domain-specific T_H9 response, wherein IL-9 secreting T_H cells act in concert with CEA N domain-specific antibodies as well as activated mast cells in preventing tumor cell engraftment. In contrast, vaccine-imparted protection was reversed upon depleting CD3⁺ T cells, neutralizing serum IL-9, pharmacologically stabilizing or by depleting of CD117⁺ mast cells, *in vivo*. The induced immune response was specific for the N domain of CEA (CEACAM5) with no autoimmune-related pathologies observed in CEA transgenic mice that express a complement of related human CEACAMs. Collectively, these results highlight the first instance of a vaccine developing a tumor Ag-specific T_H9 immune response and points to the existence of an alternate tumor eradication mechanism that can be exploited for developing metastasis-preventing immunotherapies. (Supported by OCIR-IPDC, CBCF and CIHR).

RNA- and protein-based influenza vaccines induce antigen-specific CD8⁺ T-cells identified by MHC class I pentamers with different gene expression profiles

Meldgaard, T.^{1,2,3}, Blengio, F.^{1,3,4}, Sammiceli, C.^{1,3}, Tavarini, S.^{1,3}, Mangiavacchi, S.^{1,3}, De Gregorio, E.^{1,3}, Rappuoli, R.^{1,3}, Geall, A.^{3,5}, Siena, E.^{1,3}, Nuti, S.^{1,3}, Kratzer, R.^{3,6}, Bertholet, S.^{1,3}

¹GSK Vaccines, Siena, Italy, ²University of Siena, Siena, Italy, ³Formerly Novartis Vaccines & Diagnostics, Siena, Italy, ⁴University of Turin, Siena, Italy, ⁵Avidity NanoMedicines, La Jolla, United States, ⁶Transgene, Lyon, France

Priming of antigen-specific CD8⁺ T cells by vaccination is key for subsequent viral clearance. To characterize the heterogeneity of vaccine-induced CD8⁺ T-cells, we performed gene expression profiling at the single-cell level, after delivery of RNA-based (SAM[®](H1) (A/California/2009/H1)) or MF59[®]-adjuvanted Monovalent Influenza Vaccine (aMIV (A/California/2009/H1N1)). CD8⁺ T cells were isolated from mouse splenocytes, stained with MHC class-I HA533-554 pentamer, single-cell sorted, lysed, and processed for multi-parametric RT-qPCR analysis of 96 individual genes.

SAM(H1) induced higher frequencies of pentamer+ CD8⁺ T cells compared to aMIV at all timepoints tested. Ten days after the

second immunization, Principal Component Analysis (PCA) revealed a transcriptional difference of CD8⁺ T cells induced by each vaccine, with upregulation of cytotoxic (GrzA+Grzb+) and inflammatory homing (Cxcr3+Cxcr6+) markers for SAM(H1), and survival markers for aMIV (CD27+). Refined analysis of effector(CD62L⁻CD127⁻CD44⁺), effector-memory(CD62L⁻CD127⁺CD44⁺) and central-memory(CD62L⁺CD127⁺CD44⁺), highlighted significant differences in gene expression profiles between and within the vaccines. SAM(H1) induced mostly effector-memory cells, while aMIV induced equal number of central-memory and effector-memory cells. Both vaccines induced few effector cells, and only CD8⁺ T cells from SAM(H1) showed terminally differentiated short-lived effector cells subpopulation (klrg1⁺IL7ra⁺CD62L⁻CXCR3⁻Tbet⁺Blimp-1⁺). Effector-memory, unlike central-memory, showed a transcriptional difference between the vaccines. SAM(H1) and aMIV upregulated members of the cytolytic/FasL and Tumor Necrosis Factor Superfamily pathways, respectively. In conclusion, this approach identified distinct pentamer⁺ CD8⁺ T-cell subsets elicited by different vaccines. Data is being analyzed for other timepoints and confirmed at the protein level using the CyTOF platform. Such results might unravel new vaccine-specific immune signatures possibly correlating with protection.

Cross-reactive neutralizing antibody responses of high-growth enterovirus 71 genotype B5 vaccine candidate in rabbits

Chia, M.-Y.¹, Chung, W.-Y.¹, Wang, C.-H.², Chang, W.-H.², Lee, M.-S.¹

¹National Health Research Institutes, NIIDV, Zhunan, Taiwan, Republic of China, ²Academia Sinica, Institute of Chemistry, Taipei, Taiwan, Republic of China

Enterovirus 71 (EV71) is a non-enveloped RNA virus of the family *Picornaviridae*. Based on phylogenetic analysis of the most variable VP1 gene, EV71 could be classified into 3 major genogroups (A, B and C) including 11 genotypes (A, B1~B5, and C1~C5). Since 1997, different EV71 genotypes have caused life-threatening epidemics with severe neurologic complications in Asia, including Malaysia, Taiwan, Singapore, Brunei, Vietnam, Cambodia and China. Therefore, development of EV71 vaccines is a national priority in these countries. Currently, five vaccine candidates have been evaluated in clinical trials in China (3 genotype C4 candidates), Singapore (1 genotype B2 candidate), and Taiwan (1 genotype B4 candidate). Overall, these 5 vaccine candidates could not grow very well (~10⁷ PFU/ml) in cells qualified for vaccine production. In addition, genotypes of these 5 candidates are different from the current predominant genotype B5 in Taiwan and South-Eastern Asia. Therefore, we generated high-growth EV71 genotype B5 virus (HG-B5) which could grow to high titers (~10⁸ PFU/ml) in Vero cells. Infectious HG-B5 particles were purified using sucrose gradient ultracentrifugation and collected to immunize rabbits. Rabbits (two rabbits for each group) were intramuscularly immunized with two doses of purified HG-B5 at 0 and 14 day post-immunization (DPI) using two dosages (0.05 and 0.25 ug of total protein) adjuvanted with alum. The purified HG-B5

could induce cross-reactive neutralizing antibody responses against three EV71 major genogroups. The results indicate that Vero cell-derived HG-B5 vaccine candidate is immunogenic in rabbits and has commercial potential for development of new-generation EV71 vaccines.

Multi-epitope chimaeric VLP as a therapeutic vaccine for colorectal cancer

Donaldson, B.¹, Ward, V.², Young, S.¹

¹University of Otago, Pathology, Dunedin, New Zealand, ²University of Otago, Microbiology and Immunology, Dunedin, New Zealand

The incidence of colorectal cancer (CRC) in New Zealand is more than double the world average, estimated to be responsible for almost 700,000 deaths worldwide annually. Treatment options for CRC are limited, and therapeutic vaccination is a promising alternative or supplement to conventional therapy. Therapeutic vaccines for cancer are designed to invigorate the immune system, triggering a cytotoxic immune response targeting tumour-associated antigens (TAAs). Our laboratory produces chimaeric virus-like particles (VLP) formed from the Rabbit hemorrhagic disease virus (RHDV) capsid protein VP60 as a vector for therapeutic cancer vaccines. RHDV VLP are an effective cancer vaccine vector, because they promote TAA epitope cross-presentation.

In this study, we recombinantly inserted epitopes derived from murine CRC TAAs into VLP. These VLP induced a potent cytotoxic immune response specific for these epitopes in *in vivo* cytotoxicity assays. Vaccination with VLP containing a single CRC epitope had efficacy comparable to a model antigen construct in a subcutaneous murine CRC trial, delaying tumour growth with 50% overall survival. Tumour growth rate was further delayed with a vaccine containing two different CRC epitopes, with overall survival boosted to 60%. 100% of mice cured of their primary tumour with either of these CRC vaccines were protected from rechallenge in their opposing flank, indicating the presence of persistent systemic immunity. The enhancement of vaccine efficacy by incorporating a second TAA epitope may be indicative that further improvement is possible by including more targets in a multi-epitope therapeutic vaccine.

Induction of mucosal and systemic immune responses following intranasal vaccination with liposomes containing surface-expressed peptide, encapsulated carrier protein: protection from group A streptococcus following challenge

Zaman, M., Ozberk, V., Reiman, J., Langshaw, E., Pandey, M.,

Batzloff, M., Good, M.

Institute for Glycomics, Griffith University, Southport, Australia

Group A streptococcus (GAS) infections are extremely important clinical problems due to their global health burden. Rheumatic fever and rheumatic heart disease are responsible for the majority of morbidity and mortality (estimated at 12 million cases annually with 380,000 fatalities) (1). Current leading GAS vaccine candidates are challenged by their limited efficacy

against primary GAS infections of the upper respiratory tract (URT) due to lack of mucosal antibody responses (2). This is due in large part to the lack of human approved mucosal adjuvants. We describe an innovative vaccine strategy to induce mucosal and serum antibodies against GAS in animal models based on an important neutralizing antibody determinant from the cell surface GAS M protein. Incorporation of carrier protein and M protein-based B cell epitopes onto liposomal vesicles induce potent serum and mucosal antibodies without the need for an additional adjuvant and which was capable of preventing GAS infection post challenge. The liposomal construct was capable of activating human dendritic cells, highlighting the promise of the self-adjuvanting construct to translate from murine studies to application in humans as a vaccine candidate. Our findings are an important step toward overcoming current obstacles in the development of a GAS vaccine to prevent infection at mucosal sites and community dissemination. The study provides important mechanistic insights into how liposomal particulate delivery systems can collectively induce the desired mucosal immune responses to combat GAS infection. The strategy reported here is relevant to the development of subunit mucosal vaccines against other pathogenic organisms.

A novel TB vaccine based on *Mycobacterium tuberculosis* sulphur metabolism enzymes formulated with Advax™ polysaccharide adjuvant

Counoupas, C.^{1,2}, *Pinto, R.*^{1,2}, *Ngalingam, G.*^{1,2}, *Britton, W.*^{1,2}, *Petrovsky, N.*^{3,4}, *Triccas, J.*^{1,2}

¹University of Sydney, Infectious Diseases and Immunology, Camperdown, Australia, ²Centenary Institute, TB Program, Camperdown, Australia, ³Flinders Medical Centre, Vaxine Pty Ltd, Adelaide, Australia, ⁴Flinders University, Department of Endocrinology, Adelaide, Australia

There is an ongoing need for the rational design of novel safe and effective vaccines against *Mycobacterium tuberculosis* infection. We have previously identified members of the *M. tuberculosis* sulphate assimilation pathway (SAP) as protective antigens that are expressed during multiple stages of tuberculosis disease in animal models (e.g. active and chronic phases). Fusion proteins based on CysD, the major SAP protective component, were highly immunogenic in mice, resulting in generation of a high frequency of multi-functional CD4⁺ T cells, both pre- and post-aerosol *M. tuberculosis* challenge. To further enhance vaccine potency, the lead candidate vaccine, termed CysVac2, was tested in combination with a range of adjuvants including Advax, a novel polysaccharide adjuvant derived from delta inulin. The combination of CysVac2 and Advax provided significantly reduced bacterial burden in the lungs of *M. tuberculosis*-challenged mice, with no safety or reactogenicity issues identified. Following further optimization of the CysVac2-Advax formulation, studies were undertaken into the nature of the observed protective effect. Vaccine administration resulted in a rapid influx of monocytes/macrophages and neutrophils to the site of vaccination, as well as pronounced priming of *M. tuberculosis*-specific CD4⁺ T cells, resulting in increased IFN- γ ⁺TNF⁺IL-2⁺ effector CD4⁺ T cells. As delta inulin adjuvants have

shown a good safety profile when previously trialed in humans, this particular CysVac2 vaccine formulation appears a strong candidate for further preclinical evaluation for progression to human trials.

1790

A model to study the impact of polymorphism in vaccine design, using altered peptide ligands of an immunodominant CD8 T cell epitope

Wilson, K.L., Xiang, S.D., Plebanski, M.

Monash University, Melbourne, Australia

Vaccines to complex pathogens containing polymorphic antigens, such as pre-erythrocytic malaria parasites, need to be highly immunogenic as well as broadly cross-reactive to account for antigen variability. Little is known about how adjuvant selection for inclusion in vaccines affects the breadth of the immune response being induced. Variant T cell epitope sequences with single or multiple amino acid substitutions are termed altered peptide ligands (APLs). Herein, we present a model investigating APL reactivity to the immunodominant CD8 T cell epitope of the murine malaria strain *Plasmodium berghei*, SYIPSAEKI (pb9, or KI for short). Different adjuvants, representing natural adjuvants (*ex-vivo* peptide pulsed dendritic cells), conventional inflammatory adjuvants (Montanide and poly I:C), as well as non-inflammatory nanoparticle carriers in the viral size range (40-50nm polystyrene nanoparticles), were compared for their ability to induce high homologous and heterologous (cross-reactive) immune responses. Interestingly, whereas the overall magnitude of homologous immune responses was affected by the adjuvant used, changing adjuvants did not alter the pattern of cross-reactivity. By contrast, including APLs in the vaccine formulation was able to increase the breadth of cross-reactive responses. These results indicate that it may be pertinent to consider natural or re-engineered APLs of variant epitopes as vaccine candidates in future studies.

Vaccine antigen design to maximize anti-HIV CD4+ T cell responses

*Cunha-Neto, E.*¹, *Ribeiro, S.*¹, *Santoro Rosa, D.*², *Almeida, R.*¹, *Kalil, J.*¹

¹University of São Paulo, São Paulo, Brazil, ²Federal University of São Paulo, São Paulo, Brazil

Eliciting CD4⁺ T cell responses has been essentially unexplored in the HIV vaccine field, despite the increasing importance of the CD4⁺ T cell response in protection against HIV. We used rational vaccine design to develop a DNA vaccine encoding HIV-1 B subtype or M-type conserved, multiple HLA-DR-binding CD4⁺ T cell epitopes, found to be recognized by multiple HIV-1-infected patients. Vaccines elicited broad, polyfunctional, and long-lived CD4⁺ T cell responses in BALB/c and HLA class II transgenic mice, eliciting extensive cross-clade immunity. Immunization of BALB/c mice increased CD8⁺ T cell responses against subsequent whole HIV protein immunization, and reduced viral titers after challenge with a recombinant vaccinia virus encoding HIV proteins. Immunization prior to recombinant

gp140 HIV envelope protein drastically increased the IgG2a/IgG1 ratio of elicited anti-gp140 antibodies. Immunization of Rhesus macaques induced broad IFN- γ ELISPOT responses 10-fold higher than those found in mice; we found a predominantly CD4⁺ T cell intracellular cytokine response basically consisting of IFN γ , TNF α IL-2, Granzyme B. By virtue of inducing broad responses against multiple conserved CD4⁺ T cell epitopes that can be recognized across diverse HLA class II alleles, this vaccine concept may induce T cell responses against multiple peptides in large proportion of the population. By increasing the chance of matching the responses with multiple epitopes in the infecting HIV isolate, the vaccine concept may also cope with HIV genetic variability. It may be a candidate for standalone use or in association with conventional immunogens, to increase the amplitude and coverage of the induced response.

The immunoreceptor TIGIT regulates anti-tumor and anti-viral T cell effector function

Grogan, J.

Genentech, Cancer Immunology, South San Francisco, United States

Strategies to reactivate exhausted antitumor immune responses with antibody blockade of key T cell coinhibitory receptors such as PD1/PDL1 or CTLA-4 have demonstrated transformational potential in the clinic. We recently identified T cell immunoreceptor with immunoglobulin (Ig) and ITIM domains (TIGIT), a co-inhibitory receptor on T and NK cells, which critically limits anti-tumor and other CD8⁺ T cell-dependent chronic immune responses. TIGIT is an Ig super family member expressed on the surface of activated T cell and natural killer (NK) cell subsets. TIGIT interacts with high affinity with CD155 (poliovirus receptor [PVR]). Activation of TIGIT on T and NK cells limits proliferation, effector cytokine production, and killing of target tumor cells. TIGIT is elevated in the tumor microenvironment in many human tumors, is coordinately expressed with other checkpoint immune receptors such as PD1. In models of both cancer and chronic viral infection antibody co-blockade of TIGIT and PD-L1 enhanced CD8⁺ T cell effector function, resulting in significant tumor and viral clearance respectively. This effect was abrogated by blockade of TIGIT's complementary co-stimulatory receptor, CD226, whose dimerization is disrupted upon direct interaction with TIGIT in cis. These results define a key role for TIGIT in inhibiting chronic CD8⁺ T cell-dependent responses. Therapeutic blockade of TIGIT may result in improved eradication of malignancies when used in conjunction with other anticancer therapies including those that modulate anti-tumor immune responses.

1089

Monoclonal antibodies against GARP/TGF- β 1 complexes inhibit the immunosuppressive activity of human regulatory T cells *in vivo*

Liénart, S., Coulie, P., Lucas, S.

Université Catholique de Louvain / de Duve Institute, Brussels, Belgium

Regulatory T lymphocytes (Tregs) are essential to prevent autoimmunity, but excessive Treg function contributes to cancer progression by inhibiting anti-tumor immune responses. Tregs exert contact-dependent inhibition of immune cells through the production of active TGF- β 1. On the Treg cell surface, TGF- β 1 is in an inactive form bound to membrane protein GARP and then activated by an unknown mechanism. We demonstrated that GARP is involved in this activation mechanism. Two anti-GARP monoclonal antibodies were generated that block the production of active TGF- β 1 by human Tregs. These antibodies recognize a conformational epitope that requires amino-acids GARP¹³⁷⁻¹³⁹ within GARP/TGF- β 1 complexes. A variety of antibodies recognizing other GARP epitopes did not block active TGF- β 1 production by Tregs. In a model of xenogeneic graft-versus-host disease in NSG mice, the blocking antibodies inhibited the immunosuppressive activity of human Tregs. These antibodies may serve as therapeutic tools to boost immune responses to infection or cancer, via a mechanism of action distinct from that of currently available immunomodulatory antibodies. Used alone or in combination with tumor vaccines or antibodies targeting the CTLA4 or PD1/PDL1 pathways, blocking anti-GARP antibodies may improve the efficiency of cancer immunotherapy. We recently obtained the crystal structure of GARP/TGF- β 1 complexes interacting with the Fab of a blocking anti-GARP antibody. We will also explain how these data help us understand the mechanism of action of such antibodies.

Interactions between ILC3 and tumor microenvironmental cells in lung cancer: role in the development of intratumoral tertiary lymphoid structures

Carrega, P.¹, Campana, S.², Mingari, M.³, Moretta, L.⁴, Ferlazzo, G.⁵

¹Istituto G. Gaslini, Genova, Italy, ²University of Messina, Messina, Italy, ³University of Genova, Genova, Italy, ⁴IRCCS Bambin Gesù Hospital, Rome, Italy, ⁵University of Messina, Human Pathology, Messina, Italy

Tertiary lymphoid structures (TLS) are a common finding in non-small-cell lung cancer (NSCLC) and are predictors of favorable clinical outcome. Here we show that NCR⁺ Innate Lymphoid Cells (ILC)3 are present in the lymphoid infiltrate of human non-small-cell lung cancer (NSCLC) and are mainly localized at the edge of tumor-associated TLS. This intra-tumoral lymphocyte subset is endowed with lymphoid tissue-inducing properties and, upon activation, produces IL-22, TNF- α , IL-8, IL-2 and activates endothelial cells. Tumor-NCR⁺ILC3 may interact with both lung tumor cells and tumor-associated fibroblasts, resulting in the release of cytokines primarily upon engagement of the NKp44 activating receptor. On the other hand, the interaction between

ILC3 and BDCA1⁺ dendritic cells (DCs), but not BDCA3⁺ DCs, results in ILC3 activation, proliferation and production of a large amount of relevant cytokines, including lymphotoxins, but DC-induced activation of ILC3 functions are NKp44 independent and mediated by DC-derived soluble factors.

In patients, NCR⁺ILC3 are present in significantly higher amounts in stage I/II NSCLC than in more advanced tumor stages and their presence correlate with the density of intratumoral TLS. Our results indicate that NCR⁺ILC3 accumulate in human NSCLC tissue, where they interact with different cells of the tumor microenvironment, possibly contributing to the formation of protective tumor-associated TLS.

2899

High dimensional analysis of tumor mutant antigen-specific CD8⁺ T cells shows that checkpoint blockade immunotherapy targets T cells in tumors but not the periphery

Fehlings, M.¹, Penny, H.L.¹, Gubin, M.M.², Ward, J.P.², Simoni, Y.J.¹, Wong, S.C.¹, Schreiber, R.D.², Newell, E.W.¹

¹A*STAR, Singapore Immunology Network, Singapore, Singapore,

²Washington University School of Medicine, Department of Pathology and Immunology, St. Louis, United States

Recent advances in the field of cancer immunotherapy provide evidence that checkpoint blockade mediated tumor rejection can depend on mutant tumor antigen-specific CD8⁺ T cells. However, analysis of such T cells in tumor bearing individuals is challenging due to the need to detect rare antigen-specific T cell populations in patient samples that are limited in size. Here, we evaluate CD8⁺ T cells from mice bearing progressively growing methylcholanthrene (MCA)-induced sarcomas that are susceptible to checkpoint blockade immunotherapy. By coupling mass cytometry with multiplex combinatorial tetramer staining we screened for CD8⁺ T cells targeting 82 potential mutant peptide-MHC complexes, while retaining the ability to further characterize these cells by several functional and phenotypic marker molecules. We identified significant numbers of CD8⁺ T cells restricted to two major mutant epitopes, mutant Lama4 (mLama4) and mutant Alg8 (mAlg8), simultaneously in tumors, spleens, draining and non-draining lymph nodes in untreated tumor bearing mice. Notably, antigen-specific CD8⁺ T cells from tumors were higher in frequencies and displayed higher levels of PD-1, Tim-3, and Lag-3 expression than their peripheral counterparts. Following anti-CTLA-4 therapy, we detected an increase in frequencies of mutant tumor antigen-specific CD8⁺ T cells isolated from tumors but not the periphery. In addition, whereas tumor infiltrating T cells showed a significantly reduced expression of markers associated with exhaustion, peripheral T cells were not affected. In conclusion, our approach facilitates mapping of a wide variety of tumor epitope candidates for the comprehensive analysis of rare mutant tumor antigen-specific T cells within different tissues.

T cell acute leukaemia development and chemo-resistance are mediated by dynamic interactions with heterogeneous bone marrow microenvironments

Hawkins, E.^{1,2}, Duarte, D.², Akinduro, F.², Khorshed, R.², Passaro, D.³, Nowicka, M.⁴, Strazkowski, L.⁵, Ruivo, N.², Scott, M.², Rothery, S.², Foster, K.³, Waibel, M.⁶, Johnstone, R.⁶, Robinson, M.⁴, Purton, L.⁵, Bonnet, D.³, Lo Celso, C.²

¹WEHI, Melbourne, Australia, ²Imperial College London, London, UK, London, United Kingdom, ³Francis Crick Institute, London, United Kingdom, ⁴University of Zurich, Zurich, Switzerland, ⁵St Vincent's Hospital, Melbourne, Australia, ⁶Peter MacCallum Cancer Centre, Melbourne, Australia

It is widely accepted that complex interactions between immune cells and their surrounding microenvironments contribute to normal cell function but also disease development. In light of this observed interdependency, novel interventions that target specific stromal cell lineages and their interactions with malignant lymphocytes are being sought. To this end, we studied both a mouse and human xenograft model of T cell acute lymphoblastic leukaemia (T-ALL) and developed novel intravital microscopy methods that allowed us to monitor the same cells and microenvironments in the bone marrow (BM) for up to 14 hours and repeated imaging sessions over multiple days. We observed highly dynamic interactions and promiscuous distribution of cells that migrated across the BM, without any preferential association with microenvironments. Unexpectedly, this environment-agnostic behaviour was maintained throughout disease including development of resistance to chemotherapy. Our results reveal that malignant lymphocytes do not depend on specific microenvironments for propagation of disease, nor the selection of chemo-resistant clones, suggesting a stochastic mechanism underlies these processes. Yet, while infiltration and progression are independent of the stroma, accumulation of malignant lymphocytes leads to rapid, selective remodelling of the endosteal space, resulting in a complete loss of mature osteoblastic cells whilst perivascular cells are maintained. This outcome leads to a shift in the balance of endogenous BM stroma, towards a composition associated with less efficient haematopoietic cell function. This novel, dynamic analysis of T-ALL highlights that future therapeutic interventions should target cell-intrinsic mechanisms, in order to combat the invasion by, and survival of, therapy-resistant lymphocytes.

Fibroblast activation protein induces inflammatory fibroblasts via STAT3-CCL2 signaling to promote tumor immunosuppression

Lin, Y.¹, Yang, X.¹, Shi, Y.², Li, B.¹, Dang, Y.³, Chu, Y.¹, Fan, J.², He, R.¹

¹Fudan University Shanghai Medical College, Shanghai, China,

²Fudan University Zhongshan Hospital, Shanghai, China, ³Fudan University Shanghai Medical College, Department of Biochemistry and Molecular Biology, Shanghai, China

Cancer associated fibroblasts (CAFs) recently are demonstrated to be inflammatory and mediate tumor-promoting inflammation,

however, the key molecules that determine inflammatory CAFs are poorly understood. Here we demonstrate that fibroblast activation protein-a (FAP) is required for the induction of a subset of inflammatory CAFs, as primary FAP⁺CAF, but not FAP⁻CAF, exhibited greatly increased STAT3 activation and inflammatory gene expression, particularly CCL2, and forced FAP expression endowed the normal fibroblasts with similar inflammatory phenotype. We further identified FAP as a persistent activator of fibroblastic STAT3 through FAK-c-Src-JAK2 signaling, which is dependent on its interaction with urokinase-type plasminogen activator receptor (uPAR). Moreover, FAP⁺CAF are major source of CCL2 within a transplanted murine liver tumor, and STAT3-CCL2 signaling is responsible for the tumor-promoting capability of FAP⁺CAF by enhancing tumoral recruitment of myeloid-derived suppressive cells (MDSCs) and immunosuppression, which was abrogated in *Ccr2*^{-/-} mice. Lastly, the positive correlation among fibroblastic expression of FAP, p-STAT3 and CCL2 was confirmed in a highly desmoplastic human intrahepatic cholangiocarcinoma (ICC), and increased stromal FAP levels predicted its poor outcome. Together our study reveals the critical role of fibroblastic FAP-STAT3-CCL2 axis in tumor-promoting inflammatory CAFs, and provides potential targets for specifically normalizing inflammatory CAFs to treat some inflammation and desmoplasia-associated cancers.

3694

Neutrophils are protective in cancerogenesis by altering tumor microenvironment and controlling intestinal microbiota

Ponzetta, A.¹, Galdiero, M.R.¹, Barbagallo, M.¹, Molgora, M.¹, Bonavita, E.¹, Magrini, E.¹, Polentarutti, N.¹, Garlanda, C.^{1,2}, Mantovani, A.^{1,2}, Jaillon, S.^{1,2}

¹Humanitas Clinical and Research Center, Lab of Experimental Immunopathology, Rozzano, Italy, ²Hunimed - Humanitas University, Rozzano, Italy

The view of neutrophil as a cell involved only in the early phases of inflammation has recently been challenged and neutrophils are now considered key players in the orchestration of the immune response. Though several studies relied on antibody-based neutrophil depletion to determine their contribution to tumor development, rigorous in vivo genetic evidence explaining the neutrophil role in cancerogenesis is missing.

We investigated this issue using key preclinical models of chemically-induced cancer (3-MCA induced sarcoma and AOM/DSS induced colorectal cancer, CRC) and taking advantage of a genetic model of neutrophil deficiency (i.e. *csf3r*^{-/-} mice).

Neutrophil deficiency was associated with increased susceptibility to sarcoma and CRC, and tumor microenvironment displayed protumoral features (e.g. increased frequency of M2 macrophages and Tregs, higher levels of IL-10 and reduced IFN γ concentration). In addition, in WT mice increased neutrophil infiltrate significantly correlated with reduced proliferation rate of tumor cells and adoptive transfer of naïve neutrophils reduced tumor growth in *csf3r*^{-/-} mice. Finally, the increased susceptibility to CRC in *csf3r*^{-/-} mice was dependent on intestinal microflora, and was abolished in cohousing experiments.

Collectively, our data support that genetic deficiency of

neutrophils affects the anti-tumor response and is associated with increased susceptibility to chemically-induced cancerogenesis.

Until recently neutrophil function was mostly related to acute inflammation and defense against pathogens. We (and others) have challenged this dogma and demonstrated that neutrophils represent an essential component in the control of tumor onset and development.

Tissue resident CD103⁺CD69⁺ T cells develop rapidly and do not require cognate antigen within the epidermis of a mouse model of precancerous skin

Leggatt, G., Veitch, M., Sheehan, B., McKee, S., Linedale, R., Jazayeri, S.D., Mattarollo, S.

University of Queensland, Diamantina Institute, Brisbane, Australia

Skin resident memory CD8 T cells (Trm), characterized by expression of CD103 and CD69 surface markers, are compartmentalised in the skin epithelium and play an important role in recall responses against infectious pathogens such as herpes simplex virus. Less understood is the development of Trm cells in cancer settings particularly in the early stages of non-melanoma skin cancer. Our study examines the development of CD103⁺CD69⁺ skin CD8 T cells in a mouse model of early NMSC where the HPVE7 oncoprotein expressed in keratin 14⁺ cells drives epithelial hyperplasia (K14E7 transgenic mice). The hyperplastic skin leads to a prominent accumulation of Trm cells which are resistant to male antigen mediated deletion in female mice. Upon transfer of activated, ovalbumin-specific OT-1 cells to the K14E7 transgenic mice, expression of CD103 and CD69 was upregulated on transferred OT-1 cells within the skin, but not lymph node, within one week. This suggests that skin resident cells develop rapidly in a process that does not require cognate antigen expression within the skin. The skin-resident OT-1 cells also showed reduced function while the inhibitory molecule, PD-1, was shown to be increased on endogenous CD8 T cells within K14E7 mice. Consequently, the data suggest that development of Trm-like cells can occur early in skin cancer development although the suppressive microenvironment might reduce their ability to impact on tumour progression.

STK4 regulates TLR pathways and protects against chronic inflammation-related hepatocellular carcinoma

Li, W.¹, Xiao, J.¹, Wang, H.¹, Wei, B.^{1,2}

¹Institute of Biochemistry and Cell Biology Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China, ²Wuhan Institute of Virology, Chinese Academy of Sciences, Wuhan, China

Hepatocellular carcinoma (HCC) is frequently associated with pathogen infection-induced chronic inflammation. Large numbers of innate immune cells are present in HCCs and can influence disease outcome. Here, we demonstrated that the tumor suppressor serine/threonine-protein kinase 4 (STK4) differentially regulates TLR3/4/9-mediated inflammatory

responses in macrophages and thereby is protective against chronic inflammation-associated HCC. STK4 dampened TLR4/9-induced proinflammatory cytokine secretion but enhanced TLR3/4-triggered IFN- β production via binding to and phosphorylating IL-1 receptor-associated kinase 1 (IRAK1), leading to IRAK1 degradation. Notably, macrophage-specific Stk4 deletion resulted in chronic inflammation, liver fibrosis, and HCC in mice treated with a combination of diethylnitrosamine (DEN) and CCl₄, along with either LPS or *E. coli* infection. STK4 expression was markedly reduced in macrophages isolated from human HCC patients and was inversely associated with the levels of IRAK1, IL-6, and phospho-p65 or phospho-STAT3. Moreover, serum STK4 levels were specifically decreased in HCC patients with high levels of IL-6. In STK4-deficient mice, treatment with an IRAK1/4 inhibitor after DEN administration reduced serum IL-6 levels and liver tumor numbers to levels similar to those observed in the control mice. Together, our results suggest that STK4 has potential as a diagnostic biomarker and therapeutic target for inflammation-induced HCC.

These proposed observations were published in latest *J Clin Invest.* 2015 Nov 2;125(11):4239-54.

The implications of vaccination-induced IFN-gamma signalling on the control of B-cell lymphoma and the acquisition of immune resistance

Rearden, R., Sah, A., Doff, B., Kobayashi, T., McKee, S., Leggatt, G., Mattarollo, S.

University of Queensland Diamantina Institute, Woolloongabba, Australia

Immunomodulatory therapies can effectively control haematological malignancies by promoting anti-tumour immunity. However, underdeveloped mechanistic insights and frequent tumour relapse limits the translation of many promising strategies. We previously developed a therapeutic natural killer T (NKT) cell-targeting vaccine that achieves transient control of poorly immunogenic murine non-Hodgkin B-cell lymphomas (B-NHL) and almost total control when combined with the agonistic monoclonal antibody anti-4-1BB (CD137). Therapeutic efficacy is highly dependent on the vaccine's ability to provoke rapid interferon-gamma (IFN γ) production from NKT and NK cells. By manipulating the capacity of either host or lymphoma cells to signal through IFN γ receptor (IFN γ R), we investigated whether the therapeutic effect conferred by vaccine-induced IFN γ results from immune cell activation, lymphoma IFN γ sensitivity or a combination of both. We demonstrated that successful therapeutic vaccination requires intact IFN γ signalling within host cells but not tumour cells. IFN γ R-deficient mice failed to mount an effective anti-tumour immune response following vaccination despite elevated IFN γ levels. With consecutive exposures to vaccination, lymphomas acquired increasingly therapy-resistant phenotypes and displayed a reduction in MHC-I and CD1d surface expression, independent of tumour intrinsic IFN γ signalling. Our results suggest that immunotherapy-induced IFN γ production exerts its therapeutic effect via signalling through host cells, rather than directly upon tumour cells in lymphoma. Consequently, intact IFN γ signalling within patients' immune compartment rather than tumour cell

sensitivity to IFN γ may be more critical for successful treatment. Finally, tumour IFN γ signalling alone does not drive acquired tumour resistance to vaccination, implying that additional immunoediting pathways are responsible for tumour immune escape.

Blood dendritic cell immunotherapy as consolidation therapy for acute myeloid leukaemia

Hsu, J.¹, Fromm, P.¹, Papadimitriou, M.¹, Bryant, C.^{1,2}, Orellana, D.², Gasiorowski, R.^{1,3}, Brown, R.², Ho, J.², Iland, H.², Gibson, J.², Joshua, D.², Clark, G.¹, Hart, D.¹

¹ANZAC Research Institute, Dendritic Cell Research, Sydney, Australia, ²Royal Prince Alfred Hospital, Department of Haematology, Sydney, Australia, ³Concord Repatriation General Hospital, Department of Haematology, Sydney, Australia

Acute myeloid leukaemia (AML) relapse after chemotherapy is common. Allogeneic haematopoietic cell transplantation enables immune-mediated removal of residual leukaemic blasts but graft versus host disease (GVHD) is a major risk. Dendritic cell (DC) vaccination may amplify or induce anti-leukaemic T cell responses with no risk of GVHD. Monocyte-derived DC (Mo-DC) vaccines loaded with Wilms Tumour 1 (WT1) mRNA have generated encouraging clinical results in AML but improved DC preparations are essential.

We identified the window of opportunity for blood DC (BDC) vaccination in AML after induction chemotherapy by documenting BDC subset recovery 6-12 weeks post chemotherapy. Using a human chimeric CMRF56 antibody (hCMRF56), we purified BDC from AML patients and showed that these BDC stimulated autologous viral and tumour specific T cell responses, confirming the feasibility of the strategy. Importantly, we showed that hCMRF56 does not bind to AML blasts and that it enriched both CD1c and CD141 myeloid DC. Loading BDC with *in vitro* transcribed mRNA encoded antigen results in superior, prolonged MHC I antigen presentation compared to Mo-DC, which is transitory. Stimulation of hCMRF56⁺ BDC with GM-CSF and loading with WT1 mRNA expanded functional cytotoxic antigen specific T cells.

The use of BDC has the potential to improve therapeutic efficacy by harnessing a superior antigen-presenting cell that has fundamentally different properties to *in vitro* manufactured Mo-DC. This new generation of BDC vaccine may consolidate AML remission with minimal risk and prevent the otherwise predictable relapse.

EpCAM⁺ dermal dendritic cells drive FITC/DBP-induced Th2 differentiation

Cho, Y., Kang, S.J.

Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of

Despite the reputation of dendritic cells as being the most potent antigen presenting cell, the involvement of dendritic cells

in T helper 2 cell immunity is not well established yet compared to other types of T helper responses. By using Fluorescein isothiocyanate (FITC) dissolved in acetone:dibutyl phthalate (DBP), a conventional method to induce Th2-mediated contact hypersensitivity, we sought to identify immune cells that are responsible for inducing Th2 responses. We focused on the early events by applying FITC/DBP once without inducing contact hypersensitivity. A single application of FITC/DBP was sufficient to drive Th2 responses as we observed early production of IL-4 from T cells and basophils in cutaneous lymph nodes. Although basophils produced IL-4 earlier than CD4 T cells, they were not essential for Th2 differentiation. A previous study has emphasized on the role of PDL2-positive DCs in Th2 differentiation. However, they are unable to differentiate naive CD4 T cells to Th2 cells *in vitro*. We examined the kinetics of migratory DC subsets in the setting of FITC/DBP Th2 differentiation and found the differential expression of PDL2 on each migratory DC subset. We found that EpCAM⁺ dermal DCs are required in Th2 differentiation after FITC/DBP as transient depletion of EpCAM⁺ dermal DCs failed to induce Th2 response. Surprisingly, we found that the cooperation of PDL2-negative EpCAM⁺ dermal DCs and CD11b⁺ dermal DCs are important for Th2 immune response in FITC/DBP Th2 differentiation.

Abnormalities of antigen presenting cells in type 1 diabetes

Boks, M.¹, Buchanan, K.¹, Nagl, L.¹, Harris, M.^{1,2}, Thomas, R.¹

¹University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia, ²Mater Children's Hospital, Brisbane, Australia

In type 1 diabetes (T1D) islet beta cell-specific autoimmunity promotes their inflammatory destruction by islet-reactive T-cells and progressive decline in capacity to produce insulin. Autoreactive T-cell activation is driven by antigen presenting cells, such as dendritic cells (DC), presenting islet self-antigens in draining pancreatic lymph nodes. We showed that the proportion of CD14^{lo}CD16⁺ monocytes was significantly increased in children with T1D and first degree relatives (FDR) compared to unrelated healthy control (HC) children. While the lack of CD14 and CD16 expression identifies peripheral blood (PB) DC precursors, these markers fail to distinguish the different functional DC subsets in circulation. Therefore, we further analysed the CD1c⁺ and CD141⁺ myeloid, and the CD123⁺ plasmacytoid DC subsets in PB of 11 children aged 9-13y presenting with T1D within the previous 3 months, 15 age and sex-matched FDR and 10 unrelated adult HC. The proportion of CD123⁺ pDC was significantly increased in children with T1D and FDR compared to HC. Presence of islet autoantibodies did not influence the proportion of pDC in FDR. The expression of HLA-DR by pDC of diabetic subjects was significantly higher than that of FDR or HC, indicating increased pDC activation and antigen presenting capacity. These data suggest that genetic or environmental factors increase pDC in children at risk, but a specific increase in pDC activity characterizes children who progressed to diabetes. Since pDC normally tolerate CD4⁺ T cells, this activation has important implications for the erosion of immune tolerance in this group.

1670**Effect of TNF- α on the process of Langerhans cell induction from human peripheral mononuclear cells***Otsuka, Y.^{1,2}, Koike, E.¹, Azuma, H.¹, Mayumi, N.^{1,2}, Saeki, H.², Takahashi, H.¹*¹*Nippon Medical School, Department of Microbiology and Immunology, Tokyo, Japan, ²Nippon Medical School, Department of Dermatology, Tokyo, Japan*

It has become widely known that anti-tumor necrosis factor (TNF)- α (TNF- α) agents (infliximab, etanercept, and adalimumab) are promising drugs to treat various inflammatory autoimmune diseases. However, we have to consider new-onset of various skin lesions such as lupus, eczema, alopecia-areata or psoriasis as an adverse side effect that can be triggered by the anti-TNF- α therapy. Epidermal Langerhans cells (LCs) originally derived from yolk sac or fetal liver in the pregnant state, while, after birth, they move to reside predominantly in the stratum spinosum of epidermis as sentinels and renew themselves from specialized local precursor cells in a steady state by interacting with keratinocytes through their E-cadherin as we have reported recently (*Eur. J Immunol.*, 43:270-280, 2013). However, when LCs in the epidermis were in the inflammatory phase, they may be renewed from peripheral mononuclear cells with the assistance of various cytokines, such as IL-6, TNF- α , or IL-1 β . Among them, TNF- α is essential for innate LCs to migrate from epidermal region to the T-cell rich paracortical area to generate Ag-specific primary acquired T-cell responses and thus, anti-TNF- α therapy may inhibit LC function and develop various cutaneous lesions. In the present study, we examined the effect of TNF- α on the process of induction or renewal of LCs when peripheral blood monocytes (PBMo) were stimulated with GM-CSF, IL-4, and TGF- β 1. We found up-regulation of Langerin as well as down-regulation of DC-SIGN. Thus, anti-TNF- α reagents may deteriorate renewal and function of LCs and inhibit a repair of various skin lesions.

4467**Immunomodulatory Drugs (IMiDs), lenalidomide and pomalidomide, have regulatory functions for human myeloid dendritic cells***Phan Thi, X.V., Ito, T., Inaba, M., Kibata, K., Iwata, R., Tanaka, A., Katashiba-Inagaki, N., Nomura, S.**Kansai Medical University, First Department of Internal Medicine, Hirakata City, Japan*

Dendritic cells (DCs) are pivotal in orchestrating both innate and acquired immunity. Series of recent analyses have revealed that DCs also play a pathogenic role in inflammatory and autoimmune diseases by their dysregulated function and cytokine production. According to the function of novel anti-tumor drugs, so-called Immunomodulatory Drugs (IMiDs) that have the potential to enhance T and NK cells function and to induce selective reduction of regulatory T cells, we hypothesized that these agents could modulate the functions of DCs as the center of the immunoregulatory system. Here we investigated the effect of two new analogs of thalidomide, lenalidomide (LEN) and pomalidomide (POM) on the function of human

myeloid DCs (mDCs). We found that both reagents at clinical concentration of 0.1 μ M to 1 μ M did not affect cell survival and maturation in response to TLRs (LPS, pIC, or R848) and TSLP. Either LEN or POM inhibited dose-dependently the production of Th1-type cytokine (IL-12, IFN- λ , and TNF α) and enhanced Th2-type cytokine (CCL17). Both agents significantly enhanced the production of IL-10 from mDCs, and this capacity of POM was stronger than that of LEN. As in myeloma cells, we also found that both LEN and POM downregulated IRF4 but upregulated IRF8 mRNA of mDCs. Our data suggest that IMiDs, although enhance the effector cell function, lead to regulatory action at DC phase. To further unveil the intracellular mechanism underlying the functions of IMiDs, we are now proceeding the analyses of STAT-family and PU.1 expression in this stream of action.

2073**Circulating tolerogenic monocytes are a hallmark of active human tuberculosis***Mascart, E., Dirix, V., Corbière, V., Bosse, J., Wyndham-Thomas, C., Sélis, E., Van Praet, A., Libin, M.**Université Libre de Bruxelles, Laboratory of Vaccinology and Mucosal Immunity, Brussels, Belgium*

Tuberculosis (TB) still represents a major global health problem, and the development of improved preventive and therapeutic approaches is hindered by an incomplete understanding of its pathogenesis. Effective cellular immune responses are key for protection against TB, and they are depressed in patients with active TB (aTB). The role of antigen-induced regulatory T cells (Treg) is recognized, but their mechanism of induction remains unknown. In view of the major role of antigen-presenting cells (APC) in their induction, we analyzed by flow cytometry the expression of different receptors on circulating monocytes (Mo) and dendritic cells (DC) in 15 patients with aTB, 15 latently-TB-infected (LTBI) subjects and 15 uninfected controls. The proportions of CD14⁺CD16⁻ and CD14⁺CD16⁺ Mo were higher in aTB compared to LTBI and controls ($p < 0.01$), as was that of mDC1 (CD11c⁺CD123⁻CD141⁻) ($p < 0.05$). The percentages of PDL-1⁺CD14⁺CD16⁻ Mo and mDC were higher among aTB patients than LTBI and controls ($p < 0.01$), with higher Mo PDL-1 MFI ($p < 0.01$), suggesting a role of T cell apoptosis in the down-regulated T cell responses. Analysis of ILT-3 expression, known to be expressed by tolerogenic APC and to mediate Treg cell generation, indicated higher proportions of ILT-3⁺CD14⁺CD16⁻ Mo, with higher MFI of this marker in aTB compared to LTBI subjects and controls ($p < 0.05$). We therefore not only found abnormal proportions of circulating Mo and mDC with abnormal phenotypes in aTB, but we identified high proportions of tolerogenic monocytes that could play a major role in the induction of Treg cells during aTB.

4154**Protein kinase C dependent differentiation of dendritic cells***Chavel, C., Lee, K.**Roswell Park Cancer Institute, Immunology, Buffalo, United States*

Dendritic cells (DC) are professional antigen presenting cells that are important activators of adaptive immune responses and play a role in the activation of CD8+ T cells that target tumor cells. Our lab has also previously shown that protein kinase C (PKC) β II is essential for DC differentiation and that tumor derived factors, particularly IL-6, inhibit DC differentiation by repressing the expression of PKC β II through a Stat3 dependent mechanism. However, the pathways activated downstream of PKC β II during DC differentiation have yet to be fully characterized. To study this, we used the K562 cell line, which differentiates into DCs with addition of PMA, a known chemical activator of conventional PKC isoenzymes. We have also shown previously that PMA specifically activates PKC β II in K562 cells. Addition of PMA to K562 cells showed the activation of the ERK1/2 and NF κ B pathways, including both the canonical and non-canonical NF κ B pathways. Chemical inhibition of either the ERK1/2 or NF κ B pathway yielded immature DCs with a reduced capacity to stimulate T-cell proliferation when incubated with PMA. Inhibition of ERK1/2 also showed a change in levels of RelB, a NF κ B transcription factor, with PMA treatment and during PMA induced DC differentiation. Inhibition of either the ERK1/2 or NF κ B pathways showed an increase in Foxo3a levels, indicating a role for the ERK1/2 and NF κ B pathways in Foxo3a regulation during differentiation into mature DCs. Taken together, these results show an integral role for both the ERK and NF κ B pathways downstream of PKC β II activation during DC differentiation.

T Cell Development**2246****Spatial interplay between Polycomb and trithorax complexes controls transcriptional activity in T lymphocytes***Onodera, A.¹, Tumes, D.², Kiuchi, M.¹, Kokubo, K.¹, Watanabe, Y.¹, Hirahara, K.¹, Kaneda, A.¹, Sugiyama, F.³, Suzuki, Y.⁴, Nakayama, T.¹**¹Chiba University, Chiba, Japan, ²South Australian Health and Medical Research Institute, Adelaide, Australia, ³University of Tsukuba, Tsukuba, Japan, ⁴University of Tokyo, Kashiwa, Japan*

Polycomb group (PcG) and Trithorax group (TrxG) complexes exert opposing effects on the maintenance of transcriptional status, and play a critical role in the expression of developmentally regulated transcription factors through methylation at histone H3-K27 (H3K27me₃; a repressive mark) and H3-K4 (H3K4me₃; a permissive mark), respectively. However, how they together mediate transcriptional counterregulation remains unknown. Genome-wide analysis revealed that binding of Ezh2 and Menin, central members of the PcG and TrxG complexes, respectively, were reciprocally correlated. Moreover, we identified a developmental change in the fine scale positioning of Ezh2 and Menin in differentiated

T lymphocytes compared to embryonic stem cells (ESCs). Ezh2 and Menin co-occupancy was most frequently observed in ES

cells and often lost during development into T lymphocytes. Ezh2-binding upstream and Menin-binding downstream of the transcription start site (TSS) was frequently found at genes with higher transcriptional levels, and Ezh2-binding downstream and Menin-binding upstream was found at genes with lower expression in T lymphocytes. Interestingly, of the Ezh2 and Menin co-occupied genes, those exhibiting occupancy at an identical position displayed greatly enhanced sensitivity to loss of Ezh2. Finally, we also found that different combinations of Ezh2 and Menin occupancy were associated with expression of specific functional gene groups important for T cell development. Therefore, spatial cooperative gene regulation by the PcG and TrxG complexes may represent a novel mechanism regulating the transcriptional identity of differentiated cells.

1787**Thymic precursors of CD8aa+ intestinal epithelial lymphocytes (IEL) divide into an emigrating and a retained population***Ruscher, R., Kummer, R., Lee, Y.J., Huggenberger, S., Hogquist, K.A. University of Minnesota, Minneapolis, United States*

Intestinal TCR β +CD4-CD8b-CD8a+ (CD8aa) IELs alleviate T cell induced colitis and have been suggested to play a role in virus infection and cancer. Their thymic development has been elucidated to some extent, as IEL precursors (IELp) are known to be CD4-CD8-CD5+TCR β +, but is not yet fully understood. Within the thymus, mature IELp were identified based on their expression of CD122 and MHC class I. Two major phenotypic subsets exist within this mature thymic IELp population: a PD1+Tbet- population that preferentially expresses a4b7, and a PD1-Tbet+ population with preferential CD103 expression. These two populations were also distinct in their Valpha repertoire. The PD1+a4b7+ population contains clones that are strongly self-reactive as judged by Nur77GFP and their dramatic increase in Bim deficient mice, while the PD1-Tbet+ population did not show these characteristics. Both gave rise to CD8aa IELs upon adoptive transfer into RAG-/- recipients. However intrathymic labeling revealed that PD1+a4b7+ IELp were the major thymic emigrating population, and emigration was S1P1-dependent. In contrast, PD1-Tbet+ IELp expressed CXCR3, were retained, and accumulated in the thymus with age. Preliminary immunofluorescence data furthermore indicate differential thymic cortico-medullary localization of the IELp subtypes. These experiments more precisely define the behavior of IEL precursors.

3064**Peripheral CD8 T cell receptor revision contributes to the plasticity of the immune repertoire***Dash, P.¹, Wang, G.¹, Bajracharya, R.¹, Contento, R.², McClaren, J.¹, Morris, M.¹, Love, J.C.², Doherty, P.¹, Thomas, P.¹**¹St Jude Children's Research Hospital, Immunology, Memphis, United States, ²Koch Institute for Integrative Cancer Research at MIT, Chemical Engineering, Cambridge, United States*

Using a technique for the paired amplification of TCR α and β chains from single cells, we have discovered a surprising

plasticity in the peripheral TCR repertoire, particularly under conditions of inflammation. This plasticity includes multiple instances of TCR revision in the periphery, where changes are made in the TCR coding sequence by *de novo* rearrangement. Here we describe this process in murine CD8+ T cells derived from influenza-infected lungs and human T cells derived from CMV-infected individuals *ex vivo* or in naïve single-cell cultures stimulated *in vitro*. Taking advantage of the co-expression of productive and non-productive *Tcra* alleles, we demonstrate secondary rearrangement in the TCR β locus *ex vivo*, while the *in vitro* cultures demonstrated a remarkably high rate of *Tcra* revision following strong stimulation. Not surprisingly, revision was found to be RAG-dependent. Utilizing a model of peripheral deletion of RAG2, we showed that mice deficient in revision showed delayed onset and severity of disease in an experimental autoimmune encephalomyelitis (EAE) model, and also produced a less functional T cell response following challenge with influenza virus. Additionally, in the absence of revision, the dominant NP₃₆₆ response was compromised in the recall phase while the responses to the minor epitopes were increased. Thus, peripheral TCR revision appears to be a robust process that contributes to optimal T cell functionality and repertoire diversity during infection but may also contribute to the development of autoimmunity.

3152

Tolerance by deletion and regulatory T cell differentiation arise from different TCR repertoires during two waves of thymic selection

Hu, D.Y.¹, Singh, M.², Yap, J.Y.¹, Wirasinha, R.C.³, Howard, D.¹, Archer, S.³, Goodnow, C.C.², Daley, S.R.³

¹The John Curtin School of Medical Research, The Australian National University, Canberra, Australia, ²Garvan Institute of Medical Research, Sydney, Australia, ³Monash Biomedicine Discovery Institute, Infection and Immunity, Melbourne, Australia

Thymocytes that receive a strong T cell receptor (TCR) signal may be deleted by apoptosis or diverted into the Foxp3+ T-regulatory (Treg) cell lineage. We are investigating whether this divergence is governed by the developmental stage at which thymocytes register a strong TCR signal. Analysis of apoptosis-defective mice suggests that ~50% of TCR-signalled thymocytes are deleted < 3 days after the cells proliferate as TCR^{hi} precursors. We characterise these short-lived Helios+ CCR7- PD-1^{high} thymocytes as wave 1 of thymic selection. Another subset of Helios+ thymocytes, defined by high CCR7 expression, forms ~5 days after proliferation and contains cells that upregulate Foxp3 protein 6-8 days after proliferation. The Helios+ CCR7+ thymocytes represent wave 2 of thymic selection. To compare TCRs within wave 1 or wave 2 of thymic selection with TCRs expressed by naïve CD4+ T cells, we purified thymocyte populations from TCRbeta-transgenic mice and deep-sequenced TCR-alpha transcripts. The data reveal that ~40% of TCRs were expressed selectively in wave 1 cells and these TCRs were rare or absent in CD4+ and CD8+ splenocyte samples, consistent with deletion of these TCRs. The thymic naïve CD4+ and wave 2 TCR repertoires were partially distinct from each other and were most similar to non-Treg and Treg

subsets of CD4+ splenocytes, respectively. We interpret these data as evidence that strong TCR-signalling triggers deletion of CCR7- thymocytes whereas it primes CCR7+ thymocytes for Treg differentiation. Moreover, the self-antigens that induce wave 1 and wave 2 of thymic selection would appear to be distinct.

3687

How many TCR clonotypes does a body maintain?

Lythe, G.¹, Molina Paris, C.¹, Callard, R.², Hoare, R.²

¹University of Leeds, Leeds, United Kingdom, ²University College London, London, United Kingdom

The number of T cells of one clonotype is an integer that increases or decreases by one cell at a time, starting when the clonotype is released from the thymus to the periphery, and ending with extinction of the clonotype. We present a stochastic model of naïve T-cell homeostasis based on competition between large numbers of TCR clonotypes, each with a unique recognition profile in the environment of self-pMHC stimuli. Thymic activity is included by the release of new clonotypes that compete in the pool of pre-established ones. Our point of view is to consider the stochastic dynamics of the number of T cells of one clonotype as a function of time, which increases or decreases according to the rates of cell division and death. By considering distributions of times to clonal extinction, we give estimates of clonal sizes, and hence diversity, in adult mice and humans. With the estimate that the ratio of thymic production to peripheral division of naïve CD4+ T cells is four percent, our model predicts that the number of distinct clonotypes in the human body is nine percent of the total number of naïve CD4+ T cells.

1339

Competitive signaling between STAT5 and PI3K of the IL-7R modulates T cell development and homeostasis in vivo

Cui, G., Shimba, A., Tani-ichi, S., Hara, T., Ikuta, K.

Laboratory of Biological Protection, Institute for Virus Research, Kyoto University, Kyoto, Japan

IL-7 is an important cytokine for T cell development and homeostasis. STAT5 and PI3K are two major signal molecules of the IL-7R involved in these processes. The tyrosine residue Y⁴⁴⁹ of IL-7Ra is essential for interaction and activation of both STAT5 and PI3K, while the methionine residue M⁴⁵² is additionally required for PI3K recruitment. Nevertheless, how STAT5 and PI3K signals are precisely controlled and contributed under the IL-7R has not been well understood. To characterize the differential roles of these two signals in vivo, we established two lines of IL-7Ra mutant mice, IL7R-Y449F and IL7R-M452L. Interestingly, the levels of phosphorylated STAT5 were downregulated in Y449F mice but significantly upregulated in M452L mice, whereas the levels of phosphorylated Akt were reduced in both Y449F and M452L mice. The Y449F mice showed markedly decreased T cells in thymus and periphery. In contrast, only the thymocytes at the ETP and DN2 stages were reduced in the M452L mice. In addition, the M452L mice also showed slightly increased T cells in periphery. Finally, memory precursor effector cells were

decreased in M452L mice during memory T cell development after *Listeria monocytogenes* infection. Thus, this study suggests a competition between STAT5 and PI3K for the Y⁴⁴⁹ of IL-7Ra in vivo and indicates that the balance between STAT5 and PI3K signals is important for development of early thymocytes and memory T cells.

IL-17 promotes pulmonary B-1a cell differentiation via induction of Blimp-1 expression during influenza virus infection

Lu, L., Wang, X.

University of Hong Kong, Pathology, Hong Kong, Hong Kong

B-1 cells play a key role in early protection during influenza infections by production of natural antibodies. However, the molecular mechanisms involved in regulating this process are largely unclear. In this study, we found that during influenza infection pleural cavity B-1a cells rapidly infiltrated lungs, where they underwent plasmacytic differentiation with enhanced IgM production. This process was promoted by IL-17A signaling via induction of Blimp-1 expression and NF- κ B activation in B-1a cells. Deficiency of IL-17A led to severely impaired B-1a-derived antibody production in the respiratory tract and is associated with a deficiency in viral clearance. Transfer of B-1a-derived natural antibodies rescued IL17a^{-/-} mice from otherwise lethal infections. Together, we identify a critical role of IL-17A in regulating pulmonary B-1a responses during influenza infection. Our findings provide new insights in understanding the natural antibody response by B-1a cells and its regulatory mechanisms.

The subcellular localization of viral antigen after infection shapes the antigenic profile and protective capacity of poxvirus-mediated T cell immunity

Tao, S.¹, Tao, R.¹, Patra, M.², Drexler, L.¹

¹*Heinrich-Heine-University Düsseldorf, University Hospital Düsseldorf - Institute for Virology, Düsseldorf, Germany,*

²*Helmholtz-Zentrum München and Technical University Munich, Institute of Virology, Munich, Germany*

Poxviruses engineered to express foreign genes are established tools for target protein synthesis and vaccine development in biomedical research. Modified vaccinia virus Ankara (MVA) is an attenuated vaccinia virus (VACV) strain which is currently evaluated in clinical studies for immunotherapy of infectious diseases and cancer.

Cytotoxic CD8⁺ T cell (CTL) responses play an essential role in antiviral immunity. We demonstrated the requirement of

cross-presentation of MVA-encoded antigens to efficiently prime naïve T cells, which allows for the efficient induction of early and late antigen-specific CTL in the primary response. However, there is a dramatical rearrangement of the immunodominance hierarchy in the recall response. Here, the preferential expansion of CTL specific for early viral epitopes is shaped by cross-competition, while presentation of epitopes derived from VACV late gene products is substantially delayed or completely absent. We identified the cytoplasmic poxviral factories to serve as compartments for sequestration of viral and recombinant antigens which are produced late in infection. The transient trapping in viral factories resulted in deprivation and preservation of late antigens for further processing and presentation on MHC class I. In addition, proteasomes which represent the major source of peptide ligands for MHC class I presentation, were inactive in viral factories. Subsequently, viral CD8⁺ T cell activation was significantly reduced and the protective capacity of MVA vaccines based on late antigens in mouse challenge experiments was absent. We conclude that the prolonged antigen sequestration of late antigens in this immunological impaired environment prevents efficient antigen processing and presentation to CTL.

Background: Mast cells have been shown to play a role in the pathogenesis of dengue, in mouse models. In our previous studies, we found that platelet activating factor (PAF), which is a mast cell product, played an important role in vascular leak. Therefore, we set to investigate the potential role of mast cell activation in the pathogenesis of dengue virus infection.

Methods: Serial twice daily blood samples were obtained from 38 adult patients with acute dengue from the time of admission to discharge. Mast cell tryptase level; viral loads, secretory phospholipase (sPLA2) activity and platelet activating factor (PAF) levels were assessed. All clinical and laboratory features were serially recorded until discharge of the patients. Disease severity was classified based on the WHO 2011 dengue guidelines.

Results: sPLA2 activity, mast cell tryptase level, and PAF levels were significantly elevated during the critical period in patients with severe dengue (SD) infection compared to non severe dengue infection (NSD). The highest sPLA2 activity, tryptase and PAF levels were seen on day 6 of illness, which co-occurred with the critical phase. Mast cell tryptase (p=0.006), PAF levels

($p=0.01$) and sPLA2 activity ($p=0.01$) were significantly higher in those with SD when compared to NSD during the critical phase.

Conclusion: mast cell tryptase level, secretory phospholipase (sPLA2) activity, and platelet activating factor (PAF) levels were significantly higher in SD indicating mast cell activation which is likely to play a role in the pathogenesis of vascular leak in severe dengue.

Transcriptional regulation in immune and epithelial cell types during influenza A infection

Ma, J.¹, Wijburg, O.¹, Brooks, A.¹, Reading, P.^{1,2}

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²WHO Collaborating Centre for Reference and Research on Influenza, Melbourne, Australia

In humans, infection with seasonal influenza A virus (IAV) is generally restricted to the respiratory tract. The lower airways are comprised of parenchymal cells such as airway epithelial cells (AEC) and haematopoietic cell populations such as airway macrophages (M Φ) and dendritic cells (DC). Infection of AECs by seasonal IAV results in productive virus replication whereas the infection of M Φ and DC results in abortive virus replication. Recent studies have identified antiviral host cell factors that limit intracellular replication of a range of viruses, including IAV, in epithelial cells. We previously showed that certain antiviral factors were differentially expressed in mouse M Φ and AEC following *in vitro* infection with IAV, consistent with the hypothesis that one or more differentially expressed genes may restrict productive IAV replication in M Φ /DC. However, they do not give a complete picture of the particular genes which show elevated expression at basal levels or after IAV infection in M Φ /DC.

To address this, we examined the cell intrinsic responses systemically in AEC, M Φ and DC *ex vivo*, as they form the initial epithelial-immune barrier and are the first cells to encounter and respond during IAV infection. Here we show that the differential transcription networks in epithelial and immune cell types correlate with different viral outcomes.

Severe influenza disease is associated with prolonged immune activation

Wong, S.-S.¹, Oshansky, C.^{2,3}, Xizhi, G.², Ralston, J.⁴, Wood, T.⁴, Reynolds, G.⁵, Huang, S.⁴, Thomas, P.², Webby, R.¹, SHIVERS Study Group

¹St. Jude Children's Research Hospital, Infectious Diseases, Memphis, United States, ²St. Jude Children's Research Hospital, Immunology, Memphis, United States, ³Biomedical Advancement Research and Development Authority, Office of the Assistant Secretary for Preparedness and Response (ASPR), US Dept of Health and Human Services, Washington D.C, United States, ⁴Institute for Environmental Science and Research, NCBID, Wellington, New Zealand, ⁵University of Auckland, Auckland, New Zealand

The immunological basis underlying severe influenza disease is poorly understood. We compared the immunological profile

of patients who received ambulatory care for acute respiratory illness (ARI) (N=24) vs. patients hospitalized with severe ARI (SARI, N=25) associated with PCR-confirmed influenza virus infection. Peripheral blood lymphocytes collected during acute and recovery phases were analyzed for differences in levels of myeloid dendritic cells, monocyte subpopulations, and T-cell responses. Serum cytokine levels were also assessed. Continuous variable data were log-transformed and differences between ARI and SARI were analyzed by T-test while cytokines associated with SARI were analyzed using ordinal logistic regression. We found that during the acute phase, SARI patients had significantly lower levels of CD192+ monocytes and myeloid dendritic cells compared to ARI patients ($p < 0.05$). Further, number of influenza-specific CD4+ and CD8+ T cells were generally lower in SARI during acute infection, especially the IFN γ +CD8+ T-cells ($p < 0.05$), compared to ARI individuals. However, these responses tended to be reversed during convalescence, where levels of CD16+ monocytes, circulating effector and CD8 T+ cells remained higher in the SARI patients ($p < 0.05$). Lower levels of serum cytokines MDC and IL12p40 were found to be significantly associated with SARI during the acute phase ($p < 0.05$). Conversely, higher levels of growth-related chemokines. GRO and FGF2 were associated with SARI during convalescence ($p < 0.05$). Our results suggests that patients hospitalized with severe influenza illness could experience a delay in induction of inflammatory immune responses, but a prolonged activation of cellular immune responses compared to individuals with milder infections.

Nuclear domain 10 components upregulated via interferon during human cytomegalovirus infection potentially regulate viral infection

Ashley, C., McSharry, B., Slobedman, B.
University of Sydney, Sydney, Australia

Human Cytomegalovirus (HCMV) is a ubiquitous beta-herpesvirus that causes life-threatening disease in immunocompromised and immunonaive individuals. Type I interferons (IFNs) are crucial molecules in the innate immune response to HCMV. Type I IFNs upregulate several components of the interchromosomal multiprotein aggregates collectively referred to as Nuclear Domain 10 (ND10). ND10 components also are also known to restrict herpesvirus gene expression. This raises the question, could key ND10 components (PML, Sp100 and hDaxx) act as antiviral interferon stimulated genes (ISGs) during HCMV infection? Analysis of ND10 component transcription following HCMV infection illustrated that PML and Sp100 were upregulated whilst hDaxx was not. This upregulation was independent of *de novo* viral gene expression and was also detected following treatment with infected cell supernatant suggesting that a soluble factor(s) is responsible. In cells engineered to block the production or response to type I IFNs, upregulation of PML and Sp100 was not detected following HCMV infection. IFN- β neutralising antibody pre-treatment inhibited upregulation of PML and Sp100 following both infection and treatment with infected cell supernatant. The significance of ND10 components functioning as antiviral ISGs during HCMV infection was

determined by infecting cells engineered using shRNA to have simultaneous knockdown of PML, Sp100 and hDaxx. ND10 knockdown cells were significantly more permissive to HCMV infection and, in contrast to control cells, could be infected by HCMV even with IFN- β pre-treatment. Together these data provide evidence that ND10 component upregulation is a key mediator of the antiviral activity of IFN- β .

ECM remodelling by ADAMTS5 regulates influenza-specific immunity

McMahon, M.¹, Ye, S.¹, Izzard, L.¹, Tripp, R.², McCulloch, D.¹, Stambas, J.¹

¹Deakin University, Waurn Ponds, Australia, ²University of Georgia, Athens, United States

Members of the ADAMTS (A disintegrin-like and metalloproteinase with thrombospondin-1 motifs) metalloproteinase family remodel the extracellular matrix (ECM) to facilitate immune cell migration and cell adhesion. In this current study, we infected *Adamts5*^{-/-} mice with X31 influenza virus (10⁴ pfu/mouse) and measured weight loss, viraemia and T cell immunity following acute infection. *Adamts5*^{-/-} mice showed greater weight loss and increased viraemia when compared to WT counterparts. Furthermore, we observed reduced NP₃₆₆ and PA₂₂₄ influenza specific CD8⁺ T cells in the spleen and lungs of *Adamts5*^{-/-} mice with a corresponding accumulation of these T cell specificities in the mediastinal lymph node (MLN) 10 days post infection. Critically, these responses correlated with increased expression of a key ADAMTS5 substrate; versican, in the MLNs of *Adamts5*^{-/-} mice. We therefore hypothesize that versican accumulation in the MLNs of *Adamts5*^{-/-} mice results in T cell accumulation and that ADAMTS5 is a key enzyme involved in facilitating T cell migration from the MLN to the periphery following acute influenza virus infection.

A20 levels in dendritic cells control Th17-mediated severe neutrophilic asthma

Vroman, H.¹, Bergen, I.M.¹, Lukkes, M.¹, Schuijs, M.², van Loo, G.², Lambrecht, B.N.^{1,2,3}, Hendriks, R.W.¹, Kool, M.¹

¹Erasmus MC, Pulmonary Medicine, Rotterdam, Netherlands, ²VIB-UGent, Zwijnaarde, Belgium, ³University Hospital, Ghent, Belgium

Asthma is a chronic Th2-cell-mediated inflammatory disease of the airways in response to inhaled antigens such as house dust mite (HDM). However, in severe asthma patients, Th17-cells have been implicated. Dendritic cells (DCs) drive Th-cell differentiation and are essential during sensitization and challenge in experimental allergic asthma models. Activation of DCs is controlled by A20 (*Tnfrsf3*), a negative regulator of the proinflammatory NF- κ B pathway. We hypothesize that A20 in DCs critically controls Th-cell differentiation and asthma severity in a chronic HDM-driven asthma model. *Tnfrsf3*^{fl/fl}*LysMcre*⁺ mice (DC-A20 mice) were treated 25 μ g

HDM or PBS (3xpw) for 5 weeks. Additionally, HDM-specific Th-cell differentiation was determined in DC-A20 mice after intravenously injection of Derp1-specific TCR Tg (1-der) T cells and HDM exposure. HDM-treated DC-A20^{WT} and DC-A20^{HZ} mice showed massive eosinophilic infiltration in the airways, increased mucus-producing goblet cells, and increased numbers of IL-5 and IL-13 producing CD4⁺ T cells. In contrast, DC-A20^{KO} mice developed a mixed eosinophilic/neutrophilic inflammation, and showed increased ROR γ ^t Th17-cell and AHR⁺ Th22-cell numbers in the airways. Moreover, HDM-treated DC-A20^{KO} mice exhibited even higher airway hyper-responsiveness than HDM-treated DC-A20^{WT} mice. 1-der Th-cells in DC-A20^{KO} mice showed increased differentiation into Th17-cells, whereas in DC-A20^{WT} mice they developed into Th2-cells. In conclusion, we showed that lack of A20 in DCs causes a Th17-cell response rather than a Th2-cell response to HDM. This implicates that increased DC activation is a crucial driver of Th17-cell-mediated severe neutrophilic asthma, and could be a novel therapeutic target for treatment of severe asthma patients.

Repeated exposures to common cosmetic preservative biocide methylisothiazolinone produces sensitivity to touch and pressure in sensitized ND4 female mice

Chatterjea, D., Mengistu, H., Chai, N., Landry, J.

Macalester College, Saint Paul, United States

Recent attention to the allergenic effects of the synthetic biocide methylisothiazolinone (MI) has revealed widespread sensitization to this common cosmetic preservative in populations tested. Allergic reactions to the chemical include swelling, redness, itchiness and in some cases neurologic damage and scarring. While epidemiological studies support the increased risk of developing allergic contact dermatitis and neurological complications from repeated exposure to MI in leave-on cosmetics, little is known about the mechanisms underlying tissue damage from chronic or repeated exposure to this biocide preservative. Here we show that in a model of cutaneous contact hypersensitivity, repeated exposure to MI produces not only tissue edema and up-regulation of inflammatory cytokines, but also sensitivity to touch and pressure lasting for up to 3 weeks after exposures have ceased in female ND4 Swiss mice previously sensitized with topical application of this chemical. Given the emerging evidence that allergic exposures and history of atopy are significant risk factors for the development or exacerbation of chronic pain conditions such as migraine headaches, vulvodynia and inflammatory bowel pain, it is important that we establish pre-clinical models of interaction between allergic and hypernociceptive pathophysiologies where novel therapeutic targets may be identified and validated. To our knowledge, this is the first pre-clinical model of contact hypersensitivity to MI; our current studies are focused on characterizing the cellular and molecular changes in the tissue produced by repeated MI exposure.

2920**Post transcriptional regulation of I κ B- ζ expression controls inflammatory responses***Maruyama, T.^{1,2}*¹Gifu University, Gifu, Japan, ²Tohoku University, Sendai, Japan

A nuclear I κ B family protein, I κ B- ζ can be up-regulated in T cells in response to TGF- β +IL-6 and positively regulate IL-17 gene expression cooperate with ROR γ t. However, we show that T cells specific I κ B- ζ deficient mice occurred massive inflammation with aging and produce large amount of IFN- γ . Thus, I κ B- ζ is necessary for both maintaining immune homeostasis and inflammatory responses. Previously study have reported that IL-1 β stimulation enhanced protein level of I κ B- ζ in T cells and promote pathogenic Th17 cells differentiation. We have shown that post transcriptional mechanisms were more important for stimulation specific I κ B- ζ expression (especially IL-1 β /LPS stimulation), but the mechanisms are ill define. Therefore, we hypothesis that control of stimulation specific I κ B- ζ expression plays an important role for regulation of inflammatory responses without breaking immune homeostasis.

We focus on 3'-UTR region of I κ B- ζ mRNA (which plays an important role for post transcription) and found that three putative miRNA binding elements and AU-rich element. However, these elements were dispensable for stability of mRNA expression. Next, we performed reporter assay using by I κ B- ζ 3'-UTR reporter and 9600 kinds of cDNA libraries. We identified that MyD88, a down stream molecule of IL-1 β / LPS stimulation, are key to stabilize I κ B- ζ mRNA expression. In addition, MyD88 deficiency shows less half life of I κ B- ζ mRNA expression. Thus, post transcriptional regulation by MyD88 is a key to regulate I κ B- ζ expression and pathogenic Th17 differentiation.

2577**Interaction of the probiotic strain *E. coli* O83 with the host immune system and its impact on allergic airway inflammation in mice***Zwicker, C., Drinic, M., Sarate, P., Wiedermann, U., Schabussova, I. Institute for Specific Prophylaxis and Tropical Medicine, Center for Pathophysiology, Immunology and Infectiology, Medical University of Vienna, Vienna, Austria*

For primary prevention of allergic diseases by probiotic bacteria, several different treatment approaches, like peri- or postnatal application, have been shown to be very effective. Clinical studies have suggested that the postnatal application of the probiotic *E. coli* strain O83 to newborns of allergic mothers is associated with reduced prevalence of allergies in later life.

In the present study we investigated whether maternal exposure to *E. coli* O83 during gestation and lactation can affect the development of airway inflammation in the offspring in a mouse model of type I allergy.

Surprisingly, the offspring derived from *E. coli* O83-treated dams showed significantly increased airway hyperresponsiveness (AHR) after exposure to ovalbumin compared to mice from PBS-treated mothers. Increased AHR in mice born to bacteria-treated mothers was not associated with enhanced systemic IgE levels

or elevated numbers of eosinophils in bronchoalveolar lavage fluid. However, we detected significantly increased IL-4 levels in the lungs of mice derived from *E. coli* O83-treated mothers but decreased levels of the typically AHR-associated cytokines IL-5 and IL-13 compared to control mice.

Here, we found that maternal supplementation with *E. coli* O83 during pregnancy and lactation leads to increased AHR and elevated IL-4 levels in lungs of their offspring. The role of IL-4 in this phenotype and its cellular source still need to be determined. However, this study emphasizes that the time point of application (peri- vs postnatal) of probiotic bacteria seems to be crucial for its effect on allergic diseases.

3027***Clethra barbinervis* leaf extract inhibits allergic reaction of basophilic leukemia cell line RBL 2H3***Hachiya, M.¹, Ooba, K.¹, Aradate, T.², Ogawa, R.³, Murata, T.³, Katagiri, T.¹*¹University of Toyama, Dept. Biology (Faculty of Pharmaceutical Sciences), Toyama-shi, Japan, ²University of Toyama, Dept. Biology (Faculty of Medical Sciences), Toyama-shi, Japan, ³Tohoku Medical and Pharmaceutical University, Dept. Pharmacognosy, Sendai, Japan

We examined the series of samples from the plants products affect the activation of Fc epsilon RI mediated signals in basophiles in order to find new anti-allergic reagent. As a result, we found a fact that *Clethra Barbinervis* Leaf Extract (CBLE) had strong anti-allergic effects. CBLE inhibited degranulation and TNF- α production in a concentration without cytotoxicity. Based on these facts, we had an attempt to find a mechanism of CBLE's inhibiting the activation pathway. Using RBL-2H3 cells (Rat basophilic leukemia), we analyzed the effects of CBLE to Fc epsilon RI mediated signals. As a result, CBLE was not affect to Fc epsilon expression on RBL 2H3. On that condition, we found that CBLE inhibited calcium influx induced by antigen stimulation. In other word, it means that CBLE contains some compounds regulate an early stage of this signaling. While analyzing the effects of CBLE, we also identified effective components of CBLE. CBLE has quercetin analogues, caffeic acid and epicatechin. These compounds, however, had no effects on degranulation by themselves alone respectively. These results may suggest a possibility of being of some unknown anti-allergic components in CBLE. Or, there is a possibility that shows the combined effect is effective allergy suppression of low effective compounds alone. We have a result that caffeic acid inhibits TNF- α production induced by calcium ionophore and PMA. As a conclusion, we have much possibility of developing new allergic therapeutic drugs with the combination of caffeic acid and unknown components of CLBE.

301***Toxoplasma gondii* serine-protease inhibitor-1: a novel vaccine candidate for asthma treatment***Soto, A.¹, Fenoy, I.², Sánchez, V.¹, Aldirico, M.D.I.A.¹, Perrone Sibilia, M.¹, Picchio, M.¹, Arcón, N.¹, Acosta, P.³, Martín, V.¹, Goldman, A.¹*¹Universidad Nacional de General San Martín, Buenos Aires, Argentina, ²Instituto de Investigaciones Biotecnológicas (IIB-

NTECH), Chascomús, Argentina, ³Fundación Infant, Consejo Nacional de Investigaciones Científicas y Técnicas, Cuidad Autónoma de Buenos Aires, Argentina

Serine proteases are important players in the pathogenesis of asthma, promoting inflammation and tissue remodeling. In addition, some allergens have serine protease activity. It's known that many serine protease inhibitors display immunomodulatory properties. TgPI-1 is a *Toxoplasma gondii* protein that exhibits broad spectrum inhibitory activity against serine proteases. We sought to investigate whether rTgPI-1 administration could suppress experimental asthma. BALB/c mice were intraperitoneally sensitized with ovalbumin/alum and airway-challenged. Once the asthmatic phenotype was achieved they were intranasally treated with different doses of rTgPI-1 alone (PI) or co-administrated with ovalbumin (OPI). Treatment with PI and OPI reduced 13.8% and 50.3% the airway hyperresponsiveness, respectively. This effect was accompanied by a diminished bronchoalveolar eosinophilia, mucus production and peribronchial lung infiltration. Moreover, bronchoalveolar lavage fluid from treated mice showed a reduction in IL-4 and IFN- γ levels. In agreement with these results, both treatments resulted in lower levels of IL-4, IL-5 and IFN- γ in thoracic lymph node cells stimulated with ovalbumin. Regulatory IL-10 was also diminished. Furthermore, OPI induced a reduction in ovalbumin specific T cell proliferation. Treatment did not alter ovalbumin-specific humoral response. These results show that both rTgPI-1 treatments reduced asthma hallmarks; however, OPI was more effective denoting an adjuvant capacity. The effect of rTgPI-1 in modulating allergic lung inflammation could be the consequence of a decrease in the overall local response to the allergen. Although further studies should be undertaken to completely elucidate the mechanisms involved, TgPI-1 is a promising therapeutic vaccine candidate for intervention in patients with asthma.

Microbial metabolites: a critical element in the fight against obesity and inflammatory diseases

Yap, Y.A.¹, Richards, J.L.¹, McLeod, K.H.¹, Watt, M.J.², Mackay, C.R.¹, Marino, E.¹

¹Monash University, Biochemistry and Molecular Biology, Clayton, Australia, ²Monash University, Physiology, Clayton, Australia

There has been an alarming increase in global obesity rates within the past decade. Obesity poses a serious risk for many other diseases, including type 2 diabetes mellitus (T2DM), cardiovascular disease, kidney disease and even some forms of cancer. In recent years, the spotlight has been on the role of gut microbiota, in particular the production of short-chain fatty acids (SCFA), in health and disease. SCFA (acetate, propionate and butyrate), produced through colonic microbial fermentation of indigestible dietary fibre, mediate beneficial effects through G-protein coupled receptors (GPCR), not only in the gut but also in peripheral tissues. Here we are uncovering the anti-inflammatory effects of SCFA-enriched diets in the

treatment of obesity and related metabolic dysfunctions. In the diet-induced obesity (DIO) mouse model, high fat/butyrate-yielding diets reduced body weight gain, significantly improved glucose tolerance and insulin sensitivity, and remarkably also reduced kidney damage evidenced by less PASS staining and reduced proteinuria. Additionally, we found increased lipolysis in white adipose tissue (WAT) and decreased hepatic lipogenesis in mice fed SCFA-enriched diets. Flow cytometry and histological analyses revealed interestingly, that these changes occurred concomitantly with increased Foxp3⁺ regulatory T cells in the gut, kidney and other peripheral tissues. In contrast, GPR109-deficient mice showed reduced glucose tolerance. Our findings suggest that dietary SCFAs modulate the gut microbiota, through GPCR-associated mechanisms, ameliorating inflammation in the DIO model. Therefore, we strongly believe that our results are extremely important in forming the basis for future human studies.

Lachnospiraceae protect from colitis by regulating colonic group 3 innate lymphoid cells

Surana, N.^{1,2}, Kasper, D.²

¹Boston Children's Hospital, Boston, United States, ²Harvard Medical School, Department of Microbiology and Immunobiology, Boston, United States

In previous work, we demonstrated that host-specific bacteria are required for proper maturation of the small-intestinal immune system. In sharp contrast to gnotobiotic mice colonized with normal mouse microbiota (MMb), which have a well-developed small-intestinal immune system, we demonstrated that gnotobiotic mice colonized with normal human microbiota (HMb) have an immature small-intestinal immune system indistinguishable from that of germ-free (GF) mice. Using the dextran sodium sulfate (DSS)-induced colitis model that relies heavily on the innate immune system, we have now found that—similar to GF mice—MMb mice are exquisitely sensitive to DSS colitis with a 100% mortality rate; in contrast, HMb and specific pathogen-free (SPF) mice are protected. Based on flow cytometric analysis of the colonic immune systems, we identified group 3 innate lymphoid cells (ILC3s) as the immunologic correlate of disease. Co-housing MMb and HMb mice facilitated a bi-directional transmission of microbes that led to an intermediate disease phenotype in both groups. Bioinformatic analysis of the fecal microbiota of SPF, MMb, HMb, and co-housed mice identified the bacterial family Lachnospiraceae as a microbiological correlate for protection from disease. Using semi-selective media, we cultured a Lachnospiraceae-enriched pool of bacteria from HMb mice that—when gavaged to MMb mice—led to decreased numbers of colonic ILC3s and protection from DSS-induced mortality. This work provides an immunologic explanation for why multiple cohorts of patients with inflammatory bowel disease have demonstrated that Lachnospiraceae is associated with reduced risk of disease and provides a mechanistic foundation for the potential therapeutic use of these organisms.

Aberrant accumulation of HLA-DR and reduced mucin production in colonic epithelial cells of HLA-DR4 transgenic mice and ulcerative colitis patients

Irie, A.¹, Imamura, T.², Michibata, Y.¹, Kubo, T.², Takeda, N.³, Shibuya, I.⁴, Sogo, S.⁴, Araki, K.³, Nishimura, Y.¹

¹Kumamoto University, Graduate School of Medical Sciences, Immunogenetics, Kumamoto, Japan, ²Kumamoto University, Graduate School of Medical Sciences, Molecular Pathology, Kumamoto, Japan, ³Institute of Resource Development and Analysis, Kumamoto University, Developmental Genetics, Kumamoto, Japan, ⁴Microbiological Research Institute, Otsuka Pharmaceutical Co. Ltd., Tokushima, Japan

Objective: Homozygotes of HLA-DR4/I-Ed-chimeric transgenic mice (tgm) spontaneously develop colitis similar to human ulcerative colitis (UC). We explored whether the pathogenesis of this colitis is due to the disruption of the genome structure by the transgenes or the HLA-DR4/I-Ed over-expression.

Design: The transgenes were identified to be inserted in chromosome 3 with 39 kb deletion. Using CRISPR/Cas9 system, mice with equivalent genomic deletion were established to see whether they develop colitis or not. In addition, MHC class II transactivator (CIITA) knock out background homozygous tgm were established to see HLA-DR4/I-Ed expression was involved in the pathogenesis of the colitis. Histological and cellular analyses of the colons of the tgm were performed and effect of antibiotic administration was examined.

Result: Lack of CIITA and antibiotic administration were effectively suppressed the development of the colitis, while lack of the 39 kb had no effect. Aberrantly accumulated HLA-DR4/I-Ed in the colonic epithelial cells was observed with up-regulated endoplasmic reticulum (ER) stress marker BiP (Grp78) and significant reduction of mucin-producing goblet cells. Importantly, in 3 out of 12 colonic tissues of UC patients, the association of high HLA-DR expression, reduced number and mucin production of goblet cells and BiP expression was observed.

Conclusion: The pathogenesis of the colitis observed in the homozygous tgm was likely due to the ER stress that resulted in goblet cell loss and significant reduction of mucin in the colonic epithelial cells in which HLA-DR4/I-Ed was aberrantly accumulated. Similar mechanisms could be a fundamental component of pathogenesis of some human UC cases.

Th17 cell production of amphiregulin contributes to intestinal homeostasis to microbiota

Cao, A., Yao, S., Chen, F., Cong, Y.

University of Texas Medical Branch, Microbiology and Immunology, Galveston, United States

Th17 cells produce the signature cytokines interleukin (IL)-17A (IL-17), IL-17F, IL-21, and IL-22, and have been implicated in a variety of autoimmune disorders. Despite their highly inflammatory nature, Th17 cells are highly enriched in the intestines under homeostatic conditions and primarily respond to commensal bacteria. However, it remains unclear as to their

exact role during intestinal homeostasis. We demonstrated in this report that CBir1 TCR transgenic (Tg) mice, which are specific for a commensal bacterial flagellin, were more resistant to dextran sulfate (DSS)-induced colitis than wild-type mice. CBir1 Tg mice demonstrated a higher level of intestinal Th17, and expressed higher levels of amphiregulin (Areg), which has been recently shown to be highly protective along the epithelial surfaces of the airway and intestine, than wild-type mice. Administration of Areg to wild-type mice led to decreased intestinal injury and higher level of tight-junction protein expression upon DSS insult. We further demonstrated that Th17 cells produced high amounts of Areg, and Areg inhibited T cell proliferation. Collectively, these findings reveal that intestinal Th17 cells contribute to epithelial homeostasis and immune regulation by Areg production.

Early-life respiratory bacterial infection-induced chronic lung disease is driven by a novel TLR2/IL-13/miR-21/PI3K signaling pathway

Starkey, M.R., Nguyen, D.H., Kim, R.Y., Haw, T.J., Nair, P.M., Essilfie, A.T., Horvat, J.C., Foster, P.S., Hansbro, P.M.

The University of Newcastle and Hunter Medical Research Institute, School of Biomedical Sciences and Pharmacy, New Lambton Heights, Australia

Introduction: There is a critical window in early-life where the lung and immune system are still maturing and this increases susceptibility to infection. Indeed, severe respiratory bacterial infections in early-life are a risk factor for the development of chronic lung diseases.

Methods: Neonatal wild-type (WT), TLR2 deficient (-/-), IL-13-/-, MyD88-/- and STAT6-/- mice were infected with the natural mouse pathogen *Chlamydia muridarum*, as a model of a moderate-to-severe respiratory bacterial infection in early-life. In some experiments WT mice were treated with miR-21-specific antagomirs, the pan-PI3K inhibitor LY294002, or relevant vehicle controls during early-life infection. The impact of these specific immune molecules on early-life bacterial infection-induced chronic lung disease were assessed.

Results: Neonatal respiratory infection increased TLR2, IL-13-receptor, miR-21 and PI3K expression and/or activity in the lung. TLR2 signaling induced IL-13-receptor expression, IL-13 signaling induced miR-21 expression and miR-21 increased PI3K activity. TLR2 signaling also increased the number of IL-13+ type-2 innate lymphoid cells in the neonatal lung. TLR2-/- and IL-13-/- mice were protected against deleterious infection-induced lung function changes in later-life. This TLR2/IL-13 mediated phenotype was independent of MyD88, but dependent on STAT6 signaling. Specific targeting of miR-21 and PI3K during early-life infection also prevented infection-induced chronic lung disease.

Conclusion: Early-life respiratory bacterial infections increase TLR2, IL-13, miR-21 and PI3K responses that promote the development of chronic lung disease in later-life. This study identifies a novel signaling network that may be targeted for the prevention of the long-term deleterious effects of early-life infection on lung function.

Maternal antibodies are present at the newborn's respiratory tract in the absence of a structured polymeric immunoglobulin secretory immune system (PISIS)

Vega-López, M.A., Guzmán-Bautista, E., Ramírez-Estudillo, C., Rojas, O.

CINVESTAV-IPN, Infectómica y Patogénesis Molecular, México, D.F., Mexico

We have shown that PISIS development occurs during the first 4 weeks of age in the porcine experimental translational model (Dev. Comp. Immunol. 2015. 53:271-282). However, mucosal immune protection in the newborn is still not well understood. We demonstrated that newborn piglets lack of immunoglobulin (Ig) producing cells in the respiratory tract. However polymeric immunoglobulin receptor (pIgR) positive cells are present in the trachea and bronchi submucosae. Using weaned at birth (n=6) and 2 day-old colostrum fed (n=8), SPF Vietnamese minipigs, we measured the amounts of IgG, IgM and total and secretory IgA at serum, saliva, nasal mucus, tracheal and bronchial lavages, by quantitative ELISA. Our results showed low levels of self produced IgM and IgA at birth in serum, and no or very low levels at respiratory surfaces. After 2 days of suckling, important amounts of these Igs and IgG were detected at the respiratory tract, presumably from maternal origin. Furthermore, IgA lacking the secretory component (monomeric and polymeric) were more abundant than SIgA at mucosal samples up to: 10000X in nasal secretion, 200X in saliva, 50X in tracheal lavage and 20X in bronchi lavage. Therefore, non-secretory Igs, including IgG, also reached mucosal surfaces by a non yet described mechanism (newborn's pIgR?) and these Igs may play an important role in protecting the newborn. These results suggest a compensatory role of maternal immunity in mucosal protection of the newborn while the PISIS is fully mature.

Oral administration of lactic acid bacteria prevents inflammation and steatosis in a murine model of non-alcoholic steatohepatitis (NASH) and hepatocellular carcinoma (HCC)

Tsuji, N.¹, Suabjakyong, P.¹, Watanabe, Y.¹, Kamiya, T.¹, Kimoto-Nira, H.², Kanto, T.³

¹National Institute of Advanced Industrial Science and Technology (AIST), Biomedical Research Institute, Tsukuba, Japan, ²NARO institute of Livestock and Grassland Science (NILGS), Animal Products Research Division, Tsukuba, Japan, ³National Center for Global Health and Medicine, The Research Center for Hepatitis and Immunology, Ichikawa, Japan

The number of Non-alcoholic fatty liver disease (NAFLD) patients has rapidly increased during the past couple of decades. NAFLD is a progressive form of non-alcoholic steatohepatitis (NASH), a hepatic manifestation of metabolic syndrome and highly associated with Hepatocellular carcinoma (HCC). Therefore establishment of diet-solutions, in addition to symptomatic

treatments, are keenly required. We previously reported that a majority of lactic acid bacteria are able to induce high level of anti-inflammatory interferon- β (IFN- β) from dendritic cells by stimulating endosomal Toll-like receptors. One such strain, *Lactococcus lactis* subsp. *cremoris* C60, induces high level of IL-10 also, and stabilizes oral tolerance. In the present study, we show that oral administration of C60 to NASH model mice up-regulated the level of IL-10 in the intestine and significantly improved NAFLD including steatosis, lobular inflammation, and hepatocellular ballooning. We are currently examining the role of these anti-inflammatory mediators (IL-10/IFN- β) and resultant immune regulatory cells in suppressing chronic inflammation to reveal a novel interaction between intestinal immunity and NASH. (This work was partially supported by Grant-in-Aid for Scientific Research by Yakult Bio-Science Foundation and AMED.)

Bacterial infections remain an important clinical challenge despite our extensive arsenal of antibiotics. This is exemplified by lengthy treatments of chronic infections, high mortality rates due to excessive inflammation, and an alarming increase in antibiotic resistance. One attractive strategy for improved treatments for challenging infections is to enhance endogenous anti-microbial defence. We and others have associated the Wnt pathway with bacterial infections in patients and model systems, implicating novel roles for this well-known developmental signalling pathway in immune responses to infection. However, the nature of immune-related Wnt functions remains to be clearly defined. Here we demonstrate differential expression of multiple Wnt family members in macrophages and intestinal epithelial cells in response to infection with the intracellular bacterial pathogen *Listeria monocytogenes*. *Listeria* burden was increased in Wnt-overexpressing cells, whereas treatment with small molecule inhibitors of Wnt production resulted in restriction of *Listeria* replication by infected host cells. This was associated with significant alterations in the early *Listeria*-containing intracellular compartments, suggesting that Wnt proteins guide the intracellular fate of ingested bacterial pathogens. In an *in vivo* model of *Listeria* infection, inhibition of Wnt production significantly lowered bacterial burden of infected mice underpinning the relevance of our findings to host control pathogens. These observations affirm the functions of Wnt proteins in the immune defence against infection and warrant the exploration of Wnt pathway modulation to enhance endogenous host control mechanisms against pathogenic bacteria.

Enhancement of IL-22/IL-22RA1 signaling to decrease bacterial burden and extrapulmonary dissemination during pneumococcal pneumonia

Trejejo-Nunez, G., Chen, K., Kolls, J.

University of Pittsburgh School of Medicine/Richard King Mellon Foundation for Pediatric Research/Children's Hospital of Pittsburgh, Pittsburgh, United States

Community acquired pneumonia is caused primarily by *Streptococcus pneumoniae*, which is responsible for 4 million illness episodes, 445,000 hospitalizations and 22,000 deaths annually in the US. Interleukin 22 (IL-22) is a secreted cytokine produced mainly by cells of the lymphoid lineage and innate lymphoid cells. Ligation of IL-22 to IL-22RA1 and IL-10R2 results in downstream phosphorylation of STAT3. IL-22RA1 is characteristically expressed in epithelial cells, and its activation by IL-22 is involved in the pathogenesis of extracellular organisms. We hypothesized that enhancement of IL-22/IL-22RA1 through recombinant IL-22 translates into decrease pneumococcal burden and dissemination. Wild type mice had endogenous IL-22 production upon *S. pneumoniae* lung infection as early as 5 hours post infection and IL-22KO mice had higher pneumococcal burden in lungs and extrapulmonary organs compared to wild type controls. To assess the importance of IL-22RA1 signaling in the liver, IL-22RA1 conditional knockouts were infected with *S. pneumoniae* and had higher bacterial burdens in the lung, liver and spleen compared to littermate controls. Furthermore, pretreatment with IL-22:Fc in wild type mice decreased pneumococcal burden at 24 hours post infection. Taken together, we have evidence that IL-22 has a protective role against pneumococcal burden and dissemination and enhancement of this signaling pathway may be beneficial during pneumonic process. Our data also suggests that during pneumococcal pneumonia, IL-22 signaling to hepatic IL-22RA1 controls bacterial dissemination. We propose that therapeutic use of IL-22 may decrease bacterial burden by sustaining STAT3 phosphorylation in lung and liver tissues compared to other cytokines induced during pneumonia.

Although a little over two billion people are infected with *Mycobacterium tuberculosis* resulting in significant morbidity and mortality especially in Africa, little is understood about the

dynamics of immune response and host dependent immune modulation. In this prospective cohort study, we investigated the dynamics of interferon-gamma (IFN- γ) responses and the possible role of miRNAs and sIL-7R in 61 tuberculosis cases and 150 exposed but healthy household controls (LTBI).

Antigen-specific IFN- γ responses, sIL7R plasma levels and 29 candidate miRNAs were quantified in active tuberculosis patients before, during and after TB chemotherapy and in controls.

We show from our findings that IFN- γ responses were significantly higher in TB patients than LTBI

($p = 0.0183$) but we did not observe any significant differences in IFN- γ responses during chemotherapy. 7 of the candidate miRNAs (miR-25, miR-26a, miR-29a, miR-99b, miR-101, miR-146a and miR-223) were significantly dysregulated during chemotherapy ($p < 0.05$). We detected lower sIL-7R concentrations in tuberculosis patients as compared to healthy contacts ($p < 0.001$). In addition, during therapy (about 2 months) and after recovery (> 6 months) sIL-7R concentrations were higher than prior to therapy ($p = 0.04$ and $p = 0.003$, respectively). Successful treatment and recovery restored sIL-7R levels especially in tuberculosis patients with low sIL-7R concentrations prior to therapy ($R = 0.59$, $p < 0.001$).

We concluded that differential miRNA expression of 7 miRNAs, IFN- γ and plasma sIL-7R levels are diminished in tuberculosis patients possibly affecting T-cell immunity during acute disease.

Reduced neutrophil differentiation drives aberrant neutrophil function in beta-hemoglobin disorders: understanding the molecular and cellular mechanism

Siwaponanan, P.¹, Siegers, J.², Ng, T.^{2,3}, Svasti, S.¹, Fucharoen, S.¹, Wijburg, O.⁴, Vadolas, J.²

¹Mahidol University, Thalassemia Research Centre, Institute of Molecular Bioscience, Nakornpathom, Thailand, ²Murdoch Childrens Research Institute, Cell and Gene Therapy Group, Melbourne, Australia, ³The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ⁴The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia

β -Thalassemia is an important β -haemoglobin disorder resulting in iron overload, and is associated with several abnormalities in the immune system, including defective neutrophil functions, predisposing patients to infections with bacterial pathogens. The molecular mechanisms involved in impaired neutrophil function during bacterial infection in thalassemia patients are not well understood. We used the Hbb^{th3/+} β -thalassemia mouse model and patient blood samples to investigate neutrophil function and susceptibility to infection. Hbb^{th3/+} β -thalassemia mice were highly susceptible to infection with *Streptococcus pneumoniae* (Spn). Blood and splenic neutrophils from Hbb^{th3/+} β -thalassemia mice, but not bone marrow derived neutrophils, showed defective chemotaxis, reduced opsonophagocytosis and decreased reactive oxygen species production compared with neutrophils from normal mice. Quantitative RT-PCR

analysis on mRNA from purified neutrophils demonstrated that CXCR2, CD11b, p22phox, p40phox, p67phox and p91phox gene expression levels were significantly repressed during systemic infection with *Spn*. Morphological analysis of neutrophils from uninfected animals showed a striking expansion of a subset of immature neutrophils, possibly granulocytic myeloid-derived suppressor cells (G-MDSCs), in Hbb^{th3/+} β -thalassemia mice. Comparison of expression of genes associated with neutrophil maturation showed that expression of the master transcriptional regulator for terminal myeloid differentiation and neutrophil function, PU.1, was significantly decreased in neutrophils of thalassaemic mice. Similar changes in cellular morphology and PU.1 expression in neutrophils from HbE/ β -thalassaemia patients were subsequently shown. The outcome of this study provides evidence for direct molecular mechanisms resulting in aberrant neutrophil functions in the context β -haemoglobinopathies and iron overload, which should be further explored to develop novel treatments.

Phenol-soluble modulins alpha induce G2/M phase transition delay and impair immune response of eukaryotic cells

Deplanche, M.^{1,2}, Filho, R.A.E.-A.^{1,3}, Semenovskaya, K.^{1,2}, Alekseeva, L.^{1,4}, Jardin, J.^{1,2}, Henry, G.^{1,2}, Azevedo, V.³, Germon, P.⁵, Rainard, P.⁵, Dessauge, F.⁶, Finot, L.⁶, Laurent, F.⁷, Lina, G.⁷, Vandenesch, F.⁷, Le Loir, Y.^{1,2}, Smith, D.⁸, Otto, M.⁹, Götz, F.¹⁰, Berkova, N.N.^{1,2}

¹INRA, UMR 1253, STLO, Rennes, France, ²Agrocampus Ouest, UMR 1253 STLO, Rennes, France, ³Federal University of Minas Gerais, Belo Horizonte, Brazil, ⁴Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation, ⁵François Rabelais University of Tours, Nouzilly, France, ⁶INRA, Saint Gilles, France, ⁷University of Lyon, INSERM U 1111, Lyon, France, ⁸University of Glasgow, Glasgow, United Kingdom, ⁹US National Institute of Health, Bethesda, United States, ¹⁰University of Tübingen, Tübingen, Germany

Staphylococcus aureus is responsible for a wide range of infections in human and animals. We found that *S aureus* slowed down host cell proliferation and induced a cytopathic effect. We demonstrated that *S aureus* induced a G2/M phase transition delay in host cells, which was associated with accumulation of the cyclin-dependent kinase Cdk1/cdc2 and unphosphorylated histone H3. We found that a G2 phase delay was preferential for bacterial internalization and intracellular proliferation. Using size exclusion chromatography and mass spectroscopy analysis, we identified phenol-soluble modulin alpha (PSMa) peptides as the candidates for this effect. The implication of PSMa in cell cycle alteration was confirmed by testing of synthetic PSMa and by comparison of LACwt with the isogenic mutant LAC Δ psm, which lacks the operon encoding PSMa. The delay was associated with a decrease of defensins expression in a G2 phase, suggesting that PSMa-induced G2/M phase transition delay deteriorates antibacterial state of the epithelial surface. Investigation of the response to *Escherichia coli* and *S. aureus* showed a higher expression of key cytokines IL-6, IL-8, as well as IL-32 (which is involved in dendritic cell maturation) in *E. coli*-infected host cells. Comparison of cytokines expression in

response to LACwt with isogenic mutants, which lack the operon encoding PSMs, show that PSMs inhibit interleukins production, thus impair the innate and adaptive immune response during *S. aureus* infection. Therefore we show, that PSMs alter the host cell cycle, resulting in a reduction of defense response of host' cells, that reveal a newly-identified mechanism for promoting infection.

The role of regulatory T cells in nontuberculous mycobacterial lung disease

Jung, M.¹, Kang, S.M.², Shin, E.-C.¹

¹KAIST, Daejeon, Korea, Republic of, ²Gachon University Gil Hospital, Incheon, Korea, Republic of

Although nontuberculous mycobacterial lung disease (NTMLD) are becoming prevalent worldwide, immunopathogenesis is poorly understood. NTMLD occurs in individuals with distinct predisposing conditions, suggesting specific immune dysregulation may exist. Regulatory T cells (Tregs) suppresses effector T cell functions. However, little is known about Tregs with NTMLD. To investigate immunological characters of the patients with NTMLD, especially focused on the association of Tregs and their clinical relevance in patients with NTMLD. Treg frequency and CD39 expression on Tregs were enhanced, especially subpopulation II and subpopulation III, in patients with NTMLD compared with healthy controls. Treg frequency, subpopulation II, and subpopulation III showed a tendency toward inverse correlation with total CT scores. The frequency and CD39 expression of Treg subpopulation II were positively correlated with FEV₁ in patients with NTMLD. In conclusions Tregs and Treg subpopulations are dysregulated quantitatively and qualitatively in patients with NTMLD. Enhancing frequency or activity of Tregs may be a novel therapeutic strategy to reduce inflammatory burden and improve lung function in patients with NTMLD.

Profile of events leading to innate resistance to mycobacterial infection

ADAM, L., Poux, C., Spetz, A.-L., Fernandez, C.

Stockholm University, Molecular Biosciences the Wenner-Gren Institute, Stockholm, Sweden

Pulmonary tuberculosis is a highly contagious infectious disease causing around 1 million deaths each year. Remarkably, many individuals in contact with Mycobacterium do not get infected. Increasing evidence suggests that host genetic heterogeneity affects the immune response to intracellular pathogens, such as Mycobacterium. While BALB/c and C57BL/6 mice are relatively resistant differences exist in their susceptibility towards Mycobacterium infection.

Here, we have used BALB/c and C57BL/6 BCG infection models, to highlight these differences.

We compared CD45⁺ lung populations and observed that C57BL/6 mice present higher frequencies of eosinophils, alveolar macrophages, monocytes and CD103⁺DC compared to BALB/c at steady state. Mice were then infected intranasal with

a live, either low or high BCG dose. We found that after a low BCG exposure dose, C57BL/6 were more efficient than BALB/c in the early control of bacterial growth in the lungs. However, at a higher BCG dose, both strains displayed similar CFU counts. BALB/c mice developed early inflammatory innate responses with significant increases in neutrophils, eosinophils, alveolar macrophages, CD11b⁺DC and CD103⁺DC. Whereas in C57BL/6 mice, most of the CD45⁺ subsets remained stable compared to baseline also after inoculation of a high dose, with the exception of neutrophils and CD103⁺DC that increased. Interestingly, our results suggest that the early strong inflammatory innate response observed in BALB/c is not sufficient to control mycobacterial growth. In contrast, other innate signatures and cellular parameters observed in C57BL/6 mice as well as the increase of CD103⁺DC and neutrophils seem to correlate with the early control of Mycobacterium.

Tumor cell intrinsic TLR4 signaling promotes tumor growth and metastasis

Rogava, M.¹, Bald, T.¹, Shridhar, N.¹, van den Boorn-Konijnenberg, D.², Schmid-Burgk, J.³, Hornung, V.³, Hölzel, M.², Tüting, T.¹

¹University Hospital Bonn, Experimental Dermatology, Bonn, Germany, ²University Hospital Bonn, Institute for Clinical Chemistry and Clinical Pharmacology, Bonn, Germany, ³University Hospital Bonn, Institute of Molecular Medicine, Bonn, Germany

Metastatic melanoma is the most deadly type of skin cancer as it spreads quickly. We and others have shown that Toll-like receptor 4 (TLR4) signaling in the tumor microenvironment is important for tumor cell survival and metastasis. However, the role of TLR4 signaling in melanoma cells is not entirely clear. Therefore, we hypothesized that tumor cell intrinsic TLR4 signaling contributes to melanoma cell survival and metastasis. To address this hypothesis, we utilized a mouse melanoma cell line established in our laboratory. We generated TLR4 deficient melanoma cell variants using the CRISPR/CAS9 genome editing technology. TLR4 deficient clones were validated by Next Generation Sequencing and in functional assays. As a following step, TLR4 deficient tumor cells were transplanted in immunocompetent syngeneic C57BL/6 mice and monitored for tumor growth and metastasis. Here we find that melanoma cells also express functional TLR4. Activation of TLR4 signaling in tumor cells increases proliferation and migration in vitro. Furthermore, TLR4 deficient cells demonstrate delayed growth kinetics upon transplantation into immunocompetent mice. Additionally, TLR4 deficient melanoma cells show decreased numbers of metastases in the lungs. Genetic reconstitution of TLR4 in melanoma cells reversed the observed impairment in tumor growth and metastasis. Taken together, our results provide experimental evidence that TLR4 signaling has melanoma cell-intrinsic function and promotes cell survival and metastasis. This further supports strategies to inhibit TLR4 signaling as an adjuvant treatment option for melanoma patients with a high risk for metastatic dissemination.

Exploring the mechanism for cancer associated fibroblasts recruitment and the potential therapeutic value in esophageal squamous cell carcinoma

Qi, J.¹, Zhang, L.¹, Guan, X.²

¹University of Hong Kong, Clinical Oncology, Hong Kong, China,

²University of Hong Kong, Hong Kong, China

Nowadays, a growing body of evidence suggests that cancer is the wound that never heals¹. Similar to normal wound healing, cancer development and progression requires the participation of many different cell types^{2,3}. Host cells such as fibroblasts, endothelial cells and immune cells are recruited into cancer beds to regulate survival, proliferation, invasion, metastasis, angiogenesis, cancer stem cell maintenance and even the outcome of therapy. This research focuses on cancer associated fibroblasts (CAFs), which is the major cellular component of tumor stroma. It is found that tumors frequently recruit CAFs to enhance tumor growth, invasion and angiogenesis by secreting growth factors, matrix degrading enzymes and angiogenic factors. CAFs are also able to prepare metastatic niche for tumors, even affect tumor metabolism. FGFR2 was identified to show greatest expression difference between CAFs and NFs based on microarray results. *In vivo* experiments have shown that FGFR2 (+) fibrocytes can be recruited by ESCC tumors. IF and flow cytometry data show that FGFR2(+) fibrocytes are recruited from bone marrow, circulating in peripheral blood and finally reached site of tumor. RNA sequencing data indicate that after being trained by the tumor, fibrocytes differentiate into CAFs and facilitate tumor progression. Thus blocking the tumor-CAF interaction will strongly impede the tumor growth therapeutic targeting of FGF-2 and FGFR2 may impaired cancer-stroma interaction by inhibit accumulation of CAFs in tumor tissues may serve as an effective treatment approach to hundreds of thousands of ESCC patients.

IL-17B/IL-17RB axis potentiates tumor growth and migration via activating AKT/ β -catenin pathway in gastric cancer, which accompanied by upregulation of stemness markers

Bie, Q., Ma, J., Su, Z., Wang, S., Xu, H.

Jiangsu University, Immunology, Zhenjiang, China

Background: Inflammation is a critical component involved in tumor progression. IL-17 cytokine family, has recently emerged as important players in diseases. However, the role of IL-17B/IL-17RB signal in tumor growth and migration remains unknown.

Methods: 25 patients diagnosed newly with gastric cancer(GC) were included in the study, Western blotting and immunofluorescence staining were used to determine the expression of IL-17RB, and serum level of IL-17B was measured by ELISA. The expression levels of IL-17RB, IL-17B, IL-25, Oct4, Nanog and Lgr5 mRNA were detected by qRT-PCR. In addition, MGC-803 cell line was chosen to verify the effect of IL-17RB on tumor cells via administrating IL-17RB-shRNA and AKT inhibitor, the ability of cell proliferation, migration was analyzed by colony-formation, cell scratch and transwell assay respectively,

and the expression levels of E-cadherin, N-cadherin, AKT, β -catenin and some stemness markers were detected by qRT-PCR and Western blotting.

Results: The expression of IL-17B and IL-17RB were significantly increased in cancer tissues, there were positive correlations between IL-17RB and some stemness markers. The expression of phosphorylated AKT, GSK-3 β and β -catenin were significantly increased in MGC-803 cell line which expressed higher IL-17RB. In IL-17RB-shRNA transduced MGC-803 cells, the ability of cell-proliferation and migration or expression of E-cadherin, N-cadherin, Nanog, Sox 2 and Oct 4 protein were obviously influenced. In addition, the AKT inhibitor, LY294002 could reverse IL-17B-induced upregulation of β -catenin and some stemness markers.

Conclusions: The IL-17B/IL-17RB axis promoted the growth and migration of tumor cells through up-regulating the cells stemness and activating AKT/ β -catenin pathway in GC.

1971

Low dose Irradiation retunes Immunosuppressive tumor associated macrophages (TAM), and induces immune mediated rejection of established Tumors of Pancreas

Prakash, H.

University of Hyderabad, Hyderabad, India

Inefficient migration of immune effector cells in the tumor is a major limitation of effective therapy against solid tumors in general, but more specifically in pancreatic tumours. This is believed to be due to impermeable tumor endothelium and accumulation tumor-associated macrophages (TAM) in the majority of tumors. These cells represents major barrier in therapies and have been associated with the poor prognosis in the majority of cancer patients. Therefore it is anticipated that targeted activation of the tumor microenvironment may overcome this barrier dysfunction. Among various tumor directed therapies, Radiotherapy has been recently introduced as a potential strategy to improve cancer immunotherapy and tumor immune rejection. This is the only clinically advanced approach for noninvasive, site-specific intervention in cancer patients. Majority of cancer patients are routinely irradiated with therapeutic doses of γ -radiations which range between 45-60Gy. Such high doses of γ -radiations during radiotherapy procedures frequently manifests moderate to severe local / systemic toxicities. Low dose radiation (LDR) on the other hand provides good alternatives of HDR for avoiding such toxicities. In this line, our pioneer studies (Klug and Prakash et, 2013, Prakash et al, 2016) demonstrated that low dose irradiation (2Gy) when applied either locally or systemically, effectively modified tumor microenvironment and facilitated infiltration of peripheral immune effectors cells (T-cells) in neuro endocrine, solid, highly invasive and non-resectable insulinoma in RIP1-Tag5 (RT5) mice, primary human pancreatic carcinoma as well as in xenotransplanted human melanoma. Such tumor infiltration of T cells remained strictly dependent on iNOS+ peritumoral macrophages.

Natural Killer cells display increased efficiency towards Vemurafenib resistant melanoma cell lines

Frazao, A.¹, Colombo, M.¹, Bouquet, F.², Toubert, A.¹, Caignard, A.¹, Savina, A.²

¹INSERM U 1160, IUH - Hopital Saint Louis, Paris, France, ²Roche Scientific Partner, Boulogne Billancourt, France

Melanoma is an aggressive cutaneous cancer with high metastatic potential. Presence of a BRAFV600 mutation in 60% of melanoma showed the interest of BRAF specific inhibitors such as Vemurafenib. This treatment induces high rates of clinical responses in patients but most of them relapse after several months of treatment. Lately, focus has been given to immunotherapy for melanoma tumors. Melanoma cells express stress molecules and are susceptible to lysis by Natural Killer (NK) cells, suggesting interest for combined NK-based therapies. From BRAF mutated melanoma cell lines, we generated Vemurafenib resistant cell lines by culturing the cells with increasing doses of the drug. These resistant variants were characterized and compared to the corresponding parental cell lines, susceptible to Vemurafenib. We showed that drug resistant variants are more susceptible to NK-cell mediated lysis compared to parental cell lines. Resistant cell lines induced stronger activation of NK cells. NK cells showed higher degranulation potential and production of IFN-gamma in response to stimulation with resistant variants. Comparing parental and resistant variants, we showed an increase of NKG2D ligands on resistant variants. Interestingly, we also observed increased death domain receptors (Fas and Trail-R) expression by resistant cell lines compared to their parental counterparts. Thus, certain Vemurafenib resistant variants display increased visibility to NK cells and higher susceptibility to death domain receptors apoptosis.

Altogether, our observations indicate the interest of combining BRAF inhibitors with NK based therapies.

⁶University at Buffalo, Medicine, Buffalo, United States

Ovarian cancer (OC) is often diagnosed at advanced stages. Necrosis is a hallmark of advanced cancer and releases DAMPs that activate innate immune responses. CD8⁺ T cells mediate antitumor immunity while TAMs and MDSCs can impair T cell responses. Knowledge is limited on the role of activated neutrophils in the tumor microenvironment. In ascites from patients with newly diagnosed OC, ~90% of cells were inflammatory (CD45⁺) with varying proportions of neutrophils,

monocytes and lymphocytes. Neutrophils comprised ~15% of CD45⁺ cells and the neutrophil:CD8⁺ T cell ratio was 1.5:1. In *ex vivo* studies, cell-free ascites (CFA) attracted normal donor neutrophils (NDN). Neutrophil extracellular traps (NETs) are a distinct mode of death, and we found that CFA induced NDN to generate NETs *ex vivo*. In co-culture studies, normal donor T cell proliferation was measured by [³H] thymidine incorporation. While CFA or NDN alone did not impair CD3/CD28-stimulated T cell proliferation, CFA-activated NDN completely suppressed proliferation. Suppression did not affect T cell viability or induce apoptosis, and was not reversed by the addition of arginine, N-acetyl-L-cysteine or IL-2. Suppression required T cell contact with NDN. We also found that PD-1 expression on the suppressed T cells phenocopied the unstimulated controls, suggesting that T cell-NDN contact may block activation and subsequent checkpoint upregulation. These results support a model in which neutrophils in the ascites of OC patients may suppress T cell responses, thereby abrogating anti-tumor immunity. Further studies will identify ascites constituents that activate neutrophils and contact mechanisms for neutrophil-mediated T cell suppression.

High fat diets induce colonic epithelial cell stress and inflammation that is reversed by IL-22

*Gulhane, M.*¹, *Murray, L.*², *Lourie, R.*², *Tong, H.*², *Kang, A.*³, *Schreiber, V.*², *Magor, G.*⁴, *Denman, S.*⁵, *Begun, J.*², *Florin, T.*², *Perkins, A.*⁴, *O Cuiv, P.*³, *McGuckin, M.*², *Hasnain, S.Z.*²

¹Mater Research Institute-University of Queensland, Brisbane, Australia, ²Mater Research Institute-University of Queensland, Immunity, Infection and Inflammation Group, Brisbane, Australia, ³University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia, ⁴Mater Research Institute-University of Queensland, Blood and Bone Diseases Program, Brisbane, Australia, ⁵The Commonwealth Scientific and Industrial Research Organization, Brisbane, Australia

Prolonged high fat diets (HFD) induce low-grade chronic intestinal inflammation in mice, and diets high in saturated fat are a risk factor for the development of human inflammatory bowel diseases. We hypothesized that HFD-induced obesity, oxidative stress, protein misfolding and endoplasmic reticulum (ER) stress occur in intestinal secretory goblet cells, triggering inflammatory signaling and reducing synthesis and secretion of proteins that form the protective mucus barrier. A prolonged HFD of 22 weeks elevated the intestinal inflammatory cytokine signature, alongside compromised mucosal barrier integrity with a decrease in goblet cell differentiation factor Kruppel-like factor-4 and Muc2, along with a loss in the tight junction protein, claudin and increased serum endotoxin levels. In a spontaneous model of colitis (*Winnie* mice), HFD increased ER stress, further compromised the mucosal barrier and increased the severity of pathology. We discovered using primary intestinal cells that non-esterified fatty acids directly increased oxidative and ER stress leading to protein misfolding which was suppressed by the oxidative stress suppressing cytokine IL-22. IL-22 therapy

reduced ER/oxidative stress and improved the integrity of the mucosal barrier, and reversed microbial changes associated with obesity. Consistent with epidemiological studies, our experiments suggest that high fat intake and obesity is likely to impair intestinal barrier function, particularly in early life, which at least partially involves direct effects of free fatty acids on intestinal secretory cells, and we demonstrate this can be reversed by IL-22 therapy.

Antimicrobial peptide derived from insulin-like growth factor-binding protein 5, AMP-IBP5, activates human mast cells

Niyonsaba, F.^{1,2}, *Okumura, K.*¹, *Ogawa, H.*¹

¹Juntendo University Graduate School of Medicine, Atopy (Allergy) Research Center, Bunkyo-ku, Japan, ²Juntendo University, Faculty of International Liberal Arts, Bunkyo-ku, Japan

Apart from exhibiting killing activities against invading pathogens, antimicrobial peptides (also known as host defense peptides, HDPs) broadly modulate the immune response through activation of different cell types. Recently, a novel antimicrobial peptide derived from insulin-like growth factor-binding protein 5 (AMP-IBP5) was discovered and shown to display strong antimicrobial activities at concentrations comparable to those of well-characterized HDPs such as human β -defensins and cathelicidins. Given that human β -defensins and cathelicidins are known to activate various cell types including mast cells, we hypothesized that AMP-IBP5 could also stimulate mast cells.

In the current study, we demonstrated that AMP-IBP5 activated human mast cells (LAD2 cells) to degranulate and secrete various eicosanoids such as prostaglandin D₂, E₂ and leukotriene C₄. Moreover, AMP-IBP5 enhanced intracellular calcium flux, cell migration and production of various cytokines/chemokines by mast cells. We observed that AMP-IBP5 activated human mast cells through a Mas-related G protein-coupled receptor member MrgX2, but not other MrgX receptors. Moreover, AMP-IBP5-induced mast cell activation was controlled by the phospholipase C, MAPK and NF- κ B pathways, as evidenced by their specific inhibition.

In conclusion, the present study provides novel evidence that, in addition to its microbicidal properties, host defense peptide AMP-IBP5 may also contribute to the regulation of innate immunity through activation of various functions of mast cells.

Anti-inflammatory properties of the hookworm protein Na-AIP-1

Buitrago, G., *Pickering, D.*, *Giacomin, P.*, *Shepherd, C.*, *Jones, L.*, *Loukas, A.*

Centre for Biodiscovery and Molecular Development of Therapeutics, Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Australia

Inflammatory bowel disease (IBD) is an umbrella term for a group of immune-mediated conditions, which are characterised

by idiopathic chronic inflammation of the gastrointestinal tract. Current treatment protocols for IBD are often poorly tolerated or ineffective. The decline in prevalence of human parasitic infections and concurrent increases in the occurrence of various inflammatory conditions has been recognised, provoking the hypothesis that some of these parasites may possess anti-inflammatory capabilities.

Multiple experimental studies have documented the efficacy of live helminth infection in the alleviation of symptoms of intestinal inflammation, using both human and animal models of disease. Consequently, there is now interest in the potential immunomodulatory proteins derived from helminths, which may be safer and more acceptable alternatives to live worm therapy. We have isolated and expressed a novel candidate anti-inflammatory molecule from the secretions of the hookworm *Necator americanus* (*Na*-anti-inflammatory protein (AIP)-1).

Recombinant *Na*-AIP-1 was cloned and expressed using *Pichia pastoris* and purified via immobilised metal ion affinity chromatography. Intra-peritoneal treatment of mice with recombinant *Na*-AIP-1 ameliorated clinical, immunological and histological features of disease in murine models of TNBS-induced colitis and CD4⁺ T-cell transfer-induced colitis. Thus, *Na*-AIP-1 represents an excellent candidate for further development as a novel treatment of IBD and other immune-mediated inflammatory disorders.

The impact of the pro-inflammatory cytokine TNF- α in prostate cancer development

Banzola, I.¹, Mengus, C.², Wyler, S.³, Sais, G.¹, Keller, E.X.⁴, Poyet, C.⁴, Eberli, D.⁴, Sulser, T.⁴, Spagnoli, G.C.², Provenzano, M.¹

¹University Hospital Zurich, Schlieren, Switzerland, ²University Hospital Basel, Basel, Switzerland, ³Cantonal Hospital Aarau, Aarau, Switzerland, ⁴University Hospital Zurich, Zurich, Switzerland

Prostate cancer (PCa) constitutes a major health problem due to its high prevalence in the population and the current lack of effective treatment for its metastatic, castration-resistant form. A great deal of literature suggests that inflammation might play an important role in the onset and progression of PCa, although evidence remains scant. Inflammation of the prostate is almost ubiquitous in mature men and histological analysis of prostatic samples has revealed that areas surrounding adenocarcinomas often display inflammation, specifically in lesions designated as early stages of the disease.

In this study we addressed the role of the inflammatory cytokine TNF- α in the development of PCa. We particularly focused on PCa-specific tumor-derived soluble factors (PCa-TDSFs) that have already been reported as possible mediators of PCa morbidity and on how the TNF- α -driven release of those microenvironmental modifiers might affect cancer progression. Our results showed a clear picture in which the inflammatory stimulus modulates the release and functions of TDSFs primarily involved in specific steps of PCa progression. Indeed, both cancer immune evasion and cancer aggressiveness were permanently strengthened by the TNF- α -driven modulation of factors, such as IL-6, IL-1 β and MMP9, which are involved in the mechanisms of cell proliferation, migration and invasion.

Our results argue for a role of pro-inflammatory cytokines in the transformation of localized PCa into a more aggressive and invasive form. This opens a discussion on the possibility of administering inflammatory cytokine-based cancer treatments, such as immunotherapy, and on possible modulations of their effects.

Impact of the timing of morphine administration on lipopolysaccharide-mediated lethal endotoxic shock in mice

Kato, H.¹, Fukada, T.¹, Imanishi, K.², Ozaki, M.¹, Yagi, J.¹

¹Tokyo Women's Medical University, Tokyo, Japan, ²Japan Health Sciences University, Saitama, Japan

Sepsis is a serious condition related to systemic inflammation, organ dysfunction, and organ failure. It is a subset of the cytokine storm caused by dysregulation of cytokine production. Morphine influences the severity of infection in vivo and in vitro because it regulates cytokine production. We investigated the immunological function of morphine using a mouse model of septic shock. We treated mice with α -galactosylceramide (α -GalCer, 2 μ g/mouse) to induce lethal endotoxic shock following a challenge with lipopolysaccharide (LPS, 1.5 μ g/mouse). This model represents acute lung injury and respiratory failure and reflects the clinical features of severe septic shock. We evaluated the effect of the timing of morphine (0.8 mg/mouse) administration on the survival rate, cytokine production in vivo, and histological changes of mice with LPS-mediated lethal endotoxic shock. Morphine treatment before LPS challenge suppressed lethal endotoxic shock. In contrast, when we administered after LPS, morphine exacerbated lethal endotoxic shock; hematoxylin and eosin staining revealed a marked increase in the accumulation of infiltrates comprising polymorphonuclear leukocytes and mononuclear cells in the lung, and Elastica van Gieson staining revealed the destruction of alveoli. The plasma levels of TNF- α , IFN- γ , MCP-1, and IL-12 in the group treated with morphine after LPS challenge were higher than those treated with morphine before LPS challenge. In conclusion, one of the factors that determine whether morphine exacerbates or inhibits infection is the timing of its administration. Morphine treatment before shock improved the survival rate, and morphine treatment after shock decreased the rate of survival.

Aspirin-triggered Resolvin D1, ATRvD1, reverts chronic pulmonary fibrosis in a murine model

Guilherme, R.¹, Nogueira, T.¹, Neves, J.², Canetti, C.¹, Benjamim, C.¹

¹Federal University of Rio de Janeiro, Program of Immunology, Rio de Janeiro, Brazil, ²Federal University of Rio de Janeiro, Program of Pharmacology and Inflammation, Rio de Janeiro, Brazil

Pulmonary fibrosis is characterized by diffuse chronic interstitial inflammation, increased fibroblast proliferation, and enhanced extracellular matrix synthesis and deposition. This disease is a major cause of morbidity and mortality with a prognostic of 5

years of life, and there are few treatments strategies available. The resolvin D1 (RvD1) is a lipids derivative of omega-3 PUFAs (polyunsaturated fatty acids) and has anti-inflammatory and pro-resolution effects, however their anti-fibrotic effect has not been demonstrated yet. Our aim is to evaluate the mechanisms underlying the anti-fibrotic effect of ATRvD1 on bleomycin-induced pulmonary fibrosis in mice. Pulmonary fibrosis was induced in C57BL/6 mice by administration of bleomycin (BLM - 0.06U i.t.). ATRvD1 treatment was performed at days 7 (25 µg/ Kg iv) and 10 (5 µg/ Kg) after BLM administration, and the analysis was done 14 days after. Cell population was enhanced in the BAL of BLM group and the ATvD1 treatment reduced total cells, macrophages, and neutrophils infiltration in the BAL at day 14. ATRvD1 administration reversed BLM-induced collagen and fibronectin deposition, OH-proline content, collagen I and III secretion, α-sma expression and TNF-α, MCP-1, IL-1β, TGF-β production in the lungs. A marker of fibroblast activation, FSP1, was highly expressed after BLM and ATRvD1 was able to reduce this expression. ATRvD1 has an anti-fibrotic effect by controlling inflammation and reversing fibrotic phenotypes, however further experiments are necessary to characterize the mechanism of action of ATRvD1 in the mice fibrosis.

Proinflammatory milieu and excitotoxic glutamate on glioblastoma cell infiltration

Fathima K, H., Dalavaikodihalli Nanjaiah, N.

NIMHANS, National Institute of Mental Health and Neurosciences, Neurochemistry, Bangalore, India

Background: Tumor cell migration and diffuse infiltration into brain parenchyma are the major hallmarks of Glioblastoma (GBM). GBM cells release extensive amounts of glutamate leading to excitotoxic cell death and necrosis of surrounding brain parenchyma, which triggers inflammation and release of the major proinflammatory cytokine IL-1β. Also, humans GBM cells themselves are found to overexpress IL-1β. We have previously shown that IL-1β plays a role in glioma invasion.

Objective: The objective of this study was to examine the effect of IL-1β and the activation of AMPA (α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid) and NMDA (N-methyl-D-aspartate) receptors of glutamate on glioma cell migration and matrix metalloproteinase-2 (MMP-2) activity and the possible effects of their interaction.

Materials: Cultured U87MG cells were treated with IL-1β, AMPA or NMDA and in vitro wound healing scratch assay was carried out to analyze their effect on migration of these cells. The effect on MMP-2 was analyzed using gelatin zymography for MMP-2 activity and qPCR for its mRNA expression.

Results: IL-1β showed increase in cell migration and MMP-2 activity in U87MG glioma cells. Treatment with either AMPA or NMDA increased the cell migration, while MMP-2 activity was found to increase only on NMDA treatment. IL-β induced cell migration and MMP-2 activity was enhanced on the pretreatment of cells with NMDA, but no such effect was observed on pretreatment with AMPA.

Conclusion: These results suggest that increase in migration of glioma cells in IL-β proinflammatory microenvironment

is enhanced by glutamate excitotoxicity, mainly through interaction with NMDA receptors.

DNase 1 is protective in murine experimental myeloperoxidase anti neutrophil cytoplasmic antibody associated glomerulonephritis

O'Sullivan, K.M.¹, Gan, P.-Y.¹, Lo, C.Y.², Kitching, A.R.^{1,3,4}, Holdsworth, S.R.^{1,3}

¹Monash University, Medicine, Melbourne, Australia, ²Monash University, Monash Micro Imaging, Melbourne, Australia, ³Monash Health, Nephrology, Melbourne, Australia, ⁴Monash Health, Paediatrics, Melbourne, Australia

Myeloperoxidase (MPO) anti-neutrophil cytoplasmic antibody (ANCA) associated glomerulonephritis (MPO-ANCA GN) is an important cause of renal failure. With current standard treatment 30% of patients die or become dialysis dependent within 3 years. Studies in murine models have shown that the disease is neutrophil dependent. We have shown recently in patients that glomerular neutrophil extracellular traps (NETS) are a prominent feature. Human recombinant deoxyribonuclease 1 (DNase 1) is already used safely in children with Cystic Fibrosis. DNase 1 in addition to its other anti-inflammatory properties can inhibit net formation *in vitro*. We used DNase 1 intravenously twice daily to inhibit net formation in a murine model of experimental MPO-ANCA glomerulonephritis. DNase 1 treatment significantly decreased the percentage of glomeruli with NETs as defined by co-localisation of NET components: citrullinated histone 3 (H3Cit), protein arginine deiminase 4 (PAD4), MPO and chromatin (2.5% ± SEM 1.5, versus 38% ± SEM 5.6 in saline treated, P< 0.0001) and significantly reduced the amount of extracellular MPO (P< 0.05). Functional injury as assessed by proteinuria was significantly reduced (albuminuria/creatinine ratio reduced from 0.3± 0.09 in controls versus 0.07±0.03) as was histological injury (segmental glomerular necrosis, 38.5% ± 4.2% in controls versus 13.2% ± 1.9%). Glomerular recruitment of CD4

T cells, CD8 T cells, macrophages and neutrophils, were reduced with DNase 1 treatment (all, P< 0.05). This data suggests that NET formation is a critical component of inflammatory injury in this disease and that DNase 1 is effective in inhibiting NET formation, and reducing inflammation.

2219

CCR6 intrinsic signaling promotes Th17 cell differentiation during autoimmunity

Kulkarni, N., Lal, G.

National Centre for Cell Science, Infection and Immunity, Pune, India

Background: Chemokine receptor CCR6 is a G protein-coupled receptor (GPCR) expressed on various immune cells, including Treg and Th17, and its intrinsic signaling is well characterized

in the migration of cells. Does CCR6 signaling also control the differentiation of the effector Th17 cells?

Methods: We induced colitis by giving dextran sodium sulfate (DSS) in drinking water to C57BL/6 mice or adoptively transferred naïve CD4 T cells (CD4+Foxp3rfp-CD44-CD45RBhi cells) into RAG1^{-/-} mice.

Results: CCR6+CD4⁺ T cells showed significantly increased expression of ROR γ t and IL-17 in DSS induced colitis compared to controls, and CCR6^{-/-} mice showed reduced colitis. To test the contribution of CCR6 on ROR γ t expression, we injected CCR6^{-/-} CD4 T cells (CD45.2⁺) in the CD45.1⁺ congenic mice, and mice were given DSS. Compared to the CD45.1+(CCR6+/+) CD4 T cells, CD45.2+(CCR6^{-/-}) cells did not increase ROR γ t expression. To faithfully monitor the effect of CCR6 on ROR γ t expression in Foxp3⁺ Tregs, we adoptively transferred naïve CD4 T cells from CCR6gfp^{+/-}::Foxp3rfp^{+/+} mice to RAG1^{-/-} mice. During colitis, CCR6gfp⁺Foxp3rfp⁺ Tregs showed significant increased ROR γ t expression compared to the CCR6gfp⁻ Tregs. Addition of CCL20 (CCR6 ligand) in Treg and Th17 lineages differentiation culture conditions significantly increased ROR γ t and IL-17 expression. Binding of CCL20 with CCR6 induced phosphorylation of Akt, mTOR and STAT3, and which in turn promoted the binding of ROR γ t specifically on IL-17A promoter and CNS5, and increased IL-17 reporter activity.

Conclusions: CCL20-CCR6 signaling promotes differentiation of Th17 cells, and designing strategies to block CCR6 signaling will help in controlling gut inflammation and autoimmunity.

2595

Proinsulin specific CD4⁺ T cells isolated from peripheral blood of people with type 1 diabetes have similar specificities to islet-infiltrating CD4⁺ T cells

So, M., Pathiraja, V., Tresoldi, E., Elso, C., Kay, T., Mannering, S. St Vincent's Institute of Medical Research, Melbourne, Australia

Type 1 diabetes (T1D) is an autoimmune disease caused by T-cell mediated destruction of the insulin-producing beta cells. Genetic risk for T1D is most strongly associated with HLA-DQ2 and HLA-DQ8, and the insulin gene promoter. Recently we isolated CD4⁺ T-cell clones from the residual pancreatic islets of a deceased organ donor who had T1D. Many of these clones recognized epitopes from C-peptide, a natural product of the conversion of proinsulin to insulin. All C-peptide specific clones were restricted by HLA-DQ8, or HLA-DQ8 transdimer that only forms in HLA-DQ2/DQ8 antigen presenting cells. Here we ask if similar CD4⁺ T-cell responses can be detected in peripheral blood mononuclear cells (PBMC) of individuals with recent onset T1D when stimulated with full length (31 aa) C-peptide. C-peptide responsive CD4⁺ T cells were cloned from PBMC of people with recent-onset T1D. CD4⁺ T-cell responses to C-peptide were detected in PBMC from 9/21 individuals with recent-onset T1D but 0/7 individuals with long-standing T1D. C-peptide specific clones were isolated from two recent-onset subjects. Currently, we have three C-peptide responsive clones, one from Donor 1 and two from Donor 2. All three clones recognize proinsulin 47-62, which overlaps the epitopes recognized by 4/14 islet-infiltrating CD4⁺ T cells. Two clones, one from each donor, are HLA-DQ8 restricted and one is HLA-DR restricted. This work

highlights the importance of CD4⁺ T-cell responses to C-peptide in T1D. Furthermore, it supports the notion that C-peptide specific CD4⁺ T-cells detected in PBMC have similar properties to those that infiltrate human islets in T1D.

Lupus-associated complement classical pathway proteases degrade apoptotic nuclear proteins and dampen cell activation by subclinical endotoxin

Cai, Y.¹, Yeo, J.G.^{1,2}, Leong, J.Y.³, Lu, J.¹

¹Yong Loo Lin School of Medicine, National University of Singapore, Department of Microbiology and Immunology, Singapore, Singapore, ²KK Women's and Children's Hospital, Division of Medicine, Singapore, Singapore, ³Singapore Translational Immunology and Inflammation Centre, Singapore Health Services, Singapore, Singapore

The complement system has long been investigated in host defense against microbial infections but genetic deficiency of the different complement components revealed involvements of complement in broader physiological processes. Deficiency of early (C1q, C1r/C1s and C4) but not late components of the classical pathway are strong causal risk factors for lupus-like conditions characterized by antinuclear autoimmunity. In search for a connection between these complement elements to antinuclear autoimmunity, we identified C1q recognition of the nucleolus late in apoptotic cells and we also found that this caused degradation of multiple nucleolar proteins including nucleolin and nucleophosmin-1. These C1 proteases also cleave high mobility protein box-1 (HMGB1), a well-known nuclear alarmin released by apoptotic cells which causes lupus-like conditions in mice. The cleavage inactivated HMGB1 in its ability to synergize with subclinical levels of endotoxin in the activation of monocytes, macrophages and dendritic cells. Apoptotic cells also release many autoantigens and some of these autoantigens are also cleaved by C1 proteases. In summary, our data stresses on novel substrate specificities of C1 proteases among intracellular proteins and help explain their deficiency being among the strongest risk factors for autoimmunity.

Type 1 diabetes is an organ specific autoimmune disease in which insulin-producing beta cells are destroyed by autoreactive T cells. Cytotoxic CD8⁺ T lymphocytes (CTL) and helper CD4⁺ T cells mediate beta cell destruction. Our aim is to inhibit the interaction between beta cells and CD8⁺ T cells and curb effector CD4⁺ T cell-dependent inflammation in the islets to prevent beta cell death. MHC class-I is upregulated on beta cells in

response to cytokines secreted by immune cells infiltrating into islets. Blocking cytokine signaling by overexpressing suppressor of cytokine signaling (SOCS)-1 in beta cells inhibits MHC class I upregulation and protects beta cells from CTL-mediated killing. We hypothesize that drugs that selectively inhibit JAK1 and JAK2 kinases downstream of cytokine signaling will have the same effect as SOCS-1 overexpression. JAK1/JAK2 inhibitors successfully blocked IFN γ -induced phosphorylation of STAT1 and IFN γ -induced MHC class-I upregulation in mouse and human islets. Mouse islets were protected from CTL-mediated killing in vitro by JAK1/JAK2 inhibitors. Time-lapse microscopy shows the inhibitor prevented the direct interaction between CTLs and beta cells, reducing calcium flux in the CTL and synapse duration. JAK1/JAK2 inhibitors blocked the effect of cytokines on beta cells in vivo by inhibiting MHC class I upregulation, and reduced infiltration of immune cells into islets in CD8 and CD4 mediated models of type 1 diabetes. Furthermore, JAK1/JAK2 inhibitors protected NOD mice from cyclophosphamide-induced diabetes. This preclinical study provides a platform for designing proof of concept clinical trials for blocking JAK/JAK2 signaling in human type 1 diabetes.

CCDC134 suppresses the development of experimental autoimmune encephalomyelitis in C57BL/6 mice

Huang, J., Xia, P., Gong, X., Xiao, L., Yu, B., Qiu, X.

School of Basic Medical Sciences, Peking University Health Science Center, Department of Immunology, Beijing, China

CCDC134, a cytokine-like molecule served as a potential member of the γ_c cytokine family, was previously reported to have potent antitumor effects by augmenting CD8⁺ T cell-mediated immunity. However, whether CCDC134 is actively released in central nervous system (CNS) and involved in experimental autoimmune encephalomyelitis (EAE) remains unclear. In this study, we found that CCDC134 level in mouse sera was increased in the onset and peak stage of EAE. Moreover, we demonstrated that CCDC134 was efficacious in a model of EAE that mirrors chronic progressive multiple sclerosis. A short-term systemic treatment with recombinant CCDC134 reduced clinical severity and incidence of EAE. In addition, we used CCDC134-transgenic mice model and found that the onset and severity of EAE, the appearance of inflammatory infiltrates in spinal cord and the subsequent demyelination and axonal damage were significantly alleviated in CCDC134-transgenic mice compared with control mice. We further sought to elucidate the basis of CCDC134 protective effect on EAE by characterizing the T effector/regulatory responses. And the presence/activation of encephalitogenic Th17 cells and several inflammatory mediators in peripheral lymphoid organs and CNS were down-regulated in CCDC134-transgenic mice, while a remarkable upregulation of IL-10 and TGF- β in the spinal cord of CCDC134-transgenic EAE mice was detected. These findings indicate that CCDC134 plays a pivotal role in the pathogenesis of EAE and provide insights into the role of recombinant CCDC134 as a unique therapeutic agent for the treatment of autoimmune diseases.

Molecular targets for inhibiting progression of myocarditis to inflammatory cardiomyopathy

Forsthuber, T.¹, Casabar, J.¹, Maldonado, D.¹, Forsthuber, I.¹, Al-Abed, Y.², Nalawade, S.¹

¹University of Texas at San Antonio, Biology, San Antonio, United States, ²Feinstein Institute for Medical Research, New York City, United States

Inflammatory dilated cardiomyopathy (DCMI) is a leading cause of heart failure and heart transplantation, yet there are currently no specific treatments available. Substantial evidence supports a key role for inflammation and chronic myocarditis in progression to DCMI and an autoimmune origin is supported by autoantibodies against heart tissue in myocarditis patients and induction of experimental autoimmune myocarditis (EAM) with cardiac autoantigens in animal models. Surprisingly, immunosuppressive treatments such as corticosteroid (CS) drugs are not very effective and cannot prevent DCMI. We hypothesized that macrophage migration inhibitory factor (MIF) may play a role in treatment resistance since MIF is induced by CS and counter-regulates CS-mediated immunosuppression. Here, we will present our results showing that MIF knockout mice treated with Dexamethasone (Dex) were resistant to EAM and did not progress to DCM. Furthermore, small molecule inhibitors of MIF combined with Dex were similarly effective in preventing DCMI in wild-type mice. Studies investigating the underlying mechanism implicated key chemokines and adhesion molecules in the progression of EAM to DCMI. Our results suggest that therapeutic inhibition of MIF in combination with CSs may be a novel treatment approach to prevent DCMI. Last, our studies may provide new insights into the mechanisms driving DCMI.

Complement receptor immunoglobulin (CRIg) and adaptive immunity: regulation of expression in human dendritic cells by cytokines

Small, A.^{1,2}, Munawara, U.^{1,3}, Quach, A.^{1,2}, Hii, C.^{1,2}, Abbott, C.³, Ferrante, A.^{1,2}

¹University of Adelaide, Adelaide, Australia, ²SA Pathology, Department of Immunology, Adelaide, Australia, ³Flinders University, Bedford Park, Australia

The B7 family-related protein, V-set and Ig domain (VSIg4)/Complement Receptor (CRIg) is expressed on dendritic cells (DC) and promotes T lymphocyte suppression. Thus CRIg is likely to be a control point in immune responsiveness through which cytokines exert their influence on adaptive immunity. However little is known on the interplay between cytokines which regulate immune responsiveness and expression of CRIg on DC. CRIg expression was examined at the mRNA (qRT-PCR) and protein level (western blot) in DC derived from human peripheral blood monocytes. Our data demonstrated that DC express three isoforms of CRIg. The cytokines modulated the expression of all three isoforms of CRIg in a similar manner. A key result was the finding that those cytokines (IL-10, TGF- β 1) and agents (dexamethasone, PKC inhibitors) upregulated CRIg expression also promote the development of tolerogenic DC and those which decrease expression (TNF, IFN- γ) break the tolerance function of DC. The results emphasise ways of modulating CRIg expression on DC to optimise their tolerogenic function and this may provide avenues for tackling diseases with an autoimmune origin.

The role of complement in antibody-mediated immunity against malaria in pregnancy

Opi, D.H.^{1,2}, Boyle, M.¹, Reiling, L.¹, McLean, A.¹, Zhou, J.¹, Stanicic, D.^{3,4}, Baiwog, F.³, Rogerson, S.⁵, Jawarowski, A.^{1,6,7}, Fowkes, F.^{1,8}, Beeson, J.^{1,5,9}

¹The Burnet Institute of Medical Research and Public Health, Centre for Biomedical Research, Melbourne, Australia, ²Kenya Medical Research Institute-Wellcome Trust Research Programme, Kilifi, Kenya, ³Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, ⁴Institute for Glycomics, Griffith University, Gold Coast, Australia, ⁵University of Melbourne, Department of Medicine, Melbourne, Australia, ⁶University of Melbourne, Department of Chemical and Biomolecular Engineering, Melbourne, Australia, ⁷Monash University, Department of Infectious Diseases, Melbourne, Australia, ⁸University of Melbourne, Centre for Epidemiology and Biostatistics, Melbourne, Australia, ⁹Monash University, Department of Microbiology, Clayton, Australia

Malaria in pregnancy is a leading cause globally of poor maternal health, and low birth weight and premature delivery of neonates leading to greatly increased mortality and morbidity. Malaria in pregnancy (MiP) is characterised by the accumulation of *Plasmodium falciparum*-infected red blood cells (pRBCs) in the placenta. Infection is less prevalent with successive pregnancies partly due to the acquisition of antibodies directed against parasite antigens that mediate pRBC sequestration. However, effector mechanisms of antibodies are incompletely understood. Antibody responses are predominantly IgG1 and IgG3 subtypes, supporting a potential role for complement, but this has not been defined. Using sera collected from a longitudinal cohort of 350 pregnant women from a malaria-endemic province in Papua New Guinea we have established that acquired antibodies among pregnant women promote the deposition of complement on the surface of placental-binding pRBCs through binding C1q, and activate complement leading to fixation of C3b. Interestingly, complement fixation does not lead to cell lysis or parasite killing. Instead, antibodies with complement inhibit binding of pRBCs to placental vascular receptors and enhance phagocytosis by monocytes, mechanisms likely to provide protection against MiP. Using genetically-engineered *P. falciparum*, we identified the parasite antigen PfEMP1 as the major target of complement-fixing antibodies. Analysis of longitudinal data among pregnant women supports a role for complement fixation by acquired antibodies in protection against placental infection and adverse pregnancy outcomes. These findings provide new insights into the mechanisms mediating immunity to malaria in pregnancy to advance vaccine development.

A sjogren's syndrome-like condition in Gln137Gly mutant RP S19 gene knocked-in C57BL/6J female mice

Nishiura, H., Yamanegi, K., Yamada, N., Nakasho, K.
Hyogo College of Medicine, Pathology, Nishinomiya, Japan

We have demonstrated that apoptotic cells express C5a receptor (C5aR) and produce its antagonist/agonist ligand cross-linked S19 ribosomal proteins (RP S19s) between Lys122 and Gln137 by tissue transglutaminases. We recently found that RP S19 polymer additionally interacts not only with an apoptosis inducing transcription factor delta lactoferine in apoptotic cells but also with an extracellular calcium inducer annexin A3 in macrophages. Therefore, we suggested that RP S19 polymer participates in the phagocytic clearance of apoptotic cells by macrophages via C5aR.

To validate the roles of RP S19 polymer, we prepared Gln137Glu mutant RP S19 gene knocked-in C57BL/6J mice. In comparison with wild-type female mice, in knocked-in female mice (1) numbers of CD4-/CD8- double minus cells were increased and vice versa those of CD4+/CD8+ double positive cells in thymus, (2) numbers of peripheral blood lymphocytes were decreased, (3) CD4+ single positive cell ratio to the CD8+ was increased in spleen, (4) B cells expressed an activation marker programmed cell death receptor-1 (PD-1) in spleen,

(5) anti-submandibular gland antibodies were present in plasma and
 (6) the PD-1 positive lymphocytes infiltrated into submandibular glands.

We suggested that the loss of C5aR-mediated phagocytic clearance of apoptotic cells by macrophages functions to initiate a Sjogren's syndrome-like condition in C57BL/6J female mice.

Long-term effects of gestational chronodisruption on the complement system: a novel determinant of allergy in the adulthood?

Sarmiento, J., Carmona, P., Perez, B., Espinoza, G., Henriquez, C., Folch, H.

Universidad Austral de Chile, Valdivia, Chile

Substantial evidences strongly suggest that conditions during the intrauterine period of life play a critical role on the homeostasis of immune system, and the environment of mother is an important factor that influences the susceptibility to allergic disease in the adulthood. The allergic pathology is characterized by bad-adapted T helper cells (Th) drive immune response. Different data strongly suggest that complement system factors are expressed by Th cells and involved in the regulation of Th cells polarization. We have analyzed the effects of chronodisruption on the expression of complement system factors in a well characterized animal model of gestational chronodisruption in Sprague-Dawley rats. In this model, the exposure of pregnant dams to constant light during the second half of gestation suppressed the maternal melatonin rhythm, reduced intrauterine growth and impair the fetal adrenal function. By microarrays analysis, we found that several components of the complement system were significantly deregulated in the fetal liver; which was confirmed by quantitative PCR for the up-regulation of C1qbp and the down-regulation of C3 and C9. Notably, C3 and C9 transcripts remained significantly down-regulated in the adult offspring, which was accompanied by significantly decreased levels of plasma C3 protein. Because C3 is a key factor of complement system activation that could affect the overall efficiency of the pathway, and that play important roles in the homeostasis of Th cells polarization we postulated that downregulation of C3 by gestational chronodisruption as a new mechanism of bad-adapted pathological immune response in adulthood

The complement C5a receptor, C5aR2 contributes to motor deficits in mouse models of Huntington's and Parkinson's disease

Li, R., Levin, S., Lee, J., Gordon, R., Woodruff, T.

The University of Queensland, School of Biomedical Sciences, Brisbane, Australia

Huntington's disease (HD) and Parkinson's disease (PD) are chronic neurodegenerative diseases characterised by progressive motor and cognitive dysfunction. Recent studies

have shown widespread up-regulation of innate immune complement factors by neurons and glia in the brains of HD and PD patients, which suggests that complement system may be a key contributor to disease progression of HD and PD. C5a is the most potent inflammatory effector of the complement system which functions by binding to its two receptors termed C5aR1 and C5aR2. The aim of this study was to determine the functional role of C5aR2 on motor functions in mouse models of HD and PD. We used an established model of HD, the R6/1 transgenic mouse, and a dopaminergic neurotoxin (6-OHDA) intra-striatally injected mouse model for PD. We bred the R6/1 transgenic mice with C5aR2 knockout (KO) mice and 6-OHDA injected C5aR2 KO to identify any potential protective or pathogenic function for C5aR2 in these disease models. Several behavioural tests were conducted including rota-rod, balance beam, grip strength and amphetamine-induced rotational tests. We found that 6-OHDA injected C5aR2 KO mice had better performances in both balance beam and amphetamine-induced rotational tests when compared to wild-type mice. Similarly, knocking out C5aR2 in R6/1 Huntington's mice resulted in improved motor function in rota-rod, balance beam and grip strength tests. These studies demonstrate a pathogenic role for C5aR2 in HD and PD, and identify a new potential therapeutic target to mitigate motor deficits in these diseases.

Factor B and factor H dysregulation during dengue virus infection: *in vitro* and *in vivo* evidence

Cabezas, S.¹, Rudd, P.², Mahalingam, S.², Gordon, D.¹, Carr, J.M.¹

¹School of Medicine, Flinders University, Microbiology and Infectious Diseases, Adelaide, Australia, ²Griffith University, Emerging Viruses and Inflammation Group, Southport, Australia

Dengue virus (DV) is responsible for one of the most important viral diseases in terms of geographical distribution and human morbidity. The pathogenesis of severe DV is not fully understood; however hyper-activity of the complement alternative pathway (AP) has been associated with severe disease. Our study aimed to determine the mechanisms underlying the hyper-activity of the complement AP during DV infection.

Factor B (FB) and factor H (FH) are the main regulatory factors of the AP, with FB an activator and FH a negative regulator, keeping the AP activity tightly controlled. Using Real-Time RT-PCR we quantitated FH and FB mRNA in cell lines (mouse embryonic fibroblasts [MEF], primary human umbilical vein endothelial cells [HUVEC], human monocyte-derived macrophages [MDM]) and in the AG129 mouse infected with DV. Our results show that both FB and FH mRNA levels significantly increase during DV infection, in both mouse and human cell infection models. Moreover, incubation of HUVEC with a neutralizing IFN- β antibody blocked DV-induction of FH and FB suggesting an IFN-dependent mechanism. In contrast, induction of FH and FB mRNA was observed in AG129-DV-infected mouse liver, but not kidney during the viremic phase of infection. Since the AG129 mice are IFN-receptor deficient, this implies IFN-independent induction of FH and FB also occurs in response to DV infection. Together these results support the notion that the AP is dysregulated during DV infection which may be associated with

complement-mediated effects on the vasculature and could drive development of the severe forms of DV disease.

269

The lysosomal cysteine protease legumain is required for normal Th1 induction in vitro

Freeley, S.¹, Cardone, J.¹, Gunther, S.², Reinheckel, T.², Watts, C.³, Kemper, C.¹

¹King's College London, Department of Transplant Immunology and Mucosal Biology, London, United Kingdom, ²University of Freiburg Medical Center, Institute for Molecular Medicine and Cell Research, Freiburg, Germany, ³University of Dundee, Division of Cell Signalling & Immunology, Dundee, United Kingdom

Introduction: Complement is now emerging as a critical checkpoint regulator in Th1 biology: intracellular cleavage of complement C3 into C3a and C3b by cathepsin L (CTSL) drives the autocrine activation of the C3aR and the C3b receptor CD46 on human CD4+ T cells, which is critically required for IFN γ induction upon TCR activation. Importantly, increased intracellular processing of C3 by CTSL contributes to Th1 hyperactivity in rheumatoid arthritis and can be targeted pharmacologically by CTSL inhibition. CTSL may therefore be a potential therapeutic target in autoimmune disease.

Objectives: We noticed that the lysosomal asparagine endopeptidase Legumain (AEP) is also expressed in Th1 cells. As AEP can drive proteolytic maturation/functional modulation of cathepsins B, H and L in myeloid cells and is connected with dysregulation of cellular responses, we assessed for a potential role of AEP in Th1 responses.

Methods: Purified CD4+ T cells were activated in the presence or absence of a specific Legumain inhibitor (MV026630) and assessed for intracellular CTSL maturation and C3 activation as well cell survival/proliferation and Th1 induction.

Results: Legumain inhibition caused changes in CTSL localisation and a significant and 'dose-dependent' reduction in intracellular C3a generation ($P=0.0276$) and reduced the production of both IFN γ ($P=0.0004$) and IL-17 ($P=0.0007$) without affecting cell viability or IL-4 production.

Conclusion: These data suggest that upstream regulation of CTSL activity by Legumain may control intracellular C3a generation and normal human Th1 induction. We are currently assessing the biological significance of this novel Legumain/CTSL/C3 axis in appropriate animal models.

270

Role of factor H and effects of C-terminal mutations on control of human platelet/granulocyte aggregate formation

Blatt, A.¹, Saggu, G.¹, Cortes, C.², Herbert, A.³, Kavanagh, D.⁴, Ricklin, D.⁵, Lambris, J.⁵, Valenzuela, J.⁶, Ferreira, V.¹

¹University of Toledo College of Medicine, Department of Medical Microbiology and Immunology, Toledo, United States, ²Oakland University William Beaumont School of Medicine, Department of Biomedical Sciences, Rochester, United States, ³University of Edinburgh School of Chemistry, Edinburgh, United Kingdom, ⁴Newcastle University, Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom, ⁵Perelman School of Medicine, University of Pennsylvania, Department of Pathology and

Laboratory Medicine, Philadelphia, United States, ⁶National Institute of Allergy and Infectious Diseases, NIH, Vector Molecular Biology Section, Rockville, United States

Atypical hemolytic uremic syndrome (aHUS) is characterized by renal damage and thrombosis, as a result of dysregulated complement alternative pathway (AP) activity on cell surfaces. Platelets activated during thrombosis can bind to granulocytes to form stable platelet/granulocyte aggregates (PGA), which can enhance thromboinflammation in the vasculature. Mutations in the C-terminal domains, 19 and 20, of the AP negative regulator factor H are a common cause of aHUS. We have recently shown that domains 19-20 are also critical for control of PGA formation in human whole blood stimulated with thrombin receptor-activating peptide (TRAP), yet there are no known associations between aHUS and PGA formation. Here, we determined that (a) domains 19-20, were the most critical regions of factor H for controlling the AP on human platelets and neutrophils, and in TRAP-stimulated human whole blood,

(b) factor H limits PGA formation primarily by preventing AP-mediated C5a generation, (c) aHUS-related mutations in domains 19-20 have differential effects on control of TRAP-mediated PGA formation and AP activity, as measured by C3b deposition and C5a generation, and

(d) the effects of mutations in 19-20 have similar differential effects on AP activity on isolated platelets and neutrophils.

Our results indicate a key role for factor H C-terminal domains in controlling AP activity on cells involved in PGA formation, and suggest that mutations associated with aHUS result in varying degrees of impairment of complement regulation on cell surfaces. These data have important implications for understanding pathophysiologic mechanisms of PGA formation and potential treatment options for aHUS.

271

Pathogenic role for C5aR1 in chronic inflammation and renal fibrosis in a murine model of chronic pyelonephritis

Zhou, W.¹, Choudhry, N.¹, Li, K.², Zhang, T.², Wu, K.-Y.², Song, Y.², Farrar, C.A.¹, Wang, N.², Liu, C.-F.², Peng, Q.¹, Wu, W.¹, Sacks, S.H.¹

¹King's College London, Department of Innate Immunity, Medical Research Council (MRC) Centre for Transplantation, London, United Kingdom, ²Xi'an Jiaotong University, Core Research Laboratory, the Second Affiliated Hospital, School of Medicine, Xi'an, China

C5a/C5aR1 interaction participates in the pathogenesis of a number of inflammatory diseases, including acute kidney injury. However, its role in chronic inflammation, particularly in pathogen-associated disorders, is largely unknown. Here we show that development of chronic inflammation and renal fibrosis is dependent on C5aR1 in a murine model of chronic pyelonephritis, induced by human uropathogenic *Escherichia coli* (UPEC) strain IH11128. C5aR1-deficient (*C5aR1*^{-/-}) mice showed a significant reduction in bacterial load, tubule injury and tubulointerstitial fibrosis in the kidneys following the infection, compared with C5aR1-sufficient mice. This was associated with: i) reduced leukocyte infiltration of the kidney,

specifically for the population of Ly6C^{hi} pro-inflammatory monocytes/macrophages (MO/MΦ); ii) reduced intrarenal gene expression of key pro-inflammatory factors (e.g. TNF- α , KC, MCP-1) and pro-fibrogenic factors (e.g. TGF- β , PDGF) in C5aR1^{-/-} mice following infection. Antagonizing C5aR1 reduced renal bacterial load, tissue inflammation and tubulointerstitial fibrosis. *Ex vivo* and *in vitro* studies showed that under infection conditions, C5a/C5aR1 interaction up-regulated the production of pro-inflammatory and pro-fibrogenic factors by renal tubular epithelial cells (RTEC) and MO/MΦ, whereas the phagocytic function of MO/MΦ was down-regulated. Our data demonstrate a pathogenic role for C5aR1 in chronic inflammation and renal fibrosis in an experimental model of chronic pyelonephritis. The observations suggest that C5a/C5aR1-mediated up-regulation of local inflammatory responses to UPEC and impairment of phagocytic function of phagocytes contribute to persistent bacterial colonisation of the kidney, chronic renal inflammation and subsequent tubulointerstitial fibrosis. C5aR1 may be a new therapeutic target for this disorder.

Cytokines, Interferons & Inflammation

Transfusion-related immunomodulation: Importance of cell-to-cell interactions in studying underlying mechanisms

Perros, A.^{1,2,3}, Flower, R.^{1,3}, Christensen, A.-M.^{1,3}, Dean, M.^{1,3}

¹Australian Red Cross Blood Service, Research and Development, Brisbane, Australia, ²University of Queensland, School of Medicine, Brisbane, Australia, ³Queensland University of Technology, Faculty of Health, School of Biomedical Sciences, Brisbane, Australia

Background and aims: Immune-modulation and adverse patient outcomes associated with transfusion are collectively referred to as transfusion-related immunomodulation (TRIM). Platelet concentrates (PC) are stored for 5 or 7 days, depending on the jurisdiction. During storage, platelets undergo significant biophysical changes and release soluble mediators (sCD40L, RANTES, IL-8). Laboratory models are a valuable tool to define mechanisms associated with TRIM. This study investigated the modulation of monocyte inflammatory responses by PC in an in-vitro model.

Methods: "Recipient" whole blood was cultured with PC-supernatants (PC-SN) stored for 2, 5, or 7 days at doses representing a 1, or 2-3 unit PC-transfusion. Lipopolysaccharide (LPS) was added in parallel wells to model TRIM during infection. Inflammatory responses were measured using flow cytometry. Responses from the whole blood model were also compared with responses from isolated monocyte cultures.

Results: Exposure to PC-SN alone had no impact on monocyte inflammatory responses in the whole blood model however, in the presence of LPS, monocyte production of MIP-1 β , IL-12, IL-10 and IL-6 were significantly suppressed. Dose, more than storage was associated with immunomodulation. Of note, in the isolated monocyte model, effects of PC-SN were less apparent with only IL-1 α and MIP-1 β modulated.

Conclusions: These findings suggest that the transfusion recipient's underlying condition and the number of PC transfused both contribute to a modulation of the monocyte inflammatory profile that may precipitate development of TRIM.

Further, this study highlights the importance of cell-to-cell interactions and demonstrates the limitation of using isolated cell models in the context of transfusion outcomes.

273

Serum lipid and cytokines profile in the initial and advanced insulin resistance

Marcelino-Rodríguez, I.^{1,2}, Alemán-Sánchez, J.J.³, Almeida-González, D.³, Gannar, F.^{3,4}, Brito Díaz, B.³, Rodríguez-Pérez, M.D.C.³, Cabrera de León, A.^{3,5}

¹La Laguna, Santa Cruz de Tenerife, Spain, ²University Hospital NS La Candelaria, Santa Cruz de Tenerife, Spain, ³University Hospital NS La Candelaria, Research Unit, Santa Cruz de Tenerife, Spain, ⁴Carthage University, Bizerte, Tunisia, ⁵University of La Laguna, Preventive Medicine, La Laguna, Spain

Objective: To describe the serum lipid and cytokine profile of the non-diabetic general population that suffers early insulin resistance (IR).

Methods: Cross-sectional study of 5943 non-diabetic adults from the general population. They were stratified into: group 1 (*non-IR*: C-peptide < third tertile and glycaemia < 100 mg/dL), group 2 (*early IR*: C-peptide \geq third tertile but glycaemia < 100 mg/dL), and group 3 (*advanced IR*: glycaemia \geq 100 mg/dL). Bivariate, ordinal regression and multinomial regression analysis were performed.

Results: At least 20% of the non-diabetic general adult population was part of the early IR group. They presented significant bivariate differences with the non-IR group in the serum concentration of insulin (p < 0.001), triglycerides (p < 0.001), HDL-cholesterol (p < 0.001), LDL-cholesterol (p < 0.001), non HDL-cholesterol (p < 0.001), sCD40L (p < 0.001), CRP (p < 0.004), leptin (p < 0.001) and adiponectin (p < 0.001). These associations were corroborated in the ordinal and multinomial multivariate regression models for all biomarkers but sCD40L. The *advanced IR* group presented the same biomarkers significant differences with *non-IR* group and, in addition, it also showed a significant difference for the resistin serum concentration (p < 0.001).

Conclusion: Early IR is not detected in the clinical practice because this population group shows normal glycaemia. However it presents a hazardous serum lipid and cytokine profile.

274

Serum resistin and physical activity in the general population

Marcelino-Rodríguez, I.^{1,2}, Almeida-González, D.¹, Gannar, F.^{1,3}, Rodríguez-Pérez, M.D.C.¹, Brito Díaz, B.⁴, Alemán-Sánchez, J.J.⁴, Cabrera de León, A.^{4,5}

¹University Hospital NS La Candelaria, Research Unit, Santa Cruz de Tenerife, Spain, ²University of La Laguna, La Laguna, Spain, ³Carthage University, Bizerte, Tunisia, ⁴University Hospital NS La Candelaria, Santa Cruz de Tenerife, Spain, ⁵University of La Laguna, El Sauzal, Spain

Objective: Resistin is mainly a cytokine in human being. It's been related with inflammation and ischaemic heart disease. Physical activity (PA) improves the obesity-related chronic inflammation, and prevents ischaemic cardiopathy. We explored the relationship between serum resistin and PA in general population.

Methods: Cross-sectional study of 6636 adults, randomly recruited from the general population. In addition to serum resistin and PA (in MET; 1 MET = 4,184 KJ/Kg*h), we measured: age, gender, smoking, alcohol consumption and HDL-cholesterol (HDL-c). The bivariate associations of resistin and HDL-c with PA, were adjusted for age, alcohol and smoking in multivariate regression models.

Results: Serum resistin concentration was higher in women (6,06±2,41 ng/mL) than men (5,63±2,18 ng/mL). Resistin was inversely correlated with HDL-c ($p < 0.001$). Most of PA measures were inversely correlated with resistin, but with some differences between men and woman: Time of PA ($p < 0.001$), MET spent in leisure time ($p < 0.001$), moderate leisure PA ($p < 0.001$), etc. On the contrary, most of PA measures were directly correlated with HDL-c, also with some differences between men and woman: Daily total MET ($p < 0.001$), daily active MET ($p < 0.001$), and moderate leisure PA ($p < 0.01$), etc. Men (OR=0.78 [$p < 0.05$]) and women (OR=0.75 [$p < 0.01$]) in the highest quintile of PA time, showed a decreased risk of elevated serum resistin.

Conclusion: In the general population, resistin is inversely associated to PA and HDL-c. Resistin shows a stronger association with PA than HDL-c, and it may be a good biomarker of PA.

275

Aberrant TDP-43 expression is related to obesity

Park, A., Lee, S., Lee, T.A., Park, B.

Yonsei University, Seoul, Korea, Republic of

Tat-activating regulatory DNA-binding protein-43 (TDP-43) is involved in several major neurodegenerative diseases. Cellular TDP-43 expression is tightly controlled through a negative feedback loop involving its mRNA processing. Recently, We reported that TDP-43-containing sub-nuclear bodies are specific cytokine-splicing compartments important for efficient RNA production during activation and modulation of the immune response. Here, We demonstrate that TDP-43 expression is highly elevated in the liver and adipose tissue in concert with increased IL-6 levels in high-fat diet-fed mice. IL-6 expression and RNA processing are dependent on the expression of TDP-43 in pre-adipose and adipose cells. Our findings provide valuable insight into the molecular pathology of obesity and may contribute to the development of improved therapies for treating obesity-related diseases.

276

Vorinostat ameliorates repeated corticosterone-induced depressive-like behavior in mice: Implication of stress paradigm on neuroinflammation

Athira, K.V.¹, Rajaram, M.M.¹, Mangala, L.^{1,2}, Swapnil, S.³

¹National Institute of Pharmaceutical Education and Research (NIPER)-Guwahati, Department of Pharmacology and Toxicology,

Guwahati, India, ²Gauhati Medical College, Department of Pharmacology, Guwahati, India, ³National Institute of Pharmaceutical Education and Research (NIPER)-Guwahati, DST WOS-A Scientist, Department of Biotechnology, Guwahati, India

Depression is a chronic illness projected to be the most debilitating to society by 2030. Exogenous corticosterone (CORT) administration in rodents mimics the chronic stress associated hypothalamic-pituitary-adrenal (HPA) axis dysregulation, a well-established feature found in depressive patients. Our study aimed to examine the antidepressant potential and the possible mechanism of vorinostat, a histone deacetylase inhibitor against repeated corticosterone-induced mice model of depression. Depressive-like state was induced in male Swiss albino mice, aged 6-7 weeks, weighing 20-25 g by daily injections of CORT (40 mg/kg; subcutaneous) for 21 days. Vorinostat (25 mg/kg; intraperitoneal) and fluoxetine (15 mg/kg; oral) were administered 30 min prior to the CORT injection from day 8 to 21. After 21 days, neurobehavioral tests were conducted; followed by estimation of molecular parameters in serum and hippocampus through ELISA, biochemical assays and RTPCR analysis. CORT injected mice exhibited depressive-like behavior, as indicated by the significant decrease in sucrose consumption and increase in immobility time in the forced swim test and tail suspension test. Depressive-mice showed concomitant significant increase in the levels of serum CORT, ACTH, pro-inflammatory cytokines (IL-1 β , IL-6, TNF- α), hippocampal malondialdehyde, nitric oxide, mRNA expression of GRP-78, NF κ B and C-reactive protein along with significant decrease in hippocampal BDNF as compared to normal mice. Vorinostat treatment, in a similar manner to the classical antidepressant fluoxetine, significantly ameliorated all the behavioral and molecular changes induced by corticosterone. Thus vorinostat mitigated depression via amelioration of the hippocampal neuroinflammation inflicted by the oxidative-nitrosative-endoplasmic reticulum stress associated with hypercortisolemia, thereby promoting neurogenesis.

277

Hypoxia mediated changes in human mast cell profile of genetic expression

Walczak-Drzewiecka, A., Sałkowska, A., Ratajewski, M., Dastych, J.
Institute of Medical Biology Polish Academy of Sciences, Lodz, Poland

We investigated the effect of prolonged hypoxia on profile of genetic expression of human mast cells using de novo sequencing of RNA. Culture of LAD2 mast cells were maintained for 5 days under standard conditions or under hypoxic conditions (1% O₂). Cells were harvested and lysed to obtain RNA that was next used for de novo sequencing of transcripts. Numbers of copies of each detected gene transcript were analyzed and genes showing statistically significant differences in expression under hypoxic conditions were identified.

We have observed changes in expression of 179 among analyzed 23 616 genes. Hypoxia upregulated expression of multiple genes, which products are involved in process of cell adhesion. Upregulated genes involved gene coding for proinflammatory

peptide adrenomedullin known to increase cell adhesion, genes regulating focal adhesion (TNS1) and formation of tight intercellular junctions (JAM3), several genes (ITGA3, ITGA5, ITGA7, ITGAL) coding for subunits of integrins adhesion receptors mediating mast cell adhesion to extracellular matrix and to other immune cells including lymphocytes.

Interestingly hypoxia also upregulated cytokine genes supporting Th17 differentiation (IL18 and TGF β) and receptors responding to IL17 family of cytokines (IL17RA, IL17RB). Finally, hypoxia has increased expression of genes coding for elements of epigenetic machinery such as HDAC5 and MBD1.

Pattern of changes in human mast cell gene expression suggest upregulation of mast cell adhesiveness and secretion of cytokines that might stimulate direct interaction with Th17 lymphocytes. Hypoxia may lead to prolonged changes in mast cell phenotypes as it regulated expression of genes engaged in epigenetic processes.

278

Inhibition of autophagy reduces irradiation-induced inflammation in cerebellum in the immature mouse brain

Zhu, C.^{1,2}, Wang, Y.^{1,3}, Xie, C.¹, Sun, Y.^{1,2}, Xu, Y.^{1,2}, Li, T.^{1,3}, Zhang, Y.^{1,3}

¹Gothenburg University, Gothenburg, Sweden, ²Zhengzhou University, Zhengzhou, China, ³Zhengzhou Children's Hospital, Zhengzhou, China

Objective: To investigate the effects of autophagy inhibition on irradiation-induced cell death and inflammation in the cerebellum of immature mouse brain.

Methods: Ten-day-old Atg7 neuronal knockout and wild type littermate pups were subjected to a single 6 Gy dose of whole-brain irradiation. The animals were euthanized at 6 hours or 5 days after irradiation. Neuronal cell death-related markers were evaluated at 6 h, and brain injury was evaluated at 5 days, inflammation was evaluated at both 6h and 5 days after irradiation.

Results: Cell death was evaluated at 6 h after irradiation in the cerebellum by hematoxylin and eosin staining. There was a greater number of pyknotic cells in the wild-type mice compared to the Atg7 knockout mice ($p < 0.05$). Caspase-3 activity was measured in the cerebellum at 6 h after irradiation, and the level of activity was lower in the Atg7 knockout mice compared to their wild-type litter mates ($p = 0.038$). The volumes of cerebellum were reduced at 5 days after irradiation compared to the non-irradiation controls. However, there was no difference between Atg7 knockout and wild-type mice in either irradiated or non-irradiated mice. IL-6 and KC were increased significantly in wild type mice but not Atg7 knockout mice at 6h after irradiation. There was no significant difference at 5 days after irradiation.

Conclusion: The inhibition of autophagy prevents irradiation-induced proliferating cell death and inflammation in cerebellum, and autophagy could be considered as a potential target for preventing irradiation-induced cell death and inflammation.

279

Toll-like receptor 2 promotes vascular calcification via the chondrogenic transdifferentiation of vascular smooth muscle cells

Lee, G.-L., Kuo, C.-C.

National Health Research Institutes, Miaoli County, Taiwan, Republic of China

Objective: vascular smooth muscle cell (VSMC) transformation to osteoblast/ chondrocyte Phenotype is an initiative event for arterial calcification, which is highly correlated with cardiovascular disease morbidity and mortality. Toll-like receptors (TLRs) play key roles in the development of vascular diseases, but their regulation in vascular calcification remains unclear.

Methods and results: Calcification assays by Alizarin red S staining revealed that TLR2 agonists promoted VSMC calcification. TLR2 deficiency or inhibition of TLR2 signaling with anti-TLR2 antibody suppressed TLR2 agonist-induced VSMC calcification and IL-6 production. Neutralizing anti-IL-6 antibodies impaired TLR2-mediated VSMC calcification, while addition of IL-6 recombinant protein promoted VSMC calcification. Additionally, ApoE^{-/-} mice fed high-fat diet (HFD) exhibited vascular calcium accumulation and serum IL-6 elevation, which were ameliorated in Tlr2^{-/-}ApoE^{-/-} mice. Further studies demonstrated that TLR2 agonist time-dependently increased chondrogenic transdifferentiation transcription factors SOX9 and osterix but suppressed osteo/ chondrogenic transdifferentiation transcription factor Runx2 and osteoprotegerin (OPG) in wild-type but not in Tlr2^{-/-} VSMCs. Furthermore, TLR2-induced transdifferentiation of wild-type VSMCs into chondrogenic cells was suppressed by both of neutralizing anti-IL6 antibodies and OPG recombinant protein.

Conclusions: Our results suggest that upon ligand binding, TLR2 promotes chondrogenic transdifferentiation of VSMC via modulating expression of IL-6 and OPG production, SOX9 and osterix. The chondrogenic VSMCs in turn contributes to vascular calcification during the pathogenesis of atherosclerosis.

280

Lfc attenuates tumorigenesis during colitis-associated cancer

Lin, C.¹, Chang, H.W.², Tsai, P.S.², Reinecker, H.C.³, Chiang, H.S.¹

¹National Taiwan University, Life Science, Taipei, Taiwan, Republic of China, ²National Taiwan University, School of Veterinary Medicine, Taipei, Taiwan, Republic of China, ³Gastrointestinal Unit and Center for the Study of Inflammatory Bowel Disease, Massachusetts General Hospital, Harvard Medical School, Boston, United States

Colitis-associated cancer (CAC) is a colorectal cancer subtype that is associated with inflammatory bowel disease. The recruitment and activation of immune cells enhance the production of proinflammatory cytokines and play a major role in CAC. Lfc, a guanine nucleotide exchange factor that promotes the activation of Rho GTPase by exchanging of GDP for GTP and mediates NF κ B-dependent induction of proinflammatory cytokines. Although the role of Lfc in expression of

proinflammatory cytokine is well studied, its role in the development of CAC has not been characterized. To evaluate the role of Lfc in the initiation and progression of CAC, *Lfc*^{-/-} mice were subjected to the azoxymethane/dextran sodium sulfate (AOM/DSS) recurring inflammation-driven CAC model. Lfc-deficient mice demonstrated significant weight loss compared with the wild-type animals. Surprisingly, Lfc deficiency led to enhanced expression of *Il6*, *Il10*, *Il1b* and *Tnfa* in the colons of *Lfc*^{-/-} mice. Colon histopathology also showed greatly increased crypt hyperplasia in Lfc-deficient mice compared to wild-type controls. These findings suggest Lfc functions as an attenuator of CAC through modulating proinflammatory cytokine levels in the colon.

281

Proinflammatory cytokines induced by gastric fluid aspiration in GERD (Gastro Esophageal Reflux Disease) and pulmonary fibroblast differentiation

Su, H.-H.¹, Chiang, C.-C.², Shih, W.-A.², Cheng, C.-M.²

¹*Kaohsiung Medical University, Graduate Institute of Medicine, College of Medicine, Kaohsiung, Taiwan, Republic of China,*

²*Kaohsiung Medical University, Department of Biomedical Science and Environmental Biology, Kaohsiung, Taiwan, Republic of China*

GERD (gastro esophageal reflux disease) is a reflux disease that gastric content regurgitate into esophagus. Epidemic studies indicated that micro aspiration of gastric fluid in GERD patients is associated with the prevalence of chronic respiratory diseases. Our previous studies have demonstrated that gastric fluid acts as an inflammatory mediator in macrophages and airway smooth muscle cells. We further hypothesized that, in the context of pulmonary residential cells, micro aspiration of gastric fluid initiates inflammatory microenvironment and lead to subsequent fibrotic progression. Gastric fluid treated conditioned mediums collected from NL-20 and Raw264.7 were used for the assessment of factors involved inflammatory mediators and fibroblast differentiation. The pulmonary fibroblast cells (HFL-1) was used to evaluate the fibrotic progression induced by gastric fluid. Our data shows gastric fluid significantly induced eotaxin, IGFBP-4 and IL-6 expression in pulmonary epithelial cells by cytokine array analysis. Similarly, induction of GCSF, GM-CSF, IL-6, and MCP-1 by gastric fluid was observed in macrophages treated with gastric fluid. Both conditioned mediums from NL-20 and Raw264.7 induced cell migration and α -SMA protein expression as well as actin polymerization in pulmonary fibroblast cells. By using RT-PCR and ELISA assay, we observed that IL-6, IL-8 and transforming growth factor-beta (TGF- β) were enhanced in pulmonary fibroblast cells by gastric fluid and conditioned medium treatment. In summary, our current data indicated that, the poor mixture of proinflammatory mediators induced by chronic gastric fluid aspiration in the venue of pulmonary context may cause the pulmonary fibroblast cell differentiation and is causal for subsequent pulmonary fibrosis.

282

The possible mechanism by which MicroRNA-122 controls inflammation in mice

Leu, C.-M.¹, Wei, C.-W.¹, Su, Y.-R.¹, Hsu, K.-H.¹, Chou, T.¹, Yang, F.-C.¹, Tsou, A.-P.^{2,3}, Chen, N.-J.¹, Hsu, C.-L.¹

¹*National Yang-Ming University, Institute of Microbiology and Immunology, Taipei, Taiwan, Republic of China,* ²*National Yang-Ming University, Department of Biotechnology and Laboratory Science in Medicine, Taipei, Taiwan, Republic of China,* ³*National Yang-Ming University, VYM Genome Research Center, Taipei, Taiwan, Republic of China*

MicroRNA-122 (miR-122) is the most abundant miRNA in the liver. An increase in Kupffer cells, neutrophils, IL-6, and TNF- α in the livers of *Mir122a* knockout mice indicates that miR-122 possesses an anti-inflammatory function; however, the mechanism was unclear. Here, we report moderate splenomegaly and augmentation of myeloid cells in the spleens of *Mir122a*^{-/-} mice. Intriguingly, serum IL-6 was significantly increased after LPS injection in the *Mir122a*^{-/-} mice. A low level of miR-122a was detected in peritoneal macrophages, indicating the potential of miR-122 to modulate macrophage activity. *In vitro* assay demonstrated that LPS-induced IL-6 secretion was concomitantly higher in the *Mir122a*^{-/-} macrophages. We further discovered several proteins participating in the activation of IL-6 production as miR-122a targets using a reporter assay. The expression of these miR-122a targets were significantly increased in the *Mir122a*^{-/-} macrophages. Taken together, our findings imply that miR-122 may control signal pathway regulating IL-6 production by macrophages. Because myeloid cells is critical for the development of hepatocellular carcinoma, we speculate that miR-122 may inhibit tumor formation at least in part by reducing inflammation.

283

Salivary expression of dysregulated immune/inflammatory genes provides a useful set of biomarkers in detection of oral cavity squamous cell carcinoma

Kiss, C.¹, Horváth, J.², Lábicsák, P.³, Tar, I.⁴, Szabó, A.⁵, Csósz, É.³, Scholtz, B.², Márton, I.J.⁶

¹*University of Debrecen, Department of Pediatrics, Debrecen, Hungary,* ²*University of Debrecen, Department of Biochemistry and Molecular Biology, Genomic Medicine and Bioinformatic Core Facility, Debrecen, Hungary,* ³*University of Debrecen, Department of Biochemistry and Molecular Biology, Debrecen, Hungary,* ⁴*University of Debrecen, Department of Periodontics, Debrecen, Hungary,* ⁵*University of Debrecen, Department of Maxillofacial Surgery, Debrecen, Hungary,* ⁶*University of Debrecen, Department of Restorative Dentistry, Debrecen, Hungary*

Background: Detection of reliable and sensitive salivary biomarkers in oral cavity squamous cell carcinoma (OSCC) may improve clinical outcome. RNA and protein samples transcribed and translated from immune/inflammatory genes were repeatedly detected in salivary samples of these patients. We evaluated the performance of mRNA and protein samples expressed in saliva of OSCC patients from Hungary, a country characterized by an embarrassing fourfold elevation of OSCC-

related mortality between 1970 and 2000.

Methods: Unstimulated whole saliva was obtained from 31 patients with newly diagnosed OSCC, 30 age- and gender-matched subjects and 29 young healthy subjects. Expression of putative mRNA biomarkers (DUSP1, OAZ1, H3F3A, IL1B, IL6, IL8, SAT, S100P and TNF α) and 8 normalizing genes was quantified using real-time quantitative PCR. Concentrations of IL-1 α , IL-1 β , IL-6, IL-8, TNF- α and VEGF were determined by a Luminex-based multiplex kit. To detect catalase, profilin-1, S100A9/MRP14, CD59, galectin-3-binding protein/M2BP, CD44 and keratin-19, selected reaction monitoring-based targeted proteomic method was developed.

Results: IL6 mRNA was consistently expressed in OSCC patients but not in control subjects. The best mRNA biomarker combination (DUSP1/IL6/IL8/OAZ1/H3F3A) distinguished OSCC vs. young control patients, but not vs. age-matched control patients. S100-A9, thioredoxin, IL-6 and TNF- α molecules proved to be useful protein OSCC biomarkers in the Hungarian population.

Conclusion: We developed a noninvasive method of detecting OSCC biomarkers in order to improve clinical outcome. Useful biomarker combinations included products of dysregulated immune/inflammatory genes. Differences between our results and previous analyses suggest that immune/inflammatory processes in the oral cavity may affect the performance of putative salivary biomarkers.

284

Functional interactions of IL6 and *CHRFAM7A* genes in schizophrenia pathogenesis

Venugopal, D.^{1,2}, Agrawal, R.², Kalmady, S.², Venkataram, S.², Subbanna, M.^{1,2}, Rajasekaran, A.^{1,2}, Amaresha, A.C.², Narayanaswamy, J.C.², Debnath, M.¹, Ganesan, V.²

¹National Institute of Mental Health and Neuro Sciences, Department of Human Genetics, Bangalore, India, ²National Institute of Mental Health and Neuro Sciences, Translational Psychiatry Laboratory, Department of Psychiatry, Bangalore, India

Background: CHRNA7 gene coding for $\alpha 7$ nicotinic acetylcholine receptor ($\alpha 7$ nAChR) and its partially duplicated chimeric gene CHRFAM7A have been implicated in schizophrenia. Anti-inflammatory cholinergic pathways mediated by these genes play crucial role in mitigating the effects of inflammation acted upon by cytokine such as interleukin-6 (IL6). Disruption of such regulatory feedback mechanism might be involved in immune-mediated pathogenesis of schizophrenia. However, the interaction between these two pathways at the level of gene expression (i.e. IL6 & CHRFAM7A) is yet to be evaluated.

Aim: To quantify the gene expression of IL-6 and CHRFAM7A for assessing their potential functional interactions in schizophrenia patients.

Methods: Antipsychotic-naïve schizophrenia patients (DSM-IV) [N=13] were examined in this study in comparison with healthy controls [N=29]. RNA was extracted from peripheral blood lymphocytes. IL6 and CHRFAM7A gene expression was quantified by reverse transcription-PCR using TaqMan gene expression assay.

Results: There was a significant positive correlation between IL6

and CHRFAM7A gene expression in healthy controls ($r = 0.52$; $p = 0.004$) but not in patients ($r = -0.05$; $p = 0.883$).

Conclusion: Our preliminary observations indicate possible functional interactions between IL6 & CHRFAM7A signalling pathways. Lack of this correlation in schizophrenia patients might have pathogenic significance. This needs replication and further extension in large samples.

285

Modulation of immune system by Korean red ginseng via potentiation of cell survival and inhibition of inflammation in pneumococcal infection

Lee, S.Y., Pyo, S., Rhee, D.-K.

Sungkyunkwan University, Pharmacy, Su-Won, Korea, Republic of

More than 50% of sepsis cases are caused by *Streptococcus pneumoniae* (pneumococcus), and hospital mortality related to sepsis comprises 52% of all hospital deaths. Therefore, sepsis is a medical emergency, and any treatment against the agent that produces it, is welcome. Here, the protective effect of Korean red ginseng (KRG) extract against pneumococcal infection and sepsis was elucidated. KRG-pre-treated mice (100 mg/kg of KRG) had significantly higher survival rates and body weights than those of the non-treated controls; KRG-pre-treated mice had lower bacterial number and morbidity than those of the non-treated controls. 100 mg/kg of KRG administration decreased cytokine levels including TNF- α and IL-1 β , nitric oxide level, and neutrophil infiltration 48 h post-infection, *in vivo*. In pneumococcal infection, KRG pre-treatment downregulated TLR4 and TNF- expressions in RAW 264.7 macrophage cells and increased cell survival by activating PI3K/AKT signaling. Taken together, 100 mg/kg of KRG appeared to protect host cells from lethal pneumococcal sepsis by inhibiting inflammation as well as by enhancing bacterial clearance thereby reinforcing cell survival against pneumococcal infection.

Characterising the effects of interferon lambda on dendritic cells

Pang, E.S.¹, Macri, C.¹, Pooley, J.¹, Fancke, B.¹, Lundie, R.¹, Hochrein, H.², Radford, K.³, O'Keefe, M.¹

¹Biomedicine Discovery Institute, Monash University, Clayton, Australia, ²Bavarian Nordic GmbH, Research Immunology, Martinsried, Germany, ³Mater Research Institute-University of Queensland, Brisbane, Australia

Interferon lambda (IFN- λ) is the most recent addition to the class II cytokine family. It has roles in antiviral and anti-tumour responses, as well as autoimmune disease pathogenesis. Single nucleotide polymorphisms in *IFNL* have been associated with the spontaneous clearance and improved therapeutic outcomes of hepatitis C infection. However, its mechanism of action and impacts on immunity are still unclear. Dendritic cells (DCs) are major producers of IFN- λ . As with IFN- α , plasmacytoid DCs secrete large quantities of IFN- λ in response to toll-like receptor (TLR) 7 and 9 stimulation. CD8+ and BDCA3+ conventional DCs in mice and humans respectively also produce IFN- λ when

stimulated with TLR3, which is dependent on IFN- α receptor (IFN- α R) signalling. Although IFN- α and IFN- λ bind different receptors, they both signal via JAK/STAT pathway and induce the expression of similar IFN-stimulated genes (ISGs). Recently, more reports are elucidating unique regulatory, signalling and functional mechanisms of IFN- λ compared to IFN- α , but these mechanisms in DC biology are still largely unidentified. Using IFN- λ R knockout mice, we have found that DC activation and cross-priming abilities are impaired in response to TLR3 stimulation *in vivo* and serum levels of IFN- α are reduced. Furthermore, IFN- α R expression on splenic DCs *ex vivo* is lower and stimulation with IFN- α is able to rescue DC maturation in these mice. These data suggest that distinct functions and cross-talk exist between IFN- λ and IFN- α in DCs and the identification of these specific effects could potentiate more tailored and/or synergistic therapies in the future.

Novel anti-inflammatory peptides based on chemokines

McNaughton, E.¹, Sessions, R.², Kungl, A.³, Farris, M.⁴, Broadbridge, R.⁴, Middleton, J.¹

¹Bristol University, Inflammation and Immunology, Bristol, United Kingdom, ²Bristol University, Biochemistry, Bristol, United Kingdom, ³University of Graz, Pharmaceutical Chemistry, Graz, Austria, ⁴Peptide Protein Research Ltd, Bishops Waltham, United Kingdom

Inflammation is an underlying feature of numerous chronic diseases which as yet have no effective treatment. We have identified an interest in the way leukocytes are rapidly recruited from the blood to the site of inflammation in response to chemokine molecules. Chemokines are anchored to the endothelium by glycosaminoglycans (GAGs) such as heparan sulphate (HS) and act to direct leukocytes towards areas of inflammation. We have developed peptides based on chemokines that interfere with chemokine - GAG interactions which we hypothesise will reduce leukocyte migration.

Peptides based on the chemokines CXCL8, CXCL12 and CCL5 were synthesised at PPR Ltd, Southampton employing a solid phase peptide synthesis strategy using conventional Fmoc chemistry. Peptides were purified using HPLC and analysed by mass spectrometry to give a final purity of >95%.

Compared to wildtype chemokine, the peptides exhibited a higher affinity for HS as shown by isothermal fluorescent titration. This corresponded with a reduced leukocyte migration across an endothelial monolayer using a range of peptide concentrations in response to 100ng/ml of chemokine. The optimum peptide concentration was in the picomolar range. Altering the positively charged residues in the peptide removed the inhibitory effects of the peptides. HS was shown to have an important functional role in the observed leukocyte migration as cleavage of HS from the endothelial cells significantly reduced the amount of migration ($p < 0.0001$).

Our studies suggest that peptides based on chemokines that interact with HS can reduce leukocyte migration and may act as a potential novel anti-inflammatory therapeutic.

288

ZNF19 acts as a transcription factor to direct the expression of sustained inflammatory genes

Lee, E.¹, Lee, T.A.¹, Kim, J.H.², Ra, E.A.¹, Lee, S.¹, Lee, J.E.², Park, B.¹

¹Yonsei University, Seoul, Korea, Republic of, ²Sungkyunkwan University, Seoul, Korea, Republic of

The transcription of inflammatory genes is an essential step for activating the effective host defense against microbial invaders. Here, we show that zinc finger protein 19 (ZNF19) acts as a transcription factor that is required for activating the innate immune response. In particular, *Znf19* expression was induced by infections through an autoregulatory feedback mechanism and nuclear factor- κ B (NF- κ B) activity, after which it detected persistent inflammatory signals and worked with NF- κ B to robustly produce sustained cytokines. Under lipopolysaccharide (LPS) stimulation, ZNF19 was re-translocated to the nucleus by phosphorylation-mediated dimerization. Consequently, knockdown of ZNF19 in zebrafish showed reduced *il-6* mRNA levels and a greatly decreased number of infiltrating neutrophils into an infected region, thereby leading to severe *Shigella flexneri* infection-induced mortality *in vivo*. Collectively, these observations identified ZNF19 as a transcription factor and a key inducer of the stable activation of immune cells during perpetual infections.

289

Characterization of interferon- ϵ expression in mouse mucosal and non-mucosal tissues

De Geus, E.D., Brooks, G.D., Hertzog, P.J., Mangan, N.E.

Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia

Type I Interferons (IFNs) play an important role in the early control of many pathogens, because of their direct anti-pathogen effects and their effects on both innate and adaptive immune cells. IFN ϵ was previously described by the Hertzog laboratory. In contrast to other type I IFNs, IFN ϵ is not upregulated by PRRs or virus infection. IFN ϵ is highly and constitutively expressed by epithelial cells of the female reproductive tract (FRT), where it is involved in protection against pathogens, as IFN $\epsilon^{-/-}$ mice showed increased susceptibility to infection of the FRT with Herpes Simplex Virus-2 and *Chlamidia muridarum*.

While the expression of IFN ϵ is most abundant in the FRT in mice, expression has also been shown in epithelial cells of other tissues as demonstrated in rhesus macaques, IFN ϵ protein expression was detected in lung epithelial cells lining the bronchioles, but not in alveoli. Furthermore, expression was detected in the epithelium of the jejunum and rectum.

We are currently screening male and female mouse mucosal (e.g. lung and gastro intestinal tract) and non-mucosal tissues (e.g. liver and brain) for IFN ϵ expression using immunohistochemistry, as a basis for the characterisation of this novel IFN in the immune response in mucosal tissues.

290

The role of G-CSF in chronic obstructive pulmonary disease*Tsantikos, E.¹, Lau, M.^{1,2}, Maxwell, M.¹, Anderson, G.², Hibbs, M.¹*¹Monash University, Melbourne, Australia, ²University of Melbourne, Melbourne, Australia

Chronic Obstructive Pulmonary Disease (COPD) is a major global health problem affecting tens of millions of people. It is a chronic irreversible lung disease characterized by abnormal enlargement of airspaces (emphysema), obstruction of the airways and chronic bronchitis, and persistent macrophage-rich inflammation. Progressive and permanent destruction of the lung parenchyma and airway thickening leads to unremitting breathlessness and disability. The presence of disease comorbidities, including infection susceptibility, metabolic syndrome, muscle wasting and osteoporosis, further reduce quality of life. Alveolar macrophages are believed to play a key role by secreting factors that exacerbate inflammation and cause irreversible tissue damage. Treatment of COPD involves the use of bronchodilators and potent immunosuppressive drugs, which are only partially effective at managing symptoms and is not curative, thus there is a significant unmet clinical need to develop novel treatments. Cytokine inhibition is an attractive target in COPD, as a multitude of cytokines have been linked to disease severity. Studies by our laboratory have shown that granulocyte-colony stimulating factor (G-CSF) is involved in several pathogenic mechanisms pertinent to the COPD phenotype in a well-characterized animal model of the disease. Deletion of G-CSF was able to attenuate alveolar macrophage activation, limit airway inflammation and tissue destruction and significantly reduce lung pathology. Furthermore, these animals did not develop systemic inflammation and co-morbid phenotypes compared to their G-CSF-sufficient counterparts, yet are immunocompetent upon exposure to pathogenic material. These studies show that G-CSF plays a pathogenic role in inflammatory lung disease and is a potential therapeutic target in COPD.

291

Galectin 8 present in conditioned media from breast cancer cells induces increased microvascular permeability via nitric oxide and S-nitrosylation of p120*Zamorano, P.¹, Rebolledo, L.¹, Guequén, A.¹, Ehrenfeld, P.², González, A.³, Soza, A.³, Sánchez, F.¹*¹Universidad Austral de Chile/ Instituto de Inmunología, Valdivia, Chile, ²Universidad Austral de Chile/ Instituto de Histología y Patología, Valdivia, Chile, ³Pontificia Universidad Católica de Chile/ Instituto de Reumatología, Santiago, Chile

Galectins have been involved in many essential functions including differentiation, cell-cell adhesion, cell-matrix interaction, growth regulation and apoptosis. Galectin-8 (Gal-8) is widely expressed in tumoral tissues and seems to be involved in the promoting endothelial cell migration and angiogenesis. Nitric oxide (NO) produced by NO synthase (eNOS) mediates increase in vascular permeability by S-nitrosylation of proteins from the adherens junctions. In cancer, the increase in endothelial permeability promotes the vascularization of

the tumor and dissemination of tumoral cells. Therefore we wanted to study whether or not Gal-8 have a role in endothelial permeability. We tested the hypothesis that Gal-8 present in conditioned medium from breast cancer cell lines acts on the endothelium increasing microvascular permeability via nitric oxide and S-nitrosylation of adherens junction proteins such as p120.

As a model system we use EA.hy926 cells treated with Gal-8 and conditioned medium from MCF-7 breast tumoral cells (MCF-7 CM). Permeability was measured through flux of dextran-FITC. eNOS activation was evaluated through Western-blot and S-nitrosylation of p120 was measured by biotin-switch assay. Gal-8 increases permeability, induces eNOS phosphorylation, S-nitrosylation of p120, and disruption of the adherens junction complex. These effects were inhibited in the presence of L-NMA and lactose. eNOS activation was also evaluated in vivo. Both, Gal-8 and MCF-7 CM, increase eNOS phosphorylation in the mouse cremaster. Furthermore GAL-8 activates FAK and Akt in EA.hy926 cells.

These results provide a new mechanism of action of Gal-8 through eNOS activation on the endothelial cells that can help to the progress of the tumor.

292

Modulation of pro- and anti-inflammatory cytokines contribute to the healing effect of the triterpene lupeol in cutaneous wounds in rats*Beserra, F.P.¹, Bérnago, D.A.¹, Bérnago, P.L.¹, Vieira, A.J.¹, Hussni, C.A.², Maia, G.L.d.A.³, Rozza, A.L.¹, Pellizzon, C.H.¹*¹State University of São Paulo, Department of Morphology, Botucatu, Brazil, ²Faculty of Veterinary Medicine and Animal Science, State University of São Paulo, Department of Surgery and Anaesthesiology of Large Animals, Botucatu, Brazil, ³Federal University of São Francisco Valley, Department of Pharmacy, Petrolina, Brazil

Skin wound healing is a dynamic biological process divided into three phases: inflammation, proliferation and remodeling that involve cytokines as important mediators, and the comprehension of their action may lead to new and effective therapeutic strategies. Same natural products change the cytokines levels. The aim of this study was to determine the involvement of lupeol, a triterpene derived from *Bowdichia virgilioides* in the healing process of skin wounds by the levels of cytokines in rats. We used Male Wistar rats (n=8) randomly divided into 5 experimental groups: base ointment, collagenase ointment and lupeol ointment (0.1%, 0.2% or 0.4% w/w). After anesthesia, the animals were submitted to induction of lesion by 2 cm diameter punch in the dorsal region. All animals were submitted to topical treatment, during 3, 7 or 14 days and the quantification of Tumor Necrosis Factor alpha (TNF- α), Interleukin-1 beta (IL-1 β), Interleukin-6 (IL-6) and Interleukin-10 (IL-10) levels were performed on skin samples by ELISA method removed after euthanasia. Topical treatment with lupeol ointment was shown to decrease the levels of TNF- α , IL-1 β , IL-6 in 7 and 14 days of treatment and a significant increase in IL-10 levels in 14 days. No alterations of cytokines levels were observed in the groups after 3 days of treatment. These data

indicate a reduction in the inflammatory response and clearly showed anti-inflammatory effect of lupeol topical treatment by modulating pro- and anti-inflammatory cytokines, important in the wound healing process.

Antimicrobial peptide derived from IGFBP-5 (AMP-IBP5) stimulates normal human keratinocytes beyond direct antimicrobial properties

Chieosilapatham, P.^{1,2,3}, Niyonsaba, F.^{1,4}, Kiatsurayanon, C.¹, Okumura, K.¹, Ikeda, S.^{1,2}, Ogawa, H.¹

¹Juntendo University Graduate School of Medicine, Atopy (Allergy) Research Center, Bunkyo-ku, Japan, ²Juntendo University Graduate School of Medicine, Department of Dermatology and Allergology, Bunkyo-ku, Japan, ³Chiang Mai Provincial Public Health Office, Ministry of Public Health, Department of Dermatology, Chiang Mai, Thailand, ⁴Juntendo University, Faculty of International Liberal Arts, Bunkyo-ku, Japan

The insulin-like growth factor (IGF) system plays an important role in skin growth and repair, through its ability to modulate cell proliferation, attachment, and migration. Seven IGF-binding proteins (IGFBP-1-7) have been discovered from a variety of vertebrate species, including humans. Among IGFBPs, IGFBP-5 has been reported to enhance the protein synthesis and cell migration in many cell types, including keratinocytes. Recently, it was demonstrated that IGFBP-5 undergoes proteolytic processing to produce a functional antimicrobial peptide named AMP-IBP5 (antimicrobial peptide derived from IGFBP-5). This peptide has been shown to display microbicidal activities against bacteria and fungi, even more potent than those of cathelicidin LL-37 and human β -defensin-2, the major skin-derived antimicrobial peptides (AMPs). Because AMPs activate human keratinocytes and the effects of AMP-IBP5 on these cells remain unknown, we investigated whether AMP-IBP5 would trigger keratinocyte activation. Among several chemokines/cytokines tested, AMP-IBP5 stimulated keratinocytes to increase only the production of IL-8. The molecular mechanism investigation suggested that AMP-IBP5-mediated IL-8 production was controlled by both MAPK and NF- κ B pathways, as evidenced by specific inhibitors for MAPKs and NF- κ B. We also confirmed that AMP-IBP5 upregulated ERK, but not JNK and p38, and also enhanced NF- κ B activation. In addition, AMP-IBP5 markedly stimulated keratinocyte migration and proliferation in a dose- and time- dependent manner. Taken together, the ability of AMP-IBP5 to stimulate the production of IL-8 and mediate keratinocyte migration and proliferation provides a novel evidence that this peptide may contribute to the skin immunity beyond its microbicidal ability.

294

An angiogenic peptide AG-30/5C, stimulates various functions of human mast cells

Kanazawa, K.¹, Okumura, K.¹, Ogawa, H.¹, Niyonsaba, F.^{1,2}

¹Juntendo University Graduate School of Medicine, Atopy (Allergy) Research Center, Bunkyo-ku, Japan, ²Juntendo University, Faculty

of International Liberal Arts, Bunkyo-ku, Japan

In addition to their direct antimicrobial activities against invading pathogenic microorganisms, antimicrobial peptides are also involved in various immunomodulatory functions, which have led to antimicrobial peptides being named host defense peptides (HDPs). In fact, HDPs induce the production of cytokines/chemokines, promote chemotaxis, cell proliferation and angiogenesis, and accelerate wound healing. Recently, a novel angiogenic HDP named AG-30/5C has been shown to activate numerous functions of fibroblasts and endothelial cells, in addition to its antimicrobial activity. Because mast cells reside in the vicinity of vessels and are involved in the wound healing process, we hypothesized that angiogenic AG-30/5C may activate mast cells.

In the present study, we observed that AG-30/5C caused degranulation of human mast cells and induced the production of eicosanoids such as leukotriene C₄, prostaglandin D₂ and E₂. Furthermore, we demonstrated that AG-30/5C promoted mast cell chemotaxis and stimulated the production of various cytokines and chemokines by mast cells. Investigation of the molecular mechanism by which AG-30/5C activates mast cells revealed that this peptide stimulates mast cells through the G protein, phospholipase C, MAPK and NF- κ B signaling pathways. Taken together, the current study suggests that a novel angiogenic and antimicrobial peptide AG-30/5C plays a crucial role in the recruitment and activation of mast cells, leading to the control of inflammation and wound healing.

295

Investigating the role of IL-33 in the pathogenesis of Behçet's disease

Keskin, G.¹, Inal, A.², Tutluer, S.¹, Çerçi, P.¹, Köse, K.¹, Ölmez, Ü.¹

¹Ankara University School of Medicine, Immunology, Ankara, Turkey, ²Medical School of Başkent University, Immunology, Istanbul, Turkey

Background: Behçet's disease (BD) is a multisystem inflammatory disease, characterized by oral aphthous lesions, recurrent uveitis, skin lesions, genital ulceration, and joints involvement. It's thought that immune system abnormalities play role in the pathogenesis of the disease. In BD, increased release of several cytokines may play a role in inflammatory stages of the disease. IL-33 is a member of the IL-1 cytokine superfamily. It has been reported that IL-33 plays an important role in inflammation and homeostasis. Here, we analyzed serum IL-33 concentration in patients with BD to assess its possible role in the pathophysiology of this disease.

Results: The mean serum IL-33 levels were $4,84 \pm 2,81$ pg/ml in patients with BD and $2,88 \pm 0,42$ pg/ml in the healthy controls. The mean levels of serum IL-33 were $6,16 \pm 2,94$ pg/ml in active stage and $2,86 \pm 0,54$ pg/ml in inactive stage. According to these results; serum IL-33 levels were significantly higher in patients with BD compared with healthy controls ($p < 0.01$). In addition, Serum IL-33 levels were significantly higher in the active patients compared to in the inactive patients and controls ($p < 0.001$ and $p < 0.001$). In the inactive patients with BD, serum IL-33 concentrations were found to be similar compared to healthy controls. In active Behçet's patients, the mean serum IL-33 level

was correlated with arthritis ($r=0.674$, $p < 0.05$).

Conclusion: The high levels of serum IL-33, in active patients with BD suggest that IL-33 may play a significant role in the pathogenesis of BD.

296

Pro-inflammatory cytokine and RANKL profile and osteoclast induction by osteoarthritic TMJs synovial fluid

Monasterio Ocares, G.¹, Castillo, F.¹, Garcia, K.¹, Alvarez, C.¹, Rojas, L.¹, Núñez, C.², Flores, G.³, Diaz, W.³, Vernal, R.¹

¹University of Chile, Faculty of Dentistry, Periodontal Biology Laboratory, Santiago, Chile, ²University of Chile, Faculty of Dentistry, Department of Surgery, Santiago, Chile, ³University of Chile, Faculty of Dentistry, Prosthetic Department, Santiago, Chile

Aims: The temporomandibular joint osteoarthritis (TMJ-OA) is a degenerative disorder characterized by synovitis, chronic pain, and progressive degradation and resorption of articular cartilage and subchondral bone. These degenerative changes are mainly associated with osteoclastogenesis; however, the molecular processes associated to these changes remains still unclear. This study aimed to analyze the presence and activity of osteo-destructive factors in synovial fluid (SF) of TMJ-OAs, quantifying the pro-inflammatory and osteoclastogenic cytokine levels and osteoclast activation and function.

Methodology: Five TMJ-OA and two disk-displacement without articular bone-resorption subjects were enrolled for this study. From them, 4 mL of SF were obtained by arthrocentesis and the RANKL, IL-17, and IL-22 levels were measured by ELISA. In addition, the mRNA levels for RANKL, IL-1 β , IL-4, IL-9, IL-17, IL-22, and TGF- β 1 were quantified by qRT-PCR from SF-isolated cells. Finally, 50,000 RAW264.7 cells/mL were seeded in osteo-assay[®] plates, differentiated into pre-osteoclasts with 35 ng/mL rhRANKL and then exposed to serial dilutions of the SF samples. Osteoclast activation was detected by TRAP staining and resorption areas were digitally quantified using a light-microscope.

Results: Higher levels of pro-inflammatory cytokines and RANKL were detected in samples of TMJ-OAs patients compared with disk-displacement controls. In addition, a dose-dependent osteoclast activity was detected in cells induced with TMJ-OAs samples compared with controls.

Conclusions: The higher levels of pro-inflammatory cytokines and RANKL can, at least in part, explain the degradation of articular cartilage and resorption of subchondral bone described during the TMJ-OA pathogenesis.

Funding: FONDECYT 1140904.

297

Luminex assay manufacturer-based disparity in biomarker concentrations reported in the EQAPOL proficiency program

Lynch, H., Rountree, W., Walker, L., Sempowski, G.

Duke University, Duke Human Vaccine Institute, Durham, United States

Multiplex Luminex assays are widely used for biomarker quantification in research and clinical studies due to their sample sparing capability. These assays use paired antibodies specific to an analyte to determine a concentration using a kit manufactured "standard" protein dilution curve. An international Luminex proficiency program was established within the External Quality Assurance Program Oversight Laboratory (EQAPOL) at Duke University to identify and reduce variables that negatively affect Luminex-based human assay performance through semi-annual proficiency assessments consisting of a common 5-plex kit and cytokine-spiked samples. Accuracy to the consensus mean and precision of site-reported concentrations are components of this proficiency assessment. Recently, we established a second track to assess accuracy and precision using data from each lab's choice of Luminex assay kit manufacturers. We found increased manufacturer dependent variability in reported concentrations impedes assessment of accuracy. Therefore, we tested two ways to mitigate this issue: a blinded pre-diluted internal standard to determine absolute concentration or normalization as a ratio to a calibrator sample to determine relative concentration. A common internal standard, surprisingly, did not reduce manufacturer dependent variability, suggesting there are other contributors (e.g., antibody clones). Normalizing data as a ratio to a calibrator sample, however, reduced variability between manufacturer kits. These studies suggest the need to standardize results across Luminex assay manufacturers and the importance of using a consistent manufacturer for long-term or multi-site studies.

A study of the role of autophagy and hypoxia in human inflammatory periapical lesions

Huang, H.Y.^{1,2}, Wang, W.C.^{3,4}, Huang, C.P.¹, Lin, P.Y.¹, Chen, C.Y.^{3,4}, Lin, L.M.^{3,4}, Chen, Y.K.^{3,4}

¹Ditanson Medical Foundation Chia-Yi Christian Hospital, Chia-Yi, Taiwan, Department of Dentistry, Chiayi City, Taiwan, Republic of China, ²School of Dentistry, College of Dental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, Republic of China, ³School of Dentistry, College of Dental Medicine, and Oral & Maxillofacial Imaging Center, Kaohsiung Medical University, Kaohsiung, Taiwan, Republic of China, ⁴Division of Oral Pathology & Maxillofacial Radiology, Kaohsiung Medical University Hospital, Department of Dentistry, Kaohsiung, Taiwan, Republic of China

This study aimed to determine the expression of hypoxia-related (HIF-1 α , BNIP3, and pAMPK) and autophagy-related (LC3, beclin-1, Atg5, Atg12, and p62) proteins in human inflammatory periapical lesions (radicular cyst and periapical granuloma) to explore the role of autophagy in the pathogenesis of these lesions under hypoxia circumstance. Fifteen radicular cysts and 21 periapical granulomas were included in the experimental group; 17 human healthy dental pulp tissues in the control group. ELISA was used to detect IL-1 β cytokine, whilst immunohistochemical and western blot analyses were used to examine autophagy- and hypoxia-related proteins. Kruskal-Wallis and Mann-Whitney U test were employed for statistical analyses (significant different level, $p < 0.05$). Upon ELISA, there was a significant higher IL-1 β expression in periapical lesions than normal pulp tissues.

Immunoscores of immunohistochemical expression for HIF-1 α , beclin-1, Atg5, Atg12, and BNIP3 proteins in periapical lesions (predominantly located in inflammatory, endothelial cells, and epithelial cystic linings) were higher than that of normal pulp tissues. By contrast, lower immunoscores of LC3 and p62 proteins were noted in periapical lesions as compared with normal pulp tissues. Results of immunohistochemical studies were largely compatible to those of western blot analyses where significant higher expressions of hypoxia-related and autophagy-related proteins (except p62 and LC3I) in periapical lesions were noted as compared with normal pulp tissues. In conclusion, our data indicated that autophagy could play a potential causative role in developing and maintaining of the inflamed periapical lesions under hypoxia environments offering an additional concept of the pathogenesis of human inflammatory periapical pathoses.

Gamma-Aminobutyric acid alleviates the chronic kidney disease progression and renal inflammation

Huang, H.Y., Lin, B.F.

College of Life Science, National Taiwan University, Department of Biochemical Science and Technology, Taipei, Taiwan, Republic of China

Introduction: The disease process of chronic kidney disease (CKD) is irreversible. Previous study showed that Gamma-Aminobutyric acid (GABA) have a beneficial effect on renal function in nephrectomized rats by inhibiting fibrosis and atrophy in tubuli. However, the beneficial effect of GABA on CKD and inflammatory progress are still unknown. Therefore, we further investigated the effect of GABA on renal inflammation and injury.

Materials and methods: C57BL/6 mice were fed aristolochic acid (AA; 6 mg/Kg) to establish the animal model of chronic kidney disease. The mice treatment group were given with GABA rice containing diet for 4-weeks. The urine protein, urine creatinine and serum creatinine levels were measured. HE staining and PAS were also assayed. Furthermore, MES-13 cell or mouse tubular epithelial cell (mTEC) were pre-treated with or without GABA for 1 hr, and stimulated with AA and LPS for 24 hr. The cytokine levels of MCP-1, IL-8, TGF- β , IL-1 β , ROS and HIF-1 protein were measured.

Results: B6 mice fed with AA containing diet significantly increased urine protein earlier than AA and GABA containing diet. Body weight and food intake of mice were no change. In addition, AA directly increased TGF- β and MCP-1 secretion and ROS generation in MES-13 cell. Therefore, GABA improved renal inflammation process might through decreasing inflammatory cytokines secretion and ROS generation.

Conclusions: These data showed that GABA might alleviate the inflammation during early stage of CKD. Furthermore, this study could clarify the mechanisms of GABA for improving the chronic inflammation of renal disease.

Glucocorticoid-induced leucine zipper regulates inflammation and immunosuppression through its acetylation

*Fan, H.¹, Wang, D.², Cheng, Q.¹, Jones, S.¹, Harris, J.¹, Morand, E.¹
¹Lupus Research Laboratory, Centre for Inflammatory Diseases, School of Clinical Sciences at Monash Health, Monash University, Clayton, Australia, ²Monash University/Hudson Institute Of Medical Research, Clayton, Australia*

Glucocorticoids (GC) have been widely used to inhibit inflammation and immune responses for more than six decades. Unfortunately, the broad spectrum of therapeutic effects of GC is accompanied by a range of adverse effects. Recent studies have shown that glucocorticoid-induced leucine zipper (GILZ), a glucocorticoid-induced protein, mediates many of the anti-inflammatory effects of GC and may do so without GC-triggered adverse effects. GILZ inhibits activation of macrophages, B cells, Th1 and Th17 cells. While GILZ is known to interact directly with NF- κ B, the biochemical pathways and processes involved are incompletely understood. Here we demonstrate that GILZ has a number of putative acetylation sites and TSA, a histone deacetylase inhibitor, increases acetylation of the protein. Moreover, a site mutation (Lys to Arg) at one site, K77, results in abrogation of the anti-inflammatory actions of GILZ in human microvascular endothelial cells. FLIM/FRET analysis demonstrated that acetylation at K77 is critical the interaction between GILZ and NF- κ B. This study provides new insights into how GILZ, a glucocorticoid-induced molecule, regulates anti-inflammatory and immunosuppression functions. Moreover, this information could aid in the development of novel compounds to target this important pathway.

301

NNAT plays an anti-inflammatory function in adipose tissue

*Ka, H.L., Yong, H.J., Joo, H.J., Boldbaatar, A., Yang, Y.
Sookmyung Women's University, Department of Life Systems, Seoul, Korea, Republic of*

NNAT (Neuronatin) is known to regulate ion channels during brain development and play a role in maintaining the structure of the nervous system. In the present study, the function of NNAT in adipose tissue was investigated because we found that it is overexpressed in adipose tissue of obesity patients from in silico study. NNAT was increased in white adipose tissue of *db/db* mouse compared with wild type. Since obesity is known to induce low grade inflammation systemically, NNAT expression level was examined in adipose tissue obtained from C57BL/6 mice administered with LPS. However, NNAT expression was decreased in white adipose tissue. To find out a role of NNAT in inflammation, NNAT overexpressing cells were treated with LPS. The level of NF- κ B p65 subunit was decreased and the nuclear localization of NF- κ B p65 subunit was inhibited compared with control cells. It implies that NNAT plays an anti-inflammatory function in adipose tissue.

302**Elevated high mobility group B1 levels in active adult-onset Still's disease associated with systemic score and skin rash***Kim, H.-A., Ye, Y.-M., Jung, J.-Y., Suh, C.-H., Nam, J.-Y.**Ajou University School of Medicine, Suwon, Korea, Republic of*

Objective: High mobility group box-1 (HMGB1) is a nuclear protein and such prototypical damage-associated molecular patterns mediate the immune response in the noninfectious inflammatory response. Adult-onset Still's disease (AOSD) is a systemic inflammatory disorder involved in the dysregulation of innate immunity. We investigated the serum HMGB1 level in patients with AOSD and evaluated its clinical significance.

Methods: Blood samples were collected from 40 patients with active AOSD and 40 healthy controls (HC). Of the patients with AOSD, follow-up samples were collected from 16 patients after a resolution of AOSD disease activity.

Results: Serum HMGB1 levels in patients with AOSD were higher than those of the HC (10.0 ± 5.85 vs. 5.15 ± 1.79 ng/ml, $p < 0.001$). Serum HMGB1 levels were found to be correlated with C-reactive protein (CRP) and the systemic score. The AOSD patient who had a sore throat showed a higher serum HMGB1 level than those patients who did not, and the patient with a skin rash had higher levels than the patients without. In addition, the serum HMGB1 levels were decreased after the resolution of disease activity in the AOSD patients who were followed-up.

Conclusion: The serum HMGB1 levels were elevated in AOSD patients compared to the HC, and were correlated with both CRP and the systemic score. The HMGB1 levels were associated with skin rash and a sore throat in AOSD patients. After the resolution of disease activity, serum HMGB1 levels were found to have decreased.

303**The role of IL-33 in the molecular biology of rosacea in keratinocytes***Cho, H.¹, Byun, J.Y.²**¹Dongguk University, Seoul, Korea, Republic of, ²Ewha Womans University School of Medicine, Department of Dermatology, Seoul, Korea, Republic of*

Interleukin-33 (IL-33) is a member of the IL-1 family that potently drives release of T helper-2 (Th2)-associated cytokines. IL-33 is expressed on a wide variety of cell types, including skin cells, immune cells, endothelial cells, and epithelial cells. IL-33 mediates its biological effects by interacting with the receptors ST2 (also known as IL1RL1), activating intracellular molecules in the NF- κ B and MAP kinase signaling pathways. The ST2 was an orphan receptor that was related in inflammatory process and immune disease. IL-33 as a functional ligand for ST2, it is clearly a potential mediator of diverse inflammatory diseases. Rosacea is chronic inflammatory skin disease, caused an altered innate immune response is involved in inflammatory disease. In this study, we investigated the role of IL-33 in the molecular mechanism of rosacea in keratinocytes. For induction of rosacea, Cathelicidin (LL-37 peptide) and UVB were used. After 2 days treated with LL-37 only in HaCaT keratinocytes cell lines, the growth of these cells were decreased compared to untreated

cells and the mRNA of TNF- α , IL-1 α and IL-33 were expressed. When UVB was exposed to HaCaT cells, IL-33 was also expressed. In rosacea UVB is the source of TLR2 (Toll like receptor 2) activation in skin, and downstream signaling molecules like I κ B and NF- κ B were activated for pro-inflammatory processes. We checked the activation of NF- κ B, p38, ERK using western blot analysis. We suggest that IL-33 is released in rosacea, and it is component involved in the molecular pathology of rosacea.

304**Neutrophil extracellular traps (NETs) formation mediated by oxidized LDL (oxLDL) initiates lipid accumulation in early atherosclerotic plaque***Seo, J.-W., Yang, E.-J., Choi, I.-H.**Institute for Immunology and Immunological Disease, Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Department of Microbiology and Immunology, Seoul, Korea, Republic of*

NETs are an important host defense mechanism to eliminate extracellular pathogens. Also, it is implicated in chronic inflammatory disease, such as atherosclerosis. Recent studies show that NETs components are observed in advanced lesion of atherosclerosis. However, their role in early atherosclerosis is not well examined. In this study, we investigated formation of NETs in early atherosclerosis and sought activating factor that promotes NETs formation. Wild-type and apoE-deficient mice were fed an atherogenic-diet for 4 weeks and NETs formation was evaluated using T2*-weighted MR imaging. NETs were detected in apoE-deficient mice after 2 weeks and it was more clearly detected after 3 weeks. But NETs were not detected in WT mice even after 4 weeks. Next, we isolated neutrophils from WT and apoE-deficient mice and IL-8 induced NETs formation was observed using confocal microscopy. Neutrophils isolated from apoE-deficient mice induced NETs, but the cells from WT mice do not formed NETs. Together with NETs formation in apoE-deficient mice, lipid accumulation in arterial wall was also increased in apoE-deficient mice compared to WT mice. Recent study shows that oxLDL can induce NETs in human neutrophils. So, we assessed levels of oxLDL in WT and apoE-deficient mice. Concentration of oxLDL in plasma was increased in apoE-deficient mice but not detected in WT mice and oxLDL induced NETs in *ex vivo* experiment. Collectively, our results suggest that NETs were induced in early atherogenesis and subsequently lead to lipid accumulation in arterial walls. And oxLDL is a crucial component to promote formation of NETs.

305**The proinflammatory role of matrix metalloproteinase-2 in chronic obstructive pulmonary disease***Nishihama, K.¹, D'Alessandro-Gabazza, C.N.¹, Toda, M.¹, Yasuma, T.¹, Hinneh, J.¹, Etsuko, H.¹, Kentaro, F.², Kobayashi, T.², Gabazza, E.²**¹Mie University School of Medicine, Department of Immunology, Tsu, Japan, ²Mie University School of Medicine, Department Pulmonary and Critical Care Medicine, Tsu, Japan*

Matrix metalloproteinases (MMPs) play crucial roles in the mechanism of alveolar destruction of the lungs in patients with

chronic obstructive pulmonary disease. We have reported that the overexpression of MMP-2 enhances the destructive process in emphysema induced by cigarette smoke using human MMP-2 transgenic mice (TG) exposed to inhaled cigarette smoke extract (CSE).

MMP-2-TG mice showed no phenotype in unstressed conditions, but CSE-exposed mice revealed significant emphysematous changes in the lungs compared to wild type mice within 2 weeks.

In the present study we evaluated the effect of MMP-2 on inflammation *in vivo*.

The results showed that the lungs of MMP-2 transgenic mice have significantly increased infiltration of inflammatory cells and increased level of inflammatory cytokines and chemokines compared to wild type control mice. MMP-2 transgenic mice showed increased emphysematous changes as compared WT mice and also increased the activity of proteases such as MMP-9. Overall, these results suggest that MMP-2 is a key mediator of lung tissue remodeling and inflammation in cigarette smoke induced emphysema.

306

Potential involvement of MICA (Major Histocompatibility Class I-related Chain A) in the pathogenesis of endometriosis

Carnevale Marin, M.L.^{1,2}, Coelho, V.^{1,2,3}, Rached Rached, M.⁴, Kalil, J.^{1,3,4}, Simões Abrão, M.⁵

¹Heart Institute (InCor), School of Medicine, University of Sao Paulo, São Paulo, Brazil, ²Histocompatibility and Cellular Immunology Laboratory, LIM-19, School of Medicine, University of São Paulo, São Paulo, Brazil, ³Institute for Investigation in Immunology, National Institute of Science and Technology (iii-INCT), University of São Paulo, São Paulo, Brazil, ⁴Clinical Immunology and Allergy Division, School of Medicine, University of Sao Paulo, São Paulo, Brazil, ⁵Department of Obstetrics and Gynecology School of Medicine, São Paulo University School of Medicine, São Paulo University, São Paulo, Brazil

Endometriosis (EDT) is an inflammatory disease characterized by ectopic implantation/growth of endometrial tissue. Reduced NK and T cell cytotoxicity have been implicated in the pathogenesis of endometriosis. MICA is a stress inducible molecule and its soluble form (sMICA) down-modulates the NKG2D receptor expression on CD8+T and NK cells, reducing the cytotoxic response. We evaluate sMICA levels and MICA expression in women with endometriosis and healthy controls. Soluble MICA levels were determined by ELISA in the serum and the peritoneal fluid (PF) of 153 women with endometriosis and 71 healthy controls. MICA protein *in situ* expression was analyzed in endometriotic lesions and eutopic endometrium of EDT patients (n=22), and in eutopic endometrium of controls (n=17), by immunohistochemistry. We found higher sMICA levels in the EDT (in serum and PF, $p < 0.0001$, Mann-Whitney test), especially in the PF (serum vs PF, $p < 0.0001$), both associated to severe stages of the disease ($p < 0.0001$). MICA expression was positive in 20/22 (91%) of endometriotic lesions and in the correspondent eutopic endometrium, similarly to controls (17/17). Nevertheless, the frequency of MICA high expression

was higher in EDT (11/20, 55%) than in controls (3/17, 18%) ($p=0.0397$, Fisher's exact test). The high protein expression is likely to be related to the inflammatory microenvironment and the increased levels of MICA may be involved in the reduction of the NK and CD8+ T cells cytotoxic, favoring the implantation and growth of endometrial tissue.

307

Leptin and resistin are not useful markers to predict the risk of vascular complications in type 2 diabetes mellitus

Zorena, K.¹, Jachimowicz-Duda, O.², Raczyńska, D.³, Lipowski, P.³, Wąż, P.⁴, Bartoszewicz, M.¹, Michalska, M.¹, Raczyńska, K.³

¹Medical University of Gdańsk, Department of Immunobiology and Environment Microbiology, Gdańsk, Poland, ²Diabetic Outpatient Clinic in Gdynia, Gdynia, Poland, ³Medical University of Gdańsk, Department and Clinic of Ophthalmology, Gdańsk, Poland, ⁴Medical University of Gdańsk, Department of Nuclear Medicine, Gdańsk, Poland

The onset of type 2 diabetes mellitus (T2DM) is often insidious and at diagnosis 50% of patients already have diabetes-related organ damage. Therefore there is ongoing search for risk markers of chronic vascular complications in diabetes mellitus. The aim of our study was to investigate leptin and resistin serum levels as potential markers to predict the risk of chronic vascular complications in T2DM patients.

Materials and methods: The study involved 79 subjects including 47 T2DM patients and 32 subjects at risk of diabetes. All study subjects had their clinical parameters recorded and serum leptin and resistin levels measured by ELISA method.

Results: The group of T2DM patients was older ($p=0.001$) and had significantly higher BMI ($p=0.001$), WHR ($p=0.009$), urinary albumin excretion ($p=0.003$) serum creatinin ($p=0.034$), HbA1c ($p=0.001$), fasting glucose ($p=0.001$) and systolic blood pressure ($p=0.002$) values versus the risk group. No significant between-group differences were seen in sex ($p=0.731$), diastolic blood pressure ($p=0.240$), smoking status ($p=0.70$), leptin ($p=0.92$), and resistin ($p=0.45$) levels. Prognostic value for predicting the risk of chronic diabetic complications has been found for HbA1c, total cholesterol and BMI, as assessed on their area under the curve discriminative powers. The Receiver Operating Characteristics statistical analysis has shown no discriminative values for leptin and resistin ($p=0.968$).

Conclusions: In our study sample neither leptin nor resistin occurred to be good markers for predicting the risk of chronic vascular complications in T2DM patients. Further studies on larger samples of patients are needed to better investigate the potential of leptin and resistin.

308

Regulation of Jak-Stat signaling pathway by an EF-hand motif protein

Okamoto, K., Inoue, M., Okuhama, A., Takayanagi, H.
Graduate School of Medicine and Faculty of Medicine, The University of Tokyo, Department of Immunology, Tokyo, Japan

Calcium ion (Ca^{2+}) acts as a major second messenger responsible

for a variety of intracellular signaling pathways. Proteins with the EF hand motif, a common Ca^{2+} -binding motif, are important for the intracellular Ca^{2+} signal. A number of proteins with EF hand motif that mediate the biological effects of Ca^{2+} have been identified so far, but the physiological roles of some of them remain largely unknown. Here we identified an EF-hand motif protein (hereafter called Efp) as a new regulator for Jak-STAT signaling pathway. Since Efp is expressed at high level in hematopoietic cell lineage, we newly generated the Efp floxed mice and analyzed the hematopoietic lineage-specific Efp-deficient mice by mating them with Vav-iCre transgenic mice. Efp^{fllox/-} Vav-iCre mice were born with a pale skin at the expected Mendelian ratio and die within 1 day after birth because of severe anemia. Blood test using the peripheral blood from the P0 mice revealed a decrease in the number of red blood cells and low hemoglobin in the Efp^{fllox/-} Vav-iCre mice. On the other hand, we found normal number of CD11b⁺ myeloid cells, CD3⁺ T cells and B220⁺ B cells. Notably, activation of Jak-Stat pathway by erythropoietin was inhibited in the Efp-deficient fetal liver cells, whereas IL-3 or GM-CSF-induced Jak-Stat pathway was normally activated. These results indicate that Efp regulates the Jak-Stat signaling pathway downstream of certain types of cytokines. We will also discuss roles of Efp in lymphocyte development by analyzing T- and B-cell specific Efp knockout mice.

309

In vitro comparison of 18 α -glycyrrhizin, silymarin and silybin A on activated human hepatic stellate cells

Kalantar, K.¹, Hosseini, S.Y.^{2,3}, Shahin, K.³, Ghayour, M.⁴, Rajabibazl, M.⁵, Fattahi, M.-R.³, Moini, M.³, Amirghofran, Z.⁶

Hepatic stellate cells (HSCs) activation and proliferation is the main cause of liver fibrosis, thus it seems that this cell could be the major target of current fibrosis therapy. In this study the anti-fibrotic role of three medicinal plants-derived components, including 18 α -glycyrrhizin, silymarin and silybin A was compared on activated LX-2 stellate cell, in prophylactic and therapeutic manner. The possible cytotoxic/proliferative effect of components on LX-2 cells evaluated to find the optimal dose of treatment. The HSCs then treated with herbal compounds before (in prophylactic) and after (in therapeutic manner) activation by TGF- β 1. The anti-proliferative effects of components on normal and activated LX-2 cell were measured by MTT assay. The harvested cells were introduced into real-time PCR to determine the gene expression levels of TIMP-1, COL1A1 and MMP-2 as fibrotic markers. Furthermore, TGF- β 1 production

was measured by ELISA assay on culture supernatants. MTT assay results indicated that nearly all components have significant anti-proliferative effect on activated LX-2 cells when applied in a therapeutic manner ($P < 0.01$). In prophylactic manner, only silybin A showed a significant anti-proliferative effect ($P < 0.001$). Real-time PCR was used to detect TIMP-1, COL1A1 and MMP-2 mRNA expression. The results showed that the components decrease these three genes in comparison to the control condition in therapeutic and prophylactic manner. TGF- β production from LX2 cell in presences of extracts, was significantly decrease the level TGF- β in therapeutic and prophylactic manner. Our herbal extracts exhibited some extent of inhibitory effects on TGF- β 1 activated LX-2 cells both prophylactic and therapeutic manner.

B-cell abnormalities in HIV disease are associated with increased interferon- α activity

Cha, L.¹, Abudulai, L.¹, French, M.^{1,2}, Fernandez, S.¹

¹University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia, ²Royal Perth Hospital, Department of Clinical Immunology, Perth, Australia

B-cell dysfunction, such as increased frequencies of exhausted CD21^{lo/-} B-cells and decreased isotype diversification of IgG antibody responses, is observed in HIV-1 infection. Understanding more about these defects may lead to novel therapies for enhancing antibody responses, including those induced by therapeutic HIV vaccines. Here, we have investigated the role of interferon-alpha (IFN- α). In antiretroviral therapy (ART)-naïve (n=19) and ART-treated (n=30) HIV patients, levels of plasma IP-10 and soluble (s) IFNAR2 were examined by ELISA as indicators of IFN- α activity and B-cell activation and exhaustion was assessed by enumeration of CD21^{lo/-} B-cells and serum levels of kappa and lambda free light chains (FLCs), IgG1 and IgG2. In ART-naïve patients, plasma IP-10 and sIFNAR2 levels correlated with frequencies of CD21^{lo/-} B-cells, FLCs and serum IgG1 levels ($r \geq 0.5$, $p \leq 0.03$ and $r \geq 0.6$, $p \leq 0.01$, respectively). In contrast, IP-10 and sIFNAR2 were inversely correlated with serum IgG2 ($r = -0.4$, $p = 0.09$ and $r = -0.6$, $p = 0.007$, respectively). To assess the effect of IFN- α on B cell differentiation in vitro, B cells from non-HIV donors (n=25) were stimulated for 5 days with interleukin-21 and CD40 ligand in the absence or presence of IFN- α 2b. Addition of IFN- α 2b to cultures did not alter the induction of plasmablasts (CD27^{hi}CD38^{hi}) but decreased the production of all IgG subclasses ($p \leq 0.002$) in culture supernatants, particularly IgG2 ($p < 0.0001$). Thus, increased IFN- α activity is associated with B cell activation and exhaustion in HIV patients and IFN- α exerts an inhibitory effect on IgG production which may limit isotype diversification of IgG antibody responses.

311

The indicators of systemic inflammation in patients with end-stage renal disease (ESRD), receiving different types of renal replacement therapy

Solomatina, L.^{1,2}, Kuznetsova, Y.³, Groznykh, E.⁴

¹Ural Federal University named after the First President of

Russia B.N.Yeltsin, Ekaterinburg, Russian Federation, ²Institute of Immunology and Physiology, Ural Branch of RAS, Ekaterinburg, Russian Federation, ³Ural Scientific Research Institute of Dermatovenerology and Immunopathology, Ekaterinburg, Russian Federation, ⁴Sverdlovsk Regional Hospital №1, Ekaterinburg, Russian Federation

Objective: To assess the degree of chronic systemic inflammation (CSI) in patients with ESRD receiving different types of renal replacement therapy.

The study included the following groups: patients with ESRD receiving program hemodialysis (12 hours per week, blood samples taken prior to dialysis session (n=42), renal transplant patients with normal allograft function (n=24), patients with chronic allograft dysfunction (CAD, n=23).

Chronic glomerulonephritis was the condition that resulted in the development of ESRD in all the patients.

Blood plasma was tested for the following SI indicators: CRP, IL-6, IL-8, IL-10, TNF α , D-dimers, cortisol, myoglobin, troponin I. On the basis of these markers using an original method we calculated the integral index of intensity of chronic SI (from 0 to 8 points) -CSI Score.

Results: CSI was diagnosed only in hemodialysis patients (90.9%) and in the CAD group (43.5%).

CRP level increase was found in 27.3% (hemodialysis group), 17.4% (CAD group) and 16.7% (normal allograft function group).

Mortality / graft loss were reported in 26.1% of patients (CAD group), of which CSI was found in 4 patients (66.7%) and elevated CRP levels in only 2 patients (33.3%).

Mortality / loss of kidney transplant was 16.7% in the group with normal functioning transplant, and only one patient had an increased level of CRP.

Conclusion: CSI is a severe ESRD complication in hemodialysis patients. Following the renal transplantation CSI is found only in patients with CAD. CSI Score can be used as a predictor of mortality / allograft loss in patients with CAD.

Tissue damage caused by viral hepatitis is a major cause of morbidity and mortality worldwide. Using a mouse model of viral hepatitis, we identified virus-induced early transcriptional changes in the redox pathways in the liver, including downregulation of superoxide dismutase 1 (Sod1). Sod1^{-/-} mice exhibited increased inflammation and aggravated liver damage upon viral infection, which was independent of T and NK cells and could be ameliorated by antioxidant treatment. Type I interferon (IFN-I) led to a downregulation of Sod1 and caused oxidative liver damage in Sod1^{-/-} and wild-type mice. Genetic and pharmacological ablation of the IFN-I signaling pathway protected against virus-induced liver damage. These results delineate IFN-I mediated oxidative stress as a key mediator of virus-induced liver damage and describe a mechanism of innate-immunity-driven pathology, linking IFN-I signaling with antioxidant host defense and infection-associated tissue damage.

313

Therapeutic effect of *Oleaceae* spp. ethanol extract on the IBD model

Li-Shian, S., Po-Chen, L., Yi-Ling, Y.

National Formosa University, Department of Biotechnology, Huwei Township, Taiwan, Republic of China

Inflammatory bowel disease (IBD) symptoms characterized by chronic inflammation of the gastrointestinal tract. The exact etiology and pathogenesis of these disorders remain unclear. The clinical features include diarrhea, pain, narrowing of the gut lumen leading to strictures and bowel obstruction, severe diarrhea, blood loss, and progressive loss of peristaltic function. The medical therapeutic effect of the *Oleaceae* flower has been recorded in "Ben Cao Gang Mu" traditional Chinese medical literature. It describes the usefulness of these flowers for arrest of dysentery with blood in the bowel. The scientific evidence of this effect has not yet been proved.

In this study, acute colitis was induced and ethanol extract of *Oleaceae* was administered via intragastric administration. The therapeutic effect was measured by body weight loss, colon length. The severity was calculated using disease activity index. Furthermore, MIP-2 secretion, myeloperoxidase activity and histologic examination were also been evaluated. Oral administration of ethanol extract of *Oleaceae* (1000mg/kg) has inhibitory activity on body weight loss and shortening of the colon. It also alleviate severity of colon inflammation according to the histological examination by reducing inflammatory cell infiltration to colonic mucosa, as well as the degree and extent of epithelial damage.

In summary, oral administration of ethanol extract of *Oleaceae* has inhibitory activity on the IBD model.

314**Role of IL-5 in IL-33-induced inflammation***De Vera Mudry, M.C., Bessa, J., Iglesias, A.**F. Hoffmann-La Roche Ltd., Roche Pharma Research and Early Development, Basel, Switzerland*

Introduction: IL-33 knock-in mice (ST2+/+IL33tm1/+) show a characteristic TH2 response with increased serum IL-33 and IL-5, eosinophilia, lethal non-resolving multi-organ inflammation, and altered subcellular localization of IL-33. IL33tm1/+ mice crossed with mice lacking ST2 receptor (ST2-/-IL33tm1/+) have normal serum IL-5 levels and are protected from inflammation, despite increased IL-33.

Methods: ST2-/-IL33tm1/+, ST2-/+IL33tm1/+, ST2-/-wtwt, and ST2-/+wtwt mice were sacrificed at ages 3-24 months, and tissues collected for histopathological evaluation.

Results: ST2-/-IL33tm1/+ showed no significant findings in mesenteric lymph node, small intestine, lung, heart, and bone marrow, similar to ST2-/-wtwt mice. In contrast, ST2-/+IL33tm1/+ mice showed inflammation of various tissues, similar to ST2+/+IL33tm1/+ mice. The mesenteric lymph node showed hypercellularity due to marked infiltration of plasma cells, mononuclear cells, and eosinophils that extended to the capsule and mesenteric fat. The spleen was hypercellular due to marked extramedullary hematopoiesis (myeloid and erythroid) and infiltration of plasma cells and eosinophils. The small intestine showed marked villous thickening, mononuclear and eosinophilic infiltration, and hypertrophy/hyperplasia of smooth muscle layers. ST2-/+IL33tm1/+ mice showed eosinophilic myeloid hyperplasia of bone marrow, minimal goblet cell hyperplasia of pulmonary bronchioles, and fibrosis of the cardiac pulmonary-arterial trunk.

Conclusion: ST2-sufficient ST2-/+IL33tm1/+ mice succumb to IL-33-induced inflammation due to increased IL-5, resulting in eosinophilia, eosinophilic infiltration, fibrosis, and remodeling in the gut and lung. Despite high serum IL-33, ST2-insufficient ST2-/-IL33tm1/+ mice are protected due to normal levels of IL-5. Impact statement: The IL-33 knock-in mouse model of inflammation is a tool for developing agents targeting IL-33 or its receptor ST2.

315**The role of mTORC1 in skin irritant croton oil-induced cytokine expression by mouse keratinocytes***Ohtani, M., Manabe, A., Watanabe, N.**Toho Univ., Fac. of Sci., Dept. of Biomol. Sci., Funabashi, Chiba, Japan*

The mammalian target of rapamycin complex 1 (mTORC1) regulates a diverse array of cellular responses including cell growth, metabolism, survival, and immunity. We and other groups previously demonstrated that mTORC1 regulates cytokine production in myeloid cells, but roles in non-myeloid cells such as keratinocytes remain unclear. In this study, we investigated the role of mTORC1 in skin irritant croton oil-induced cytokine expression in mouse keratinocyte cell line PAM212 cells. The expression of cytokines/chemokines such as GM-CSF, TSLP, IL-1 and MIP-2 mRNA was induced in PAM212 cells stimulated with croton oil. Western blot analysis revealed

that the phosphorylation p70S6K and 4EBP1, downstream targets of mTORC1, was decreased upon croton oil stimulation and was completely blocked by the treatment with mTORC1 inhibitor rapamycin. Rapamycin also increased the expression of GM-CSF, TSLP and IL-1 α mRNA induced by croton oil. In addition, intracellular cytokine staining and ELISA analysis revealed the increase in GM-CSF protein by rapamycin in PAM212 cells, suggesting that mTORC1 negatively regulates GM-CSF expression. To address the mechanism(s) of regulation of GM-CSF gene expression by mTORC1, we examined the promoter activity of *Csf2* (GM-CSF). Luciferase reporter assay demonstrated that the sequence between -688 to +290 is necessary in response to croton oil and of the sequence between -34 to +49 is sensitive to rapamycin. We are currently investigating the transcription factor associated with mTORC1.

316**Activated protein C inhibits rheumatoid synovial fibroblast invasion and prevents inflammatory arthritis in mouse models***Xue, M.¹, Dervish, S.^{1,2}, Little, C.³, March, L.⁴, Jackson, C.¹**¹University of Sydney, Sutton Arthritis Research Laboratory, Kolling Institute of Medical Research, St Leonards, Australia, ²University of Sydney, Westmead Institute, Westmead, Australia, ³University of Sydney, Raymond Purves Research Laboratory, Kolling Institute of Medical Research, St Leonards, Australia, ⁴University of Sydney, Rheumatology, Royal North Shore Hospital, St Leonards, Australia*

Aim: To investigate whether activated protein C (APC), a physiological anticoagulant with anti-inflammatory properties, can inhibit aggressive properties of rheumatoid synovial fibroblasts (RASf) and prevent inflammatory arthritis.

Methods: RASf isolated from patients with rheumatoid arthritis (RA) after surgery were treated with APC, TNF- α or IL-17. Cell viability/proliferation was measured by MTT assay, cytokines and cell signaling molecules by ELISA and western blot, matrix metalloproteinase (MMP)-2 and MMP-9 by zymography, and cartilage degradation by 1,9-dimethylmethylene blue (DMMB) assay. The in vivo effect of APC was evaluated in mouse antigen- and collagen -induced arthritis (AIA and CIA) models.

Results: In vitro, APC reduced IL-1 β , IL-17 and TNF- α production RASf and inhibited IL-17-stimulated cell proliferation and NF- κ B activation in RASf. When co-incubated with RASf and cartilage tissues, APC reduced RASf-induced cartilage degradation and inhibited MMP-9 production in control and TNF-stimulated conditions. In vivo, APC and endothelial protein C receptor (EPCR) were expressed by the synovial joint. APC decreased the incidence and the severity of CIA, inhibited pannus formation, and cartilage and bone destruction within the joint in DBA/J1 mice, 20 days after the second immunization. The serum levels of IL-1 β , IL-6, IL-17 and TNF- α were significantly lower in response to APC treatment in CIA model. In AIA model, APC significantly reduced total histological score and cartilage degradation at day 4 and day 28, after intra-articular injection of methylated bovine serum albumin in C57BL6 mice.

Conclusion: APC suppresses inflammation and invasion of RASf and inhibits the development and severity of inflammatory arthritis.

317

Type-I Interferon dependent degradation of microRNA isoforms in mouse macrophages*Nejad, C.¹, Pépin, G.¹, McCoy, C.E.², Gantier, M.¹*¹Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia, ²Hudson Institute of Medical Research, Centre for Cancer Research, Clayton, Australia

Innate immune activation by pathogens promotes global transcriptional changes in infected cells, quickly affecting the levels of messenger RNAs and non-coding RNAs such as microRNAs (miRNAs). Previous reports indicate that the intracellular levels of select miRNAs can be rapidly down-regulated following innate activation. Given the extreme stability of miRNAs, these reports suggest that select miRNAs could be actively degraded upon innate immune activation. Here we show that the intracellular levels of abundant miRNAs are not decreased upon TLR activation of mouse bone marrow derived macrophages (BMDMs). miR-221 was the exception, with a >80% decrease following TLR4 and TLR3 stimulation, but not when stimulated by other TLRs. The miR-221 decrease was independent on a transcriptional event given that pri-miR-221 levels were increased upon stimulation. miR-221 levels were strongly reduced following IFN- β treatment of BMDMs, consistent with an involvement of TRIF in the TLR3/4-induced miR-221 decrease. Accordingly, miR-221 levels were not impacted on by TLR3/4 in IFN- α/β receptor 1 deficient BMDMs. Studies of miR-221 levels following *Drosha* deletion suggested that this miRNA was not intrinsically unstable following biogenesis, and was rather actively degraded by IFN- β treatment. Indeed, we discovered that miR-221 decrease by TLR signalling was restricted to a long variant of this microRNA, presumably more sensitive to 3'-5' exonucleases. Similar results were found for the closely related miR-222 isoforms. Collectively, our results demonstrate an isoform-specific degradation of abundant miRNAs upon IFN- β treatment of BMDMs, likely impacting the innate immune program in these cells.

318

Impact of a nonsteroidal anti-inflammatory drug (NSAID) on serum MCP1 & clinical observations during lipopolysaccharide (LPS) induced inflammation in swine*Myers, M.¹, Smith, E.², Messenheimer, J.², Lewandowski, A.², Groesbeck, C.², Zhang, W.², Swain, T.², Chiesa, O.A.², Deaver, C.M.²*¹US Food and Drug Administration, Center for Veterinary Medicine, Laurel, United States, ²U.S. Food and Drug Administration, CVM/Office of Research, Laurel, United States

The capacity of the veterinary NSAID flunixin meglumine (flunixin) to affect the outcome of an acute LPS induced systemic inflammatory response in swine was evaluated. Flunixin was given either 1 h before or 1 h after a single i.v. administration of lipopolysaccharide (LPS; 2 μ g/kg). Blood samples for MCP1 assessment were collected at 0, 1, 3, 6, 8, & 24 h after LPS administration using an in-dwelling catheter inserted prior to LPS administration. MCP1 concentrations were determined using a swine-specific ELISA. Clinical observations included rectal temperature, heart rate (HR), respiration rate

(RR), skin redness (SR), lethargy, and respiratory character (RC). RR, HR, and clinical scores for RC, SR, and lethargy were elevated from 1 h through 24 h post-LPS administration. Flunixin administration reduced the LPS-induced increase in RR and RC. Flunixin administration had no impact on the LPS-induced increase in the clinical scores for SR or lethargy, regardless of when it was administered. Plasma concentrations of MCP-1 were induced within 1 h of LPS administration, and remained elevated through 8 h, returning to baseline values by 24 h post-LPS. Flunixin had no impact on serum MCP1 levels regardless of time of administration. The severity of the clinical results suggests that the administered LPS challenge dose resulted in toxicity beyond the expected systemic inflammatory response. While these results suggest that RR and RC are potential clinical endpoints useful in assessing the anti-inflammatory action of NSAIDs, the severity of morbidity further suggests the model needs to be refined.

Absence of CCR5 axis exaggerates thrombus formation through reduced uPA and tPA expression in murine DVT model*Nosaka, M.¹, Ishida, Y.¹, Kimura, A.¹, Kuninaka, Y.¹, Mukaida, N.², Kondo, T.¹*¹Wakayama Medical University, Forensic Medicine, Wakayama, Japan, ²Kanazawa University, Division of Molecular Bioregulation, Cancer Research Institute, Kanazawa, Japan

Deep vein thrombosis (DVT) is multifactorial and often results from a combination of risk factors such as genetic conditions, obesity, drugs, pregnancy, aging, trauma, and malignancy. And DVT is a complex biological event, with endothelial injury, venous stasis and blood hypercoagulability. In this study, we examined the pathophysiological roles of CCL3/CCL5-CCR5 axis in the resolution of DVT in *Ccr5* KO mice. Upon the ligation of the inferior vena cava (IVC) of the mice, venous thrombi formed and grew progressively until 5 days, and, thereafter, the thrombus weight decreased. We observed the thrombi until 21 days after IVC ligation. Immunohistochemically, in WT mice, intrathrombotic CCR5-positive cells were detected in the whole course of the observation period and increased gradually with time after IVC ligation. Concomitantly, *Ccr5* expression was detected in the thrombi. When *Ccr5* KO mice were treated in the same manner, thrombus size was much larger in *Ccr5* KO mice than in WT ones. Moreover, the blood flow of the IVC was less recovered in *Ccr5* KO mice than in WT ones. And intrathrombotic *Plat* and *Plau* mRNA expression was significantly reduced in *Ccr5* KO mice than WT mice. In WT-derived macrophages but not *Ccr5* KO-derived ones, recombinant CCL3 and CCL5 treatment enhanced gene expression of *Plau* and *Plat*, respectively. These observations indicated that CCR5-deficiency impaired fibrinolytic activity and collagen production, both indispensable steps for thrombus resolution. Collectively, the absence of CCR5 can have a detrimental role in the thrombus resolution by suppressing uPA and tPA expression respectively.

Mevalonate kinase deficiency leads to decreased prenylation of Rab GTPases

Munoz, M.A.¹, Jarczyluk, J.¹, Skinner, O.P.¹, Preston, A.¹, Ali, N.¹, Palendira, U.², Quinn, J.M.W.¹, Argent, E.³, Tangye, S.G.⁴, Brown, A.J.⁵, Ziegler, J.B.⁶, Mehr, S.⁷, Rogers, M.¹

¹Garvan Institute of Medical Research, Bone Biology, Darlinghurst, Australia, ²Centenary Institute, University of Sydney, NSW, Camperdown, Australia, ³Sydney Children's Hospital, Dept. of General Paediatrics, Randwick, Australia, ⁴Garvan Institute of Medical Research, Immunology, Darlinghurst, Australia, ⁵University of New South Wales, School of Biotechnology and Biomolecular Sciences, Darlinghurst, Australia, ⁶Sydney Children's Hospital, Dept. of Immunology and Infectious Diseases, Randwick, Australia, ⁷Children's Hospital at Westmead, Dept. of Immunology and Allergy, Sydney, Australia

Mevalonate kinase deficiency (MKD) is caused by mutations in a key enzyme of the mevalonate-cholesterol biosynthesis pathway. A recurrent autoinflammatory disorder characterised by inflammasome-mediated processing of IL-1b. It is currently believed that the inflammatory phenotype of MKD is triggered by temperature-sensitive loss of mevalonate kinase activity and reduced biosynthesis of isoprenoid lipids required for the prenylation of small GTPase proteins. However, previous studies have not clearly shown any change in protein prenylation in patient cells under normal conditions. With lymphoblast cell lines from 2 compound heterozygous MKD patients, we used a highly sensitive *in vitro* prenylation assay, together with quantitative mass spectrometry, to reveal a subtle accumulation of unprenylated Rab GTPases in cells cultured for 3 days or more at 40°C compared to 37°C. This included a 3-fold increase in unprenylated Rab7A, Rab14 and Rab1A. Inhibition of SREBP activation by fatostatin led to more pronounced accumulation of unprenylated Rab proteins in MKD cells but not parent cells, suggesting that cultured MKD cells may partially overcome the loss of isoprenoid lipids by SREBP-mediated upregulation of enzymes required for isoprenoid biosynthesis. Furthermore, while inhibition of Rho/Rac/Rap prenylation promoted the release of IL-1b, specific inhibition of Rab prenylation by NE10790 had no effect in human PBMC or human THP-1 monocytic cells. These studies demonstrate for the first time that mutations in mevalonate kinase can lead to a mild, temperature-induced defect in the prenylation of small GTPases, but that loss of prenylated Rab GTPases is not the cause of enhanced IL-1b release in MKD.

321

Epigenetic-immunological axis of resveratrol-mediated amelioration of acute lung injury

Algheta, H.F.K.^{1,2}, Mohammed, A.K.^{1,2}, Zumbun, E.¹, Elliot, D.¹, Nagarkatti, P.¹, Nagarkatti, M.¹

¹University of South Carolina, School of Medicine, Department of Pathology, Microbiology and Immunology, Columbia, South Carolina, United States, ²University of Baghdad, College of Veterinary Medicine, Baghdad, Iraq

Resveratrol (RES) is a plant-derived phenol that has antioxidant and anti-inflammatory properties, and has been explored as a

possible treatment against inflammatory diseases. In this study, we explored the role of RES in suppressing inflammation induced by an inhaled super-antigen, staphylococcal enterotoxin B (SEB). To this end, mice were pretreated with RES or vehicle and the acute lung injury (ALI) was induced by dual-dose administration of SEB. All SEB exposed mice pretreated with vehicle succumbed, while all mice pretreated with RES survived. Total RNA was extracted from lung infiltrate for microRNA (miRNA) microarray analysis and data showed several miRNAs were altered upon RES treatment. Downregulation of miR-193a-3p, miR-148a-3p, and upregulation of miR-3103-5p which target TGF- β , SOCS3 and VEGF- α , respectively were confirmed by real-time PCR. Importantly, TGF- β upregulation is known to result in increased Treg cells and reduced activated CD4⁺ cells, as seen with RES treatment where the lymphocyte subsets in the lungs were significantly lower than vehicle-treated mice. We conclude that RES treatment protects against super-antigen induced inflammation by immobilizing T-cells and thereby decreasing vascular endothelial dysfunction at the site of exposure, possibly by acting through miRNAs (Supported by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357).

322

TNF- α -MEK-ERK1/2 signaling contributes to invasiveness of U87MG glioblastoma cells

Dalavaikodihalli Nanjaiah, N., Ramaswamy, P.

National Institute of Mental Health and Neuro Sciences (NIMHANS), Department of Neurochemistry, Bengaluru, India

Glioblastoma the most aggressive and deadliest form of primary brain tumor accounts for 60% of all glial tumors. These tumors remain incurable, and patients have a median survival time of less than 15 months despite substantial progress in early diagnosis and combined modality therapy including surgical therapy, radiotherapy and chemotherapy. Glioblastoma cells are capable of exploiting tumor microenvironment for their survival and progression. We hypothesized that inflammatory cytokine tumor necrosis factor (TNF)- α milieu, contributes to growth and spread of glioblastoma and probably through mitogen-activated/extracellular signal-regulated kinase kinase (MEK) - extracellular signal-regulated kinase (ERK) 1/2 signaling axis. We investigated the effect of TNF- α on proliferation of U87MG cells by MTT assay, viability by trypan blue dye exclusion assay, migration by scratch wound-healing assay, invasion by *in vitro* trans-well Matrigel invasion assay and expression and activity of matrix metalloproteinases (MMP)-2 and MMP-9 by reverse transcriptase-PCR and gelatin zymography respectively. Migration and invasion of U87MG cells were significantly increased in the microenvironment of TNF- α , without any effect on proliferation or glioma cell viability. Inhibition of MEK kinase and ERK1/2 attenuated the TNF- α induced migration and invasion of U87MG cells. These findings point to the role of inflammatory microenvironment in the migration and invasion of glioma and demonstrate MEK-ERK1/2 pathway in TNF- α mediated growth and spread of glioblastoma. Targeting TNF- α -MEK-ERK1/2 signaling is worth considering in the management of invasion of glioblastoma.

323**Suppression of cutaneous inflammatory reactions by oral administration of whole dihomo- γ -linolenic acid-producing *Saccharomyces cerevisiae****Watanabe, N., Ohtani, M., Uemura, H.**Toho University, Fac. of Sci., Dept. of Biomol. Sci., Funabashi, Chiba, Japan*

Polyunsaturated fatty acids have many biological activities and play important roles in human health and nutrition. Dihomo- γ -linolenic acid (DGLA, C20:3n-6) is known to have an anti-inflammatory activity, but its range of effects was not well studied because of its limited natural sources. Taking advantage of genetic tractability of *Saccharomyces cerevisiae*, we have previously constructed DGLA-producing yeast strain by introducing two types of desaturase and one elongase genes to convert endogenous oleic acid (C18:1n-9) to DGLA. In this study we investigated the efficacy of oral intake of heat-killed whole DGLA-producing yeast cells on skin inflammation such as irritant contact dermatitis (ICD) and allergic contact dermatitis (ACD).

In a murine ICD, topical application of croton oil induced ear swelling along with the production of chemokines and accumulation of infiltrating cells into the skin sites. These inflammatory reactions were significantly suppressed in a dose-dependent manner by oral intake of the DGLA-producing yeast for only 7 days. This suppression was not observed by the intake of the γ -linolenic acid (C18:3n-6, an immediate precursor of DGLA) producing yeast, indicating DGLA itself suppressed the inflammation. Further analysis demonstrated that DGLA exerted an anti-inflammatory effect via prostaglandin E1 formation. In addition to ICD, ACD-induced ear swelling and cellular infiltration to the inflamed site induced was also suppressed by the same treatment. Oral administration of the DGLA-producing yeast is considered to be a simple but efficient method to suppress inflammatory responses because purification of fatty acids was not required and a small amount of DGLA was effective.

324**Type I interferons in the regulation of mucosal immune responses in the female reproductive tract***Mangan, N.¹, Mielke, L.², De Geus, E.¹, Gould, J.¹, Cumming, H.¹, Woodhouse, I.¹, Gearing, J.¹, Hansbro, P.³, Hertzog, P.¹**¹Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Disease, Clayton, Australia, ²Walter & Eliza Hall Institute, Department of Medical Biology, Melbourne, Australia,**³Hunter Medical Research Institute & The University of Newcastle, Newcastle, Australia*

In the female reproductive tract (FRT), homeostasis is maintained to enable embryo implantation and development in parallel with priming of the immune system, to protect against localised infection from mucosal pathogens including sexually transmitted infections (STIs). Type I Interferons (IFNs) are important cytokines and regulators of the host innate immune response to infections, including STIs. IFN *epsilon* (IFN ϵ) is a novel type I IFN that was discovered in our laboratory and its expression is most abundant in the epithelial cells of the uterus,

where there is constitutive expression unlike other type I IFNs. Importantly, using IFN $\epsilon^{-/-}$ mice we have demonstrated that this novel cytokine protects mice from experimental models of STIs - *Chlamydia muridarum* and HSV-2, and regulates levels of FRT-NK cells, a subset of innate lymphoid cells (ILCs). We now extend our mechanistic studies to assess the role of type I IFNs including IFN ϵ in the induction and regulation of resident mucosal ILC subsets in the FRT. ILCs have been demonstrated as key regulators/effectors of mucosal immune responses in the lung and the intestine. However, the role of these cells in the physiology and infection of the FRT has not been fully elucidated. We now characterise the composition and function of ILC subsets in the hormone regulated FRT. Importantly, we demonstrate type I IFN regulation of FRT-ILC subsets. These studies may identify new therapeutic strategies for targeting and manipulating the innate immune response in disease, through regulation of the endogenous control mechanisms.

325**The role of the P2X7 receptor in an imiquimod-induced psoriasis-like mouse model***Geraghty, N.^{1,2}, Watson, D.^{1,2}, Fuller, S.³, Sluyter, V.^{1,2}, Sluyter, R.^{1,2}**¹University of Wollongong, Wollongong, Australia, ²Illawarra Health and Medical Research Institute, Wollongong, Australia,**³University of Sydney, Medical School Nepean, Sydney, Australia*

Psoriasis is a chronic inflammatory skin disorder that manifests as plaque- or pustular-like lesions due to epidermal hyperplasia and leukocyte infiltration. The damage-associated molecular pattern receptor P2X7 is up-regulated in lesional psoriatic skin of humans and promotes inflammatory immune responses characteristic of psoriasis in human skin explants. This study investigated the role of P2X7 in the development of imiquimod-induced psoriasis-like inflammation in mice. AldaraTM cream (containing 5% imiquimod) was applied daily to the ears of mice for 6 days (days 0-5) to induce psoriasis-like inflammation. Ear swelling was measured daily; from days 0 to 6. On day 6, epidermal hyperplasia and cutaneous inflammation were assessed by histology, and leukocyte percentages (T cells, macrophages and neutrophils) determined by flow cytometry. Imiquimod treatment induced ear swelling in both BALB/c and C57BL/6 mice. However, compared to BALB/c mice, ear swelling was significantly reduced in C57BL/6 mice, which encode a partial loss-of-function (P451L) mutation in the *P2RX7* gene. Epidermal hyperplasia and cutaneous inflammation in imiquimod-treated skin was similar between BALB/c and C57BL/6 mice. Imiquimod-induced ear swelling, epidermal hyperplasia, and cutaneous inflammation were similar between C57BL/6 (wild-type) and P2X7 knockout mice. Further, imiquimod-treated skin demonstrated increased percentages of T cells (CD45⁺CD3⁺), macrophages (CD45⁺Ly6G⁺CD11b⁺), and neutrophils (CD45⁺Ly6G⁺CD11b⁺), which were similar between C57BL/6 (wild-type) and P2X7 knockout mice. Collectively, this study demonstrates that although genetic deletion of the *P2RX7* gene does not prevent imiquimod-induced psoriasis-like disease in this mouse model, investigation into the role of P2X7 in human psoriasis pathogenesis is warranted.

326**Characterising the novel regulation and function of interferon epsilon in the female reproductive tract**

Bourke, N.¹, U-Shane, S.¹, Lim, S.², DeWeerd, N.², Marks, Z.², White, M.², Mesiano, S.², Gargett, C.³, Mangan, N.², Hertzog, P.^{2,4}

¹Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia, ²Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia, ³Hudson Institute of Medical Research, The Ritchie Centre, Clayton, Australia, ⁴Monash University, Melbourne, Australia

We identified a novel type I interferon (IFN), IFN ϵ , which differs from other family members as it is constitutively expressed in the female reproductive tract (FRT) and not pathogen regulated in mice, where it is a critical regulator of FRT immunity. IFN $\epsilon^{-/-}$ mice are more susceptible to sexually transmitted infections (STIs) and IFN ϵ regulates FRT innate and adaptive immunity (Fung et al, *Science* 2013). However its expression, regulation and function in the human FRT has not previously been characterised. We have developed novel reagents (recombinant protein, monoclonal antibodies) to fully characterise the regulation and function of IFN ϵ in humans. We have generated a panel of monoclonal antibodies and found IFN ϵ expressed throughout the human FRT, however expression was in different epithelial layers between the upper FRT (endometrium, fallopian tube) and lower FRT (ectocervix, vagina), indicating that IFN ϵ may have different functions at these sites. We also found that the sex hormone progesterone (P4) inhibits expression of IFN ϵ *in vitro* and that *in vivo*, IFN ϵ levels are lower in P4 dominated secretory phase of menstrual cycle, when the FRT is known to be most susceptible to STIs. As P4 based contraceptives have previously been linked with increased susceptibility to STIs (including HIV), we are now examining IFN ϵ levels in women on hormone based contraceptives. We are also exploring the local immune responses directly activated by IFN ϵ in the FRT. In summary, IFN ϵ is highly expressed in the human FRT and emerging as a potential key modulator of FRT mucosal immune responses.

327**Identifying the role of fruit phytochemicals in modulating allergen-induced lung inflammation**

Shaw, O.M.^{1,2}, Sawyer, G.¹, Harper, J.L.², Hurst, R.D.¹

¹The New Zealand Institute for Plant & Food Research Ltd, Food & Wellness, Palmerston North, New Zealand, ²The Malaghan Institute for Medical Research, Inflammation and Arthritis, Wellington, New Zealand

Epidemiological evidence indicates that increased fruit and vegetable consumption can improve lung function and reduce airway inflammation. Research also indicates that these benefits are associated with the modulation of the immune system rather than with reduced free-radical activity. Using a mouse model of allergen-induced lung inflammation, we sought to determine the effects of a number of fruits on acute lung inflammation and to identify potential mechanisms of action. We found that New Zealand-grown blackcurrants high in delphinidin anthocyanin

glycosides, significantly ($P < 0.05$) inhibited ovalbumin-induced epithelial production of the eosinophil chemokine, CCL11, and a 38% decrease in lung eosinophilia. Boysenberry, with a high cyanidin:delphinidin glycoside ratio, inhibited allergen-induced eosinophil infiltration by 63% in conjunction with reduced inducible nitric oxide synthase (iNOS) and increased arginase, but did not inhibit production of the allergy-related mediators CCL11, IL-4, IL-13, or IgE. In contrast, a Boysenberry preparation containing low cyanidin glycosides effectively inhibited CCL11 and reduced eosinophil infiltration by 44% into the lung. Interestingly, a combined preparation of blackcurrant and low cyanidin Boysenberry administered at sub-therapeutic concentrations still reduced allergen-induced cell infiltration by 38%, but had no effect on CCL11 production. This study shows that different individual fruits can protect against lung inflammation via different mechanisms of action which may be related to their phytochemical compositions. Combining these fruits may provide synergistic therapeutic benefits in protection from airway inflammation.

328**MicroRNAs mediate the crosstalk between the cytokines prostaglandin E2/IL-6 in the inflammatory tumor microenvironment**

Li, P., Zhu, Z.

Shanghai Jiaotong University, Ruijin Hospital, Shanghai, China

The inflammation in the tumor microenvironment contributes to the progress of tumor. The inflammatory cytokines are key messengers. Prostaglandin E2 (PGE2) and interleukin (IL)-6 signal pathways are involved in the crosstalk between tumor and stromal cells. However, how PGE2-mediated signaling modulates this crosstalk remains unclear. Here, we show that microRNA (miR)-149 links PGE2 and IL6 signaling mediating the crosstalk between tumor cells and CAFs in gastric cancer (GC). miR-149 inhibited fibroblast activation by targeting IL6 and miR-149 expression was substantially suppressed in the CAFs of GC. miR-149 negatively regulated CAFs and their effect on GC development both *in vitro* and *in vivo*. CAFs enhanced epithelial to mesenchymal transition (EMT) and the stem-like properties of GC cells in a miR-149-IL6-dependent manner. In addition to IL6, PGE2 receptor 2 (PTGER2/EP2) was revealed as another potential target of miR-149 in fibroblasts. Furthermore, *H. pylori* infection, a leading cause of human gastric cancer, was able to induce cyclooxygenase-2 (COX-2)/PGE2 signaling and to enhance PGE2 production, resulting in the hypermethylation of miR-149 in CAFs and increased IL6 secretion. Our findings indicate that microRNA mediates the crosstalk between the cytokines PGE2 and IL-6 in GC and highlight the potential of interfering miRNAs in stromal cells to improve cancer therapy. These findings shed light on the mechanism of action of the PGE2-IL-6 activation loop and further highlight the significance of this loop in tumorigenesis.

329

Siglec1 feedback suppresses antiviral innate immune response by inducing TBK1 degradation via the ubiquitin ligase TRIM27

Zheng, Q.¹, Hou, J.², Zhou, Y.², Yang, Y.¹, Xie, B.³, Cao, X.^{1,2,3}

¹National Key Laboratory of Medical Molecular Biology & Department of Immunology, Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Beijing, China, ²National Key Laboratory of Medical Immunology & Institute of Immunology, Second Military Medical University, Shanghai, China, ³Institute of Immunology, Zhejiang University School of Medicine, Hangzhou, China

Type I interferon (IFN) production plays pivotal roles in host antiviral innate immune response, but excessive production of type I IFN leads to the development of immunopathological conditions. The mechanisms for tightly regulating host type I IFN production are currently of great interest. Here, we found that lectin family member Siglec1 expression was upregulated by viral infection in macrophages, which was dependent on IFNAR/JAK/STAT1 signaling pathway. Siglec1 was then identified to negatively regulate viral infection-triggered type I IFN production. Mechanistically, Siglec1 associates with DAP12 to bind and activate the scaffolding function of SHP2, and then SHP2 recruits E3 ubiquitin ligase TRIM27, which induces TBK1 degradation via K48-linked ubiquitination at Lys251 and Lys372. Therefore, viral infection-induced upregulation of Siglec1 feedback inhibits type I IFN production in antiviral innate response. Our study outlines a new way of negative regulation of type I IFN production, which may help virus to escape immune elimination.

330

Exploring the immunosuppressive potential of venom-derived molecules

Ryan, R.^{1,2}, Ikonomopoulou, M.^{1,3}, Haigh, O.¹, Lutzky, V.¹, Jimenez Martinez, R.^{1,2}, Ratnatunga, C.^{1,3}, Wong, Y.^{1,3}, Leal Rojas, I.⁴, Lopez, A.^{1,2}, Fry, B.³, Herzig, V.³, King, G.³, Miles, J.^{1,3}

¹QIMR Berghofer, Brisbane, Australia, ²Griffith University, Brisbane, Australia, ³University of Queensland, Brisbane, Australia, ⁴Translational Research Institute Australia, Brisbane, Australia

The life threatening danger posed by the bite or sting of a venomous animal is due to the unique combinations of potent, specific, and fast-acting molecules contained within venom. A single drop of venom may contain thousands of unique molecules, each with pre-programmed mechanism of action. These molecules rapidly disrupt vital biological processes in predators and/or prey. Ironically, the same characteristics that make venom deadly offer an ideal platform for the exploration of novel therapeutics and biological pathways. As such, venom represents a vast, largely unexplored source of novel drug discovery. There are currently six FDA approved venom-derived drugs. Venom-derived compounds could be used to control immune responses through high affinity targeting of surface receptors and immune pathways. This study involved mapping potent new immunomodulating compounds via the systematic scanning of a large venom BioBank across peripheral blood

mononuclear cells. The anti-inflammatory effects of venoms, crude venoms, and synthetic venom peptides were quantified using multiplex CBA and LEGENDplex. The results showed that certain venom components could potentially neutralise the effects of mitogen-induced production of various pro-inflammatory cytokines. Apoptosis detection assays showed that cytokine modulation was not due to cytotoxicity and multiparametric flow cytometry show that the compounds acted on defined immune cell lineages. Studies examining the mode of action are ongoing. Indeed, synthetic production of these bioactive molecules could catalyse the development of venom peptides as simple, fast-acting drugs for controlling or fine-tuning the function of the human immune system.

331

IL-6 deficiency results in specific cytokine responses in a mouse model of irritant contact dermatitis

Gallucci, R., Lockett-Chastain, J., Calhoun, K., Fremph, B.

University of Oklahoma, Pharmaceutical Sciences, Oklahoma City, United States

Irritant contact dermatitis (ICD) is an acute inflammatory response in skin to chemical irritants that is ranked the 2nd most prevalent occupational injury associated with workman's compensation. Interleukin-6 (IL-6) is a pro-inflammatory cytokine that is closely associated with healing and decreased levels are associated with more severe ICD. Inflammatory cytokines can effect the course and severity of ICD by mediating cell type, number, and activity of infiltrate following irritant exposure. To examine the role of IL-6 in the cytokine response during ICD, IL-6KO and C57 mice were exposed to the irritant benzoalkonium chloride (BKC) for up to 7 days. Skin protein was extracted and evaluated via multiplex (36 plex) assay. IL-6KO mouse skin displayed expression profiles and dynamics quite varied from WT. Many proinflammatory cytokines such TNF-alpha, IFN-gamma, and IL-1beta were not significantly different between strains. However, several anti-inflammatory or pro-healing cytokines/chemokines were decreased in IL-6KO skin including, IL-10, IL-13, IL-22, CXCL5 and CXCL10. Additionally, mRNA expression of alternatively activated macrophage cytokine/chemokine associated receptors such as IL-4R and CCR1 were significantly decreased in IL-6KO mouse skin. Overall, these results further confirm a role for IL-6 in determining the cytokine milieu that may determine the severity and affect the resolution of ICD.

332

Investigating venom-derived molecules that augment human immune function

Jimenez-Martinez, R.^{1,2}, Ikonomopoulou, M.^{1,3}, Haigh, O.¹, Lutzky, V.¹, Leal-Rojas, I.⁴, Ryan, R.^{1,2}, Ratnatunga, C.^{1,3}, Wong, Y.^{1,3}, Lopez, A.^{1,2}, Fry, B.³, Herzig, V.³, King, G.³, Miles, J.J.^{1,3}

¹QIMR Berghofer Medical Research Institute, Brisbane, Australia, ²Griffith University, Brisbane, Australia, ³University of Queensland, Brisbane, Australia, ⁴Translational Research Institute Australia, Brisbane, Australia

The millions of bioactive compounds found within animal venoms are a veritable war chest of novel immunotherapeutics. Recent discoveries have resulted in six venom-derived drugs currently approved by the FDA for diseases such as blood disorders and diabetes. Venom-derived compounds are known to be highly potent and highly selective for ion channels as well as other key biological pathways. To date only an infinitesimally small fraction of venom-derived compounds have been investigated for medical applications. The aim of this project is the systemic scan of a vast venom biorepository to map novel venom-derived peptides with immunomodulatory function. Using resting and stimulated human leucocytes, we performed high-throughput, multiplex scanning of venom activity using Cytometric Bead Array readout. We found 20% of crude venoms activated or enhanced cytokine production between 2-1,500 fold. From the top crude venom hits, we found candidate compounds that enhanced T cell proliferation to greater extent than classical adjuvants. We performed reverse-phase high-performance liquid chromatography (RP-HPLC) and identified the active venom fractions. Using Matrix-assisted laser desorption/ionization Time-of-Flight Mass Spectrometry (MALDI-TOF MS) we mapped the purity and molecular weights of the bioactive venom compounds. Current research aims to determine the sequence of these immunomodulatory peptides using Edman degradation and produce them synthetically for mode-of-action studies and further *in vitro* and *in vivo* characterization. We anticipate this research will help catalyze development of new classes of peptide-based immunostimulatory compounds to help augment vaccine effectiveness and enhance effects of current and future immunotherapeutic strategies.

Cigarette smoke induces mtROS-dependent senescence of CD4+ Th17 lymphocytes

Kerbrat, S.^{1,2}, Baskara, I.¹, Dagouassat, M.^{1,2}, Delost, M.^{3,4}, Henry, A.^{1,2}, Baillou, C.^{3,4}, Decrouy, X.^{1,2}, Lemoine, F.^{3,4}, Boczkowski, J.^{1,2}, Le Gouvello, S.^{1,2}

¹Université Paris Est Créteil, Créteil, France, ²Inserm U 955, Créteil, France, ³UPMC, Paris, France, ⁴Laboratoire de Biothérapies de l'Hôpital Pitié-Salpêtrière, Paris, France

Introduction: The pathogenic role of CD4+ T lymphocytes (LTCD4+) producing IL-17A (Th17) is described in inflammatory diseases, such as MS, PR, COPD, and cancer. Smoking, which is a pejorative parameter for these diseases, is associated with systemic and pulmonary Th17 expansion. We evaluated the potential role of cigarette smoke (CS)-induced oxidative stress in the modulation of senescence and inflammatory potential of Th17.

Methods: CCR6+ Th17 and other "non-Th17" LTCD4+ of healthy donors are exposed to cigarette smoke extract (CSE). ROS production is measured by flow cytometry analysis of H2DCF-DA oxidation. Immunofluorescence analysis of p16 expression evaluated senescence. Inflammatory response is evaluated by expression of relevant genes (RT-qPCR).

Results: CSE induces higher production of ROS and expression of p16 in Th17 compared to other LTCD4+ subsets. Expression of TNF α is more increased in CSE-exposed Th17. Treatment with

the antioxidant NAC or with the mitochondrial uncoupling drug, FCCP, reduced CSE-induced ROS in all LTCD4+ cell subsets, but the higher production of ROS in Th17 compared to other LTCD4+ is maintained. Conversely, FCCP treatment reduced p16 expression to the same level in Th17 as in other CD4+ T cell subsets, whereas NAC diminished p16 expression without changing the differences between LTCD4+ subsets.

Conclusion: Our results show that Th17 present a higher susceptibility to CS-induced mtROS-dependent senescence compared to other LTCD4+. We demonstrate for the first time that mitochondrial uncoupling is effective to dampen Th17 senescent phenotype in oxidative stress conditions, and as such, identify a potential new therapeutic anti-inflammatory strategy for Th17-associated chronic diseases.

334

Macrophage migration inhibitory factor could be involved in early inflammatory phase of gouty arthritis

Kim, H.-R., Lee, S.-H.

Konkuk University School of Medicine, Rheumatology, Seoul, Korea, Republic of

Objectives: This study aimed to determine monosodium urate (MSU)-induced MIF production and the role of MIF in gouty arthritis.

Methods: Peripheral blood and clinical data were obtained from 98 patients (31 patients with acute gouty arthritis and 67 patients with intercritical gout). Synovial fluid (SF) was obtained from patients with acute gouty arthritis and SF white blood cells and neutrophils were counted. SF and serum levels of MIF, interleukin (IL)-1, IL-8 and leukotriene B₄, were measured using enzyme-linked immunosorbent assay (ELISA) and their relationship was analyzed. Peripheral blood mononuclear cells (PBMC) were isolated and cultured with MSU crystal, the production of MIF was determined.

Results: SF MIF level was higher in acute gouty arthritis than osteoarthritis. Serum MIF was higher in patients with intercritical gout than patients with acute gouty arthritis or healthy volunteers. SF MIF level was positively correlated with SF WBC and neutrophil counts, IL-1 β and IL-8 levels in acute gouty arthritis. Serum MIF level was correlated with IL-1 β and IL-8 levels in patients with intercritical gout. MSU crystal induced MIF production in PBMC with maximal effect at 100mg/ml.

Conclusions: MIF was highly produced in gouty arthritis and MSU induced MIF production. MIF could be involved in early inflammatory phase in acute gouty arthritis.

335

Functional interplay between type I and II interferons is essential to limit influenza A virus-induced tissue inflammation

Stifter, S.^{1,2}, Bhattacharyya, N.^{1,2}, Feng, C.^{1,2}

¹The University of Sydney, Discipline of Infectious Diseases and Immunology, Sydney, Australia, ²The Centenary Institute, Tuberculosis Research Program, Sydney, Australia

Influenza A virus infection is characterised by exuberant

pulmonary inflammation due to the influx of monocytes and neutrophils. It is unclear however, which components of the host immune response regulate this process. Our recent work shows that in addition to its known anti-viral activity, STAT1 signaling coordinates host inflammation during IAV infection in mice. This regulatory mechanism is dependent on both type I IFN and IFN- γ receptor signaling and, importantly, requires functional interplay between the two pathways. As such, type I IFNs act to promote monocyte recruitment to the lungs of infected mice as well as to prevent excessive activation of monocytes by IFN γ . Interestingly, we show that type I IFNs preferentially regulate IFN γ signalling in Ly6C^{lo} compared to Ly6C^{hi} mononuclear cell populations. In the absence of type I IFN signaling, Ly6C^{lo} monocytes/macrophages become phenotypically and functionally more proinflammatory than Ly6C^{hi} cells, revealing an unanticipated function of the Ly6C^{lo} mononuclear cell subset in tissue inflammation. In addition to their effects on mononuclear cells, type I IFNs also suppress the recruitment of neutrophils into IAV-infected tissues, however the full neutrophil-suppressive effect requires the co-operation of both type I and II IFNs. Our study demonstrates that IFN interplay links innate and adaptive anti-viral immunity to orchestrate tissue inflammation and reveals an additional level of complexity for IFN-dependent regulatory mechanisms that function to prevent excessive immunopathology while preserving anti-microbial functions.

Disruption of TNF receptor assembly elicits an IL-27 response to suppress T_H17-mediated experimental colitis in an IL-10-dependent manner

Fu, S.-H.¹, Lin, M.-H.², Wang, Y.-L.³, Yeh, L.-T.¹, Sytwu, H.-K.¹

¹National Defense Medical Center, Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan, Republic of China, ²Kaohsiung Medical University, Department of Microbiology and Immunology, Institute of Medicine, College of Medicine, Kaohsiung, Taiwan, Republic of China, ³Chang Gung Memorial Hospital, Center for Vascularized Composite Allotransplantation, Taoyuan, Taiwan, Republic of China

The soluble pre-ligand assembly domain (PLAD) of tumor necrosis factor receptor 1 (TNFR1) interferes with receptor trimerization to block downstream signaling and mediates Th17 suppression. We explored therapeutic effect of recombinant PLAD.Fc protein on a spontaneous experimental colitis model. A T cell-specific BLIMP-1 knockout mouse model was established and characterized as a Th1/Th17-mediated colitis, resembling Crohn's disease. Mice at 9 weeks of age were treated with PLAD.Fc protein at 5 mg/kg of body weight twice per week for 16 weeks, and the presence of colitis was monitored by the appearance of diarrhea, weight loss and histological scoring of colon pathology. Activation status, cytokine profiles, and transcription factors in T cells were further analyzed. In PLAD.Fc-treated group, the weight lost was recovered and mild disease score revealed by a low level of cellular infiltrate, moderate crypt elongation and reduced thickening of the bowel wall. PLAD.Fc downregulates T cell pathogenicity by suppressing the levels of IFN- γ , IL-17, IL-21, IL-22, IL-23R, GM-CSF and TNF- α in CD4⁺ T cell.

Moreover, IL-27 expression level was induced at an extremely high level along with dramatically increased production of IL-10 in sera from PLAD.Fc-treated mice. The proportions and expression levels of IL-10 and IL-10R in Th1 and Th17 cells were significantly higher in the lymphoid organs of PLAD.Fc-treated mice. Furthermore, PLAD.Fc-restraining pathogenic phenotype of Th1 and Th17 cells is retracted when IL-10 is neutralized. PLAD.Fc protects BLIMP-1-deficiency mice from colitis by eliciting an IL-27 response and promoting IL-10 production by effector T cells as a self-regulatory mechanism.

337

Peripheral kappa-opioid receptor (KOR) stimulation exerts anti-inflammatory effects in lipopolysaccharide (LPS)-activated macrophages

Fazalul Rahiman, S.S.^{1,2}, Morgan, M.³, Gray, P.^{4,5}, Shaw, P.¹, Cabot, P.¹

¹The University of Queensland, School of Pharmacy, Brisbane, Australia, ²Universiti Sains Malaysia, School of Pharmaceutical Sciences, Penang, Malaysia, ³The University of Queensland, Institute for Molecular Bioscience, Brisbane, Australia, ⁴The University of Queensland, School of Medicine, Brisbane, Australia, ⁵Princess Alexandra Hospital, Department of Anaesthesia, Brisbane, Australia

Under inflammatory conditions, kappa opioid receptors (KOR) are upregulated at peripheral sensory neurons accompanied with production of opioid peptides from leukocytes. Activation of KOR by kappa (κ)-agonists has been shown to regulate immune responses in addition to producing analgesia. This study aimed to examine the effects of KOR stimulation by selected κ -agonists in LPS-activated macrophages. Phorbol 12-myristate 13-acetate (PMA)-differentiated THP-1 cells were established as an *in vitro* model for macrophages in inflammation. LPS (1 μ g/mL) was used to induce the activation of nuclear factor-kappa B/p65 (NF- κ B/p65) translocation and the release of interleukin-1 β (IL-1 β) and tumor necrosis factor-alpha (TNF- α) followed by co-incubation with dynorphin 1-17, dynorphin 1-7 and U50,488H at specified concentrations and duration. Modulation of the above inflammatory mediators was also examined in the presence of ML-190, a selective KOR antagonist. High-content cellular imaging was used to quantify the nuclear localisation of immunolabelled NF- κ B/p65. The levels of cytokine release were determined using a commercial AlphaLISA kit for IL-1 β and TNF- α . Results showed that dynorphins (1-17 and 1-7) and U50,488H attenuated NF- κ B/p65 nuclear translocation. The release of IL-1 β and TNF- α was inhibited by dynorphin 1-7 and U50,488H whereas DYN 1-17 only reduced IL-1 β without any effect on TNF- α release. Inhibition of NF- κ B/p65 and cytokine release by κ -agonists was significantly antagonised by ML-190. These findings indicate that peripheral activation of KOR exerts anti-inflammatory properties in LPS-initiated signal transduction in macrophages through inhibition of NF- κ B/p65 nuclear translocation and pro-inflammatory cytokine production, thereby limiting the exacerbation of inflammation.

PEP-1-SIRT2 causes COX-2 expression via the MAPK pathways in rabbit articular chondrocytes

Kim, S.-J.

Kongju National University, Gongju, Korea, Republic of

SIRT2 is a member of the mammalian sirtuin protein family, primarily found in the cytoplasm. It regulates numerous cellular processes including aging, DNA repair, cell cycle, and survival under stress conditions. However, the biological function and mechanism of the SIRT2 protein is not well understood in normal cells such as primary chondrocytes. In this study, we examined the effects of SIRT2 on inflammation in rabbit articular chondrocytes by using a cell-permeative PEP-1-SIRT2 protein. Our results indicate that PEP-1-SIRT2 caused an inflammatory response by inducing the expression of cyclooxygenase-2 (COX-2) and prostaglandin E₂ (PGE₂). In addition, after treatment with PEP-1-SIRT2, phosphorylation of both p38 and ERK was observed. Inhibition of ERK with PD98059 (PD) suppressed PEP-1-SIRT2-induced COX-2 expression. Reduction in PEP-1-SIRT2-induced inflammatory response was observed upon inhibition of p38 by SB203580 (SB). The same pattern was demonstrated in PEP-1-SIRT2-induced inflammatory response during culture with serial passages. During expansion to four passages, levels of COX-2 and SIRT2 increased and activated ERK and p38. Furthermore, PEP-1-SIRT2 enhances and inflammatory response through the ERK and p38 pathways in rabbit chondrocytes in vitro. These findings suggest that PEP-1-SIRT2 induces inflammation through the p38 and ERK pathways in rabbit articular chondrocytes.

Proinflammatory cytokines production and metal hypersensitivity in patients with failed orthopedic implants

Podzimek, S., Prochazkova, J., Janatova, T., Vinsu, A., Bartova, J., Duskova, J.

School of Dental Medicine, First Faculty of Medicine and General University Hospital, Charles University, Prague, Czech Republic

In most of patients orthopedic implants heal well, nevertheless, there are some individuals, in whom orthopedic implants fail for reasons, which remain unclear.

The aim of our study was to determine metal intolerance and to monitor production of selected pro-inflammatory cytokines in patients with failed orthopedic implants and in patients with allergy to metals and with need of orthopedic implant surgery. The study groups included 35 patients with failed orthopedic implant and 15 patients with suspected allergy to metals and with need of orthopedic implant surgery. Cytokine production after lymphocyte cultivation with chromium, cobalt, titanium and zirconium antigens was determined.

Direct correlation between implant failure and intolerance to its composition in approximately 40 % of patients with failed implants has been determined. In these patients, production of pro-inflammatory cytokines was influenced the most by stimulation by titanium in patients with diagnosed titanium intolerance. Titanium exposure in patients with titanium intolerance will likely lead to titanium implant failure.

Acknowledgements: The study was supported by PRVOUK-P28/LF1/6 (Charles University of Prague, Czech Republic) and by project 14-37368G (Grant Agency, Czech Republic).

Virus infections impact structural bone cell populations

Maltby, S.^{1,2}, Lochrin, A.^{1,2}, Donges, B.^{1,2}, Tay, H.^{1,2}, Plank, M.^{1,2}, Stewart, J.^{1,2}, Foster, P.^{1,2}

¹Priority Research Centre for Healthy Lungs, Newcastle, Australia,

²Hunter Medical Research Institute, Department of Microbiology and Immunology, School of Pharmacy and Biomedical Sciences, Faculty of Health, Newcastle, Australia

Virus infections cause a variety of symptoms and negatively impact health. We have a detailed understanding of how the immune system responds at sites of infection to destroy viruses. However, growing evidence suggests that viruses also have long-term effects throughout the body, including changes in the bone marrow. The bone marrow serves as the site of immune cell production and also houses cells that maintain bone structure. Regulation of the bone marrow must be delicately balanced to deal with infection, while maintaining long-term bone health. Our previous studies identified increased myeloid cell production as a key feature of infection. This occurs following acute lung infection with pneumonia virus of mice (PVM) and in early stages of systemic lymphochoriomeningitic virus (LCMV) infection. Intriguingly, we also noted decreased structural bone cell populations (including osteoblasts) following infection. Osteoblast numbers decrease during stages of increased systemic inflammation. During chronic LCMV infection, osteoblast numbers remain decreased well after systemic inflammation resolves. Our current studies are addressing the mechanisms underlying these changes and the functional consequences on bone integrity. While bone structural cells are obviously important for the long-term maintenance of bone integrity, they also play key roles regulating hematopoiesis. The regulation of these cells is important for the development of appropriate immune responses to clear infection and directing pathology induced by infection.

This research was funded through fellowships from the Canadian Institutes for Health Research (CIHR) and the University of Newcastle and funding support from the Hunter Medical Research Institute.

Role of IL-21 in the development of autoimmune myositis

Kageyama, T., Iwamoto, T., Tanaka, S., Suto, A., Nakajima, H.

Graduate School of Medicine, Chiba University, Allergy and Clinical Immunology, Chiba, Japan

Objective: IL-21 has been shown to be involved in the development of various autoimmune diseases; however, the role of IL-21 in autoimmune myositis remains unknown. In this study, we investigated the role of IL-21 in the development of autoimmune myositis.

Methods: We examined serum levels of IL-21 in patients

with inflammatory myopathies and healthy donors. We also investigated the roles of IL-21 in the development of experimental autoimmune myositis (EAM) by using IL-21-deficient mice.

Results: Serum levels of IL-21 were significantly increased in patients with inflammatory myopathies as compared to those in healthy donors ($n = 17$, each, $p < 0.05$). Upon the induction of experimental autoimmune myositis, muscle weakness was less obvious in IL-21-deficient mice as compared to that in wild-type (WT) mice. While the numbers of CD4⁺ T cells, CD8⁺ T cells, and B cells in the affected muscle were similar between EAM-induced IL-21-deficient mice and WT mice, the number of CD11b⁺ cells was significantly decreased in the muscle of EAM-induced IL-21-deficient mice. The numbers of germinal center B cells and GM-CSF-producing gd T cells in the draining lymph nodes were significantly decreased in EAM-induced IL-21-deficient mice as compared to those in EAM-induced WT mice. GM-CSF production was significantly impaired in IL-21-deficient CD27- gd T cells.

Conclusion: IL-21 is involved in the development of autoimmune myositis presumably by inducing the production of GM-CSF in gd T cells.

Opuntiol/Opuntioside-I: a novel suppressor of cytokine, chemokine and lipid mediators in in-vivo and in-vitro inflammatory models

Roome, T.¹, Ali, P.¹, Aziz, S.¹, Razzak, A.¹, Faizi, S.², Abidi, L.², Lubna, L.²
¹Dow Diagnostics Reference and Research Laboratory, Dow International Medical College, Dow University of Health & Sciences, Molecular Pathology, Department of Pathology, Karachi, Pakistan,
²H.E.J Research Institute of Chemistry, Dr. Panjwani Center of Molecular Medicine and Drug Research, International Centre for Chemical and Biological Science, University of Karachi, Karachi, Pakistan

Cytokines are signaling proteins including chemokines, interleukins, interferons, lymphokines and tumor necrosis factor that induce immune-based inflammatory responses. Elevated levels of cytokines provoke a broad range of cellular and physiological response and inflammation. *Opuntia dillenii* belongs to genus *Opuntia* have shown remarkable effects as an anti-inflammatory agent. In the present investigation we have evaluated novel compounds Opuntiol and Opuntioside-I derived from *Opuntia dillenii* have shown significant decrease in various cytokines (interleukins) and chemokines in a dose dependent manner. Cytokines i.e. Tumor necrosis factor- α (TNF- α), Interleukin 1 β (IL-1 β), interleukin 6 (IL-6), interleukin 10 (IL-10) and chemokine i.e. keratinocyte chemottractant (KC), JE, and monocyte chemottractant factor-1 (MCP-1) were evaluated in the absence and presence of opuntiol and opuntioside-I administered orally 60 minutes prior to induction of peritonitis via carrageenan and zymosan, respectively using ELISA. At highest dose 20mg/kg Opuntiol/Opuntioside-I inhibited IL-1 β , IL-6, TNF- α , JE, KC and MCP-1 by 50-90%, whereas IL-10 levels were unchanged in all doses. Additionally, marked decline in mRNA expressions of pro-inflammatory cytokines (TNF, IL-1 β , IL-6, IL-10) and chemokines (KC and MCP-1) were observed after i.p. treatment with 20mg/kg of Opuntiol/Opuntioside-I during

zymosan induced peritonitis using RT-PCR. IL-1 β , IL-6 and TNF- α activating NF-KB signaling pathway induced by JAK/STAT and I κ B pathways which proceed with upregulation of various inflammatory gene such as COX2 and iNOS, growth factors, cytokines etc. Hence, Opuntiol/Opuntioside-I inhibiting the levels and reducing the expression of aforementioned cytokines and chemokine can be a potential immunomodulatory agent against Asthma, Rheumatoid arthritis, Atherosclerosis, Chronic bronchitis, Psoriasis etc.

The effect of glomerulus specific over-expression of TGF- β 1 in streptozotocin-induced diabetic mouse model

Yasuma, T.¹, Nishihama, K.², Takeshita, A.², Hinneh, J.¹, Harada, E.¹, D'Alessandro-Gabazza, C.¹, Toda, M.¹, Yano, Y.², Gabazza, E.¹
¹Mie University Graduate School of Medicine, Immunology, Tsu, Japan, ²Mie University Graduate School of Medicine, Diabetes and Endocrinology, Tsu, Japan

Objective: Diabetic nephropathy (DN) is one of the major microvascular complications of diabetes and one of the leading causes of death among patients with diabetes, but the efficacy of available strategies for the prevention of DN remains poor. TGF- β (transforming growth factor- β) is well identified as a central mediator in fibrosis. We prepared glomerulus specific TGF- β 1 transgenic mice and evaluated the effect of TGF- β 1 in streptozotocin (STZ)-induced diabetic mouse model.

Methods: We injected saline (SAL) or STZ to podocin-hTGF- β 1 transgenic mice (hTGF- β 1Tg) and control mice (WT). Mice were divided into 4 groups (WT/SAL, WT/STZ, hTGF- β 1Tg/SAL, hTGF- β 1Tg/STZ). Blood glucose and insulin were measured. Intraperitoneal glucose tolerance test (IPGTT) was performed. Pathological evaluations of kidneys were done after sacrifice.

Results: Compared with WT/STZ group, blood glucose levels of hTGF- β 1Tg/STZ group were significantly higher. Aggravation of glucose tolerance and higher HOMA-IR were observed in hTGF- β 1Tg/STZ mice compared with WT/STZ mice. Interstitial fibrosis and glomerulosclerosis were histologically more advanced in hTGF- β 1Tg/STZ mice compared with WT/STZ mice.

Conclusion: Glomerulus specific over-expression of TGF- β 1 causes nephropathy more rapidly in streptozotocin-induced diabetic mouse model. This TG mouse can be used to develop diabetic nephropathy mouse model in a short time.

Discriminating between IDA and ACD using TfR as indicators of iron status an oxydative balance

Zaharov, T.
 Odense University Hospital, H. C. A. Children's Hospital, Odense C, Denmark

The concentrations of the TfR (soluble receptor for transferrin) positively correlated with total mass of tissue receptors, increased in response to a deficiency of iron and, conversely, negatively correlated with the content of cellular iron.

Methods: Blood was collected from children with iron/nutritive deficient anemia, ($n=20$), IDA group, from children with

inflammations and/ or recurrent infections (n=53) with anemia syndrome, ACD group, and from healthy controls (n=19). Serum concentrations of soluble transferrin receptor were determined using the Quantikine[®] Human immunoassay kit (R&D Systems) in nmol/l. Plasma nitric oxide (NO) concentration was measured by Cayman Chemical's photometric test ($\mu\text{mol/L}$).

Results: The TfR concentration was increased (mean \pm SD), $52,48 \pm 21,36$ in IDA patients, and was normal ($29,67 \pm 3,81$) in controls and for more than 55% of the ACD patients ($20,4 \pm 8$). The TfR/log ferritin was significantly low ($p < 0.001$) in the ACD group, $11,82 \pm 5,68$ compared to IDA ($55,46 \pm 33,16$) and controls ($24,40 \pm 3,49$), while NO value were extremely high in the ACD group: 123 ± 41 vs IDA 70 ± 49 ; Control 49 ± 12 .

Conclusion: The determination of sTfR is necessary in the differential diagnosis of these two anemias. One explanation proposed for this inadequate sTfR secretion is that the anemia is adaptive; to reflects a reduced rate of oxygen use by tissues in response to increased oxidative stress induced by pro-inflammatory state of the organism. One colorful description of this process is that the "hematologic thermostat has been turned down a bit".

345

Interplay between the pro-oxidant and antioxidant systems (AOS) in relation to iron homeostasis (IH)

Zaharov, T.

Odense University Hospital, H. C. A. Children's Hospital, Odense C, Denmark

As there is strong evidence for inflammation and oxidative stress (OS) in anemia of chronic syndrome (ACS), the aim of this study was to elucidate the relationship between oxidative imbalance and cellular immune response and to ask whether these processes are linked with IH. Blood was collected from 53 children with inflammations and/ or recurrent infections with ACS, from 19 healthy, controls (C), in comparing to 20 children with IDA (iron deficient anemia). Erythrocyte catalase (CAT), erythrocyte superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px) were assayed spectrophotometrically with Synchron CX5 analyzer, Beckman. Plasma nitric oxide (NO) concentration was measured by Cayman Chemical's photometric test.

Results: (mean \pm SD): GSH-Px (U/gHb): ACS $39,55 \pm 16,55$; IDA $41,09 \pm 11,90$; C $59,66 \pm 11,78$; SOD (U/gHb): ACS: $1046,41 \pm 153,03$; IDA $1200,22 \pm 185,26$; C $1262,8 \pm 187,81$; CAT (U/g Hb): ACS $10,95 \pm 4,63$; IDA $15,05 \pm 4,05$; C $14,85 \pm 5,77$. NO ($\mu\text{mol/L}$) ACS 123 ± 41 ; IDA 70 ± 49 ; C 49 ± 12 . We observed a significant decrease in the level of all three enzyme in the first, ACS group with significance $p < 0,001$ compared to the controls, as well as the activities of CAT and SOD in relation to IDA group, but there was no significant difference in in the level of GSH-Px between IDA and ACS groups.

Conclusions: A strong association between antioxidant defense, OS, and IH was revealed and these findings show that ACS is associated with increased OS. We could indirectly conclude increased RBC liability to lipid peroxidation in ACS. Decreased AOS correlates with an increased cellular inflammatory response, whereas both concur with erythron and iron status.

346

Changes in cellular iron metabolism (CIM) during chronic inflammatory states (CIS) leading to iron sequestration manifesting as the anemia of chronic disease (ACD)

Zaharov, T.

Odense University Hospital, H. C. A. Children's Hospital, Odense C, Denmark

ACD is result of a complex network of events, acting at the transcriptional and translational levels to alter the expression of proteins involved in the uptake, storage and ironutilization. This paper focuses on the role of nitric oxide (NO) of CIM during CIS. To determine effects of NO on the expression of sTfR (soluble transferrin receptor) we examined also capacity of RBC antioxydative systems (AOS) in 53 children with CIS (I group) compare with 19 healthy children. STfR value was determined using the Quantikine[®] Human immunoassay kit (R&D Systems), NO easured by Cayman Chemical's photometric test, Erythrocyte catalase (CAT, U/gHb), superoxide dismutase (SOD, U/gHb) and glutathione peroxidase (GSH-Px, U/gHb) were assayed spectrophotometrically with Synchron CX5 analyzer, Beckman.

Results: GSH-Px: $39,55 \pm 16,55$ vs. $59,66 \pm 11,78$; SOD $1046,41 \pm 153,03$ vs. $1262,8 \pm 187,81$; CAT $10,95 \pm 4,63$ vs. $14,85 \pm 5,77$; NO ($\mu\text{mol/L}$): 123 ± 41 vs. 49 ± 12 in strongly negatively correlation with sTfR ($p < 0.001$) $20,4 \pm 8$ vs. $29,67 \pm 3,81$, TfR/log ferritin $11,82 \pm 5,68$ vs $24,40 \pm 3,49$, respectively.

Conclusions: sTfR expression was reduced in relation to high NO and low AOS wich proves that NO is one of the factors launching the complicated network of regulatory signals constituting an attempt to establish an equilibrium that might have role to protect from the potential damages during CIS, by removing "the hammer above the anvil" in the oxidative system. Maybe that we call moderate disease is the attempt of the organism to solve the conflict with the least possible damages. Isn't the interaction between iron homeostasis, NO activity and oxygenation exactly the first regulation attempt?

347

The role of gut-derived flagellin following burn injury

Eaves-Pyles, T.^{1,2}, Grimes, L.³, Szabo, C.^{2,4}

¹University of Texas Medical Branch, Microbiology and Immunology, Galveston, United States, ²Shriner's Hospital for Children, Galveston, United States, ³University of Texas Medical Branch, Galveston, United States, ⁴Univeristy of Texas Medical Branch, Anesthesiology, Galveston, United States

Burn injury is associated with a loss of gut barrier function consequentially resulting in systemic dissemination of gut-derived bacteria and their products, namely flagellin. Because we detected flagellin in the serum of burn patients, we investigated whether gut-derived flagellin was a primary or secondary contributor to intestinal dysfunction and systemic inflammation following burn injury. As such, human intestinal epithelial cells (IECs), were exposed to flagellin (50 or 500 ng) and *E. coli* (EC; 1×10^5) that is a gut isolate as follows: 1) flagellin added 30 min prior to EC, 2) flagellin and EC added simultaneously, or 3) EC added 30 min prior to flagellin. Our results showed that luminal

flagellin and EC modulated one another, which influenced cytokine secretion and translocation of EC and flagellin. EC added with or pre-flagellin affected the ability of flagellin to stimulate TLR5 and NF- κ B activation. Additionally, we found marked differences in the gut microbiome of mice gavaged with flagellin then immediately given a 30% burn or burned 2 hours pre- or post-burn. In these mice, gut-derived flagellin induced MCP-1 secretion in the serum, mesenteric lymph nodes and lungs 24 and 48h post-burn. The timing of flagellin gavage and burn altered the gut microbiome changes and induced systemic secretion of cytokines. Together our results demonstrate that gut-derived flagellin can function as a luminal immunomodulator, in addition to being a primary or secondary contributor to systemic inflammation depending on the dose and timing of flagellin's presence in conjunction with normal intestinal flora.

Macrophage migration inhibitory factor-induced autophagy is involved in thrombin mediated endothelial cell hyperpermeability

Yeh, T.M.¹, Chao, C.-H.²

¹National Cheng Kung University, Medical Laboratory Science and Biotechnology, Tainan, Taiwan, Republic of China, ²National Cheng Kung University, Institute of Basic Medicine, Tainan, Taiwan, Republic of China

Sepsis is a disease in which systemic inflammation-induced vascular leakage and disseminated intravascular coagulation lead to multiple organ failure. Despite a high mortality and morbidity, there is currently no specific drug for sepsis. Thrombin, a serine protease that mediates key sepsis-related pathologies, both activates coagulation cascades and acts as a mediator to induce vascular hyperpermeability and inflammation. Previously, it has been shown that thrombin can induce endothelial cells to secrete macrophage migration inhibitor factor (MIF). MIF is a pro-inflammatory cytokine that is increased in sepsis and can cause endothelial hyperpermeability via autophagy. However, it is unclear whether MIF-induced autophagy is involved in thrombin-mediated vascular hyperpermeability. Herein, we show that thrombin treatment induced hyperpermeability, which was accompanied by VE-cadherin translocation in the human microvascular endothelial cell line (HMEC-1). Additionally, thrombin could induce MIF secretion and autophagy in HMEC-1 cells. Inhibition of MIF by an antibody or inhibitors could reduce thrombin-induced endothelial hyperpermeability and autophagy. However, inhibition of autophagy prevented only endothelial hyperpermeability, not MIF secretion. Blockade of autophagy using Atg5 shRNA further confirmed these findings. Finally, both MIF and autophagy inhibitors reduced thrombin- and lipopolysaccharide-induced vascular leakage *in vitro* and in mice, respectively. Together, our data suggest that autophagy in endothelial cells may represent a common pathway that mediates both thrombin and cytokine-induced vascular leakage in sepsis.

349

The effect of Parvoviridae VP1 unique region in H9c2 cardiomyocytes

Tzang, B.-S.^{1,2}, Lin, D.-W.², Shi, Y.-F.², Lin, C.-Y.², Hsu, T.-C.²

¹Chung Shan Medical University, Department of Biochemistry, School of Medicine, Taichung, Taiwan, Republic of China, ²Chung Shan Medical University, Institute of Biochemistry, Microbiology and Immunology, Taichung, Taiwan, Republic of China

Human parvovirus B19 (B19) and Human Bocavirus (HBoV) belong to Parvoviridae, are the only two parvoviruses known to be pathogenic in humans. Both VP1 unique region (VP1u) exhibit the secreted phospholipase A2 (sPLA2)-like enzymatic activity. Previous studies showed that B19 infection may trigger heart disease, such as myocarditis, cardiomyopathy, and pericarditis. Moreover, B19-VP1u may play an important role in the pathogenesis of myocarditis. However, the effect of B19-VP1u and HBoV-VP1u in H9c2 cardiomyocytes is not clear.

Methods: We have constructed the B19-VP1u/B19-VP1uD175A/HBoV-VP1u/ HBoV-VP1uV12A gene in a cytomegalovirus episomal vector, pEGFP-C1 and transfected it into H9c2 cardiomyocytes. Both VP1u and mutant expression in transfected cells were monitored and assessed by fluorescence microscopy, RT-PCR and Western blot.

Results: The expressions of TNF- α , IL-1 β , IL-6, NF- κ B (p-p65), and IKK- α protein were significantly increased in the B19-VP1u-transfected cells than that of the control. Additionally, the expression of IL-1 β and IL-6 proteins was significantly increased in the HBoV-VP1u-transfected cells than that of the control. Notably, the expression of TNF- α and NF- κ B (p-p65) was significantly inhibited by the siRNA in the B19-VP1u-transfected cells than that of the control. No significant variation of TNF- α , IL-1 β , IL-6, NF- κ B (p-p65), and IKK- α protein was observed in cells transfected with pEGFP-B19-VP1uD175A and pEGFP-HBoV-VP1uV12A than that of the control.

Conclusions: Altogether, these findings revealed the different effects of B19-VP1u and HBoV-VP1u on the stimulation of inflammatory signaling in cardiac H9c2 cells. Moreover, B19-VP1u rather than HBoV-VP1u likely plays more important roles in the pathogenesis of B19-related myocarditis.

Clinicopathologic evaluation of chickens infected with a recombinant virulent clone of Newcastle disease virus containing an insert for IL-4 expression

Marcano, V.^{1,2}, Cardenas Garcia, S.^{1,2}, Susta, L.³, Diel, D.⁴, Miller, P.², Afonso, C.², Brown, C.¹

¹University of Georgia, Veterinary Pathology, Athens, United States, ²Southeast Poultry Research Laboratory, Exotic & Emerging Avian Viral Diseases Research, Athens, United States, ³Ontario Veterinary College, University of Guelph, Department of Pathobiology, Guelph, Canada, ⁴College of Veterinary Medicine, University of Illinois, Department of Pathobiology, Urbana, United States

Newcastle disease (ND) is the most economically important disease of poultry, with velogenic strains causing 100% mortality in less than 5 days in unvaccinated poultry flocks.

It is the high consequence animal pathogen most reported to the OIE, with 61 countries reporting severe outbreaks in 2014. This stresses the need of better understand mechanism of pathogenesis, specifically the role of the innate immune response during infection. Mammalian interleukin-4 (IL-4) is an immunoregulatory cytokine that triggers antigen-specific Th2 responses. IL4 has a wide array of functions most of which ultimately stimulate the humoral immunity. Little is known regarding the role of chicken IL4 (chIL4) during infection, however, there is evidence that chIL4 behaves in a manner similar to its mammalian equivalent.

At the Southeast Poultry Research Laboratory (SEPR) of the USDA we have created a virulent recombinant NDV expressing chIL4 (rZJ1-IL4) during replication to determine if IL4 expressed during challenge in naïve animals is capable of inducing protective immune responses. In this experiment birds were infected with rZJ1-IL4 a control virus, rZJ1-GFP, or a sham vaccine. Clinicopathologic disease was compared between groups. Insertion of the IL4 gene into an infectious NDV clone resulted in successful replication of the virus and generation of IL4 protein along with viral transcription and translation. rZJ1-IL4 infected birds had a slightly less severe but more prolonged form of the disease. Pathologic changes were compared between groups, with notably decreased damage in multiple organs in the rZJ1-IL4 birds, suggesting a decreased innate response in the IL4 group.

Acute inflammation is characterised by accumulation of tissue fluid, neutrophil infiltration and tissue damage and is mediated by loss of endothelial barrier function resulting in vascular leak. The Eph/ephrin receptor ligand system may play a role in the pathogenesis of inflammation by modifying endothelial barrier function mediated through Rho-GTPase signalling. We cultured pulmonary vascular endothelial cells (PVEC) and exposed them to lipopolysaccharide (LPS) stimulation (10 ng/mL) and measured Eph/ephrins and inflammatory cytokines (TNF- α) by quantitative PCR. Our results show that EphA1, EphA2 and ephrinA1 were upregulated in PVECs in response to LPS stimulation. We also confirmed upregulation of TNF- α gene. Wild type (WT) and EphA2 knockout mice (EphA2 KO) were then subjected to caecal ligation and puncture (CLP) induced sepsis and monitored for survival. All WT mice (n=12) were dead by day 6; however, 25% (n=5) of the EphA2KO (n=19) mice survived to 10 days. Serum pro-inflammatory cytokine levels (i.e. TNF- α) were significantly higher in WT mice compared to EphA2 KO mice at all intervals (i.e. 3 and 12 hours post CLP). However, levels of MIP1 α and MIP1 β were significantly higher at 3 hours post

CLP in WT mice compared to EphA2 KO mice but no significant difference at 12 hours post CLP. We conclude that Eph/ephrin receptor signalling plays a role in mediating inflammation in the CLP infectious model of systemic inflammation (i.e. sepsis), whereby EphA2KO mice have decreased serum TNF- α levels and increased survival. Targeting Eph/ephrin signalling pathways may therefore be a future therapeutic approach in severe sepsis.

352

Monocyte inflammatory profile differs between individuals, and altered lipid levels may partly contribute to these differences

Patel, V.¹, Williams, H.¹, Li, S.², Fletcher, J.¹, Medbury, H.¹

¹Vascular Biology Research Centre, Department of Surgery, Westmead Hospital, University of Sydney, Westmead, Australia, ²Institute of Clinical Pathology and Medical Research, Westmead Hospital, University of Sydney, Westmead, Australia

In various diseases, such as atherosclerosis, intermediate monocyte levels are elevated. Considered 'inflammatory', they are a possible treatment target. However, as they remain a minor subset (5-10%), the function of the other subsets in disease is important to discern.

To compare the inflammatory profile of monocyte subsets in individuals and relate this to their lipid levels.

Blood was collected from controls and lipid analysis performed. Monocyte subset expression of M1 and M2 markers and production of cytokines (post LPS or PMA stimulation) was determined by whole blood flow cytometry.

No individual subset was distinctively inflammatory. Upon LPS stimulation, intermediates produced more TNF α , IL-1b and IL-6 than classical and non-classical (all P < 0.001), but with PMA, classicals produced more IL-1b than the other subsets (P < 0.001) -TNF α and IL-6 were not induced. Classicals expressed higher levels of M2 (anti-inflammatory), and lower levels of M1 (inflammatory) markers than the other subsets, suggesting they were less inflammatory. Importantly, a greater variation in cytokine production was seen between participants, than between subsets. Indeed, the level of cytokine production by one subset, correlated with that of the next (all P < 0.01). Differences between individuals were related to their lipid levels. LPS-stimulated IL-1b production (by all subsets) correlated positively with Chol/HDL (P < 0.025), ApoB/A1 (P < 0.005) and inversely with HDL (P < 0.025) and ApoA1 (P < 0.025). Upon PMA stimulation, classical IL-1b correlated with cholesterol, LDL (both P < 0.01) and ApoB (P < 0.025).

Perturbation of lipid levels is associated with inflammatory changes in all monocyte subsets.

Prolyl endopeptidase (PE) activity in the immune system of smoking mice

Abdalla, T.¹, Abdul Roda, M.², Li, J.-D.¹, Blalock, J.E.^{1,3}, Gaggar, A.^{1,3,4}, Xu, X.^{1,3}

¹University of Alabama at Birmingham, Medicine, Birmingham, United States, ²Utrecht University, Pharmaceutical Sciences, Utrecht, Netherlands, ³UAB Program in Protease and Matrix

Biology, Birmingham, United States, ⁴Birmingham VA Medical Center, Birmingham, United States

Rationale: Prolyl endopeptidase (PE) is expressed in various organs and cleaves collagen into the matrikine proline-glycine-proline (PGP), leading to the ongoing process of neutrophil recruitment. Using cigarette smoke (CS), an environmental stimulus causing elevated PGP levels, airway inflammation, and chronic lung disease, we explored PE levels within the immune system of smoke-exposed mice.

Methods: Balb/c mice pretreated either with saline or N-benzyloxycarbonyl-prolyl-proline (ZPP), a selective inhibitor of PE, were exposed to air or CS for 6 weeks followed by bronchoalveolar lavage analyses. PE activity assays were conducted for spleen and thymus lysate while T and B cell purification was completed via nylon column isolation, allowing for PE activity analysis in specific immune cell types.

Results: Neutrophilic airway inflammation was induced by CS exposure and inhibited in the mice with ZPP treatment. PE activity was elevated in the spleens of CS-exposed mice compared with air-exposed mice and smoking mice treated with ZPP showed complete inhibition of PE activity. The PE activity of isolated splenic T and B cell were measured and T cells showed increased PE activity levels compared to B cells. Thymus lysates were unchanged between treatment groups.

Conclusion: PE activity is strongly modulated in CS-exposed mice in both lung and spleen, highlighting the inhibitory effects of ZPP on smoke-induced inflammation. Further research will continue on the study of the effect of smoke-induced PE activity as a new regulator of both innate and adaptive immune responses in the lung.

354

Efficacy of activated vitamin D analogues paricalcitol for acute dextran sodium sulfate-induced colitis in mice

Chen, T.¹, Liu, Y.²

¹Hebei General Hospital, Department of Gastroenterology, Shijiazhuang, China, ²Huashan Hospital Fudan University, Department of Gastroenterology, Shanghai, China

Objective: To investigate the effects of Paricalcitol on intestinal inflammation and its mechanism.

Methods: 30 BALB/c mice were divided into five groups: normal control(A), colitis control(B), treatment with low dose(C), treatment with medium dose(D), treatment with high dose(E). Acute colitis was induced by DSS according to standard procedures. Mice were treated by intragastric administration with Paricalcitol or placebo on day 1, 4, 7. DAI score, Serum calcium, histopathological score, the mRNA expression of TNF- α , IL-6, IL-10, IL-17, VDR, P38 MAPK and MKP- 1 and the protein expression of P38, P-P38 and MKP- 1 were detected.

Results: DAI score, histopathological score, TNF- α , IL-6, IL-17, P38 MAPK were high in group B and low in A,C,D,E. ($P < 0.05$) The length of the colons, IL-10, VDR, and MKP- 1 were low in group B and high in A,C,D,E. ($P < 0.05$).

Conclusion: Paricalcitol demonstrated significant anti-inflammatory properties in experimental colitis by inducing the expression of MKP-1 which blocked P38 MAPK pathway.

355

The anti-pulmonary fibrotic effect of FMI-1, one phenylethanoid compound from *Osmanthus spp.*

Shi, L.-S., Chuang, Y.-M., Tseng, Y.-F., Ye, Y.-L.

National Formosa University, Department of Biotechnology, Yunlin County, Taiwan, Republic of China

FMI-1 is one phenylethanoid compound derived from *Osmanthus spp.* It has been reported to possess anti-oxidant, anti-inflammatory, antitumor invasion and migration, photoprotective, and neuroprotective effects. Pulmonary fibrosis is a chronic inflammation, progressive and fatal interstitial lung diseases. It is revealed that transforming growth factor- β (TGF- β) is a master switch cytokine during pulmonary fibrosis. The cause of pulmonary fibrosis is characterized by the excessive deposition of extracellular matrix proteins within the pulmonary interstitium. In this study, we used mouse lung fibroblast cell line, primary lung fibroblast cell culture and bleomycin-induced pulmonary fibrosis model to investigate the anti-fibrotic effect of FMI-1. FMI-1 can suppress lung fibroblast cell proliferation and collagen expression through pSMAD 2/3 pathway. In the animal model, FMI-1 also has therapeutic effect. Lung function index such as Rrs (respiratory resistance), Ers (respiratory elastance), G (tissue damping), and H (tissue elastance) by FMI-1 treated mice are all decreased. Transforming growth factor- β 1 (TGF- β 1) and interleukin-6 (IL-6) also decreased after treat FMI-1 in bronchoalveolar lavage fluid by FMI-1 treated mice. In the future, we hope this study can provide the possibilities of FMI-1 for prevention or treatment of pulmonary fibrosis.

356

Interleukin-17-induced microRNA-873 contributes to the pathogenesis of experimental autoimmune encephalomyelitis by targeting A20 ubiquitin-editing enzyme

Liu, X., He, F., Pang, R., Zhao, D., Qiu, W., Shan, K., Zhang, J., Lu, Y., Li, Y., Wang, Y.

Nanjing Medical University, Immunology, Nanjing, China

Interleukin 17 (IL-17), produced mainly by T helper 17 (Th17) cells, is increasingly recognized as a key regulator in various autoimmune diseases, including human multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE). Although the aberrant expression of microRNAs (miRNAs) has been shown to contribute to the pathogenesis of MS and EAE, the mechanisms underlying the regulation of abnormal miRNA expression in the astrocytes upon IL-17 stimulation remain unclear. In the present study, we detected the changes of miRNA expression profiles both in the brain tissue of EAE mice and in the cultured mouse primary astrocytes stimulated with IL-17. We first identified microRNA-873 (miR-873) as one of the co-up-regulated miRNAs *in vivo* and *in vitro*. Further studies showed that miR-873 overexpression, demonstrated by targeting the mRNA of A20 (TNF α -induced protein 3, TNFAIP3), remarkably reduced A20 expression and promoted NF- κ B activation *in vivo* and *in vitro* as well as increasing the production of inflammatory

cytokines and chemokines (i.e. IL-6, TNF- α , MIP-2 and MCP-1/5). More importantly, silencing the endogenous miR-873 or A20 gene with lentiviral vector of miR-873 sponge or A20 short hairpin RNA *in vivo* significantly lessened or aggravated inflammation and demyelination in the central nervous system (CNS) of EAE mice, respectively. Taken together, these findings indicate that miR-873 up-regulation in the astrocytes induced by IL-17 promotes the production of inflammatory cytokines and aggravates the pathological process of EAE mice through regulating the A20/NF- κ B pathway, which provides a new insight into the mechanism of inflammatory damage in MS.

357

Prevention of colitis and colitis-associated colorectal cancer by a novel small molecule

Lin, Y.-T.¹, Wei, T.-T.¹, Tseng, R.-Y.¹, Shun, C.-T.^{2,3}, Lin, Y.-C.^{1,4,5}, Fang, J.-M.⁶, Chen, C.-C.¹

¹College of Medicine, National Taiwan University, Department of Pharmacology, Taipei, Taiwan, Republic of China, ²Graduate Institute of Forensic Medicine, National Taiwan University College of Medicine, Taipei, Taiwan, Republic of China, ³National Taiwan University Hospital, Department of Pathology, Taipei, Taiwan, Republic of China, ⁴National Taiwan University Hospital, Department of Oncology, Taipei, Taiwan, Republic of China, ⁵Far-Eastern Memorial Hospital, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China, ⁶National Taiwan University, Department of Chemistry, Taipei, Taiwan, Republic of China

Chronic intestinal inflammation is a well-known risk factor for colorectal cancer (CRC) development. Metabolic inflammation (metaflammation) and alteration of gut microbiota (dysbiosis) have been found to elicit CRC with rising annual incidence. Chemoprevention is an important strategy to reduce cancer-related mortality. In this study, we designed and synthesized a small molecule that simultaneously inhibited 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMGR) and histone deacetylases (HDACs).

This small molecule showed both preventive and therapeutic effect in DSS acute colitis mouse models. It ameliorated intestinal inflammatory symptoms, shortening of colon length, loss of crypts, destruction of epithelial integrity, infiltration of inflammatory cells and release of pro-inflammatory cytokines. In addition, in azoxymethane/dextran sodium sulfate (AOM/DSS)-induced CRC mouse model, this small molecule also protected against mucosa dysplasia and adenocarcinoma formation. mRNA of pro-inflammatory cytokines and chemokines, expression of COX-II and cyclin D1 in inflammation and tumor tissues as well as the penetration of macrophages and neutrophils in tumor surrounding zones were all reduced by it. Stemness of CRC and release of endotoxin were also attenuated by this small molecule in AOM/DSS model.

Our results demonstrated that this small molecule showed promising effect on the chemoprevention of CRC, and serum endotoxin level might serve as a potential biomarker for its chemoprevention.

358

Interleukin-17A promotes the growth and tumorigenicity of CT26 colon cancer cells

Kim, Y.S.

Chungnam National University, College of Natural Sciences, Department of Biochemistry, Daejeon, Korea, Republic of

Interleukin-17A is a member of the IL-17 family, and is known as CTLA8 in the mouse. It is produced by T lymphocytes and NK cells and has proinflammatory roles, inducing cytokine and chemokine production. However, its role in tumor biology remains controversial. We investigated the effects of locally produced IL-17A by transferring the gene encoding it into CT26 colon cancer cells, either in a secretory or a membrane-bound form. Expression of the membrane-bound form on CT26 cells dramatically enhanced their proliferation *in vitro*. The enhanced growth was shown to be due to an increased rate of cell cycle progression: after synchronizing cells by adding and withdrawing colcemid, the rate of cell cycle progression in the cells expressing the membrane-bound form of IL-17A was much faster than that of the parental cells. Both secretory and membrane-bound IL-17A induced the expression of Sca-1 on the cancer cells. When tumor clones were grafted into syngeneic BALB/c mice, the tumor clones expressing the membrane-bound form IL-17A grew rapidly; those expressing the secretory form also grew faster than the wild type CT26 cells, but slower than the clones expressing the membrane-bound form. These results indicate that IL-17A promotes tumorigenicity by enhancing cell cycle progression. This finding should be considered in treating tumors and immunerelated diseases.

359

A novel regulator of NF κ B signaling enhances I κ B α ubiquitination and promotes inflammatory disease development

Okuyama, Y.^{1,2}, Atsumi, T.^{1,3}, Jiang, J.-J.^{1,3}, Nakamura, A.³, Ogura, H.^{1,3}, Meng, J.^{1,3}, Kamimura, D.^{1,3}, Shii, N.², Hirano, T.^{1,3}, Murakami, M.^{1,3}

¹Institute for Genetic Medicine and Graduate School of Medicine, Hokkaido University, Division of Molecular Neuroimmunology, Sapporo, Japan, ²Tohoku University Graduate School of Medicine, Department of Microbiology and Immunology, Sendai, Japan, ³Graduate School of Frontier Biosciences, Graduate School of Medicine, and WPI Immunology Frontier Research Center, Osaka University, Laboratory of Developmental Immunology, Suita, Japan

The inflammation-amplifier is a regulator of chronic inflammation in non-immune cells such as endothelial cells and fibroblasts, and is critical for the development of various diseases and disorders. The inflammation amplifier is activated by the simultaneous activation of NF κ B and STAT3, and enhances the expression of NF κ B targets critical for inflammation development. A functional genome wide screen found over 1,000 candidate genes as positive regulators of the inflammation amplifier. We selected a regulator candidate gene, SAG1. SAG1-deficient cells suppressed the expression of several NF κ B targets, including IL-6, CCL20 and LCN2 after IL-17 and IL-6

stimulation, but not of STAT3 targets such as SOCS3, suggesting that SAG1 regulates the NF κ B pathway but not the STAT3 one. A deficiency of SAG1 by using lentiviruses carrying SAG1-shRNA in the joints suppressed the development of a model NF κ B-mediated disease, the cytokine-induced arthritis. In the NF κ B signaling pathway, I κ B α degradation and p65 nuclear localization were suppressed in SAG1-deficient cells after TNF α stimulation, but upstream events, such as the phosphorylation of IKK α / β , NF κ B, and I κ B α , were unaffected. TNF α -mediated reporter activation was also inhibited in SAG1-deficient cells. These results suggest that SAG1 regulates I κ B α degradation in the cytoplasm. Mechanistic analysis showed that SAG1 directly associated with β TrCP, an E3-ligase, to increase the integrity of an ubiquitination complex, SCF leading to the ubiquitination of I κ B α . These effects on NF κ B-related inflammation suggest SAG1 is a potential therapeutic target for various diseases and disorders.

360

Potential roles and mechanisms of CXCR3 and TLR4 in response to CXCL10 in rheumatoid arthritis

Kim, B., Jin, W.J., Lee, Z.H.

Seoul National University School of Dentistry, Cell and Developmental Biology, Seoul, Korea, Republic of

Rheumatoid arthritis (RA) is a chronic autoimmune disease which is characterized by constant joint inflammation and destruction of bone and cartilage. We previously reported that CXCL10 is crucially implicated in joint inflammation and bone destruction in arthritis. However, the specific mechanism by which the recruitment of inflammatory cells and osteoclastogenic cytokine production are regulated by CXCL10 in RA is not fully understood. Here, we found that CXCL10 induced migration of inflammatory cells through CXCR3-mediated, but not TLR4-mediated, ERK activation. Interestingly, both receptors CXCR3 and TLR4 were required for CXCL10-stimulated production of osteoclastogenic cytokines in CD4⁺ T cells, where NFATc1 expression was essential for CXCL10-induced RANKL expression. Based on the *in vitro* results, infiltration of F4/80⁺ macrophages into synovium, serum concentrations of osteoclastogenic cytokines, and bone destruction were all reduced, leading to decreased progression of arthritis in CXCL10^{-/-} and CXCR3^{-/-} mice compared to WT mice in collagen-antibody induced arthritis model. Taken together, these findings highlight the importance of CXCL10 in the pathogenesis of RA and provide the previously unidentified insights into the detailed mechanisms underlying the infiltration of inflammatory cells and the production of osteoclastogenic cytokine in CXCL10-induced development of arthritis.

Human neutrophils a new therapeutic target of Tamoxifen

Espinoza, G.¹, Perez, B.², Morales, N.¹, Borlone, C.¹, Folch, H.¹, Moran, G.¹, Sarmiento, J.¹

¹Universidad Austral de Chile, Valdivia, Chile, ²Universidad Austral de Chile, Escuela de Graduados Facultad de Ciencias Veterinarias, Valdivia, Chile

Tamoxifen is a selective estrogen receptor modulator used as treatment of estrogen-positive human breast cancer; its efficacy has been attributed to cell growth arrest and induction of apoptosis in neoplastic cells. Recent studies have demonstrated that tamoxifen produced a reduction of neutrophilic inflammation in acute lung inflammation model in mice and horses. Tamoxifen is metabolized by hepatic cytochrome P450. The antagonist activity for the binding of 17- β -Estradiol nuclear receptors of estrogen α and β (nER α / β) is mediated by the metabolites 4-hidroxytamoxifeno (4-OH) and 4-hidroxy-N-desmethyltamoxifen, but not by tamoxifen. Recently, a membrane receptor for G protein coupled estrogen called GPR30 has been described, for which tamoxifen has an agonist activity. We assessed cell viability by Annexin V/propidium iodide apoptosis assay, phagocytosis capacity performing phagocytosis assay with latex particles opsonized IgG-FTC, measuring both by flow cytometry. Additionally, a respiratory burst assay was carried out using opsonized zymosan in human neutrophils obtained from peripheral blood. Finally, nuclear estrogen receptors (17- β -Estradiol) and membrane GPR30 agonists and antagonists (ICI 182,780 and G15) were employed for assessing whether these receptors are involved in the effects produced by tamoxifen in this study. We detected that tamoxifen does not affect cell viability, neither phagocytosis. On the other side, tamoxifen inhibited the respiratory burst in a dose-dependent way. Interestingly, agonists and antagonist estrogen receptors did not block neither reproduce this effect in the respiratory burst. This study gives preliminary information of the potential of tamoxifen on new therapies for controlling neutrophilic inflammatory disorders in human.

362

Evidence for a key role for neutrophils in rheumatoid arthritis

Goldberg, G.¹, Chatfield, S.^{1,2}, Murphy, J.¹, D'Silva, D.¹, Pang, E.S.¹, O'Neill, C.², Tadros, S.², Grebe, K.¹, Chen, Y.¹, Smyth, G.¹, Ng, M.³, Inouye, M.⁴, Busfield, S.³, Wilson, M.³, Andrews, A.³, Wilson, N.³, Wicks, I.^{1,2,4}

¹Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²Royal Melbourne Hospital, Parkville, Australia, ³CSL Limited, Parkville, Australia, ⁴University of Melbourne, Parkville, Australia

Rheumatoid arthritis (RA) is characterised by a persistent, but poorly understood interplay between innate and adaptive immunity. Neutrophils are the predominant cell type in inflamed RA synovial fluid (SF). In this study we evaluated the role of

neutrophils in RA. Neutrophil growth factors, chemokines and neutrophil-extracellular traps (NETs) were determined by immunoassay of serum and synovial fluid from RA patients and neutrophil phenotype in peripheral blood (PB) was analysed by flow cytometry. Transcriptional differences in SF and PB neutrophils from RA donors and in white blood cells (WBCs) from both healthy donor and RA patients were determined by RNAseq. Circulating neutrophil proportions and numbers were increased in RA patients (n=73) compared to healthy donors. Neutrophil proportion and number correlated with disease activity in RA patients. G-CSF, GM-CSF and neutrophil chemoattractants, including IL-8, were elevated in SF of RA patients when compared with paired serum samples. NETs were markedly increased in SF of RA patients when compared with both osteoarthritis SF and RA PB. Pathway analysis of WBC transcription profiles identified G-CSF as an upstream regulator of differential gene expression in peripheral RA WBCs (n=50) when compared with healthy donor WBCs (n=50). Analysis of transcription profiles from blood and SF neutrophils from RA patients revealed a decrease in degranulation and cell death-related genes in SF neutrophils. These data together provide evidence that neutrophils contribute to the pathogenesis of RA, provide potential biomarkers for monitoring disease activity and suggest that G-CSF may be a new therapeutic target in RA.

The different transformatin of the phenotype CD16⁺CD11b⁺ neutrophilic granulocytes in acute viral and acute bacterial infections

Nesterova, L.¹, Kolesnikova, N.², Chudilova, G.², Lomtadidze, L.², Kovaleva, S.², Avdeeva, M.³, Rusinova, T.²

¹Peoples' Friendship University of Russia, Department of Allergology and Immunology, Moscow, Russian Federation, ²Kuban State Medical University, Department of Clinical and Experimental Immunology, Krasnodar, Russian Federation, ³Kuban State Medical University, Department of Disease of Infection, Krasnodar, Russian Federation

Modern data demonstrate: neutrophilic granulocytes (NG) can very quickly realize the antibacterial and antiviral defense. Membrane molecules CD16 and CD11b of NG take part in the implementation of the phagocytosis and/or ADCC in infectious processes of the different nature. We had studied the population CD16⁺CD11b⁺NG in two groups of patients both sexes in age 18-28 years with acute viral and bacterial infections:

group I - 25 patients with acute bacterial tonsillitis (ABT),
group II - 28 patients with acute viral tonsillitis - EBV infection (AEBVI).

Control group included 25 healthy adults.

Comparative analysis of the redistribution of the intensity of the equipment functionally important receptors CD16 and CD11b have detected using the flow cytometry method. Three different subpopulations CD16^{bright}CD11b^{bright}, CD16^{bright}CD11b^{dim}, CD16^{dim}CD11b^{bright} were found in normal and pathological conditions. The subpopulation CD16^{bright}CD11b^{dim}NG dominated in 91,02±5,23% in healthy individuals; in patients with the acute viral infection the subpopulation CD16^{bright}CD11b^{bright}NG dominated in 75,8±4,5% of cases and in patients with the acute

bacterial infections the subpopulation CD16^{dim}CD11b^{bright}NG dominated in 88,6±5,9% of cases. Thus, the membrane equipment of receptors of CD16⁺ and CD11b⁺ was changed in early stage of the acute viral and acute bacterial infections. We propose that very high levels of the expression of CD16 and CD11b molecules in the subpopulation CD16^{bright}CD11b^{bright}NG in patients with the acute viral infection are necessary for realization ADCC in the antiviral defense. From the other side, in the subpopulation CD16^{dim}CD11b^{bright}NG the leading role have CD11b molecules that trigger phagocytosis in early stage of the acute bacterial process.

364

NE, CD80 and CD 86 colocalized in NETs

Rodriguez, F.M.¹, Novak, I.T.C.²

¹National University of Cordoba. Faculty of Medicine, Cordoba, Argentina, ²National University of Cordoba. Faculty of Medicine, Institute of Cell Biology, Cordoba, Argentina

Polymorphonuclear neutrophils (PMNs) activated in vitro may express molecules normally associated with antigen presenting cells (APCs). In inflammatory conditions, PMN can release extracellular traps (NETs) composed of chromatin, histone and granule proteins, which trap and kill microbes. NETs have also been implicated in autoimmunity, thrombosis, tissue injury and in cancer immunoediting. Neutrophil elastase (NE) has been shown to play an important role in the degradation of the extracellular matrix, is stored in azurophilic granules and contributes to antimicrobial activity in the phagosome. In previous work we described CD80 and CD86 colocalized in NETs at 30 min of challenge. NETs decreasing activation threshold of T cells. During the formation of NETs NE translocates from the granules to the nucleus via an unknown mechanism. It is described that NE colocalized with chromatin at 120 min after neutrophil activation. We perform the generation of NETs in autologous leukocytes cultures, challenged with lipopolysaccharide (LPS) and perform marking B7-1(CD80) and B7-2(CD86) costimulatory molecules and NE. In LPS assay at 120 min CD80 and CD86 are detected on the cell surface colocalized with NE in NETs, but not in the control paired blood samples. Here, the expression of costimulatory molecules in NETs, would allow PMNs to play function as APCs and modulatory functions of various subpopulations of T cells, could influence the cell environment through the B7-1/B7-2:CD28/CTLA-4 pathway. The NE in NETs may be one adverse effect on host tissues. These findings could have relevance for a break in immune tolerance mediated by NETs.

365

Basophils gain the capacity of antigen presentation through the import of MHC class II molecules from dendritic cells

Miyake, K., Shiozawa, N., Nagao, T., Yoshikawa, S., Yamanishi, Y., Karasuyama, H.

Tokyo Medical and Dental University (TMDU), Department of Immune Regulation, Tokyo, Japan

Recent studies demonstrated that basophils play significant roles in chronic allergic inflammation and protective immunity against parasites. Moreover, it has been reported that basophils express MHC class II (MHCII) and can present antigens to naïve CD4 T cells as well as they provide IL-4, leading to Th2 differentiation. However, the mechanisms that regulate MHCII expression on basophils remain elusive.

First, to determine what induces the expression of MHCII on basophils, we generated bone marrow-derived basophils in the presence of various cytokines. We discovered that basophils elicited by GM-CSF plus IL-3 expressed significantly higher levels of MHCII compared to those elicited by IL-3 alone. In contrast, the expression at mRNA level in GM-CSF-elicited basophils is comparable to IL-3-elicited basophils, and is almost negligible compared to expression in dendritic cells (DCs). These data suggest that basophils acquire MHCII molecules from other cells in the culture, rather than they transcribe MHCII by themselves. Indeed, when DCs were depleted from the culture, the MHCII expression on basophils was significantly reduced. Conversely, when purified basophils were co-cultured with DCs, the MHCII expression on basophils was enhanced. Finally, we found that basophils expressing acquired MHCII could present antigenic peptides to naïve T cells and promote their proliferation.

Taken together, our data suggested that basophils acquire MHCII molecules from DCs and these basophils can present antigens to naïve T cells. These data will provide new basophil-DC axis which may be required for antigen presentation by basophils.

366

Tpl2 is required for neutrophil antimicrobial functions and bacterial killing

Acuff, N., Elmore, J., Li, X., Rada, B., Watford, W.
University of Georgia, Athens, United States

Tumor progression locus 2 (Tpl2) is a serine/threonine kinase that promotes inflammatory cytokine production by activating the MEK/ERK pathway. Tpl2 has been shown to be important for eliciting the inflammatory properties of macrophages, however, there is relatively little known about Tpl2's contribution to neutrophil effector functions. This is an important consideration, since neutrophils provide the first line of defense against infection in the innate immune system. We found that Tpl2 is expressed in both human and murine neutrophils, suggesting a potential function for Tpl2 within this lineage. Despite significantly higher proportions of bone marrow neutrophils in *Tpl2*^{-/-} mice compared to wild type mice, *Tpl2*^{-/-} mice have significantly reduced proportions of circulating neutrophils. In response to infection, neutrophils secrete inflammatory cytokines and produce reactive oxygen species (ROS), which promote bacterial killing. Tpl2 ablation impaired neutrophil TNF- α production in response to LPS stimulation, superoxide generation in response to the chemotactic peptide formyl-methionyl-leucyl-phenylalanine (fMLP), and killing of the extracellular bacterium, *Citrobacter rodentium*. These results implicate Tpl2 in the regulation of multiple neutrophil antimicrobial pathways, including inflammatory cytokine secretion and oxidative burst. Furthermore, they suggest that Tpl2 functions early during infection to bolster neutrophil-

mediated innate immunity against extracellular bacteria.

367

IL-4 signals hamper neutrophil expansion and migration during infection and inflammation

Woytschak, J., Boyman, O.

University of Zurich, University Hospital Zurich, Department of Immunology, Zurich, Switzerland

Upon tissue damage or infection, circulating neutrophil granulocytes (neutrophils) are the first immune cells entering the affected site where they contain invading pathogens and contribute to leukocyte recruitment and restoration of tissue integrity. Interestingly, patients suffering from atopic dermatitis, an allergic skin disease driven by type 2 cytokines including interleukin-4 (IL-4), show a lack of skin neutrophils and a propensity to cutaneous bacterial infections. We hypothesized that IL-4 might interfere with neutrophil recruitment and function. We found that both homeostatic and increased levels of IL-4 dominantly inhibited neutrophil recruitment from the bone marrow (BM) to the circulation and skin during bacterial infection. These effects were a result of IL-4 acting directly on neutrophils to restrict their expansion in the BM and their chemotaxis towards C-X-C chemokine receptor 2 (CXCR2)-binding chemokines via two mechanisms: firstly, IL-4 signals in neutrophils enhanced p38 mitogen-activated protein kinase levels, which in turn suppressed phosphoinositide 3-kinase (PI3K), thus inhibiting CXCR2-mediated PI3K activation and chemotaxis; and secondly, IL-4 interfered with CXCR2-CXCR4-mediated control of neutrophil retention in the BM. These data suggest a novel role of IL-4 in inhibiting neutrophil expansion and migration during infection and inflammation.

368

Myocardial ischemia/reperfusion injury is mediated by polymorphonuclear neutrophils through direct activation of phospholipase D (PLD) and mTOR

Ganesan, R.¹, Henkels, K.¹, Pavlov, V.², Stahl, G.², Gomez-Cambroneo, J.^{1,2}

¹Wright State University, Biochemistry and Molecular Biology, Dayton, United States, ²Brigham and Women's Hospital, Harvard Medical School, Center for Experimental Therapeutics and Reperfusion Injury, Boston, United States

During ischemia/reperfusion injury (I/RI), leukocytes release cytokines and exacerbate inflammation causing cardiac dysfunction, while neutrophils produce oxygen radicals that worsen the initial myocardial infarction. Phospholipase D is a cell membrane remodeling and signaling protein implicated in the pathology of I/RI. We analyzed I/RI by ejection fraction, infarct size and serum Troponin levels in wild-type, PLD1^{-/-} and PLD2^{-/-} mice. PLD-deficient mice or inhibition of PLD in WT mice protected against I/RI. Removing PLD2 yielded a slightly better outcome, suggesting PLD2 contributed more to the injury than PLD1, particularly at longer (>4 h) reperfusion times. Three cell signaling mechanisms were investigated: mTOR pathway, Aurora Kinase A and Cyclin-D3. Gene expression of the mTOR

pathway was increased in response to I/RI in WT mice and abrogated in PLD-KO mice suggesting PLD augmented mTOR pathway during IR/I. PLD1^{-/-} mice have lower expression of CCND3/Aurora Kinase A, while PLD2^{-/-} mice expressed more phospho-CyclinD3. We detected neutrophil-associated Ly6G after adoptive transfer of neutrophils during I/RI. Myocardial PMN accumulation was increased following I/R and PLD inhibitors abrogated PMN accumulation. Less myocardial PMN accumulation was observed in PLD-KO mice following IR/I. Adoptive transfer of fluorescently labeled PLD2^{-/-} or PLD1^{-/-} PMN into PLD1^{-/-} or PLD2^{-/-} mice, respectively, demonstrated that PLD1 containing (PLD2^{-/-}) PMNs accumulated more significantly in the myocardium following I/RI. This study demonstrates for the first time the specific mechanistic contribution of mammalian PLD1 and PLD2 to MI/R injury in a murine model and their role in neutrophil infiltration.

Identification of molecules critical for neutrophil extracellular trap formation

Aihara, R., Fukui, Y.

Kyushu University, Division of Immunogenetics, Medical Institute of Bioregulation, Fukuoka, Japan

Neutrophils are highly motile leukocytes that play important roles in the innate immune response to invading pathogens. Neutrophils rapidly migrate to the site of infections and kill pathogens by producing reactive oxygen species (ROS) and forming neutrophil extracellular traps (NETs). Because NETs are involved in vascular inflammation and autoimmune response, identification of the molecules critical for NETs formation is important to develop effective therapeutic strategy for these diseases. We found that DOCK2 and DOCK5, atypical guanine nucleotide exchange factors (GEFs), critically regulate ROS production in mouse neutrophils through Rac activation. Consistent with this, NETs formation was severely impaired in mouse neutrophils lacking both DOCK2 and DOCK5. Similar results were obtained when human neutrophils were treated with CPYPP, a small-molecule inhibitor of these DOCK GEFs. In addition, we recently identified a molecule that regulates ROS production and NETs formation, independently of Rac activation. Based on these findings, we will discuss the molecular mechanism controlling NETs formation.

370

Novel characterisation of mast cell phenotypes from peripheral blood mononuclear cells and identification of progenitor and activated mast cell phenotypes in chronic fatigue syndrome

Nguyen, T.^{1,2}, Johnston, S.^{1,2}, Chacko, A.^{1,2}, Gibson, D.², Cepen, J.², Smith, P.¹, Staines, D.¹

¹*Menzies Health Institute Queensland, National Centre for Neuroimmunology and Emerging Diseases, Parklands, Australia,*

²*Griffith University, School of Medical Science, Parklands, Australia*

Background: Mast cells (MCs) mediate inflammation through neuropeptides and cytokines, along with histamine and reactive oxygen species (ROS). The aim of this study was to determine

mast cell phenotypes in isolated PBMCs, in non-fatigued controls and CFS patients. The study further determined receptor expression of RAGE and its ligand high mobility group box 1 protein (HMGB1).

Methods: Twelve moderate CFS (aged 39.25±3.52 years), severe CFS patients (aged 43.00±4.02 years) and healthy controls (n=13, mean age 42.69 ± SD3.87 years) were included in this study. CFS patients were classified according to the 2011 International Consensus Criteria. LSRFortessa X-20 Flow cytometry was used for identification of phenotypic peripheral mast cells in PBMCs using exclusion marker Lin2 cocktail and inclusion markers following comparative investigation. HMGB1 and soluble RAGE (sRAGE) expression in plasma was measured by sandwich ELISA assay.

Results: There was a significant increase in CD117+CD34+FCeRI-chymase- mast cell populations in moderate and severe CFS compared with healthy controls. There was a significant increase in CD40 ligand and MHC-II receptors on differentiated mast cell populations in the severe CFS compared with healthy controls and moderate CFS. There were no significant differences for HMGB1 and sRAGE.

Conclusions: We report for the first time, significant increase of naïve MCs in moderate and severe CFS patients compared with healthy controls. Moreover, a significant increase was found in CD40 ligand and MHC-II receptors on differentiated mast cells in severe CFS patients. Peripheral MCs may be present in CFS pathology, however further investigation to determine their role is required.

371

Control of mast cell differentiation by neuropeptide galanin

Yamaguchi, T., Ikeda, Y., Kawabata, K.

National Institutes of Biomedical Innovation, Health and Nutrition, Laboratory of Stem Cell Regulation, Osaka, Japan

Mast cells play an important role in the pathogenesis of allergic diseases. Activated mast cells can secrete wide variety of mediators, such as histamine. They are generally classified into two phenotypically distinct populations: connective tissue-type mast cells (CTMCs) and mucosal-type mast cells (MMCs). However, the molecular basis determining the different characteristics of these mast cell subclasses remains unclear. At first, we studied the generation and characterization of CTMCs and MMCs derived from mouse bone marrow mast cells (BMMCs). The number of Safranin O-positive cells and the expression levels of MCP-4 mRNA were increased in the BMMC-derived CTMCs (BM-CTMCs) as compared with those in BMMCs. In addition, the expression of MCP-1 and MCP-2 was elevated in the BMMC-derived MMCs (BM-MMCs). These results showed that the BM-CTMCs and BM-MMCs had characteristics similar to CTMCs and MMCs. We also found that the expression of galanin receptor 2 was elevated in BM-MMCs as compared with that in BM-CTMCs. Next, we compared the expression of MCP mRNA levels in BMMCs by quantitative RT-PCR analysis, and found that galanin could induce the expression of MCP-1 and MCP2 mRNA and could reduce the expression of MCP-4 mRNA, showing that galanin could promote the differentiation of BM-MMCs and inhibit the differentiation of BM-CTMCs. Moreover, administration of galanin antagonist into mice decreased the

number of MMCs and prevented the DSS-induced colitis. These results suggest that galanin promotes the *in vivo* differentiation of MMCs. Our results provide important insights into the molecular mechanisms underlying the differentiation of mast cells.

372

Particulate matters activated inflammation-induced neutrophils

Miyake, T., He, C., Song, Y., Morita, K., Kanazawa, T., Yoshida, Y.
University of Occupational and Environmental Health,
Immunology and Parasitology, Kitakyushu, Japan

Epidemiological studies have shown the respiratory and cardiovascular effects of particulate matters (PMs). We previously demonstrated that PMs caused neutrophilic alveolitis and bronchitis; however, the effects of PMs on recruited neutrophils are not well understood. To characterize the response to PMs, the effects of different size particles on thioglycolate broth-induced neutrophils were investigated. Peritoneal exudate neutrophils from BALB/c mice, which were harvested 4 hour after the i.p. injection of 2ml of 4% thioglycolate broth were used for following experiments. Flow cytometric analysis shows most of collecting cells are CD11b+Gr1+ cells. It was observed that neutrophils phagocytosed FITC-labeled commercial particles (1 μ m, 3 μ m, and 10 μ m) with different sensitivity by fluorescence microscopy. ATP-based cell viability assay showed that PMs did not changed cellular ATP levels. Inflammatory cytokines such as tumor necrosis factor- α (TNF- α) and interleukin-6 (IL-6) production from LPS-activated neutrophils were elevated by PMs treatment. These results suggested that phagocytosed PMs activate inflammatory neutrophils.

Innate Receptors & Inflammasomes

Expression and function of IL-1R8 (TIR8/SIGIRR), a regulatory member of the IL-1 receptor family in platelets

Anselmo, A.¹, Riva, F.¹, Gentile, S.¹, Soldani, C.¹, Barbagallo, M.¹, Mazzon, C.¹, Feruglio, F.¹, Polentarutti, N.¹, Carullo, P.¹, Angelini, C.¹, Bacci, M.¹, Mendolicchio, G.L.¹, Voza, A.¹, Nebuloni, M.², Mantovani, A.¹, Garlanda, C.¹

¹Humanitas Clinical and Research Centre, Rozzano, Italy,

²University of Milan, Milan, Italy

IL-1R8, also known as single Ig IL-1-Related Receptor (SIGIRR) or TIR8, is a member of the IL-1R family that negatively regulates responses to IL-1R family members and TLRs. Here we report that IL-1R8 is expressed on human and murine platelets and megakaryocytes. Despite normal levels of circulating platelets IL1R8-deficient (*Il1r8*^{-/-}) mice showed increased homotypic and heterotypic (platelet-neutrophil) aggregation triggered by ADP and IL-1 or LPS. Moreover IL-1R8-deficient mice showed increased soluble P-selectin levels and increased platelet-neutrophil aggregates after systemic LPS administration. Commensal flora depletion and IL-1R1 deficiency abated platelet hyperactivity and the increased platelet/neutrophil aggregation observed in

Il1r8^{-/-} mice *in vitro* and *in vivo*, suggesting a key role of IL-1R8 in regulating platelet TLR and IL-1R1 function. In a mouse model of platelet-dependent pulmonary thromboembolism, IL-1R8-deficient mice showed an increased frequency of blood vessel complete obstruction.

Finally, in a small cohort of patients with severe systemic inflammatory conditions, the expression of platelet IL-1R8 was dramatically abated and it was associated to platelet-derived microparticle release.

Altogether our results highlight a new and efficient mechanism through which platelets, which have a large repertoire of TLRs and IL-1 receptors, regulate thrombocyte activity and identify IL-1R8 as a novel non-redundant player in tuning platelet activation during immunity and inflammation.

374

Contribution of MyD88 and protein kinase D1 to the pathogenesis of polyarthritis spontaneously occurring in IL-1R antagonist-deficient mice

⁵University of Tennessee Health Science Center, Medicine, Memphis, United States

It is thought that rheumatoid arthritis (RA) may be initiated in part by signaling through Toll-like receptors (TLRs) that contribute to the development of a self-perpetuating reaction leading to chronic inflammation and pathogenic auto-reactive Th1/Th17 development. IL-1R antagonist-deficient (*IL-1rn*^{-/-}) mice develop polyarthritis that mimics human RA. We investigated whether a TLR signaling adaptor MyD88 and its downstream protein kinase D1 (PKD1) play a role in the pathogenesis of arthritis in *IL-1rn*^{-/-} mice. Onset of arthritis was significantly delayed in *MyD88*^{-/-}*IL-1rn*^{-/-} mice compared to *MyD88*^{+/+}*IL-1rn*^{-/-} mice. Serum cytokine levels, and macrophage accumulation, matrix metalloproteinase activities and cartilage damage in joints were significantly lowered in *MyD88*^{-/-}*IL-1rn*^{-/-} mice, indicating a critical role for MyD88 in the development and progression of arthritis in *IL-1rn*^{-/-} mice. Because PKD1 is essential for proinflammatory responses mediated by MyD88-dependent TLRs and is hyperactivated in synoviocytes of RA patients, we further investigated the contribution of PKD1 to the development of arthritis in *IL-1rn*^{-/-} mice. Suppression of PKD1 expression *in vitro* resulted in inhibition of TLR-mediated cytokine production in *IL-1rn*^{-/-} macrophages. Daily treatment with a PKD inhibitor substantially reduced the incidence and severity of arthritis in *IL-1rn*^{-/-} mice. In addition, deletion of the PKD1 gene significantly delayed development of arthritis and reduced the severity of arthritis in *IL-1rn*^{-/-} mice. Our findings demonstrated that MyD88 and PKD1 are essential for development of arthritis in *IL-1rn*^{-/-} mice. This also implies that PKD1 might be one of the key factors that modulate proinflammatory responses in RA, and may serve as a therapeutic target.

375

Major role for NLRP3 inflammasome in colitis progression*Perera, A.P., Ranson, N., Sohal, S., Eri, R.**University of Tasmania, School of Health Sciences, Launceston, Australia*

Inflammatory bowel disease is a group of intestinal disorders characterised by inflammation of the small intestine and colon. IBD pathogenesis is very elusive and to investigate the main cause of IBD, a number of mouse models have been developed. Inflammasome complex formation involving the innate NLR family receptors, mainly NLRP3, has been extensively studied in mouse models. Inflammasome results in secretion of mature IL-1 β , a major pro-inflammatory cytokine involved in IBD. Unfortunately, the precise role of NLRP3 hasn't been defined due to contrasting results in mouse models. To address the controversial findings we have studied the role of NLRP3 in a well suited spontaneous model of colitis, namely Winnie. Winnie mice have a missense mutation in the MUC2 gene which results in a reduction of intestinal mucus production which is similar to that seen in human ulcerative colitis patients. We have generated Winnie mice that are deficient for NLRP3 which are not embryonically lethal. These mice will be assessed for clinical, histological and immunological parameters to understand the phenotype at 4, 8 and 16 weeks of age. We expect the differential phenotypical and functional expression triggered by the lack of NLRP3 in Winnie/NLRP3^{-/-} against Wild type and NLRP3^{-/-} controlled groups will show that NLRP3 ameliorates colitis. This study is the first to address the inflammatory role of NLRP3 in the Winnie/NLRP3^{-/-} mouse model. The findings will be important because they could lead to a potential target for the development of novel therapeutics for patients with colitis and colitis associated cancer.

376

Immunophenotyping of monocytes during human sepsis shows impairment of antigen-presentation, a shift towards non-classical differentiation and up-regulation of Fc-immunoglobulin receptor*Mota, N.V.F.¹, Brunialti, M.K.C.¹, Machado, F.R.², Assunção, M.³, Azevedo, L.C.P.⁴, Salomao, R.¹**¹Disciplina de Infectologia, Escola Paulista de Medicina, Hospital São Paulo, Universidade Federal de São Paulo - UNIFESP, Medicine, Sao Paulo, Brazil, ²Disciplina de Anestesiologia, Escola Paulista de Medicina, Hospital São Paulo, Universidade Federal de São Paulo - UNIFESP, Medicine, Sao Paulo, Brazil, ³Hospital Israelita Albert Einstein, Sao Paulo, Brazil, ⁴Hospital Sírio Libanês, Sao Paulo, Brazil*

Objective: We aimed to characterize the phenotype of monocytes from septic patients and their association with clinical outcomes.

Methods: Sixty one septic patients and thirty-one healthy volunteers (HV) were enrolled in the study. Samples were obtained from patients at admission (n=61), after 7 (n=36) and 14 days (n=22) of therapy. Cells were stained with the following antibodies: CD14-PerCP, CD163-PE, CD206-FITC, CD16-APC-Cy7, CD64-PE-Cy7, CD86-BV421, CD200R-FITC, PD1-BV510, PDL1-PE, CCR1-Alexa-Fluor-647, CCR2-Alexa-Fluor-647, CXCR2-PE-Cy5,

HLA-DR-PE-CF594. Isotypes or FMO controls were used. Results are expressed as percentage of positive cells or as geometric mean fluorescence intensity (GMFI).

Results: Monocytes from septic patients showed decreased expression of HLA-DR, CD86, CD200R, CXCR2 and CD163, compared to HV. CD206, CD64, PD-1 e PDL-1 expression was up-regulated in patients. Among the patients, expression of HLA-DR, CD86, CD64, PD-1 and PDL-1 was lower in non-survivors than in survivors. In follow-up samples, increased expression of CD86, HLA-DR and CXCR2 was observed after 7 and 14 days; CD16 GMFI decreased over time, resulting in an increase of CD16lo expression on day 14 samples; CD206 and CD163 were higher in admission samples than in follow-up ones.

Conclusion: Monocytes from septic patients shown impairment of antigen presentation as characterized by low HLA-DR, increased inhibitory PD-1 and PDL-1, and decreased co-stimulatory CD86. We found conflicting results regarding differentiation towards M2, with increased expression of CD206 and decreased CD163 on monocytes from septic patients, while the subset of non-classical monocytes was demonstrated by increased CD16hi. Co-stimulatory (CD86) and inhibitory receptors (PD1 and PDL1) were down-regulated in non-survivors.

377

Inflammasome-dependent IL-1 β release depends upon membrane permeabilisation*Diamond, C.E.^{1,2}, Bagnall, J.², Paszek, P.², Daniels, M.J.², Mortellaro, A.¹, Brough, D.²**¹SigN A*STAR, Singapore, Singapore, ²University of Manchester, Manchester, United Kingdom*

Interleukin-1 β (IL-1) is an essential mediator of inflammation after infection and injury. This proinflammatory cytokine is produced as an inactive precursor, which must be cleaved to its active form via a molecular complex called the inflammasome. IL-1 β is released from the cell via an unknown process, as it lacks the signal peptide required to be conventionally secreted. Several release processes have been proposed, including the use of secretory lysosomes, exosomes and the shedding of microvesicles from the plasma membrane. Until recently, research into this process has been limited by conventional biochemical methods only measuring population dynamics, yet evidence shows much heterogeneity among an immune cell population.

Using lentiviral transfection of a newly developed vector that codes for a fluorescently labeled version of IL-1 β (Venus-IL-1 β) into a bone marrow derived macrophage cell line, we have visualized IL-1 β release on a single cell level in real-time, with confocal microscopy. To simultaneously monitor membrane integrity we included the cell-impermeant nucleic acid stain propidium iodide (PI) in the cell culture medium. The addition of the inflammasome activator ATP caused a simultaneous drop in Venus-IL-1 β fluorescence and increase in PI fluorescence, revealing an intriguing insight into IL-1 β secretion; membrane permeability is required for release of IL-1 β . This process occurs alongside the death of the cell, but its regulation is separate from the non-specific release of proteins during cell death.

Unravelling the secrets of IL-1 β secretion offers key insights into the initiation of the inflammatory cascade and unconventional protein release.

378

Salt (sodium chloride) preferentially down-regulates IL-1 β production by gestation-associated tissues

Bryant, A., Scott, L.M., Radley, G., Chong, Y.Y., Jones, R.H., Thornton, C.

Institute of Life Science, Swansea University Medical School, Swansea, United Kingdom

Widespread westernization of diet has caused a rise in average salt (sodium chloride; NaCl) intake to levels well in excess of recommended physiological requirements. Due to the positive association of salt intake with blood pressure, pregnant women have been advised to follow a low salt diet to reduce the risk of developing pre-eclampsia. However, the evidence for this from clinical studies is inconclusive.

Here we examine the impact of altered NaCl levels on lipopolysaccharide (LPS) induced cytokine production by the placenta and choriodecidua. Term placenta and choriodecidua from elective sections were cultured in media supplemented with increasing concentrations of NaCl (10 - 50mM) \pm LPS (10ng/ml) and cytokine production examined. Additional media supplements used were sucrose, sodium gluconate (NaGlu), potassium chloride (KCl) and sodium bromide (NaBr) to determine if any effect of NaCl was mediated through changes in osmolarity, sodium or chloride levels.

A dose dependent decrease in LPS induced IL-1 β by both the placenta and choriodecidua was observed; there was no effect on TNF α and IL-10. The inhibitory effect of NaCl was replicated in both KCl and NaBr supplemented media, suggesting it was dependent on the increase in negative ions and not mediated by changes in sodium level or osmolarity.

The presence of elevated chloride/negative ions down-regulated the secretion of IL-1 β by gestational associated tissues suggesting possible effects of chloride and other anions on inflammasome activity by these tissues.

Different TLR ligands exhibit contrasting influences on the adhesive properties of human endothelial cells

du Mez, E.¹, Johnson, R.^{2,3}, Kho, D.^{2,3}, Moller-Olsen, C.¹, Feisst, V.^{1,4}, Locke, M.⁵, O'Carroll, S.^{2,6}, Graham, S.^{2,3}, Angel, C.^{1,4}

¹University of Auckland, School of Biological Sciences, Auckland, New Zealand, ²University of Auckland, Centre for Brain Research, School of Medical Sciences, Faculty of Medical and Health Sciences, Auckland, New Zealand, ³University of Auckland, Department of Pharmacology and Clinical Pharmacology, School of Medical Sciences, Faculty of Medical and Health Sciences, Auckland, New Zealand, ⁴University of Auckland, Maurice Wilkins Centre, Auckland, New Zealand, ⁵University of Auckland, Department of Surgery, South Auckland Clinical Campus, Middlemore Hospital, Auckland, New Zealand, ⁶University of Auckland, Department of Anatomy, School of Medical Sciences, Faculty of Medical and Health Sciences, Auckland, New Zealand

Toll-like receptors (TLR) are expressed by antigen presenting cells, which use TLRs to identify foreign pathogens in order to stimulate an appropriate immune response. Earlier studies however, have also detected TLR mRNA expression by human endothelial cell lines. These studies focussed on assessing changes in cytokine secretion in response to TLR ligands but they didn't establish whether TLR ligands influence the adhesive properties of endothelial cells. For the first time we demonstrate that different TLR ligands exhibit contrasting influences on endothelial adhesion.

Using multicolour immunohistochemistry we demonstrate that both blood endothelial cells (BECs) and lymphatic endothelial cells (LECs) express TLR7 and TLR9 protein *in situ* in human skin. Thereafter, we sought to determine whether ligands recognised by TLR7 and TLR9 influenced the adhesive properties of the human dermal microvascular endothelial cell line, HMEC-1. Initially using immunocytochemistry, we confirmed that HMEC-1 cells expressed TLR7 and TLR9 protein. Subsequent experiments using xCELLigence technology demonstrated that different TLR7 (R837, R848 and CLO75) and TLR9 (ODN2006, ODN2216 and ODN2395) ligands displayed contrasting effects on the temporal basolateral adhesive properties of HMEC-1 cells. The trans-endothelial electrical resistance of cell:cell junctions was also measured using ECIS technology following TLR stimulation to assess effects on barrier integrity. These data showed that all three TLR7 ligands increased cell:cell adhesion, in contrast to the decreased adhesion observed with TLR9 ligands.

By establishing how the endothelial barrier is influenced by different TLR ligands we may be able to identify novel therapeutic applications for synthetic TLR ligands.

IL-1R8 deficiency increases the susceptibility of LPR mice to develop B-cell lymphoma

Riva, F.¹, Ponzone, M.², Polentarutti, N.³, Bertilaccio, S.², Anselmo, A.³, Feruglio, F.⁴, Innocenzi, A.², Veliz-Rodriguez, T.², Simonetti, G.², Muzio, M.², Mantovani, A.³, Garlanda, C.³

¹University of Milan, DIVET, Milan, Italy, ²San Raffaele Hospital, Milan, Italy, ³Istituto Clinico Humanitas, Rozzano (Milano), Italy, ⁴Charles River, Calco, Italy

The association among autoimmunity, chronic inflammation and malignancy has been described and confirmed by epidemiological studies. In particular, patients suffering from autoimmune diseases are prone to develop B-cell Non-Hodgkin's Lymphomas, but the mechanisms triggering the transition from benign B-cell proliferation to malignancy are still poorly understood. We investigated the role of IL-1R8 gene (also known as SIGIRR or TIR8), already known to be associated with autoimmunity, in the development of lymphoma. Indeed, the ability to dampen signalling from IL-1R and TLR family members confers IL-1R8 the ability to act as regulator of inflammation, cancer-related inflammation and autoimmunity. In this study we describe the occurrence of malignant lymphoma in B6lpr/lpr/il-1r8 $^{-/-}$ and B6lpr/lpr mice. Both strains developed a B-cell lymphoma during their late age, but in B6lpr/lpr/il-1r8 $^{-/-}$ mice, it occurred with higher frequency and earlier, and was more aggressive, causing higher mortality. Histopathologic

analysis of spleen and lymph nodes of B6lpr/lpr/il-1r8-/- mice documented clear-cut Diffuse Large B-cell lymphoma (DLBCL) areas arising within a context of atypical lymphoproliferative disorder. These results were corroborated by both molecular analysis and transplantation experiments. Clonal rearrangement was present in both strains, however, only recipients of spleen or lymph node cells collected from B6lpr/lpr/il-1r8-/- mice developed DLBCL. In human, IL-1R8 expression was down-modulated in different lymphoma cell lines, compared to healthy B cells. These observations unveil the involvement of IL-1R8 in the occurrence and development of DLBCL, suggesting its potential role in targeted therapy. In addition, we propose B6lpr/lpr/il-1r8-/- mice as a novel model of autoimmunity-associated B cell lymphomas.

381

Phosphorylated tyrosine kinase Syk interacts with ESCRT-0 upon TLR3 activation in murine C8D1A microglial cells

Toka, F.^{1,2}, Mielcarska, M.B.², Bossowska, M.², Gregorczyk, K.P.², Wyzewski, Z.²

¹Ross University School of Veterinary Medicine, Biomedical Sciences, Basseterre, Saint Kitts and Nevis, ²Warsaw University of Life Sciences-SGGW, Preclinical Sciences, Warsaw, Poland

Toll-like receptor 3 (TLR3), found in endosomes, identifies the double-stranded ribonucleic acid (dsRNA), an intermediary during replication of many viruses. TLR3 is expressed in the cells of the central nervous system (CNS), where it serves to control infections of herpesviruses (HSV-1 or HSV-2). Humans or animals with deficiencies in TLR3 signalling are highly susceptible to these infections, hence a justified endeavor to investigate immunological mechanisms behind TLR3 mobility and regulation in the CNS. Our study, conducted on murine C8D1A microglial cell line, shows that following cell stimulation with poly(I:C) (polyinosinic-polycytidylic acid, dsRNA mimetic) tyrosine kinase Syk is immediately phosphorylated. The purpose of activity of Syk kinase is Hrs (*Hepatocyte growth factor*-regulated tyrosine kinase substrate), a component of the ESCRT-0 protein complex (Endosomal sorting complex required for transport-0). ESCRT plays a role in protein trafficking to multi-vesicular bodies and lysosomal compartments. Our findings indicate the existence of interaction between ESCRT-0 and TLR3, after receptor stimulation. Establishment of Syk as an important mediator between TLR3 and ESCRT-0 in the TLR3 signalling pathway in microglial cells after stimulation with poly(I:C) may indicate that TLR3 mobility, en route to the endosomes, is regulated by ESCRT-0. Although recent studies have shown that ESCRT pathway plays an important role in TLR7 and TLR9 sorting and recycling, molecular mechanisms which govern TLR3 allocation and TLR3-mediated elicitation of antiviral innate immune response in cells of the CNS remain weakly understood and require further investigation.

382

Cow's milk hydrolysates modulate Toll-like receptor-mediated activation

Kiewiet, M.B.G.¹, Dekkers, R.², Gros, M.², van Neerven, J.², de Vos, P.¹, Faas, M.M.¹

¹University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands, ²FrieslandCampina, Amersfoort, Netherlands

Hydrolyzed cow's milk proteins are thought to elicit effects on the innate and adaptive immune system. Recently, Toll-like receptors (TLRs) have been suggested to be involved in the underlying mechanism of these effects. Therefore, we studied the TLR activation and inhibition capacity of a range of whey and casein hydrolysates.

To screen for immunomodulatory effects, we isolated peripheral blood mononuclear cells (PBMC's) from healthy volunteers and stimulated them with whey, casein and their hydrolysates. Cytokine production was measured by Luminex. Moreover, hydrolysate induced TLR dependent signaling was assessed by incubating the THP-1-XBlue-MD2-CD14 and the THP-1-XBlue-MyD88 deficient reporter cellline (Invitrogen) with the hydrolysates. Individual TLRs were studied using HEK-Blue hTLR reporter cells (Invitrogen). All cells were stimulated with 2 mg/ml hydrolysate for 24 hours.

Stimulation of PBMCs showed that whey and several of the whey hydrolysates induced both IL-10 and TNF α cytokine production, while casein hydrolysates had no effect. Whey hydrolysates with different levels of hydrolysis (between 3.1 and 15%) increased TLR2,3,5 and 9 ($p < 0.05$) activation, while casein hydrolysates did not have an effect on TLR activation. On the other hand, casein and casein hydrolysates inhibited ligand-induced activation of TLRs (mostly TLR 5 and 9) up to 69% ($p < 0.05$), while whey hydrolysates did not.

Overall, we found that generally whey hydrolysates induced cytokine production and TLR activation, while casein hydrolysates did not induce cytokine production and generally showed TLR inhibition. This knowledge could contribute to a better understanding of the immunomodulatory effects of hydrolysates.

383

The role of dysregulated TLR signaling in lung tumorigenesis

Yap, G.^{1,2,3}, Lim, L.^{1,3}

¹National University of Singapore, Physiology, Singapore, Singapore, ²NUS Graduate School for Integrative Sciences and Engineering, Singapore, Singapore, ³National University of Singapore, Inflammation and Cancer Laboratory, Immunology Programme, Singapore, Singapore

Toll-like receptors (TLRs) form a part of the larger family of pattern recognition receptors (PRRs), and they play an important protective role in innate immunity. Found on immune cells, TLRs recognize and bind to a wide array of conserved microbial structures called pathogen associated molecular patterns (PAMPs) that will result in the triggering of anti-microbial and anti-viral responses. Recently however, TLRs have been found

on various cancer cells and are furthermore discovered to be functional. In this study, TLR signaling in lung cancer cells and its role in viral-induced tumorigenesis were investigated. Basal expression levels of TLRs were determined using real time PCR and different lung cancer cell lines showed varying levels of TLRs. Activation of certain TLRs signaling pathway via specific TLR agonists showed a possible role of dysregulated TLRs signaling in lung tumorigenesis. As expected, the level of TLRs present in the cell is able to influence the extent of which the cell responds to TLR agonists' treatment. Only H460 cell line which has highest expression of TLR3, showed a decrease in cell viability upon treatment with transfected poly (I:C). Other TLR agonists showed no significant effect on cell viability upon treatment. TLR3 activation in H460 led to a decrease in NfκB promoter activity, thus suggesting a possible signaling pathway. This study deepens our understanding of the role of TLRs in lung tumorigenesis. The role of ANXA1 in dysregulated TLR signaling was also investigated.

The miR-20a-5p regulates M.tb-induced cell apoptosis through targeting JNK2 in human macrophage

Zhang, G.^{1,2}, Liu, X.³, Wang, W.², Zhang, M.², Zeng, G.⁴, Zhou, B.², Feng, C.G.¹, Chen, X.²

¹The University of Sydney, Infectious Diseases and Immunology, Sydney, Australia, ²Shenzhen Third People's Hospital, Guangdong Key Lab of Emerging Infectious Diseases, Shenzhen, China, ³Sun Yat-sen University, The Fifth Affiliated Hospital, Zhuhai, China, ⁴Sun Yat-sen University, Zhongshan School of Medicine, Guangzhou, China

Depends on the cell death pathway, macrophage could be either beneficial or detrimental to Mycobacterium tuberculosis (Mtb) inside the cell. To facilitate its survival and dissemination, Mtb has developed strategies to promote cell death via necrosis, which avoid through apoptosis. However, the mechanisms underlying these strategies remain to be elucidated. MicroRNAs (miRNAs) are small non-coding RNAs that function in various cellular processes such as differentiation, proliferation, and apoptosis through post-transcriptional regulating target gene expression. In this study, we focused on the potential role of miR-20a, which has been reported to promote gastric cancer cell proliferation and inhibit cell apoptosis, in regulating the cell death pathway of human macrophage. Our findings have demonstrated that Mtb infection significantly inhibited miR-20a-5p expression in monocytes and macrophage. In consistence, miR-20a-5p expression was significantly decreased in the plasma, the whole blood, and CD14 monocytes of active pulmonary TB patients ($P < 0.01$). Functional assay demonstrated that inhibition of miR-20a-5p expression significantly increased apoptosis of Mtb infected macrophage, which is corroborated with that over-expression of miR-20a-5p significantly reduced apoptosis. Mechanism study indicated that miR-20a-5p modulates the expression of BCL2 and BIM expression through directly targeting JNK pathway. Thus, our results uncover a novel regulation of innate immune response during mycobacterial infection, dependent on the down-regulation of miR-20a-5p to promote macrophage apoptosis in attempt to facilitate Mtb clearance.

NLRX1 attenuates damage following traumatic brain injury through negatively regulating NF-κB signaling

Allen, L.¹, Meza, A.¹, Brickler, T.¹, Coutermarsh-Ott, S.¹, Ives, A.¹, Bertke, A.², Theus, M.¹

¹Virginia Tech, Department of Biomedical Sciences and Pathobiology, Blacksburg, United States, ²Virginia Tech, Department of Population Health Sciences, Blacksburg, United States

Mechanical trauma to the CNS results in the disruption of the cellular microenvironment leading to massive necrotic and apoptotic loss of neuronal and glia populations. The progressive cascade of secondary events, including ischemia, inflammation, excitotoxicity and free radical release contribute to neural tissue damage. Members of the NLR family of pattern recognition receptors are essential mediators of the host immune response. Recently, our lab and others identified a novel sub-group of NLRs that function as negative regulators of inflammation. One of the members of this sub-group, NLRX1, is a potent regulator of interferon, NF-κB and autophagy signaling. Thus, we hypothesized that NLRX1 attenuates Traumatic Brain Injury (TBI) through the negative regulation of overzealous innate immune system signaling. To evaluate this hypothesis, we utilized *Nlr1^{-/-}* mice in a controlled cortical impact (CCI) injury model. The *Nlr1^{-/-}* mice exhibited significantly larger brain lesions and increased motor deficits following CCI injury. We also observed significant proliferation of microglia within the *Nlr1^{-/-}* lesions compared to wild type animals. Mechanistically, our data indicates that NLRX1 attenuates TBI progression through the microglia compartment via negative regulation of NF-κB signaling and IL-6 production. Together, our data extends the function of NLRX1 beyond its currently characterized role in host-pathogen defense and identifies this highly novel NLR as a significant modulator of TBI progression.

386

Mal D96N provides new insights into TLR induced signal transduction and inflammation independent of MyD88

Dowling, J., Tate, M.E., Bourke, N.M., Lauterbach, M.A., Golenbock, D.E., Mansell, A.

Hudson Institute of Medical Research, Center for Innate Immunity and Infectious Disease, Melbourne, Australia

Mal is a critical adaptor in TLR2 and TLR4 induced inflammation, facilitating recruitment of MyD88 to these TLRs and is often regarded as a 'bridging' adaptor. However, recent studies have identified roles for Mal in IFNγR and TLR9 signaling. It is the most polymorphic of TLR adaptors, where one single nucleotide polymorphism (SNP), D96N is protective by reducing inflammatory responses demonstrating the critical role Mal plays in modulating the strength of immune responses. We have generated mice expressing this SNP, (MalD96N). BMDMs from D96N mice display reduced inflammatory responses to lipopolysaccharide, LPS (TLR4), producing significantly less IL-6, TNFα, delayed MAP kinase activation and transactivation of NF-κBp65. Critically, MalD96N mice are protected from LPS-induced lethality. Reduced levels of IL-6, TNFα, IL-1β and MCP-1

were also detected in serum following challenge. Latest work describes a role for Mal in maintaining integrity of the intestinal barrier in the non-hematopoietic compartment during infection to *S. typhimurium*, suggesting functions of Mal independent of its 'bridging' role in TLR signaling. While functional studies have been conducted in innate cells there is increasing awareness of the importance between the epithelial barrier and innate immunity during infection. We found that MalD96N gastric epithelial cells, but not BMDMs, display enhanced *S. typhimurium* uptake and MalD96N intestines express substantially reduced Claudin-3, ZO-1 and occludin mRNA compared to WT. Future work aims to clarify results by examining *S. typhimurium* infection in WT, MalD96N and Mal-/- mice. These studies will help elucidate roles for Mal in TLR-signaling and inflammation independent of MyD88.

Membrane-bound lactoferrin modulates the function of human polymorphonuclear leukocytes partially through TLR-4

Hu, X.M., Xu, Y.R., Dong, H.L., Wang, J., Gao, X.M.
Institutes of Biology and Medical Sciences, Soochow University, Suzhou, China

Lactoferrin (LTF) is a soluble iron-binding glycoprotein of the transferrin family mainly present in mammalian body fluids. Soluble LTF is a versatile molecule that not only regulates the iron homeostasis, but also harbors direct microbicidal and immune-modulating abilities. In contrast, little is known about the function of membrane-bound LTF (mLTF), although its expression on human polymorphonuclear leukocytes (huPMNs) has been reported for decades. Given that LTF/anti-LTF antibodies represent a potential diagnostic/prognostic biomarker and a therapeutic target in patients with various immune disorders, we wished, in the present study, to generate a novel human LTF (huLTF)-specific monoclonal antibody (mAb) suitable for detailed analyses on the expression and function of mLTF. By using the traditional hybridoma cell fusion technology, we obtained a murine IgG1(kappa) mAb, M-860, against huLTF. M-860 is highly efficient in binding to natural huLTF in ELISA, but exhibits no recognition of natural bovine/murine LTF and denatured huLTF in ELISA & Western blot. Moreover, M-860 detects mLTF by FACS and captures endogenous huLTF in total cell lysates of huPMNs. Functionally, M-860 is capable of inducing the activation of huPMNs, which is independent of phagocytosis but signals partially through TLR-4. These data indicate that mLTF serves as a surface receptor on huPMNs, and, upon binding to its ligand like M-860, is capable of modulating the function of huPMNs partially through TLR-4. Thus, detailed analyses on the expression and function of mLTF will further our understandings on the role of LTF in health and disease.

388

ATP stimulated P2X7R enhances IL-1 β secretion during *Neisseria gonorrhoeae* infection through a NLRP-3 inflammasome independent pathway

Garcia, K.¹, Ortiz, C.¹, Escobar, G.¹, Mendoza, P.¹, Beltran, C.², Vernal, R.¹, Escobar, A.¹

¹University of Chile, Faculty of Dentistry, Santiago, Chile, ²University of Chile, Faculty of Medicine, Santiago, Chile

Background: *Neisseria gonorrhoeae* (Ngo) is the etiological agent of the sexually transmitted disease gonorrhea. This Gram-negative bacterium has developed multiple immune evasion mechanisms involving the innate and adaptive immune responses. Recent findings have reported that P9-17 Ngo strain can reduce the IL-1 β levels present in culture supernatants of induced human monocyte-derived-macrophages (MDMs). In addition, current data strongly suggest that P2X7 Receptor (P2X7R) is a major component in NLRP3 inflammasome stimulation and subsequent IL-1 β maturation.

Objectives: To analyze the role of ATP-stimulated P2X7R in the IL-1 β maturation pathway in Ngo-infected MDMs.

Methods: Human MDMs were infected with P9-17 Ngo strain (MOI=100) and then stimulated with ATP 5 mM. The secreted levels of IL-1 β were quantified by ELISA. To determine if any NLRP3 inflammasome component was affected by stimulation with ATP, the expression of NLRP3, ASC, and Caspase-1 were assessed by qRT-PCR. In addition, the mature form of IL-1 β was intracellularly detected by immunofluorescence and active Caspase-1 levels were quantified by flow cytometry.

Results: ATP stimulation of P2X7R enhances the secretion of IL-1 β in Ngo-infected MDMs and modifies the NLRP3 expression; however, it does not affect Caspase-1 expression and activity. In addition, in Ngo-infected MDMs, an increment in the cytoplasmic levels of mature form of IL-1 β was detected; however, it was not detected culture supernatants.

Conclusions: ATP and P2X7R have a role in the enhanced secretion of IL-1 β in Ngo-infected MDMs by a Caspase-1 independent pathway. Therefore, the P2X7/IL-1 β secretion pathway could play a role in the pathogenesis of gonorrhea.

389

Effect of damps in inflammasome generation in monocytes from pregnant women with preeclampsia

Romao-Veiga, M., Matias, M.L., Rocha Ribeiro, V., Rezeck Nunes, P., Medeiros Borges, V.T., Araujo Jr, J.P., Peracoli, J.C., Serrao Peracoli, M.T.
Sao Paulo State University, Botucatu, Brazil

Preeclampsia (PE) is considered as a major cause of maternal and fetal morbidity and mortality. Plasma of preeclamptic women has elevated levels of molecular structures associated with stress and cell death which can bind to receptors of innate immunity cells and activate an intracellular complex called inflammasome. This study investigated the state of activation both endogenous and induced by Hyaluronan (HA) and monosodium urate (MSU) in monocytes of these patients. Peripheral blood was obtained from 20 preeclamptic (PE), 20 normotensive (NT) pregnant women and 20 non-pregnant (NP) women. Plasma was employed to determine the concentration of HA, uric acid and HMGB1.

Peripheral blood monocytes were separated and cultured with or without HA or MSU. Inflammasome activation was evaluated by RT-qPCR and determined by ELISA. Plasma levels of HA, uric acid and HMGB1 were increased in PE group than in the other groups. In PE group HA stimulation led to an increase in mRNA of NLRP1, NLRP3, caspase-1, IL-1beta, TNF-alpha and HMGB1. All groups studied had IL-1beta increased protein levels detected by ELISA. MSU stimulation increased NLRP3, caspase-1, IL-18, TNF-alpha and HMGB1 mRNA expression in PE and NP groups, and higher protein levels of IL-18 and TNF-alpha in PE group. The endogenous up-regulation of NLRP1, NLRP3, caspase-1, IL-1beta and TNF-alpha mRNA expression in monocytes confirms the activated profile of these cells in PE. NLRP3, caspase-1 and HMGB1 activation by HA and MSU suggest the participation of these DAMPs in the inflammatory process in the pathogenesis of preeclampsia.

390

Inflammasomes and intestinal inflammation

Ranson, N.¹, Mitchell, B.², Fanning, S.², Kunde, D.¹, Eri, R.¹

¹University of Tasmania, Launceston, Australia, ²Launceston General Hospital, Launceston, Australia

Background and aims: Inappropriate innate immune responses to invading bacteria and cellular stress contribute to disease development in inflammatory bowel disease (IBD). A key initiating event in the host's immune response is thought to be the activation of the inflammasome complex which enhances the maturation of interleukin (IL)-1 β and IL-18 by providing a signalling platform for the activation of caspase-1. Mice studies have contributed to the overall understanding of inflammasomes, however many have been overshadowed by controversy and others lack consistency. Given the limited number of human inflammasome studies the overall aim of this study was to investigate the expression of different inflammasome complexes in IBD.

Methods: qRT-PCR was performed on inflamed and non-inflamed colon biopsies from 44 ulcerative colitis (UC) patients, 21 Crohn's disease (CD) patients and non-IBD controls from a Tasmanian cohort. The cellular localisation of inflammasomes was determined using immunohistochemistry, immunofluorescence and confocal imagery performed on paraffin embedded sections from inflamed tissue. Targeted RNA sequencing of inflammatory genes was used to identify potential candidate SNPs.

Results: This study describes the gene expression and cellular localisation of inflammasomes in human IBD. Results indicate different expression profiles and localisation of key inflammasome complexes in UC and CD. This study also highlights the possibility of an inflammasome biomarker for distinguishing disease phenotypes.

Significance: Despite conventional treatment may IBD patients still experience active disease therefore targeting specific inflammasomes to reduce IL-1 β levels may represent a more effective treatment option.

391

Early endosome autoantigen 1 controls unconventional caspase-1 release after NLRP3 inflammasome activation

Baroja-Mazo, A.¹, Compan, V.², Pelegrín, P.¹

¹Murcia's Biomedical Research Institute (IMIB-Arrixaca), Murcia, Spain, ²Université de Montpellier, Montpellier, France

Caspase-1 is a protease that controls the release of different leaderless proteins, including its own release. Caspase-1 secretome comprises the well studied pro-inflammatory cytokines IL-1b and IL-18, and the alarmin HMGB1. However, little is known about the unconventional release pathway for caspase-1. The release of IL-1b includes microvesicle shedding, lysosomal release and exosome budding. Although endosomal compartments have been suggested to play a role in unconventional protein secretion, IL-1b failed to co-localize with endosome markers, such as early endosome antigen 1 (EEA1), and pro-IL-1b processing by caspase-1 in macrophages has been found to be a cytosolic event that precedes its release. Here we found that activation of the NLRP3 inflammasome in macrophages, mature caspase-1 traffics close to endosomes where it cleaves the endosomal docking protein EEA1. Activation of NLRP3 inflammasome by different means resulted in the processing and release of EEA1. Pharmacological or genetic inhibition of caspase-1 activation abolished the processing and release of EEA1. EEA1 knock-down resulted in a decrease of caspase-1 and IL-1b release after NLRP3 inflammasome activation, but do not affect the release of NLRP3 and ASC particles from macrophages. Our data suggest that the cleavage of the endosome docking protein EEA1 by caspase-1 could affect endosome fusion to form giant endosomes and allow endosomes to fuse with the plasma membrane. This could be a protection mechanism to maintain the integrity of the plasma membrane and preserve cell viability after inflammasome-activation. This caspase-1 dependent mechanism could be used as a release pathway for different cytosolic proteins.

392

NLRP3-independent caspase-8 activation is involved in IL-1 β release induced by melittin

Martín-Sánchez, F.¹, Martínez-García, J.J.¹, Rivas, L.², Pelegrín, P.¹

¹Murcia's Biomedical Research Institute (IMIB-Arrixaca), Murcia, Spain, ²Centro de Investigaciones Biológicas CSIC, Madrid, Spain

Melittin, the main component of bee venom, is a cytolytic molecule reported to be able to induce NLRP3 inflammasome activation in macrophages. In addition, previous studies have shown that bee venom induces apoptosis through caspase-8/caspase-3 pathway activation. However, the molecular mechanisms for this inflammasome activation remain poorly understood. Recently, caspase-8 has been suggested to participate in processing and release of IL-1 β , meanwhile caspase-3 has been involved in IL-18 degradation. The aim of this study was to understand the molecular cascades by which melittin induce pro-inflammatory cytokine release. We found that melittin induces classical NLRP3 inflammasome activation by potassium depletion, leading to the formation of ASC specks, caspase-1 activation and IL-1 β maturation and secretion, but

interestingly not IL-18. However, the use of NLRP3, ASC or caspase-1 knock-out BMDMs reduced, but not completely abolished IL-1 β release by melittin, being approximately 30% of IL-1 β released independent of inflammasome and caspase-1. In addition, as expected, caspase-8/caspase-3 pathway was induced by melittin in macrophages, this activation was independent on caspase-1. Inhibition of caspase-8 was able to reduce approximately 30% of the IL-1 β secretion induced by melittin. In addition, caspase-8 inhibition blocked caspase-3 activity leading to an increase in IL-18 secretion. These results suggest that melittin induces IL-1 β processing and secretion mainly via the classical NLRP3/caspase-1 inflammasome pathway, but also by a caspase-8-dependent but NLRP3-independent pathway. In addition, caspase-8 activating caspase-3 appears implicated in degradation of IL-18 and could explain the lack of IL-18 release induced by melittin.

393

Engagement of functional cGAS-STING signalling in immortalized SV40 mouse embryonic fibroblasts

Pépin, G.¹, Ferrand, J.¹, Nejad, C.¹, Hornung, V.², Gantier, M.¹

¹Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia, ²Ludwig-Maximilians University, Gene Center and Department of Biochemistry, Munich, Germany

Cyclic guanosine monophosphate-adenosine monophosphate synthase (cGAS) is a key detector of cytoplasmic DNA, which can activate the adaptor protein STING to induce a broad antiviral program in mammalian cells. Recently, several viral oncogenes such as the large T antigen of simian virus 40 (SV40), have been proposed to antagonise the cGAS-STING pathway in response to transfected foreign DNA. However, it is not clear if this potential effect of viral oncogenes is applicable to other cGAS substrates. In this report, we show that endogenous DNA damage by-products can activate a functional cGAS-STING response in SV40-immortalized mouse embryonic fibroblasts (MEFs). This activation leads to increased expression of many interferon-stimulated genes, resulting in a strong antiviral protection against Semliki Forest Virus infection in a STING-dependent manner. Collectively, these results establish that SV40 immortalized MEFs retain a functional cGAS-STING pathway and that they could be used as a useful tool in immunological studies investigating this pathway.

394

Deubiquitinating enzyme USP50 is a critical regulator for NLRP3 inflammasome activation

Lee, J.Y., Park, S.H.

Sungkyunkwan University, Biological Sciences, Suwon, Korea, Republic of

NLRP3 is an important component of the inflammasome-mediated immune response that promotes Caspase-1-dependent production of interleukin 1beta (IL-1beta). Its signaling pathway requires the recruitment of adaptor protein ASC after recognition of danger signals. Although NLRP3-mediated inflammasome

signaling pathway is extensively studied in a number of groups, the post-translational modifications regarding the components of NLRP3 signaling pathway such as NLRP3 and ASC remains unclear. In this study, we performed RNAi-based screening in human THP1 cells by using human deubiquitinating enzyme (DUB) siRNA library to identify specific DUBs involved in the regulation of NLRP3 inflammasome activation. Through these systematic approaches, we finally identified USP50 promoting the deubiquitination of the adaptor ASC protein. USP50 specifically bound to ASC and deubiquitinated the K63-linked polyubiquitination of ASC. USP50-knockdown THP1 cells showed the decreased activation of Caspase-1 and subsequently the reduced expression of IL-1beta after stimulation with alum crystals or nigericin. Therefore, our results for the first time demonstrate the underlying molecular mechanism that USP50 is a crucial regulator for NLRP3-mediated inflammasome signaling pathway through deubiquitinating the adaptor ASC protein.

395

TLR10 as an innate receptor

Lee, S.M., Yan, S., Yip, T., Li, S., Ip, K., Peiris, J.

The University of Hong Kong, HKU-Pasteur Research Pole and Centre of Influenza Research, Hong Kong, Hong Kong

Among the ten members of toll-like receptors (TLRs) in human, TLR10 remains an orphan receptor without known agonist and function. Since its discovery, multiple attempts have been tried to investigate its function, mechanism of activation or the signaling pathway. However, despite the correlation observed between the induction of TLR10 and viral or bacterial infection, its exact function in innate immune aspect remains unclear. In this study, we aim to identify the potential TLR10 ligand and characterize its associated adaptor protein(s) or signaling molecule(s) upon activation. We revealed that TLR10 physically bound dsRNA in vitro, whilst such binding was favorable at a pH condition similar to that within endosomes. Myeloid differentiation primary response gene 88 (MyD88) was recruited to activate TLR10 for signal transduction which led to interferon regulatory factor (IRF)-7 regulated interferon (IFN) expression. Our result demonstrates that TLR10 is a novel innate receptor which could sense dsRNA within endosomes and subsequently recruit MyD88 to regulate IFN expression mediated via IRF7.

396

Modulating innate immune responses to biomaterial-induced inflammation

Christo, S.¹, Diener, K.^{1,2}, Manavis, J.³, Grimbaldston, M.⁴, Bachhuka, A.⁵, Vasilev, K.⁵, Hayball, J.^{1,2,6}

¹University of South Australia, Adelaide, Australia, ²University of Adelaide, Adelaide, Australia, ³SA Pathology, Adelaide, Australia, ⁴Centre for Cancer Biology, University of South Australia and SA Pathology, Adelaide, Australia, ⁵Mawson Institute, Adelaide, Australia, ⁶University of Adelaide, School of Medicine, Adelaide, Australia

Detailing the inflammatory mechanisms of biomaterial-implant induced foreign body responses (FBR) has implications for

revealing targetable pathways that may reduce leukocyte activation and fibrotic encapsulation of the implant. We have adapted a model of poly(methylmethacrylate) (PMMA) bead injection to perform an assessment of the mechanistic role of the ASC-dependent inflammasome in this process. We first demonstrate that ASC^{-/-} mice subjected to PMMA bead injections had reduced cell infiltration and altered collagen deposition, suggesting a role for the inflammasome in the FBR. We next investigated the NLRP3 and AIM2 sensors because of their known contributions in recognising damaged and apoptotic cells. We found that NLRP3 was dispensable for the fibrotic encapsulation; however AIM2 expression influenced leukocyte infiltration and controlled collagen deposition, suggesting a previously unexplored link between AIM2 and biomaterial-induced FBR.

397

Linking MIF and NLRP3 in the pathogenesis of IL-1 dependent inflammatory disorders

Lang, T., Lee, J., Fan, H., Cheng, Q., Morand, E., Harris, J. Monash University, Lupus Research Group, Centre for Inflammatory Diseases, Clayton, Australia

Introduction: Macrophage migration inhibitory factor (MIF) is a pluripotent pro-inflammatory factor that acts as a mediator of innate immunity and is implicated in the pathogenesis of a number of autoinflammatory disorders, including Gout. Levels of serum MIF correlate with disease outcomes and clinical studies have shown correlations between elevated levels of IL-1 β and MIF in serum of patients with autoimmune disorders. To date, it is unclear whether MIF specifically regulates the expression and secretion of IL-1 family cytokines.

Methods and results: We inhibited MIF in murine bone marrow-derived macrophages using the small molecule inhibitor, COR123625. We show that depletion of MIF in macrophages significantly reduced IL-1 cytokine family release in response to NLRP3-activating stimuli, but has no effect on the secretion of TNF- α , IL-6 and MCP-1 (CCL2). Moreover, diminished IL-1 responses were independent of NF- κ B function and production of pro-IL-1 β . Instead, MIF depletion specifically inhibits NLRP3-mediated responses as IL-1 cytokine secretion was unaffected following activation of the AIM2 or NLRC4 inflammasomes.

Conclusions: Our findings reveal a novel role for MIF in the modulation of IL-1-dependent inflammatory responses, linking MIF directly to NLRP3 inflammasome activation. This study for the first time implicates a specific role for MIF in the release of IL-1 family cytokines and highlights the potential of targeting MIF in IL-1-dependent pathologies.

398

Involvement of NLRP3 inflammasome in *P. gingivalis*-accelerated atherosclerosis and periodontal disease

Kurita-Ochiai, T.¹, Yamaguchi, Y.², Kobayashi, R.¹, Ando, T.²

¹Nihon University School of Dentistry at Matsudo, Matsudo, Japan,

²Tokyo Women's Medical University, Shinjuku, Japan

Periodontal pathogen, *Porphyromonas gingivalis* (*P. g*) has

been shown to accelerate atherosclerotic lesion development in hyperlipidemic animals. We examined a possible association between the inflammasome in atherosclerosis induced by *P. g* infection using Apolipoprotein E deficient spontaneously hyperlipidemic (ApoE^{sh}) mice, and further investigated the effect of NLRP3 deficiency on vascular inflammation and bone loss. Mice were orally infected with *P. g* 33277 (wild type, WT), KDP136 (gingipain-nell mutant), KDP150 (FimA-deficient mutant) 5 times a week for 3 weeks and sacrificed at 18 weeks. Bacteria were detected two days after final infection from each organ. Furthermore, alveolar bone loss, lesion area in the proximal aorta, IL-1 β , IL-18, and TNF- α secretion in peritoneal macrophage, and gene expression of NLRP3, pro-IL-1 β , pro-IL-18, pro-caspase-1 in the gingival tissue and aorta was measured. Oral infection with *P. g* WT significantly increased alveolar bone loss, lesion area of aortic sinus covered with atherosclerotic plaque. IL-1 β , IL-18, and TNF- α production in peritoneal macrophage, gingival or aortic gene expression of NLRP3, pro-IL-1 β , pro-IL-18, and pro-caspase-1 compared with KDP136 or KDP150 challenge. *P. g* genomic DNA was detected in the aorta, gingival tissue, liver, and spleen of WT-challenged-mice not of KDP136- or KDP150-challenged mice. Furthermore, WT-induced expression of pro-IL-1 β and pro-IL-18 mRNA in gingival tissue and aorta were significantly decreased in NLRP3-knockout mice. These results indicate that NLRP3 inflammasome, followed by a response from the IL-1 family, may play a critical role in periodontal disease and atherosclerosis induced by *P. g* challenge through sustained inflammation.

399

Dual action of the cytosolic viral sensor MDA-5 in tumor killing and immune modulation triggers type I interferon-dependent antitumor immunity

Wang, X.-Y.(^{1,2}), Yu, X.¹

¹Virginia Commonwealth University School of Medicine, Human and Molecular Genetics, Richmond, United States, ²Massey Cancer Center, Richmond, United States

Melanoma differentiation-associated gene 5 (MDA-5/IFIH1) functions as a major cytosolic innate pattern recognition receptor that recognizes double-stranded RNA (dsRNA). We show that ectopic expression of MDA-5 via replication incompetent adenovirus (*Ad.Mda-5*) causes cytotoxicity and type I interferon (IFN) production in mouse and human prostate cancer cells. This dual activity of MDA-5 requires the adaptor protein IFN- β promoter stimulator 1 (IPS-1/MAVS) and could be functionally uncoupled. Deletion of N-terminal caspase-recruitment domains (CARDs) has no effect on MDA-5-initiated intracellular death signaling in cancer cells, but compromise its capacity to induce IFN- β expression. In contrast to cancer cells that are susceptible to MDA-5-mediated cytotoxicity, normal cells are highly resistant but display a robust type I IFN response. Intratumoral delivery of *Ad.Mda-5* led to regression of established prostate cancers and development of long-lasting antitumor immunity, which was executed through activation of cytotoxic T lymphocytes and/or natural killer cells. Our mechanistic studies using the CARDs-truncated MDA-5 mutant, genetic silencing of IPS-1, and antibody blockade of the IFN-

α/β -receptor reveals that type I IFN signaling is indispensable for protective antitumor immunity induced by in situ MDA-5 therapy. It is the first report that deliberately targeting evolutionarily conserved MDA-5-IPS-1-mediated viral sensing pathway in the tumor can provoke systemic mobilization of both innate and adaptive components of the immune system for tumor destruction. Since the immunosuppressive tumor microenvironment presents a major challenge for successful cancer immunotherapy, our study provides an innovative strategy to reprogram the tumor immune compartment for restoring effective antitumor immunity.

401

Activin A regulates neutrophil activation via Smad3 pathway

Qi, Y.¹, Cui, X.², Ge, J.³, Liu, Z.¹

¹College of Basic Medical Sciences, Jilin University, Department of Immunology, Changchun, China, ²College of Basic Medical Sciences, Jilin University, Department of Genetics, Changchun, China, ³College of Basic Medical Sciences, Jilin University, Department of Physiology, Changchun, China

Activin A, a member of transforming growth factor beta (TGF- β) superfamily, acts as a pro-inflammatory factor in acute phase response. Neutrophils are involved in inflammatory response and are the original source of activin A in inflammation. However, whether activin A can directly act on neutrophils is still unclear. In the present study, we found that the type IIA receptor of activin (ActRIIA) was co-expressed with Ly-6G, a marker of neutrophils, on neutrophils of mouse by immunofluorescent staining and flow cytometry, and activin β A, ActRIIA, ActRIIB and Smad3 mRNA were expressed in neutrophils detected by RT-PCR, as well as activin A promoted Smad3 phosphorylation in neutrophils identified by Western blotting. Furthermore, the results showed that the lipopolysaccharide-stimulated peritoneal neutrophils of mouse could release activin A *in vitro*, and activin A stimulated respiratory burst, induced nitric oxide (NO) and interleukin-6 (IL-6) production of the cultured peritoneal neutrophils, while it inhibited migration of neutrophils by transwell method. Additionally, the results revealed that effect of activin A on IL-6 release from neutrophils was significantly attenuated by activin signaling molecule Smad3 knock-down. These above data indicate that activin A can act directly on neutrophils by an autocrine/paracrine manner and may play an important role in regulating activation of neutrophils via Smad3 pathway.

402

Dynamic changes in gene regulatory networks control subcapsular sinus macrophage fate and function

Nguyen, A.^{1,2}, Moran, I.^{1,2}, Tanaka, M.³, Tangye, S.^{1,2}, Brink, R.^{1,2}, Phan, T.^{1,2}

¹Garvan Institute of Medical Research, Immunology Division, Sydney, Australia, ²UNSW Australia, Faculty of Medicine, Sydney, Australia, ³Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan

CD169+ subcapsular sinus (SCS) macrophages are strategically positioned at the lymph-parenchyma interface of the lymph node and play a critical role in both the innate and adaptive immune response. SCS macrophages act as “fly paper” and extend processes into the subcapsular space to sample afferent lymph for antigen. Once captured, antigen is then relayed and presented to the B cells in the underlying follicle, a step that is critical for initiation of the antibody response. This intimate contact between SCS macrophages and B cells can be subverted by lymphotropic viruses to gain entry into the follicle and transfect B cells. Inflammation can also disrupt the integrity of the SCS macrophage barrier, possibly by inducing their migration into the follicle and inflammasome-mediated cell death. Recently, we identified lymph-node resident memory T and B cells that occupy a unique niche in the subcapsular region where they scan SCS macrophages. Despite the central role of these cells in immunity, little is known about the underlying molecular networks that govern SCS macrophage function under steady-state conditions and following inflammation, and the niche factors they provide to attract and maintain memory cells in this location. To address this we used a CD169 reporter mouse to track the origin and fate of SCS macrophages by intravital two-photon microscopy, and perform RNAseq analysis of steady-state and inflamed SCS macrophages. Our data defines dynamic changes in gene transcription networks that specify distinct functions for SCS macrophages in infection and immunity.

403

Porphyromonas gingivalis-derived RgpA-Kgp complex activates the macrophage urokinase plasminogen activator system

Fleetwood, A.¹, O'Brien-Simpson, N.², Veith, P.², Lam, R.², Achuthan, A.¹, Cook, A.¹, Singleton, W.², Lund, I.³, Reynolds, E.², Hamilton, J.¹

¹The University of Melbourne, Department of Medicine (RMH), Melbourne, Australia, ²The University of Melbourne, Melbourne Dental School, Melbourne, Australia, ³Copenhagen University, Finsen Laboratory, Copenhagen, Denmark

Urokinase plasminogen activator (uPA) converts plasminogen to plasmin, resulting in a proteolytic cascade that has been implicated in tissue destruction during inflammation. Periodontitis is a highly prevalent chronic inflammatory disease characterized by destruction of the tissue and bone that support the teeth. We demonstrate that stimulation of macrophages with the arginine- and lysine-specific cysteine protease complex (RgpA-Kgp complex), produced by the keystone pathogen *Porphyromonas gingivalis*, dramatically increased their ability to degrade matrix in a uPA-dependent manner. We show the RgpA-Kgp complex cleaves the inactive zymogens, pro-uPA (at consensus sites Lys¹⁵⁸-Ile¹⁵⁹ and Lys¹³⁵-Lys¹³⁶) and plasminogen, yielding active uPA and plasmin, respectively. These findings are consistent with activation of the uPA proteolytic cascade by *P.gingivalis* being required for the pathogen to induce alveolar bone loss in a model of periodontitis and reveal a new host-pathogen interaction in which *P.gingivalis* activates a critical host proteolytic pathway to promote tissue destruction and pathogen virulence.

404**Interaction of S100 proteins and the cytoskeleton in phagocytes***Russo, A., Wolf, M., Roth, J., Vogl, T.**Institute of Immunology, Münster, Germany*

Background: Phagocytic functions, such as adherence, migration and phagocytosis are based on the rearrangements of the cytoskeleton. These processes are controlled by intracellular signaling pathways leading to the activation of specific protein kinases and the transient elevation of intracellular calcium concentration. However, the molecular links coordinating the interplay of different cytoskeletal compartments and membrane receptors are not well defined. We previously demonstrated that the major calcium-binding proteins in monocytes, S100A8 and S100A9, can act as cross linker of microtubules dependent on an intracellular calcium concentrations.

Methods: Using Hoxb8 monocytes from wild type and S100A9^{-/-} mice, functional cell assays, immunofluorescence studies and biochemical analysis, we will investigate the role of S100A8/A9 proteins during cellular dynamics of phagocytes.

Results: First immunofluorescence studies confirmed the cross-linking of microtubules and F-actin by S100A8/A9 is dependent on calcium. Furthermore, phosphorylation of S100A9 abrogates cross-linking under the same conditions. In a two chamber filter-based transmigration assay, S100A9^{-/-} monocytes show an decreased number of transmigrated cells after 4 hours of migration.

Conclusion: We provide evidence that S100A8/A9 is associated with microtubules and is strongly involved in crosslinking of actin filaments and MTs with subsequent impact on phagocyte adhesion and transmigration. These findings reveal a novel function of S100A8/A9 in cytoskeletal reorganization as well as transmigration and adhesion of phagocytes.

405**M2-macrophages for stroke treatment***Chernykh, E., Shevela, E., Starostina, N., Morosov, S., Davydova, M., Sachno, L., Ostanin, A.**Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation*

There is a growing body of evidence that monocytes/macrophages may be implicated in the repair of the brain tissue and mediate neurological improvement following stem cell therapy. In the present study we evaluated the safety and clinical efficacy of M2 macrophages in non-acute stroke patients. Thirteen patients (12 males and one female with median 63 years) diagnosed with ischemic (n=10) or hemorrhagic (n=3) stroke have been subjected to M2 cell transplantation (study group). On average 22.0×10^6 of autologous M2 macrophages were injected via intrathecal introduction. Thirteen matched case-control stroke patients with standard therapy formed the control group. There were no any serious adverse effects following M2 cell injection. One patient in the study group and two patients in the control group died during the 6-mo follow-up period due to recurrent stroke. In the study group NIHSS score decreased from 11 to 6 ($p=0.007$) in a 6-mo follow-up

period, whereas the patients in the control group showed a less pronounced neurological improvement (from 11 to 8; $p=0.07$). The improvement of NIHSS score ≥ 3 in the study group was observed in 75% versus 18% in the control group ($p_{\text{FET}}=0.03$). Of note, peripheral blood cells of responder patients differed from that of non-responders by lower spontaneous production of IL-10, FGF- β , PDGF, VEGF and higher stimulation indexes of IL-1 β , TNF- α , IFN- γ and IL-6. These findings suggest the intrathecal administration of M2 cells in stroke patients is safe and leads to a better neurological recovery through the immunomodulatory activity of M2 macrophages.

406**The role of the bone morphogenetic proteins 9 and 10 in endothelial inflammation***Mitrofan, C.G., Appleby, S., Morrell, N.**University of Cambridge, Medicine, Cambridge, United Kingdom*

Atherosclerosis is characterised by chronic inflammation in the vascular wall. Bone morphogenetic proteins (BMPs), BMP2, 4 and 6 signalling via the type-I activin like kinase (ALK) receptors ALK2 have been involved in the inflammatory processes that accelerate atherosclerosis. The endothelial BMP receptor, ALK1, in complex with the bone morphogenetic protein receptor II (BMPRII) signal specifically in response to the circulating BMP9 and 10. Reduced BMPRII endothelial expression has been shown to induce inflammation *in vitro* and in a mouse model of atherosclerosis. We therefore questioned whether BMP9 and 10 signalling via BMPRII confers protection against endothelial inflammation by maintaining endothelial integrity.

Endothelial:monocyte interactions were investigated using an *in vitro* flow-based system. Surface expression of E-selectin, vascular cell adhesion molecule-1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1) were quantified using flow cytometry on human aortic endothelial cells (HAECs).

BMP9 and 10 concentration-dependently increased monocyte recruitment to TNF- α -stimulated HAECs. BMP9 and 10 also increased E-selectin and VCAM-1 surface expression on TNF- α -stimulated endothelial cells. Knockdown of ALK2 reduced the surface expression levels of adhesion molecules.

Pre-treating the endothelium with high concentrations of BMP9/10 followed by TNF- α treatment enhanced the inflammatory response through increased expression of selectins and adhesion molecules and ultimately by upregulating monocyte recruitment. These findings suggest that at high concentrations, BMP9 and 10 signal through the ALK2 receptor, which in turn enhances the surface expression levels of adhesion molecules, ultimately resulting in increased monocyte adherence. These findings are relevant to the potential therapeutic use of BMP9 and 10 in cardiovascular disease.

407

The role of zinc in macrophage antimicrobial responses

Stocks, C.J.¹, Kapetanovic, R.¹, Bokil, N.¹, Phan, M.-D.², Lo, A.², Schembri, M.², Sweet, M.J.¹

¹Institute for Molecular Bioscience, The University of Queensland, Brisbane, Australia, ²School of Chemistry and Biological Sciences, The University of Queensland, Brisbane, Australia

Macrophages utilise a host range of strategies to eliminate micro-organisms, however certain pathogens are able to evade these and persist within this innate immune cell. *Salmonella* species including *Salmonella enterica* serovar Typhimurium (*S. Typhimurium*) survive and replicate within this intracellular niche, whilst more recently certain strains of *Uropathogenic E. coli* (UPEC) have also been shown survive in macrophages. Regulated zinc trafficking has emerged as a novel antimicrobial mechanism, but specifics regarding its function and role in host defence are not well understood. Recent studies in our laboratory and others, have shown that Toll-like receptor signalling promotes the accumulation of vesicular zinc within human macrophages, with this being harnessed for microbial clearance via metal ion toxicity. These zinc vesicles co-localise with engulfed UPEC strain EC958 and a Δ SPI-1 mutant of *S. Typhimurium*, whilst wild-type *S. Typhimurium* evades zinc-containing vesicles. Intracellular EC958 and *S. Typhimurium* up-regulates the zinc exporter *ZntA*, peaking at 24 hours, indicating exposure of intramacrophage bacteria to zinc stress. For wild-type *S. Typhimurium*, *zntA* expression peaks at 6 hours and declines by 24 hours, suggesting active subversion of zinc-mediated defence. To further investigate this, zinc-stress reporter constructs were designed in EC958 whereby the transcription of *zntA* is coupled to the expression of GFP. The inducible expression of *zntA* and GFP was shown to be highly specific to zinc, with research ongoing to directly visualise the zinc-stress response during bacterial infections. Current research into zinc trafficking is aimed at identifying key molecular players in this response.

408

CD11b alveolar macrophage upregulation is a hallmark of acute and chronic inflammatory lung diseases

Duan, M.¹, Steinfort, D.², Smallwood, D.², Hew, M.³, Ernst, M.⁴, Anderson, G.⁵, Irving, L.², Hibbs, M.⁶, Chen, W.¹

¹La Trobe Institute for Molecular Science, Biochemistry and Genetics, Melbourne, Australia, ²Royal Melbourne Hospital, Respiratory Medicine, Melbourne, Australia, ³Alfred Hospital, Allergy, Immunology and Respiratory Medicine, Melbourne, Australia, ⁴Olivia Newton-John Cancer Research Institute, Melbourne, Australia, ⁵University of Melbourne, Pharmacology, Melbourne, Australia, ⁶Monash University, Immunology, Melbourne, Australia

Residential tissue macrophages differentially facilitate organ homeostasis yet also underlie the pathological processes of many acute and chronic diseases. This is particularly true for alveolar macrophages (AMΦs), which predominate within the alveolar airspaces where they are implicated in organ homeostasis, pathogen detection and chronic lung disease pathogenesis.

We have previously shown that AMΦ CD11b expression is an unexpected and translatable marker of lung inflammation in humans and mice. Using an internally standardised flow cytometry approach which compares CD11b expression levels on AMΦs with anchor expression levels in blood neutrophils, we demonstrated that the presence or absence of AMΦ CD11b upregulation and lung eosinophilia could be used to identify distinct inflammatory profiles in mice for the induction and resolution of endotoxin challenge, influenza virus infection and in two genetic models of chronic obstructive pulmonary disease (COPD). Notably, heightened AMΦ CD11b expression was also a novel hallmark of acute lung exacerbations in the SHIP-1^{-/-} model of COPD and the identification of analogous AMΦ profiles in respiratory disease patients highlighted CD11b upregulation as a conserved hallmark of lung inflammation. To elucidate the functional phenotype of AMΦ CD11b upregulation, we have now characterised the proteome of CD11b negative versus CD11b positive alveolar macrophages in response to different acute inflammatory stimuli. Anti-viral as well as classically pro-inflammatory signalling pathways were selectively associated with AMΦ CD11b regulation, and confirms AMΦ CD11b upregulation as a pro-inflammatory pathway in acute and chronic inflammatory lung diseases.

409

The comprehensive understanding of the metabolic profile in RAW264.7 murine macrophage during endotoxin tolerance

Ito, Y., Tabata, S., Tomita, M., Fukuda, S.
Keio University, Tsuruoka, Japan

In the intestinal environment, host immune cells interact with commensal microbiota to maintain intestinal homeostasis. Macrophages are one of the most important immune cells in activating the innate immune response by recognition of foreign antigens. The decrease in macrophage response on repetitive antigen stimulation is called endotoxin tolerance. However, molecular mechanisms underlying endotoxin tolerance are still not fully understood. Macrophages change their metabolism drastically in response to the antigen. In this study, we focused on RAW264.7 mouse macrophage cells and comprehensively investigated global changes in metabolism by Capillary Electrophoresis - Time-of Flight Mass Spectrometry (CE-TOFMS, Agilent Technologies) when endotoxin tolerance was induced by lipopolysaccharide (LPS) from *Escherichia coli* serotype O55:B5. RAW264.7 cells were stimulated with LPS for 12 hours and then washed with phosphate buffer saline solution. These cells were then repeatedly stimulated with LPS for 6 hours and then metabolism was analyzed by CE-TOFMS. It was observed that nucleotide sugars such as UDP-N-Acetylglucosamine were accumulated during endotoxin tolerance. In addition, the metabolic pathway switched to the hexosamine biosynthesis pathway which biosynthesized UDP-N-Acetylglucosamine from glycolysis during endotoxin tolerance. These results suggested that repetitive antigen stimulation activated metabolism of nucleotide sugars in macrophage. UDP-N-Acetylglucosamine is known to be related to glycosylation of NF-κB and suppresses the innate immune response. In conclusion, these results

suggest that nucleotide sugar metabolism affects endotoxin tolerance in suppressing NF- κ B. As endotoxin tolerance is known to be related to sepsis and other diseases, these findings may contribute to clinical progress in these aspects.

Intrinsically disordered *Mycobacterium tuberculosis* protein PPE37 induces proliferation of tolerogenic immune cells and apoptosis by N and C terminal domains, respectively

Ahmad, J.^{1,2}, *Farhana, A.*³, *Babu, M.M.*⁴, *Srinivasan, A.*¹, *Ehtesham, N.Z.*², *Hasnain, S.E.*⁵

¹All India Institute of Medical Sciences, Department of Biophysics, New Delhi, India, ²National Institute of Pathology, New Delhi, India, ³Centre for DNA Fingerprinting and Diagnostics, Hyderabad, India, ⁴MRC Laboratory of Molecular Biology, Cambridge, United Kingdom, ⁵Kusuma School of Biological Sciences, Indian Institute of Technology, New Delhi, *Contributed Equally, India

Mycobacterium tuberculosis (*M.tb*) harbors the highest percentage (14.5%) of intrinsically disordered proteins (IDPs) among bacterial and archaeal genomes. Although their significance vis-à-vis pathogenicity and host pathogen interaction is largely unknown, their abundance may favor pathogen survival both by immune evasion, and possibly facilitating host-pathogen interactions.

The PE/PPE/PGRS protein family of *M.tb*, present nowhere in the living kingdom other than the genus *Mycobacterium*, displays unusually high levels of disordered/partially-disordered stretches. A member of this family, PPE37, is highly expressed under iron stress conditions and is localized to cell membrane. PPE37 is cleaved by *M.tb* protease into an iron-binding N-terminal part and a C-terminal highly disordered region, which harbours the eukaryotic NLS motif that localizes it to the nucleus of infected macrophages. Recombinant N-terminal segment was found to interact and internalize within the monocytic THP-1 cells leading to their proliferation and differentiation into CD11c, DC-SIGN positive semi-mature dendritic cells, known to induce immune tolerance. These cells also demonstrated a high IL-10, negligible IL-12 and low TNF- α secretion, an environment suitable for maintenance of tolerogenic immune cells. The nuclear-targeted C-terminal segment induced apoptosis of the infected host cell through mechanism that involves caspase-3 but without DNA damage.

Our data provide evidence supporting the role of intrinsically disordered stretch within a PPE protein in performing contrasting functions to modulate the host processes possibly through molecular mimicry and cross-talk in two spatially distinct host environments so as to benefit *M.tb* in terms of survival and pathogenesis.

411

Macrophages programmed by apoptotic cells inhibit epithelial-mesenchymal transition in lung alveolar epithelial cells via PGE₂, PGD₂, and HGF

Yoon, Y.-S., Choi, Y.-H., Kang, J.L.

Ewha Womans University, Physiology, Seoul, Korea, Republic of

Apoptotic cell clearance results in the release of growth factors and the action of signaling molecules involved in tissue homeostasis maintenance. Here, we investigated whether and how macrophages programmed by apoptotic cells inhibit the TGF- β 1-induced Epithelial-mesenchymal transition (EMT) process in lung alveolar epithelial cells. Treatment with conditioned medium derived from macrophages exposed to apoptotic cells, but not viable or necrotic cells, inhibited TGF- β 1-induced EMT, including loss of E-cadherin, synthesis of N-cadherin and α -smooth muscle actin, and induction of EMT-activating transcription factors, such as Snail1/2, Zeb1/2, and Twist1. Exposure of macrophages to cyclooxygenase (COX-2) inhibitors (NS-398 and COX-2 siRNA) or RhoA/Rho kinase inhibitors (Y-27632 and RhoA siRNA) and LA-4 cells to antagonists of prostaglandin E₂ (PGE₂) receptor (EP4 [AH-23848]), PGD₂ receptors (DP1 [BW-A868C] and DP2 [BAY-u3405]), or the hepatocyte growth factor (HGF) receptor c-Met (PHA-665752), reversed EMT inhibition by the conditioned medium. Additionally, we found that apoptotic cell instillation inhibited bleomycin-mediated EMT in primary mouse alveolar type II epithelial cells *in vivo*. Our data suggest a new model for epithelial cell homeostasis, by which the anti-EMT programming of macrophages by apoptotic cells may control the progressive fibrotic reaction via the production of potent paracrine EMT inhibitors.

412

Mer signaling leads to transactivation of anti-inflammatory target gene arginase 2 of liver X receptor via STAT1 transcription factor in macrophages

Kim, S.-Y., Lim, E.-J., Kang, J.L.

Ewha Womans University, Physiology, Seoul, Korea, Republic of

Mer receptor tyrosine kinase (Mer) plays a central role in intrinsic inhibition of the inflammatory response by immune cells. Previously, we demonstrated that the Mer signaling increases the transcriptional liver X receptor (LXR) activity to promote the resolution of acute sterile inflammation. Here we aimed to understand the downstream pathway of Mer signaling after growth arrest-specific protein 6 (Gas6) treatment leading to LXR expression and transcriptional activity in mouse bone-marrow derived macrophages (BMDM). We show the role of signal transducer and activator of transcription1 (STAT1), which acts as an enhancer of LXR expression and LXR-mediated transcription of target genes in BMDM. Gas6-induced STAT1 phosphorylation, and LXR and the target gene expression were inhibited in BMDM from Mer^{-/-} mice or by the specific inhibitor of PI3K, or Akt. Gas6-induced Akt phosphorylation was reduced in BMDM from STAT1^{-/-} mice or BMDM in the presence of STAT1 specific inhibitor, fludarabine. Gas6-induced LXR activity was enhanced through an interaction between LXRA and STAT1 on the DNA promoter of Arg2, which was dependent on STAT1. We show that Gas6 inhibited LPS-induced nitric oxide production through Mer/STAT1/LXR pathway-dependent Arg2 induction in macrophages. Our data suggest that Gas6/Mer signaling leads to increased transcriptional LXR activity and its target genes, including Arg2, in macrophages via STAT1 pathway, consequently exerting the anti-inflammatory response.

413

Immunization of recombinant antigen EpC1 from *Echinococcus granulosus* on macrophage regulation*Li, J.¹, Wang, H.¹, Ding, J.², Zhen, X.¹, Wen, H.¹, Zhang, W.¹**¹The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China, ²School of Preclinical Medicine, Xinjiang Medical University, Urumqi, China*

Alternatively activated macrophages (AAMacs) are key to promoting Th2 responses and have been associated with a variety of roles during helminth infection. *Echinococcus granulosus* (E.g) induces a polarized Th2 immune response in its intermediate hosts. Here we investigated the effects of its infection and a recombinant antigen, termed rEpC1, derived from E.g, on murine macrophage *in vivo* and *in vitro*.

Methods: Peritoneal exudate cells (PECs) from E.g and E.m infection mice were harvested by adherence method and then the activation status of macrophages was analyzed by evaluating the expression of genetic markers of alternative activation (Fizzl, Ym1, and Arg1). Then we constructed the rEpC1 and injected hydatid cyst fluid (HCF) or rEpC1 intraperitoneally 6 or 9 times, delivered on alternate days. After 2 days of the final injection, PECs were harvested and analyzed and activation status of macrophages. T-cell cytokine production was assessed by culturing spleen cells with HCF and rEpC1. Supernatants were removed after 72hrs and the concentrations of cytokines were measured by CBA kit. AAMacs were recruited to the peritoneum of mice after E.g and E.m infection. In addition, *in vitro* studies showed that HCF and rEpC1 can directly convert bone marrow macrophages to an alternatively activated phenotype. Our studies suggest that the rEpC1 activates macrophages as an initial step in the induction of Th2 responses by E.g infection to defense against the host immune response.

414

Influenza vaccines induce NF- κ B activations and enhancement of TLR expressions in macrophages*Sato, K.¹, Asanuma, H.¹, Ato, M.², Tashiro, M.¹, Odagiri, T.¹, Itamura, S.¹**¹National Institute of Infectious Diseases, Influenza Virus Research Center, Tokyo, Japan, ²National Institute of Infectious Diseases, Department of Immunology, Tokyo, Japan*

Influenza vaccines induce protective immunity via induction of antibody production against subsequent infections, and a variety of different vaccine types are currently available. It has been known that inactivated influenza vaccines induce, through TLR7, type I IFN, which influences vaccine-specific antibody production. Previously, we showed that NF- κ B/AP-1 activations by inactivated whole-virion influenza vaccines were correlated with type I IFN induction. To explore these signaling in detail, the effect of an RIG-I inhibitor, which results in inhibiting TBK1/IKKe, and of an endosomal acidification inhibitor, which results in suppressing endosomal TLR-mediated signaling, was evaluated. PMA-differentiated THP-1 cells were preincubated with either of the inhibitors, and then co-cultured with various concentrations of inactivated whole virion vaccines. After 20 h incubation with vaccines, NF- κ B/AP-1 activities were measured.

Not only the inhibition of TBK1/IKKe but that of endosomal acidification suppressed the NF- κ B activations by vaccines. In addition, both inhibitors also reduced the NF- κ B activity levels in MyD88-deficient THP-1 cells. Upon stimulation with various TLR-specific ligands, TLR7 signaling to activate NF- κ B was not detected in the MyD88-deficient cells. In other experiments, some TLR expressions were enhanced by the vaccine treatment. The enhancement of TLR expressions was not affected by the treatment of both TBK1/IKKe inhibitors and endosomal acidification inhibitors. Taken together, the activations of NF- κ B by vaccines might be mediated through TLR3 as well as TLR7 and RIG-I pathways. Further study will clarify signal transductions of influenza vaccines in macrophages.

415

Quercetin suppressed imiquimod-induced activation of alveolar macrophages*Oyabu, S., Matsushima, M., Omura, A., Ogasawara, N., Ochi, H., Kusatsugu, Y., Atsumi, K., Takemura, K., Kawabe, T.**Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan*

Respiratory viral infections that cause chronic airway and lung disease can result in the activation of the innate immune response. Alveolar macrophages (AMs), one of the first lines of defense in the lung, are abundantly located in alveoli and the respiratory tract. Flavonoids found in fruits and vegetables exhibit cytoprotective effects on various types of cells. In this study, we investigated the effect of quercetin on AMs activated by imiquimod, a ligand of Toll-like receptor (TLR) 7. In both a mouse AM cell line (AMJ2-C11 cells) and mouse bronchoalveolar fluid cells, we demonstrated that quercetin attenuated the TLR7-induced expression of TNF- α and IL-6. In AMJ2-C11 cells, quercetin also attenuated the TLR7-induced CD40 expression; attenuated the translocation of p65; induced translocation of Nrf2 from cytosol to nucleus; and induced heme oxygenase (HO)-1 expression. Notably, tin protoporphyrin IX (SnPP), an inhibitor of HO-1, also attenuated TLR7-induced transcription of the TNF- α and IL-6 genes, suggesting that the effect of quercetin is mediated by HO-1. These results suggest that dietary supplementation with quercetin may have efficacy in the treatment of respiratory viral infection.

416

Critical role of selective autophagy adaptor protein p62 in quercetin-induced Nrf2 activation*Kusatsugu, Y., Matsushima, M., Oyabu, S., Ochi, H., Atsumi, K., Ogasawara, N., Takemura, K., Kawabe, T.**Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan*

Flavonoids are polyphenolic compounds included in vegetables and fruits. We have reported that quercetin, one of the flavonoids, exhibited cytoprotective effects via nuclear factor-E2-related factor 2 (Nrf2)-heme oxygenase (HO)-1 pathway in mast cells, epithelial cells, and fibroblasts. However, the molecular mechanisms how quercetin activates Nrf2 is

still poorly understood. Autophagy, one of the important cytoprotective mechanisms, is an intracellular bulk degradation system for the maintenance of cellular homeostasis in response to cellular stresses. It has been reported that quercetin could induce autophagy. Recently, autophagy has been reported to activate Nrf2 through selective autophagy-adaptor protein p62. In this study, we investigated the involvement of autophagy on quercetin-induced Nrf2 activation, especially focusing on p62. Mouse macrophage cell line, RAW 264.7 cells were used and treated with quercetin for 8-24 hr. We found that quercetin could induce the conversion of LC3-I to LC3-II, a molecular marker for autophagy. Quercetin could also induce selective autophagy by inducing the expression and phosphorylation of p62. Based on these results, we suggested that quercetin-induced Nrf2 activation might be included in p62-mediated pathway.

417

Extracellular ATP acting as a danger signal activates the P2X7 receptor in macrophages for the release of a specific secretome

de Torre-Minguela, C., Barberà-Cremades, M., Gomez, A.I., Baroja-Mazo, A., Martín-Sánchez, F., Pelegrin, P., Murcia's Biomedical Research Institute (IMIB-Arrixaca), Murcia, Spain

We aimed to obtain a better characterization of P2X7 receptor (P2X7R) secretome in both M1 and M2 polarized macrophages. The changes in P2X7R secretome were analyzed by LC-MS/MS and antibody array technology. ELISA and western blot were then used to validate P2X7R secretome. The activation of P2X7R-signaling pathways leading to protein release was studied using a pharmacological approach including specific P2X7R antagonists and P2X7R-deficient mice, as well as NLRP3- or Casp1-deficient macrophages. We identified the release of 25 proteins associated with P2X7R and 9 relevant proteins for the inflammatory process were selected for further validation: macrophage mannose receptor, CD14, cathepsin B, cystatin B, thioredoxin, annexin A1, peptidyl-prolyl cis-trans isomerase A, TNF- α and CCL-2. We compared their secretion with the control release of IL-1 β and the p10 subunit of active caspase-1, two well established proteins released upon P2X7R stimulation. We characterized the different P2X7R molecular signaling leading to protein release, which are activated at different times and affecting unconventional and conventional release pathways. P2X7R activation was responsible for the secretion of more proteins than the ones controlled by the inflammasome/caspase-1 pathway. Furthermore, we found that P2X7R induces in M2 polarized macrophages the release of anti-inflammatory proteins that could contribute to the resolution of the inflammation. The characterization of P2X7R-secretome in macrophages contributes to novel conceptual advances into the general biology of macrophages and the release of anti-inflammatory proteins in M2 macrophages, suggesting for the first time a potential role for P2X7R during the resolution of inflammation.

419

Interferon lambda drives a pro-inflammatory phenotype in macrophages

Read, S.¹, Ramezani-Moghadam, M.¹, Schibeci, S.², George, J.¹, Ahlenstiel, G.¹

¹Westmead Institute for Medical Research, University of Sydney, Storr Liver Centre, Sydney, Australia, ²Westmead Institute for Medical Research, Centre for Immunology and Allergy Research, Sydney, Australia

Interferon lambdas (IFNLs) are potent antiviral cytokines that are widely implicated in many chronic inflammatory diseases. While IFNLs are best known for their role in clearance of hepatitis C virus infection, there is substantial data supporting their role in acute viral infections such as influenza and viral gastroenteritis, as well as chronic autoimmune and liver disease. Numerous tissues have reported IFNL expression, but there remains controversy over which PBMC subsets are responsive to IFNL and thus contribute to inflammatory activity in chronic diseases.

Upon examining IFNL sensitivity *in vitro*, we demonstrate macrophages but not monocytes are more responsive to IFNL3 than myeloid and plasmacytoid dendritic cells; the only other leukocyte populations with a significant IFNL response. To investigate the role of IFNLs on macrophage maturation and function, human monocytes from healthy subjects were differentiated using either GM-CSF (M1 skewed) or M-CSF (M2 skewed), alone or in combination with IFNL3. M1 macrophages expressed more IFNL receptor (IFNLR1) and were more responsive to IFNL3, supporting their role as pro-inflammatory cytokines. Moreover, IFNL3 increased the expression of numerous inflammatory/chemotactic cytokines and activation markers as measured by qPCR and flow cytometry respectively. Functionally, macrophages differentiated in the presence of IFNL3 were more phagocytic towards apoptotic cells and more chemo-attractant towards CD3, NK and NKT cells.

Lastly, we demonstrated an accumulation of IFNLR1 expressing macrophages in numerous chronic inflammatory conditions, supporting their potential to drive a pro-inflammatory state. Our data suggests that IFNL contributes to chronic inflammation by driving a pro-inflammatory macrophage phenotype.

420

A novel alveolar-like macrophage to study influenza A infection *in vitro*

Wood, C.¹, Logue, C.², Silman, N.², Jackson, S.¹, Fejer, G.¹

¹Plymouth University, Plymouth, United Kingdom, ²Public Health England, Porton Down, United Kingdom

Influenza A (IAV) primarily infects and replicates within the respiratory tract, with its infectious and entry mechanisms well characterised in non-immune epithelial cells. However, lung Alveolar Macrophages (AMs) play pivotal roles in the defence against IAV, but yet the mechanisms of viral pathogenesis in these cells are much less understood. Much of our current understanding on IAV induced innate immune responses comes from transformed macrophage cell lines or primary bone marrow derived or peritoneal macrophages, due to the limited

availability of AM's. This limits the understanding we have of IAV pathogenesis within this distinct and specialised branch of macrophages.

The recently described MPI cells (Fejer *et al.*; 2013, PNAS) represent a novel, non-transformed, continuously growing macrophage model that could bridge this gap in our understanding, as they closely resemble AMs. Our aim is to study innate responses in this model, with regards to IAV. It is expected that IAV infection will elicit a distinct innate immune response in MPI cells that closely resembles that of AM's. Moreover, by taking advantage of the unlimited availability of MPI cells and the availability of cells from various gene deficient backgrounds we hope to identify specific innate sensors and mechanisms that lead to the IAV induced innate immune response.

421

Tumours from patients with colorectal cancer may dysregulate gut macrophage function and phenotype

Norton, S., Taylor, E., Dunn, E., Munro, F., Black, M., McCall, J., Kemp, R.

University of Otago, Dunedin, New Zealand

In contrast to many cancers, a high infiltration of macrophages in colorectal cancer has been associated with improved prognosis for patients. Cytokines and other stimuli from the tumor microenvironment affect monocyte to macrophage maturation and subsequent phenotype and function. We used a novel flow cytometry panel in both tumor and paired non-tumor bowel from colorectal cancer patients. Heterogeneous macrophage populations, ranging from gut conditioned to a more conventional monocyte-derived macrophage phenotype, were identified in the tissues. The frequency of macrophage subsets with a gut-conditioned phenotype was lower in tumor compared to non-tumor bowel. The frequency of macrophages expressing high CD206 and CD163, both associated with an anti-inflammatory phenotype, was also decreased in the tumour tissue compared to non-tumour bowel. The microenvironment strongly affects macrophage phenotype. Colorectal cancer patient PBMCs were cultured in both tumour and NTB conditioned media, which were assessed for cytokine content using a multiplex assay. Conditioned media that contained high levels of IL-6 and/or TNF α supported an anti-inflammatory macrophage phenotype. This study grants new insight into macrophage function in colorectal cancer and provides methods to examine them *ex vivo* from human tissue.

422

Murine macrophage phagocytosis of devil facial tumour disease cells

Li, X.¹, Lyons, A.B.², Korner, H.¹, Woods, G.¹

¹Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, ²School of Medicine, University of Tasmania, Hobart, Australia

The Tasmanian devil (*Sarcophilus harrisii*) is the world's largest marsupial carnivore. A transmissible cancer known as Devil Facial Tumour Disease (DFTD) threatens its existence. The disease is

fatal as there is no protective immune response. There is no evidence for innate immune responses such as NK cell activity or phagocytosis against the cancer cells to compensate for lack of MHC expression. The aim of this study was to investigate macrophage phagocytosis as a potential defence mechanism against DFTD. As tumour necrosis factor (TNF) is an important cytokine in macrophage activation we also investigated the involvement of TNF in macrophage phagocytosis. Bone marrow derived macrophages (BMDMs) were generated from C57BL/6 wild type (WT) and C57BL/6 TNF^{-/-} (TNF^{-/-}) mice. DFTD cells were labelled with CFSE and co-incubated with CellTrace™ Violet labelled BMDMs. Phagocytosis of DFTD cells was investigated by confocal microscopy and flow cytometry. The results revealed that DFTD cells can be phagocytosed by WT and TNF^{-/-} BMDMs with similar efficiency. It would appear that TNF signalling is not involved in macrophage phagocytosis of DFTD cells before activation. Following activation by exposure to IFN γ /LPS, TNF^{-/-} BMDMs had higher phagocytosis efficiency and lower nitric oxide production compared to WT controls. In addition, using nitric oxide (NO) inhibitor failed to alter phagocytosis efficiency in IFN γ /LPS activated TNF^{-/-} macrophages. Our results indicate that DFTD cells can be phagocytosed and that TNF appears to reduce IFN γ /LPS activated macrophage phagocytosis. NO is unlikely to account for the increased phagocytosis by TNF^{-/-} BMDMs.

423

CD169 identifies an anti-tumor macrophage subpopulation in human hepatocellular carcinoma

Wu, Y., Zhang, Y., Zheng, L.

Sun Yat-sen University, Guangzhou, China

Macrophages are a major component of most solid tumors and can exert both anti- and pro-tumorigenic functions. Although the immunosuppressive/pro-tumor roles of macrophages have been widely examined, significantly less is known about macrophage subpopulations that have potential anti-tumor properties in humans. In the present study, a population of CD169⁺ macrophages with relatively high expression levels of HLA-DR and CD86 was identified in human hepatocellular carcinoma tissues. The frequency of CD169-expressing macrophages within cancer nests was significantly lower compared with that found in paired non-tumor areas. *In vitro* experiments revealed that in the presence of anti-CD3 stimulation, CD169⁺ macrophages could significantly enhance the proliferation, cytotoxicity, and cytokine production capacity of autologous CD8⁺ T cells in a CD169 molecule-dependent manner. Autocrine TGF- β produced by tumor-stimulated macrophages was involved in the down-regulation of CD169 expression on these cells. Moreover, CD169⁺ macrophage accumulation in tumor tissues was negatively associated with disease progression and predicted favorable survival in hepatocellular carcinoma patients, which was in contrast to the trend observed for total CD68⁺ macrophages. Therefore, CD169 may act as a costimulatory molecule for cytotoxic T cell activation, and could define a population of tumor-infiltrating macrophages with potential anti-tumor properties in human hepatocellular carcinoma tissues.

Roles of macrophages in transplantation of tissue-engineered cartilage in mice

Fujihara, Y.¹, Hikita, A.², Takato, T.¹, Hoshi, K.¹

¹The University of Tokyo Hospital, Department of Oral-maxillofacial Surgery, Dentistry and Orthodontics, Tokyo, Japan, ²The University of Tokyo, Department of Cartilage & Bone Regeneration (Fujisoft), Tokyo, Japan

In regenerative medicine, tissue reactions after transplantation of engineered tissues could affect the regeneration and maturation. In our previous studies, tissue-engineered cartilage consisting of C57BL/6 mice chondrocytes and poly-L-lactic acid (PLLA) scaffolds were transplanted in EGFP transgenic mice, and it was shown that the host-derived EGFP-positive cells were mostly F4/80-positive macrophages. This study was conducted to elucidate the properties and effects of macrophages in transplantation of tissue-engineered cartilage. As to methods, human chondrocytes were cultured and embedded in PLLA scaffold, and then transplanted subcutaneously in athymic mice. After a certain period of time, they were harvested and analyzed using real-time RT-PCR and ELISA. Expression of cytokines related to M1 macrophage was increased from 1 to 2 weeks after transplantation. Meanwhile, arginase I-positive M2 macrophages became distinct around 2 weeks, suggesting that the shift of macrophage from M1 to M2 could occur around 2 weeks. By partially depleting macrophages for initial 7 days with clodronate liposome, more cartilage matrix was produced in tissue-engineered cartilage. It was suggested that suppression of early-stage macrophages, which were considered to be M1-prone, may be advantageous for promoting cartilage maturation.

Accelerated atherosclerosis in the context of rheumatoid arthritis

Bäcklund, A.¹, Johansson, M.², Ria, M.³, Ketelhuth, D.F.¹, Tsirikla, P.¹, Chernogubova, E.¹, Jin, H.¹, Bäcklund, J.², Eriksson, P.¹, Maegdefessel, L.¹, Holmdahl, R.², Hansson, G.K.¹, Hamsten, A.¹

¹Karolinska Institutet, Medicine Solna, Stockholm, Sweden, ²Karolinska Institutet, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden, ³Karolinska Institutet, Institute Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden

It is well recognized that patients with chronic inflammatory diseases, such as rheumatoid arthritis (RA) have an increased risk for cardiovascular disease (CVD) compared with the general population. It has also been suggested that CVD presented in RA patients is of an altered, more aggressive, phenotype compared to subjects without RA. Thus, there is a need to gain a deeper understanding of how the exacerbated inflammatory

state of arthritis affects the atherosclerosis process when both syndromes are presented in the same individual. We have developed a novel murine model where the human relevant genes of CVD (deficiency of Low Density Lipoprotein (LDL) receptor, thus increased LDL levels) and RA (MHCII, thus susceptible to collagen-induced arthritis) have been crossed into the common C57Bl6/J strain, enabling both arthritis and atherosclerosis being presented simultaneously. This model mirrors the clinical state where the systemic inflammation of arthritis enhances atherosclerosis progression, where mice presenting arthritis have a significant increase in atherosclerotic lesion progression compared with their non-arthritic littermates. Interestingly, there was an inverse correlation with cholesterol levels, but a positive correlation with macrophages, and macrophage associated cytokines but not T cells. This model thus demonstrates that the lipid levels are vital in initiation of lesion development but it is the enhanced innate immune system that is driving the lesion acceleration in a chronic inflammatory state. This novel combined model is now available to be used to investigate altered clinical treatment strategies or novel treatments of atherosclerosis in the context of arthritis.

Correlation between the metabolome and binder of ST2 receptor in chronic periodontics in elderly

Borges, A.¹, Carvalho, M.², Venturini, G.³, Vieira, C.⁴, Paulino, T.⁵, Botelho Miguel, C.⁶, Oliveira, C.⁷, Pereira, A.³, Binignat, O.⁸, Rodrigues, W.^{4,8,9}

¹Faculdade Mineirense - Fama, Odontology, Mineiros-GO, Brazil, ²Faculdade Mineirense - FAMA, Odontology, Mineiros, Brazil, ³Heart Institute (InCor)/Univ of Sao Paulo Med Sch, São Paulo, Brazil, ⁴Federal University of Uberlandia, Uberlandia, Brazil, ⁵Federal University of GoiasTriangulo Mineiro - CEFORES, Uberaba, Brazil, ⁶Federal University of Triangulo Mineiro, Uberaba, Brazil, ⁷Faculdade Mineirense - Fama, Mineiros-GO, Brazil, ⁸Federal University of GoiasTriangulo Mineiro, Uberaba, Brazil

Introduction: High relationship of senescence with the emergence and/or compromise of disease in oral cavity is a triggering factor of disease in this age group including chronic periodontal disease (CPD). Some markers have been associated with disease prognosis, as well as systemic diseases, such as ST2 binder.

Objectives: Evaluate the correlation between metabolites and ST2 receptor binder in crevicular fluid in the elderly.

Methods: All procedures were approved by the Ethics Committee in Research of the Federal University of Triangulo Mineiro, under number: 017430/2014. Twenty individuals were selected after applying the inclusion and exclusion criteria. They were divided into 2 groups, CPD (N = 10 - Clinical evaluation + probing depth higher or equal to 3 mm, and at least presence of marginal bleeding at a site) without disease - Control (n = 10). To the assessment of metabolites was performed the metabolome (triplicate - GC/MS Agilent -7890B GC; 5977A MS). The ELISA was performed for the detection and quantification of IL-33 (R&D Systems). The Prism software was used for statistical evaluation.

Results: Were identified 969 metabolites, of which 64 were selected to analyze. After analysis 5 metabolic (2,3

dihydroxypropyl icosanoate, glycerol, serine, 5-aminovaleric acid e putrescine) obtained a ratio CPD/Control greater than 2. The elevation was accompanied of increase of the ST2-binder, where was found a positive correlation.

Conclusion/discussion: The data point to a relationship of metabolic activity inducible IL-33/ST2 in CPD in the elderly.

ATF4 reprograms T cell metabolism and control differentiation of T cell subsets

Du, W.¹, Xia, R.¹, Yang, X.², Lu, B.¹

¹University of Pittsburgh School of Medicine, Pittsburgh, United States, ²Tsinghua University, Beijing, China

T cell metabolism is strongly influenced by the extracellular tissue microenvironment such as the oxidizing status. The underlying molecular mechanisms are not well understood. Here, We demonstrated that the oxidative environment induced ATF4 in activated T cells. ATF4 is a basic leucine-zipper (bZip) transcription factor, which regulates cellular redox state and amino acid metabolism. ATF4 deficient

T cells had a severe aberration in metabolism as illustrated by global gene expression profiling and biochemical analysis. Lack of ATF4 resulted in T cell autonomous defects in the function of Th1 cells. In vivo, ATF4 deficiency resulted in altered antitumor immune responses and exacerbated autoimmune inflammation. Our study establishes that ATF4 plays an important role in T cell metabolism and is important for the Th1 type immune response.

428

The impact of intestinal lymph extravasation on adipose tissue function and whole body insulin resistance

Cao, E.¹, Watt, M.², Hu, L.¹, Porter, C.¹, Trevaskis, N.¹

¹Monash University, Monash Institute of Pharmaceutical Sciences, Melbourne, Australia, ²Monash University, Department of Physiology, Melbourne, Australia

Insulin resistance (IR) underpins a spectrum of prevalent and inadequately treated cardiometabolic diseases, including type 2 diabetes (T2D). Excess adipose, particularly visceral adipose tissue (VAT) in the abdomen, increases the risk of IR. The expanded VAT releases pathogenic mediators that promote IR. *db/db* mice showed significantly enhanced lymphatic vessel permeability and in mice with hyperpermeable lymphatics the surrounding adipose is expanded. The content of inflammatory and metabolic mediators in intestinal lymph is also increased in response to high fat diet (HFD). Our aim is to determine whether intestinal lymph access to VAT is increased in HFD thereby promoting VAT expansion and pathogenic changes that promote IR.

Immunofluorescence analysis of mesenteric lymph vessels and Evans blue lymphangiography showed that in mice fed HFD vs chow fat diet (CFD) there were increased initial lymph capillary lymphangiogenesis and the permeability of collecting mesenteric lymph vessels. Metabolomics and flow cytometry analysis revealed increases in lipid species, pro-inflammatory mediators and CD4+ and CD8+ T cells in the HFD vs CFD fed

lymph. Finally, to determine whether increased lymph access to VAT promotes pathogenic changes in adipocytes with the potential to induce IR, co-culture of adipocytes with intestinal lymph enhanced adipocyte adipogenesis, inflammation, lipogenesis, and lipolysis. These effects were greater on treatment with HFD vs CFD fed lymph. Current results provide evidence that intestinal lymph access to VAT is increased in HFD thereby promoting VAT expansion and pathogenic changes that promote whole body IR. These studies advance the fundamental understanding of the pathogenic drivers of IR.

429

Tributylin attenuate, but do not revert, the metabolic and inflammatory changes associated with obesity through GPR43-dependent and independent mechanisms

Sato, F.T.^{1,2}, Murata, G.M.³, Ferreira, C.M.⁴, Vieira, A.T.⁵, Marino, E.², Rodrigues, H.G.⁶, Hirabara, S.M.⁷, Crisma, A.R.³, Cruz, M.M.⁴, Alonso-Vale, M.I.C.⁴, Câmara, N.O.S.⁸, dos Santos, M.F.⁹, Curi, R.³, Vinolo, M.A.R.¹

¹University of Campinas / Institute of Biology, Department of Genetics, Evolution and Bioagents, Campinas, Brazil, ²Monash University, Department of Biochemistry & Molecular Biology, Melbourne, Australia, ³University of São Paulo / Institute of Biomedical Sciences, Department of Physiology and Biophysics, São Paulo, Brazil, ⁴Federal University of São Paulo, Department of Biological Science, Diadema, Brazil, ⁵Federal University of Minas Gerais / Institute of Biological Sciences, Department of Biochemistry and Immunology, Belo Horizonte, Brazil, ⁶University of Campinas / Faculty of Applied Sciences, Limeira, Brazil, ⁷Cruzeiro do Sul University / Institute of Physical Activity Sciences and Sports, São Paulo, Brazil, ⁸University of São Paulo, Department of Immunology, São Paulo, Brazil, ⁹University of São Paulo, Department of Cell and Developmental Biology, São Paulo, Brazil

The non-healthy obesity is associated with low degree chronic inflammation involved in dysfunction of several organs and tissues. We investigate the effect of a tributyrin (Tb), pro-drug of a butyrate, a short chain fatty acid produced by bacterial fermentation on a diet induced obesity model (DIO). After 2 months on high fat diet (HFD), C57BL/6 obese mice were treated with 2 g/kg body weight, three times a week or placebo. After 6 weeks of treatment, Tb mice had lower weight gain, better fasting glucose, glucose and insulin tolerance and a decrease in the liver weight and hepatic triglycerides content. Although no difference in white adipose tissues (WAT) weight were observed, a reduction of relative and absolute number of M1-macrophages and IL1- β and MCP-1 mRNA content were present in Tb mice. Tb reverses some but not all the metabolic and inflammatory changes present in obese animals. When we treated obese GPR43 knockout mice with Tb, at the same conditions as the previous experiment, we didn't found alterations of weight gain, insulin tolerance and WAT M1 and M2 macrophages, suggesting the participation of GPR43 on Tb effects. Although this result, we found an improvement in basal glycaemia and glucose tolerance on Tb animals, indicating an independent effect of Tb between the glycemic parameters and weight gain without alteration in insulin tolerance. These results, indicate that the effects of tributyrin on obese animals depends partially of GPR43 receptor.

430**Cell surface Glut1 levels distinguish human CD4 and CD8 T lymphocyte subsets with distinct effector functions**

Cretenet, G., Clerc, I., Matias, M., Mongellaz, C., Dardalhon, V., Taylor, N.

CNRS, Institut de Genetique Moleculaire de Montpellier, Montpellier, France

CD4 and CD8 T lymphocyte activation requires the generation of sufficient energy to support new biosynthetic demands. Following T cell receptor (TCR) engagement, these requirements are met by an increased glycolysis, due, at least in part, to induction of the Glut1 glucose transporter. As Glut1 is upregulated on tumor cells in response to hypoxia, we assessed whether surface Glut1 levels regulate the antigen responsiveness of human T lymphocytes in both hypoxic and atmospheric oxygen conditions. Notably, Glut1 upregulation in response to TCR stimulation was significantly higher in T lymphocytes activated under hypoxic as compared to atmospheric oxygen conditions. Furthermore, TCR-stimulated human T lymphocytes sorted on the basis of Glut1-Low and Glut1-High profiles maintained distinct characteristics, irrespective of the oxygen tension. T cells activated in hypoxia divided less than those activated in atmospheric oxygen. However, in both oxygen conditions, Glut1-High lymphocytes exhibited increased effector phenotype acquisition, augmented proliferation and a skewing towards a cytotoxic fate, resulting in an inverted CD4/CD8 ratio. Consistent with these data, Glut1-High T lymphocytes displayed an enhanced ability to secrete IFN- γ as well as IL-17. Thus, Glut1 surface levels identify human T lymphocytes with distinct effector functions in both hypoxic and atmospheric oxygen tensions. Our data showing that Glut1 acts as a gauge of T lymphocyte function fosters the development of novel therapeutic strategies for manipulating T cell responses, notably in the context of anti-tumoral adoptive T cell therapy.

431**Evidence against a role for NLRP3 - driven inflammation in the *db/db* mouse model of type 2 diabetes**

Kammoun, H.L.¹, Allen, T.L.¹, Henstridge, D.C.¹, Barre, S.¹, Coll, R.C.², Butler, M.S.², Roberston, A.A.B.², O'Neill, L.A.³, Murphy, A.J.¹, Cooper, M.A.², Febbraio, M.A.^{1,4}

²Institute for Molecular Bioscience, The University of Queensland,

Brisbane, Australia, ³Trinity Biomedical Sciences Institute, Trinity

College, Dublin, Ireland, ⁴Garvan Institute of Medical Research, Sydney, Australia

Type 2 diabetes (T2D) is considered a chronic, low grade inflammatory disease. Activation of the Nod-like receptor protein 3 (NLRP3) inflammasome, and secretion of its target interleukin 1 β (IL1 β), have been implicated in pancreatic β cell failure in T2D. Specifically targeting the NLRP3 inflammasome to prevent β cell death without compromising all IL1 β -associated immunity could represent a valuable therapeutic option for T2D. We recently demonstrated that MCC950, a compound that specifically inhibits the NLRP3 inflammasome can prevent autoinflammation and autoimmune diseases in

mice *in vivo* (Coll et al. *Nat Med.* 21: 248-255, 2015). Accordingly, we hypothesized that treating a diabetic (*db/db*) mouse with MCC950 would prevent pancreatic β cell death and delay, if not completely prevent, the onset of T2D. We treated *db/db* and littermate controls with MCC950 via their drinking water for 8 weeks. We verified the bioavailability of MCC950 in the blood of all treated animals. We did not detect, however, any differences in body weight, fat or lean mass when comparing the MCC950 treated *db/db* with the control group. Moreover, oral glucose tolerance tests showed similar glucose handling of the MCC950 *db/db* compared with the vehicle *db/db* and both *db/db* groups showed a progressive loss of β cell function when measuring plasma insulin over the course of the treatment. Finally, we did not detect any differences in circulating immune cell profiles between the 2 groups. These data suggest that, in *db/db* mice, NLRP3 driven-pancreatic IL1 β inflammation does not play a key role in the pathogenesis of disease.

432**Glucose and fatty acids in T cell-metabolism and their roles in immune regulation**

Kojima, H., Kashiwakura, Y., Kanno, Y., Hashiguchi, M., Kobata, T.

Dokkyo Medical University, School of Medicine, Department of Immunology, Tochigi, Japan

The glycolytic pathway plays a pivotal role in energy supply for cellular functions. We found that CD4⁺CD25⁺ regulatory T cells (Trs) were less dependent on glycolysis than CD4⁺CD25⁻ conventional

T cells (Tcvs), suggesting that Trs depend on oxidative phosphorylation more than Tcvs. Mitochondria (Mit) are key organelles for energy supply. It was found that the contents of Mit in Trs were similar to those in Tcvs at resting status. On the other hand, it was found that activated Trs contained less Mit than activated Tcvs. In addition, mitochondrial activity in activated Trs was less than that in activated Tcvs. These findings suggested that ATP demand and/or supply in Trs upon activation might be less than those in Tcvs. In fact, ATP production in activated Trs was significantly less than that in activated Tcvs. Though, activated Trs produced ATP significantly higher than resting Trs, suggesting that they may mainly utilize energy source other than glucose. Since fatty acids are well known as one of ATP sources, effects of fatty acids on T cell activation were assessed. To address this issue, palmitic acid (PA) was added into mixed lymphocyte cultures (MLCs). The addition of PA decreased T cell activation in MLCs including Trs more than in Tr-depleted MLCs. It is possible that PA affects Trs rather than other T cells. As the result, Trs energized with PA strongly inhibited Tcv activation. To confirm this hypothesis, assessment of effects of PA on ATP production among T cell-subsets is in progress.

433**A lipid metabolite profile in atherosclerotic plaques associated with increased inflammation and cardiovascular risk**

Tomas, L.¹, Björkbacka, H.¹, Edsfeldt, A.¹, Danielsson, A.¹, Wigren, M.¹, Grufman, H.^{1,2}, Persson, A.^{1,2}, Prehn, C.³, Adamski, J.^{3,4}, Nilsson, J.¹, Gonçalves, I.^{1,2}

¹Lund University, Department of Clinical Sciences Malmö, Malmö, Sweden, ²Malmö University Hospital, Department of Cardiology, Malmö, Sweden, ³Institute of Experimental Genetics, Helmholtz Zentrum München, Neuherberg, Germany, ⁴Institute of Experimental Genetics, Life and Food Science Science Center Weihenstephan, Freising-Weihenstephan, Germany

Atherosclerosis is characterized by the retention of lipids and chronic inflammation in the vasculature. In the present study we asked whether a certain lipid profile in carotid human atherosclerotic plaques is associated with a more inflammatory plaque phenotype and with future cardiovascular events (CE). Carotid plaques (n=159) from patients with and without cerebrovascular symptoms were analyzed for levels of 148 different lipids by electrospray ionization tandem mass spectrometry and phenotyped by measuring inflammatory mediators in homogenates and by immunohistochemical staining of sections.

By using 5 different clustering algorithms the lipid composition of each plaque was classified into two major clusters with different lipid profiles. Symptomatic plaques were significantly overrepresented in cluster 2 (76%, $p < 2.7 \times 10^{-5}$), whereas cluster 1 contained more asymptomatic plaques (60%, $p < 2.7 \times 10^{-5}$). In addition, cluster 2 was found to harbor more plaques with a high vulnerability index (CD68/ORO/Glycophorin A/Masson/ α -Actin; 68%, $p < 1.2 \times 10^{-9}$) as well as more inflammatory plaques (MCP-1/IL-6/IL-1 β ; 73%, $p < 1.3 \times 10^{-10}$), whereas the opposite was true for cluster 1 regarding vulnerability and inflammatory score. A reduced risk for future CE was found for cluster 1 ($p < 0.032$).

After adjusting for possible confounders (age, LDL, HDL, smoking, β -blockers, WBC and eGFR) the hazard ratio for future CE was 0.438 ($p = 0.039$). Adjusting for Framingham risk factors yielded similar results.

These results indicate that the lipid composition of human atherosclerotic plaques is associated with a pro-inflammatory plaque phenotype and increased risk of future CE.

434**Western-type diet induces myelopoiesis and modulates haematopoietic stem cell proliferation**

Karimi Azardaryany, M.¹, Ramezani-Moghadam, M.¹, Bendall, L.², Liddle, C.¹, George, J.¹, Esmaili, S.¹

¹Storr Liver Centre, The University of Sydney and The Westmead Institute for Medical Research, Sydney, Australia, ²Centre for Cancer Research, The Westmead Institute for Medical Research, The University of Sydney, Westmead, Australia

Consumption of a "western-type" diet is associated with obesity and the metabolic syndrome and is linked to widespread meta-inflammation. In obesity, expansion of bone marrow

haematopoietic stem cell and progenitor cells (HSPCs) leads to monocytosis that contributes to the accumulation of macrophages in adipose tissue and to atherosclerosis. Hypercholesterolaemia also induces monocytosis and expansion of HSPCs. We hypothesized that the cholesterol component of a western-type diets plays an important role in HSPC proliferation. We fed C57BL6 mice either a normal chow (NC) diet or a diet rich in sucrose (34%), cholesterol (2%), 0.5% sodium cholate (bile acid) (Atherogenic diet [ATH]) or a high sucrose diet without added cholesterol and cholate (HS) for 8 weeks. HS diet fed mice demonstrated the hallmarks of metabolic syndrome including insulin resistance and obesity. However, ATH diet fed mice were resistant to weight gain. Only the ATH diet induced hepatosplenomegaly with infiltration of immune cells in the liver and spleen. In bone marrow, we detected an increase in the number of HSPCs characterised as Lin⁻ CD45⁺ Sca-1⁺ c-Kit⁺ (LSK) (10-fold, $p = 0.001$) in ATH diet fed mice. The ATH diet also increased the number of Long-Term HSCs (2-fold, $p = 0.001$), characterised as LSK CD48⁻ CD150⁺, compared to the normal chow diet. Despite developing the metabolic syndrome, mice fed a HS diet did not demonstrate an increase in the number of inflammatory and stem cell subsets, indicating that cholesterol in combination with bile acids drives inflammation and stem cell proliferation.

435**Metabolic adaptation of polymorphonuclear neutrophils activated with pro-inflammatory cytokines**

Lachhab, A.^{1,2}, Brisebois, B.¹, Pelletier, M.^{1,2}

¹CHU de Québec-Université Laval Research Center, Infectious Diseases and Immunity Research Division, Quebec, Canada, ²Laval University, Quebec, Canada

Pro-inflammatory cytokines IL-6, TNF and IL-1 β are involved in chronic inflammatory diseases. They can modulate the responses of immune cells like polymorphonuclear neutrophils (PMNs), but their impact on their bioenergetics is not well defined. Using the extracellular flux analyzer, we observed a quick and robust glycolytic response in TNF-activated PMNs compared to IL-1 β - or IL-6-activated cells. TNF also induced rapid oxygen consumption, an effect enhanced with IL-1 β . IL-6 or IL-1 β alone had no effect on PMNs' oxygen consumption. At the molecular level, we observed that TNF- and IL-1 β -activated PMNs had enhanced gene transcripts coding for pro-inflammatory cytokines and for the metabolic adaptor *HIF-1A*. The expression of the glucose transporter *GLUT-3* and the amino acid transporters *CD98* and *ASCT2* transcripts were only modulated by TNF. Pre-incubation of PMNs with a competitive inhibitor of glucose revealed that the cytokine-activated oxidative burst depended on glycolysis. Since carbohydrates regulate this process, we examined the effect of sugars on TNF and IL-1 β -activated PMNs. The cytokine-induced oxidative burst occurred in the presence of sugar-free medium, or in media containing glucose and galactose. Surprisingly, this effect was completely inhibited in the presence of mannose, even when glucose and galactose were added. Moreover, the induction of pro-inflammatory cytokine transcripts in response to TNF and IL-1 β was significantly increased in PMNs when mannose was

used compared to glucose-, galactose- or sugar-free medium. These results indicate that pro-inflammatory cytokines exert different effects on PMNs' energy metabolism and that the carbohydrate nature can influence their cytokine expression and functional responses.

436

The ribonuclease Regnase-1 plays a role in iron homeostasis and anemia

Yoshinaga, M., Mino, T., Takeuchi, O.

Institute for Virus Research, Kyoto University, Kyoto, Japan

Iron homeostasis is tightly controlled during inflammatory responses. The coordinate regulation of iron homeostasis is largely dependent on the post-transcriptional control. However, the players and mechanisms of post-transcriptional regulation in the iron homeostasis have not been fully understood. Our group previously found a ribonuclease, named Regnase-1, destabilizes a set of pro-inflammatory cytokine mRNAs, including *Il-6* and *Il-12p40*. In this study, we investigated the role of Regnase-1 in the control of iron homeostasis and anemia through the analysis of Regnase-1-deficient mice. We found that Regnase-1-deficient mice showed severe iron deficiency and anemia, which was partly rescued by the intraperitoneal iron supplementation. Regnase-1-deficient mice did not show the signs of excess blood loss, and iron deficiency observed in Regnase-1-deficient mice was not rescued by the lack of lymphocytes. These findings suggest that Regnase-1 is critical for dietary iron absorption, and this function is largely independent of the control of inflammation. To identify Regnase-1 target mRNAs responsible for the iron uptake, we conducted the transcriptome analysis in duodenum, where iron uptake takes place, and found that several iron-controlling genes, including *Egln3*, were up-regulated under Regnase-1 deficiency. The overexpression of Regnase-1 accelerated the decay of the *Egln3* mRNA via its 3' untranslated region. Consistently, the expression of *Egln3*-regulated HIF-2 α target genes was impaired in Regnase-1-deficient mice compared with iron-deficient control mice. Furthermore, the abrogation of *Egln3* activity rescued the iron deficiency in Regnase-1-deficient mice. Taken together, Regnase-1 not only regulates inflammation but also prevents the development of anemia, by regulating the duodenal iron uptake.

437

Hepatic endogenous HMGB1 plays important roles in non-alcoholic fatty liver disease

Deng, M., Loughran, P., Billiar, T., Scott, M.

University of Pittsburgh, Surgery, Pittsburgh, United States

High-mobility group box 1 (HMGB1) is an abundant chromatin-associated nuclear protein and released into the extracellular milieu in non-alcoholic fatty liver disease (NAFLD). However, the function of intracellular HMGB1 in NAFLD is currently unknown. To determine the role of hepatic endogenous HMGB1 in NAFLD, we generated HC-specific HMGB1^{-/-} (HC- HMGB1^{-/-}) mice and induced NAFLD with high fat diet (HFD). At 8 weeks after HFD

administration, specifically deletion of HMGB1 dramatically exacerbated the pathogenesis of hepatosteatosis, evidenced by significantly higher body weight, total fat content, and liver fat content in HC- HMGB1^{-/-} than in control mice. The increase of liver fat content in HC- HMGB1^{-/-} mice with HFD was associated with decreased β -oxidation gene expression (*Lcad*, *Mcad*, and *Vlca*) in liver compared to control mice. Interestingly, at 16 weeks after HFD administration, the difference between HC- HMGB1^{-/-} and control mice in body weight, total fat content, and liver fat content diminished. However, there are more immune cells infiltration and collagen formation in the liver in HC- HMGB1^{-/-} than in control mice. Additionally, liver damage and was correlated to histology changes. We found that these were associated with significantly more reactive oxidative species (ROS) production in the liver in HC- HMGB1^{-/-} mice compared to control. Together, the above data indicate that hepatic endogenous HMGB1 plays important role in hepatosteatosis via regulation of β -oxidation. Lack of hepatic endogenous HMGB1 enhanced liver injury and inflammation at late stage of NAFLD, which may be mediated via increased ROS production in hepatocyte.

438

HIF-1 α stabilization through metabolic hypoxia via glutaminolysis in progressive pulmonary tuberculosis

Torres Rojas, M.¹, Abarca Rojano, E.², Huerta Yopez, S.³, Hernández Pando, R.⁴, Rangel Santiago, J.³, Mayoral Márquez, H.⁵, Domínguez López, M.L.⁶

¹Hospital Infantil de México Federico Gómez, Unidad de Investigación en Enfermedades Oncológicas, México, Mexico,

²Instituto Politécnico Nacional, Laboratorio de Respiración Celular, Escuela Superior de Medicina, México, Mexico, ³Hospital Infantil de México Federico Gómez, Unidad de Investigación en Enfermedades Oncológicas, México, Mexico, ⁴Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Departamento de Patología Experimental, México, Mexico, ⁵Instituto Politécnico Nacional, de Respiración Celular, Escuela Superior de Medicina, México, Mexico, ⁶Instituto Politécnico Nacional, Laboratorio de Inmunoquímica I, Escuela Nacional de Ciencias Biológicas, México, Mexico

Tuberculosis is a disease caused by the infection of *Mycobacterium tuberculosis*. According to the last report of the World Health Organization, in 2013 were reported 9 million of new tuberculosis cases and 1.5 million of deaths because of it, becoming the second cause of death caused by an infectious disease. During the infection many processes occur but inflammation is an angular event in the physiopathology of its evolution and can be triggered and promoted by multiple mechanisms. Is of our interest the study of the role played by HIF-1 α in this process and the mechanisms involved on its stabilization. Using tissue microarrays of postmortem lung samples, ones infected with tuberculosis and others none infected, we found out that HIF-1 α is significantly expressed in the infected ones, phenomenon that is also looked with the expression of *Mycobacterium tuberculosis* antigens, suggesting that there is a relation between the progression of the disease

and the presence of HIF-1 α . We also found that glutaminolysis enzymes: glutaminase 1 (enzyme that catalyzes the conversion of glutamine to glutamate) and glutamate dehydrogenase (enzyme that catalyzes the conversion of glutamate to α -ketoglutarate) are statistically increased, also related with the overexpression of succinylated proteins and the succinate receptor GPR91. With these results we suggest the presence of a state of metabolic hypoxia in which glutaminolysis is used as an anaplerotic way of producing succinate and consequently the stabilization of HIF-1 α by a competitive inhibition of the prolyl hydroxylase enzymes, finally promoting inflammation.

439

Adipose renin angiotensin system mediates fatty acid-induced endoplasmic reticulum stress in adipose tissue

Ramalingam, L.^{1,2}, Kalupahana, N.³, Moustaid-Moussa, N.^{1,2}

¹Texas Tech University, Nutritional Sciences, Lubbock, United States,

²Texas Tech University, Obesity Research Cluster, Lubbock, United States,

³Faculty of Medicine, University of Peradeniya, Department of Physiology, Peradeniya, Sri Lanka

Angiotensin System (RAS), a key regulator of blood pressure and fluid balance, has been linked to metabolic disorders. RAS components including its precursor angiotensinogen (Agt) and hormone product Angiotensin II are also locally generated in adipose tissue. Accumulation of free fatty acids causes lipotoxicity leading to inflammation and endoplasmic reticulum (ER) stress in adipose. However, the exact mechanisms are not completely understood. Hence, we hypothesize that ER stress in adipose tissue caused by FFA may be mediated through the RAS. To test the hypothesis, mice overexpressing angiotensinogen in the adipose were fed high fat diet supplemented with or without captopril (Angiotensin converting enzyme inhibitor). Markers of ER stress including C/EBP homologous protein (CHOP) and activating transcription factor 4 (ATF4) were significantly decreased in adipose tissue from Agt-Tg mice treated with captopril compared to vehicle-treated Agt-Tg littermate mice. Experiments are currently underway to further dissect these mechanisms in cultured adipocytes treated with fatty acids and/or specific RAS inhibitors. Further, miRNA profiling in adipose tissues from Agt-Tg and Wt mice revealed differential expression of several miRNAs between these 2 genotypes. Specifically, miRNA 99, known to regulate ER stress as was significantly higher in adipose tissue from Agt-Tg compared to Wt mice. Quantitative PCR validation of these findings are underway. In conclusion, RAS system is a potential mediator of fatty acid induction of ER stress that may promote obesity. Identification of novel mechanisms such as miRNAs regulating these pathways may provide novel means to reduce Agt-linked obesity and insulin resistance.

Glucosamine inhibits CD122 expression through the inhibition of glycolysis pathway in T cells

Kim, E.J.^{1,2}, Yoo, H.S.^{1,2}, Na, K.^{2,3}, Jeon, M.-S.^{1,2,3}

¹Inha University School of Medicine, Molecular Biomedicine, Incheon, Korea, Republic of, ²Inha University Hospital, Translational

Research Center, Incheon, Korea, Republic of, ³Inha University School of Medicine, IRIMS, Incheon, Korea, Republic of

D-glucosamine (GlcN) is known to have a therapeutic role in osteoarthritis (OA) by promoting the formation of joint cartilage. Molecular mechanisms how GlcN influences on immune cells are not fully understood. In this study, we investigated to understand the mechanism how GlcN influences on the T cell activation *in vitro*. We obtained the following results; 1) GlcN inhibited the T-cell proliferation and division. 2) This inhibition was not caused by apoptosis. 3) The initial activated state of the T cells was maintained in the presence of GlcN without cell division. 4) Interleukin-2 (IL-2) production was significantly increased in GlcN-treated T cell culture medium. 5) IL-2 receptor beta chain (CD122) was significantly decreased by GlcN. Thus, the increased IL-2 detection was occurred by the decreased CD122 expression. 6) GlcN markedly reduced the IFN- γ expression. 7) CD122 expression was reduced in T cells by the neutralizing IFN- γ . Thus, the level of IFN- γ production could regulate the CD122 expression. 8) We could detect the high glucose level in T cell culture medium treated with GlcN. This result could suggest that the glucose uptake might be blocked by GlcN. Taken together GlcN suppressed the IFN- γ production through the decreased glucose metabolism which resulted in the inhibition of CD122 expression. Therefore, the decreased CD122 expression impaired the T cells functions.

441

STAT5 signaling is a key regulator of glycolysis during immediate activation of naive, but not memory CD4+ T-lymphocytes

Jones, N., Cronin, J., Panetti, S., Thornton, C., Francis, N.

Swansea University, Medical School, Swansea, United Kingdom

Upon stimulation, CD4+ naive (NV) T-lymphocytes undergo rapid proliferation and clonal expansion resulting in a pool of effector (EM) T-lymphocytes that actively target the infection. The majority of this effector pool undergoes apoptosis post-infection, with the surviving cells resulting in a small viable, central memory (CM) population that will remain in the blood to provide a rapid response should reinfection occur. In order to carry out their specific roles, NV, EM and CM T-lymphocytes must obtain energy in the form of ATP.

Here we show that resting EM and CM cohorts have higher baseline metabolism than their NV counterparts, along with higher mitochondrial content. Upon activation with α CD3/28 we found that NV T-lymphocytes rapidly increase their glycolytic rate, with this immediate glycolytic switch being dependent on STAT5 signaling. Inhibition of STAT5 with N-((4-Oxo-4H-chromen-3-yl)methylene)nicotinohydrazide (100 μ M) significantly reduced glycolysis in NV, but not EM or CM T-lymphocyte suggesting divergent pathways of activation in memory populations. This divergence is not observed at the functional level with STAT5 inhibition significantly reducing the production of interferon- γ , interleukin-2 and expression of the activation marker CD69, without altering cell viability in NV, EM and CM populations.

These data suggest a key role for STAT5 during the initial

activation of NV CD4+ T-lymphocytes, but a differential signalling pathway for metabolic reactivation of memory populations.

442

UV-irradiation of skin enhances glycolytic flux in bone marrow-differentiated dendritic cells

Hart, P.¹, McGonigle, T.¹, Keane, K.², Newsholme, P.², Ghaly, S.¹, Carter, K.¹, Anderson, D.¹, Scott, N.¹, Goodridge, H.³

¹Teleton Kids Institute, Perth, Australia, ²Curtin University, School of Biomedical Sciences, Perth, Australia, ³Board of Governors Regenerative Medicine Institute, Cedars-Sinai Medical Centre, Los Angeles, United States

Following UV irradiation of skin, dendritic cells (DCs) differentiating from the bone marrow (BM) of mice have a reduced ability to prime new immune responses; their reduced immunogenicity is maintained for at least 16 weeks in UV-chimeric mice. We hypothesized that different metabolic states underpin changes in DC function. Compared with DCs from the BM of non-irradiated mice, DCs from the BM of UV-irradiated mice produced more lactate and utilized greater amounts of glucose, a profile that was supported by greater glycolytic flux when incubated in low-serum-containing medium. Responses to a mitochondrial stress test were similar suggesting that the DCs from the BM of UV-irradiated mice had not switched from a profile of oxidative phosphorylation, but were imprinted for greater glycolytic responses. After microarray profiling, RT-qPCR confirmation and Ingenuity pathway analysis, greater expression of the enzyme, 3-hydroxyanthranilate 3,4-dioxygenase, was identified as a potential contributor to increased glycolysis by BM-differentiated DCs. This enzyme provides the final step of the biosynthetic pathway from tryptophan to quinolinate, the universal de novo precursor to the pyridine ring of nicotinamide adenine dinucleotide (NAD), and may provide a mechanism to ensure sufficient NAD is available to support enhanced glycolysis. Increased lactate production was also measured for DCs from the BM of 16-week engrafted UV-chimeric mice and suggests long-lasting imprinting of progenitor cells for altered immunometabolism in their progeny cells. This study provides evidence of changes to metabolic states that associate with altered DC function.

443

Sensitivity to restimulation-induced cell death is linked to glycolytic metabolism in human CD8+ T cells

Larsen, S., Bilenkin, A., Snow, A.

Uniformed Services University of the Health Sciences, Pharmacology, Bethesda, United States

Restimulation-induced cell death (RICD) regulates immune responses by restraining effector T cell expansion and limiting nonspecific damage to the host. RICD is triggered by re-engagement of the T cell receptor (TCR) on a cycling effector T cell, resulting in apoptosis. It remains unclear how RICD sensitivity is calibrated in T cells derived from different individuals or subsets. Here we show that aerobic glycolysis strongly correlates with RICD sensitivity in human CD8+ effector

T cells. Reducing glycolytic activity or glucose availability rendered effector T cells significantly less sensitive to RICD. We found that active glycolysis specifically facilitates the induction of pro-apoptotic Fas ligand upon TCR restimulation, accounting for enhanced RICD sensitivity in highly glycolytic T cells. Collectively, these data indicate that RICD susceptibility is linked to metabolic reprogramming, and that switching back to metabolic quiescence may help shield T cells from RICD as they transition into the memory pool.

444

Rebamipide protects against atherosclerosis via regulation of Th17/Treg balance and oxLDL-induced foam cells formation

Kim, S.-Y., Jhun, J.Y., Kim, E.-K., Jeong, J.-H., Cho, M.-L.

Catholic University of Korea, Rheumatism Research Center, Catholic Research Institute of Medical Science, Seoul, Korea, Republic of

Atherosclerosis is a chronic inflammatory disease regulated by T lymphocyte subsets, especially a vascular inflammatory process in the presence of an excess amount of lipid. We reported that rebamipide reduced Th17 cells differentiation and also enhanced regulatory T (Treg) cells. Thereby we have used APoE deficient mice to inquire into whether rebamipide can treat atherosclerosis. We verified that aortas from APoE deficient mice that were treated rebamipide had less atherosclerotic lesions than APoE deficient mice (negative control) and positive control had by oil red O staining. In addition, we stained splenocytes from APoE deficient mice and confirmed that CD4+CD25+Foxp3+ regulatory T(Treg) cells were increased in rebamipide treated mice group compared with negative and positive controls. Moreover, we also confirmed that rebamipide could treat obese arthritis in vivo. Furthermore, we investigated that rebamipide could suppress ox-LDL induced foam cell formation in vitro. In conclusion, rebamipide can make balance between inflammatory T helper cells and Treg cells during processing atherosclerosis in a mouse model of accelerated atherosclerosis. Thus, rebamipide can be a therapeutic agent to suppress the progress of inflammatory diseases.

445

Platelet activating factor receptor in adipose tissue macrophages is associated with anti-inflammatory phenotype and metabolic homeostasis

Jancar, S.¹, Ribeiro Filgueiras, L.¹, Mainard Koga, M.¹, Kiyotaka Ishizuka, E.¹, B Montes, M.¹, José Rios, F.²

¹University of São Paulo, Department of Immunology, Institute of Biomedical Science, São Paulo, Brazil, ²University of Glasgow, Institute of Cardiovascular and Medical Sciences, British Heart Foundation Glasgow Cardiovascular Research Centre, Glasgow, United Kingdom

Metabolic dysfunction is associated with adipose tissue inflammation and macrophage infiltration. The Platelet Activating Factor Receptor (PAFR) is expressed in several cell types and binds to PAF and a wide range of oxidized phospholipids. Engagement of PAFR in macrophages drives them towards

the anti-inflammatory phenotype. In the present study, we investigated whether genetic deficiency of PAFR affects the phenotype of adipose tissue macrophages (ATM) and its effect on glucose and insulin metabolism. PAFRKO mice presented increased gene expression of *Ccr7*, *Nos2*, *Il6*, and *Il12*, associated to pro-inflammatory mediators, and reduced expression of the anti-inflammatory *Il10* in the epididymal adipose tissue. Moreover, the adipose tissue of PAFRKO presented higher pro-inflammatory macrophages, characterized by an increased frequency of *F4/80+CD11c+* cells. Blood monocytes of PAFRKO mice also exhibited a pro-inflammatory phenotype (increased frequency of *Lys6C+* cells) and PAFR-ligands were detected in the serum of both PAFRKO and WT. Regarding metabolic parameters, compared to WT, PAFRKO mice had:

- i) higher weight gain and serum glucose concentration levels;
- ii) decreased insulin-stimulated glucose disappearance;
- iii) insulin resistance in the liver;
- iv) increased expression of *Ldlr* in the liver.

When mice were fed high fat diet some of these changes were potentiated, particularly in the liver. Together these results indicate that endogenous ligands of PAFR are responsible for maintaining the anti-inflammatory profile of blood monocytes and adipose tissue macrophages under physiological conditions. In the absence of PAFR signaling, monocytes and macrophages acquire pro-inflammatory phenotype, resulting in adipose tissue inflammation and metabolic dysfunction.

NK cells link obesity-induced adipose tissue stress to inflammation and insulin resistance

Wensveen, F.M.¹, Valentić, S.¹, Jelenčić, V.¹, Šestan, M.¹, Turk Wensveen, T.², Theurich, S.³, Glasner, A.⁴, Mendrila, D.⁵, Štimac, D.², Wunderlich, F.T.³, Brüning, J.C.³, Mandelboim, O.⁴, Polić, B.¹

¹Faculty of Medicine, Department for Histology and Embryology, Rijeka, Croatia, ²University Hospital Rijeka, Department of Internal Medicine, Rijeka, Croatia, ³Max Planck Institute for Metabolism Research Cologne, Cologne, Germany, ⁴The Lautenberg Center for General and Tumor Immunology, The Hebrew University Hadassah Medical School, Jerusalem, Israel, ⁵University Hospital Rijeka, Department of Surgery, Rijeka, Croatia

Obesity is an increasingly common health issue that predisposes people to metabolic disorders such as insulin resistance (IR), which can progress to diabetes mellitus type 2 (DM2). An important underlying cause of obesity-induced IR is chronic systemic inflammation derived from accumulating pro-inflammatory macrophages in visceral adipose tissue (VAT). Currently, it is unknown which signal initiates adipose tissue macrophage (ATM) activation in VAT.

We find that a phenotypically distinct VAT-resident NK cells provide a crucial link between obesity-induced adipose stress and ATM activation in VAT. Ligands for the NK cell-activating receptor *NKp46/Ncr1* are expressed in human and mouse VAT. Feeding with high-fat diet causes up regulation of *Ncr1*-ligands on adipocytes, leading to localized activation and cellular increase of NK cells. *IFN γ* produced by these cells drives early pro-inflammatory macrophage differentiation and promotes obesity-induced insulin resistance. Lack of NK cells, *Ncr1* or *IFN γ*

prevents macrophage activation in VAT and greatly ameliorates glucose tolerance and insulin sensitivity. Therapeutic blocking of *Ncr1*-signaling forestalls ATM activation. Our study identifies NK cells as key regulators of macrophage polarization and insulin resistance in response to obesity-induced adipose stress. The NK-ATM axis therefore provides an attractive new target for early treatment of patients with metabolic syndrome to prevent progression to DM2.

447

Altered nutrient levels caused by B cell lymphoma leads to dysfunctional natural killer cells

Kobayashi, T.¹, Tuong, K.¹, Man, K.², McKee, S.¹, Leggatt, G.¹, Kallies, A.², Mattarollo, S.¹

¹University of Queensland Diamantina Institute/Translational Research Institute, Woolloongabba, Australia, ²Walter & Eliza Hall Institute, Melbourne, Australia

Natural killer (NK) cells are of paramount importance in immune protection against cancers. Optimal anti-tumour immunity requires functional NK cells. Cumulative evidence suggests that efficient cellular metabolism is not only required for maintaining cells, but also is a driving force for specific immune cell functions. In blood cancers, where tumour cells and host immune cells are co-located, tumour cells can impact on immune cell metabolism, which can lead to immune system dysfunction. Here, we found that the metabolic signatures of NK cells are distinct from other lymphocyte populations, having the highest lipid intake and storage capacity compared with that of B cells, T cells, and NKT cells. We also found that, in murine c-myc-driven B cell lymphoma-bearing mice, NK cells showed altered metabolic profiles associated with their developmental, survival, and functional defects. These defects were measured by a decrease in the number, abnormal subset compositions, down-regulated NK activating receptors and suppressed effector molecule production (*IFN- γ* and Granzyme B) respectively. We next hypothesized that the cellular metabolism of NK cells is compromised due to altered availability of nutrients. To this end, we studied metabolite levels in the system and observed that altered amounts of fatty acids and amino acids released by tumour cells led to defects in *AKT/mTORC1* signalling and up-regulation of apoptosis, both of which eventuate in the observed NK cell dysfunction.

This study has demonstrated how blood cancers negatively regulate NK cell metabolism and their functions, and has discovered a potential immunometabolic checkpoint target for cancer immunotherapies.

448

The effect of matrix metalloproteinase-2 for the islets of streptozotocin-induced diabetic mouse model

Takeshita, A.¹, Yasuma, T.¹, Nishihama, K.¹, Hinneh, J.², D'Alessandro-Gabazza, C.², Harada, E.², Toda, M.², Yano, Y.¹, Gabazza, E.²

¹Mie University Graduate School of Medicine, Diabetes and Endocrinology, Tsu-City, Japan, ²Mie University Graduate School of Medicine, Immunology, Tsu-City, Japan

Background: Matrix metalloproteinase-2 (MMP-2) is one of the enzymes that decompose extracellular matrix. Although previous reports refer to effect of MMP-2 for islet of pancreas, its detailed role is still unclear.

Objective: To investigate the role of MMP-2 in pancreatic beta cell of streptozotocin (STZ)-induced diabetic mouse model.

Methods: We injected saline (SAL) or STZ to 15-week-old human matrix metalloproteinase-2 over-expression transgenic mice (hMMP-2Tg) and 17-week-old control mice (WT). Mice were divided into 4 groups (WT/SAL, WT/STZ, hMMP-2Tg/SAL, hMMP-2/STZ). Measurement of blood glucose, intraperitoneal glucose tolerance test (IPGTT) and glucose induced insulin secretion test were performed. Mice were killed after 4 weeks of injection. Pathological evaluations of pancreas were done after sacrifice.

Results: Compared with WT/STZ group, blood glucose levels of hMMP-2Tg/STZ group were significantly lower at 14, 21 and 28 days after injection. IPGTT suggest that the changes of blood glucose were milder in hMMP-2Tg/STZ group than WT/STZ group. Glucose induced insulin secretion test revealed the levels of serum insulin of hMMP-2Tg/STZ mice were higher than those of WT/STZ group. Larger islet was significantly preserved in hMMP-2Tg/STZ group against WT/STZ group.

Conclusion: Over-expression of hMMP-2 may be protective against STZ-induced diabetic mellitus.

Dipeptidyl peptidase 9 enzyme activity alters expression of genes that are important in neonatal immunity, insulin signalling and metabolism

Chen, Y.^{1,2}, Gall, M.^{1,2}, Zhang, H.^{1,2}, McCaughan, G.^{2,3}, Yu, D.^{1,4}, Gorrell, M.^{1,2}

¹Centenary Institute, Molecular Hepatology Laboratory, Newtown, Australia, ²University of Sydney, Sydney Medical School, Sydney, Australia, ³Centenary Institute, Liver Injury and Cancer Program, Newtown, Australia, ⁴Children's Cancer Institute, Kensington, Australia

Dipeptidyl peptidase 9 (DPP9) is a ubiquitous intracellular protease that is up-regulated in activated T and B cells, macrophages and many tumours. DPP9 can influence antigen processing and secretion of pro-inflammatory cytokines. Newly identified DPP9 substrates include two key immune regulators, C-X-C motif chemokine 10 (CXCL10) and interleukin-1 receptor antagonist (IL-1RA), calreticulin and adenylate kinase 2, indicating potential roles of DPP9 in immune function, energy metabolism and homeostasis.

Our homozygous mice lacking DPP9 enzyme activity (*Dpp9* gene knock-in; *Dpp9* gki) display neonatal lethality. Taqman PCR arrays and sequential qPCR assays on neonatal liver and gut revealed differential expression of genes involved in innate immunity, insulin signalling and metabolic pathways, suggesting a less active IL-1 β /TNF α -induced NF- κ B pathway, enhanced insulin sensitivity, dysregulated glucose metabolism including increased hepatic gluconeogenesis and extrahepatic glucose uptake and utilization, disrupted long-chain-fatty-acid uptake, increased VLDL uptake and clearance of circulatory HDL from blood in *Dpp9* gki neonatal mice compared to wild type. *In vitro* mechanistic studies indicated that effects of DPP9 enzymatic activity on neonatal metabolism may occur

via modulating AMPK phosphorylation. The dysregulation of both metabolic genes and the NF- κ B mediated inflammatory pathway in *Dpp9* gki neonatal mice may be linked, and would be expected to exacerbate any other pathogenic process that occurs in the *Dpp9* gki neonates, and so might contribute to the neonatal lethality seen in *Dpp9* gki mice.

These data point to important biological roles for DPP9 in inflammation and metabolism in newborn mice.

T-cells induced by oral gluten challenge in patients with coeliac disease confirm the in vivo effects of gluten hydrolysed by intestinal bacteria from gnotobiotic mice

Russell, A.¹, Caminero, A.², Galipeau, H.J.², Mccarville, J.L.², Johnston, C.W.³, Bernier, S.P.², Jury, J.², Tye-Din, J.A.¹, Casqueiro, J.⁴, Surette, M.G.^{2,5}, Schuppan, D.⁶, Magarvey, N.A.³, Verdu, E.F.²

¹Walter and Eliza Hall Institute of Medical Research, Immunology, Parkville, Australia, ²Farncombe Family Digestive Health Research Institute, McMaster University, Hamilton, Canada, ³DeGroot Institute for Infectious Disease Research, McMaster University, Biochemistry and Biomedical Sciences, Hamilton, Canada, ⁴Universidad de Leon, Microbiología, Leon, Spain, ⁵DeGroot Institute for Infectious Disease Research, McMaster University, Hamilton, Canada, ⁶Institute for Translational Immunology and Research Centre for Immunotherapy, Johannes Gutenberg University, Mainz, Germany

Coeliac disease (CD) is a gluten-mediated autoimmune condition. At least 30% of the population carry the genetic predisposition for CD, but only 2-4% develop disease, implicating a role for environmental factors in disease onset. Intestinal dysbiosis in CD has been implicated, but the mechanism remains unclear. The ability of intestinal bacteria isolated from CD (*Pseudomonas aeruginosa* (*Psa*)) and non-CD (*Lactobacillus spp*) subjects to hydrolyse wheat gluten/gliadin protein and a 33mer peptide from gliadin containing immunogenic T-cell epitopes was confirmed in a gnotobiotic mouse model. We sought to assess the immunogenic potential of these hydrolysed end-products in human CD volunteers.

HLA-DQ2.5+ CD patients in remission consumed wheat-bread for 3 days. PBMCs were collected before (D0) and after (D6) commencing the challenge. An overnight IFN- γ ELISpot assay was used to enumerate T-cells responding to a range of peptides generated by incubation of bacteria with pepsin/trypsin-digested (PT) gliadin or 33mer.

Gluten-specific T-cells were detected on D6 but not D0. Responses were substantially increased to PT-gliadin (~2x) and 33mer (~3x) after deamidation, and significantly increased by incubation with *Psa* (~5x). In contrast, PT-gliadin incubated with *Lactobacillus spp.* was less immunogenic than PT-gliadin alone. Disease-specific polyclonal T-cells induced by oral feeding challenge were useful to confirm the in vivo relevance of hydrolysed gliadin and 33mer. The findings indicate that human small intestinal bacteria participate in the metabolism of gluten peptides, and these effects differ between bacteria isolated from CD compared to non-CD patients. This describes a potential mechanism through which dysbiosis could modulate CD risk.

451

A SAXS based model of a tip pilin protein of *Lactobacillus rhamnosus* GG: insight in its structural properties*Bhattacharjee, A.¹, Douillard, F.P.², Sèle, C.³, Rasinkangas, P.², Klievink, J.¹, Messing, M.¹, de Vos, W.M.^{1,4}*¹University of Helsinki, Research Program Unit, Immunobiology, Helsinki, Finland, ²University of Helsinki, Department of Veterinary Biosciences, Helsinki, Finland, ³University of Helsinki, Institute of Biotechnology, Helsinki, Finland, ⁴Wageningen University, Laboratory of Microbiology, Wageningen, Netherlands

Lactobacillus rhamnosus GG is a well-characterized probiotic strain that displays health-promoting properties for the host. *L. rhamnosus* GG establishes interaction with the intestinal mucosa using mucus-binding pili, protruding protein fibers with a length that equals that of the producing bacterium. These pili have been shown to be an important colonization and persistence factor in the gastrointestinal tract. Specifically, the pilin subunit SpaC, located at the tip of the pili in *L. rhamnosus* GG has mucus-binding properties. It is a large (90 kDa) multi domain protein and has some typical features of gram positive pili proteins. However, the binding domains of SpaC are still largely unknown. Hence, we determined the low resolution structure of purified SpaC by small angle X-ray scattering technique. This gave a clear idea of the envelope of the big protein. Subsequently, we did fit in the pre-modelled individual domains of SpaC in the experimentally determined envelope of SpaC. The resulting structure provided extensive insights into the intra molecular peptide bonds in SpaC and beyond. Preliminary mass spectrometry data also supported the presence of intra- and inter-molecular peptide bonds in the tip pilin of SpaC. Thus, we provided a model of the molecular architecture of the tip pilin of GG, providing a working basis to further explore its role in host interaction and signaling.

452

Nutrition-induced changes in microbiome alter inflammatory airways disease outcome*Maddox, D.**Mayo Clinic, Allergic Diseases & Internal Medicine, Rochester, United States*

A recent cohort study suggested that a high intake of fibers in food protects from early death from several causes. Other investigators have reported that intake of grain fibers modulates cytokine levels in blood, and their data actually suggests that certain grain fibers actually reduce pro-inflammatory cytokine levels. The human microbiome contributes many physiologically important moieties to the bloodstream, and some recent studies suggest that grain-related carbohydrates induce changes in the microbiome that are pro-inflammatory on a systemic basis. We here report that patients presenting with chronic non-allergic inflammatory airways disease [chronic rhinosinusitis with nasal polyposis and bronchial asthma] improve clinically when nutritional patterns are modified to exclude grain-related foods. This clinical improvement exceeds the results expected from pharmacologic management alone. This result seems to beg the question of whether the carbohydrate associated with grain-

related foods is more important in modulating microbiome components, or the fiber is the more important element. When grain-related foods are reduced in the nutritional pattern, vegetable-related elements tend to increase, and experiments that isolate storage carbohydrate from structural fiber content will be necessary in order to understand which element predominates in this improved clinical outcome.

453

Polymyxin B modulation of maternal gut microbiome during pregnancy and lactation alters neonatal immunity*Nyangahu, D.¹, Jaspan, H.^{1,2}*¹University of Cape Town, Cape Town, South Africa, ²Seattle Children's Research Institute, Seattle, United States

Introduction: The pioneer microbiome in neonates may affect future actions of the immune system. How antibiotic use during pregnancy and lactation may influence neonatal microbiome and immunity is not clear.

Methodology: Pregnant BALB/c mice were treated with polymyxin B 5 days prior to giving birth and while nursing or just while nursing. We killed pups 14 days postpartum and investigated the splenic immunity.

Results: Pups born to mothers treated during either gestation or nursing had significantly increased body weight when compared to controls. However, maternal antibiotic treatment during both gestation and nursing did not associate with a change in neonatal weight. We observed a significant decrease in the proportions of CD4+ T cells in the spleen of pups born to mothers treated with Polymyxin B during gestation ($p=0.005$). Analysis of the activation status of splenic CD4+ T cells in pups showed, pups born to mothers treated with polymyxin B throughout gestation and nursing or in gestation or nursing alone had significantly lower proportions of effector T cells when compared to pups born to untreated mothers. The frequency of T regulatory cells was significantly higher in pups nursed by antibiotic treated mothers ($p=0.011$). Neonatal B cell alterations by maternal antibiotics were less marked. We observed a trend towards decreasing proportions of B cells in infant mice born to mothers treated with polymyxin B during either gestation or lactation.

Conclusions: Maternal microbial perturbations during gestation and nursing are critical for immune development in neonates.

454

Therapeutic bacterial transplantation for atopic dermatitis*Myles, I.**National Institutes of Health (NIH), NIAID, Bethesda, United States*

Atopic dermatitis (AD) is characterized by reduced barrier function, reduced innate immune activation, and susceptibility to *Staphylococcus aureus*. Host susceptibility factors are suggested by monogenic disorders associated with AD-like phenotypes, and can be modulated through topical steroids or calcineurin inhibitors. *S. aureus* is another known contributor to AD pathogenesis, and can be mitigated by antibiotics or bleach baths. Recent work has revealed that the skin microbiome

differs significantly between healthy controls and patients with AD. However, little is known about the contribution of dysbiosis to AD symptoms or if microbiome modulation could provide therapeutic benefit. In various cellular and culture-based models, we found that commensal Gram-negative (CGN) bacteria taken from healthy human volunteers but not from patients with AD were associated with enhanced barrier function, innate immunity activation, and control of *S. aureus*. Treatment with CGN from healthy controls improved outcomes in a mouse model of AD. These findings may hold therapeutic promise for AD patients.

455

Differences in the breast ductal fluid microbiome from healthy women vs. women with a history of breast cancer

Chan, A.A.¹, Bashir, M.^{2,3}, Duval, K.^{4,5}, Vaishampayan, P.A.², Love, S.⁵, Lee, D.J.¹

¹John Wayne Cancer Institute, Translational Immunology, Santa Monica, United States, ²Jet Propulsion Laboratory, California Institute of Technology, Biotechnology and Planetary Protection Group, Pasadena, United States, ³Medical University of Graz, Division of Endocrinology and Metabolism, Graz, Austria, ⁴University of California Los Angeles, Breast Center, Westwood, United States, ⁵Doctor Susan Love Research Foundation, Encino, United States

Recent studies have reported the presence of bacterial DNA in human breast tissue and milk, leading to a paradigm shift in breast physiology, and a potential role for microbes to stimulate antitumor immunity in breast cancer. Our previous work described *Sphingomonadaceae* family members to be greater in paired normal vs. breast tumor tissue from breast cancer patients. Here we studied the breast ductal microbiome using nipple aspirate fluid (NAF), which is constantly secreted and absorbed by breast ductal epithelium, to investigate the ductal microbiome and its potential association with breast cancer. We used 16S amplicon DNA sequencing to compare nipple skin as well as the NAF microbiome between healthy control women (HC) and women with a history of breast cancer (BC) While the skin microbiome from BC vs. HC showed no differences, we found that the NAF microbiome from BC vs. HC showed statistically significant community-wide differences. The genus *Alistipes* was significantly higher in NAF from BC while an unclassified genus from the *Sphingomonadaceae* family was significantly higher in NAF from HC. The association of *Sphingomonadaceae* with a healthy state in this second independent study suggests a potentially protective role in breast cancer. We detected bacterial DNA in human breast ductal fluid and found that breast ductal microbiome differs based on health status with regard to a woman's history of breast cancer. These findings warrant further investigation of the breast ductal microbiome and the potential role for specific microbes or their genes to promote antitumor immunity in breast cancer.

456

Circulating microRNA as a biomarker for diagnosis of tuberculosis

Yuan, L., Cao, S.L., Shen, A.P.

Shihezi University, Shihezi, China

The aim of the study was to explore whether certain microRNA (miRNA) could serve as biomarkers for active pulmonary TB and latent tuberculosis infection diagnosis. Plasma was collected from healthy controls, active pulmonary tuberculosis (PTB) patients and latent tuberculosis infection (LTBI) patients. Expression levels of circulating miR-155-5p, miR-21-5p and miR-29a were validated and compared by RT-qPCR. The expression levels in plasma of miR-155-5p, miR-21-5p, miR-29a in the active pulmonary TB group were increased 12.27, 4.73 and 3.82 times compared to healthy controls. By ROC curve analysis of active pulmonary TB and healthy controls, the area under the curve (AUC) were 0.938, 0.880, 0.808. MiR-155-5p and miR-21-5p levels were increased 3.21 and 2.39 times in LTBI compared with healthy controls. Furthermore active TB patients had higher expression levels of miR-155-5p, miR-21-5p, miR-29a compared with LTBI patients, 3.82, 1.98 and 8.50 times respectively. Thus significant and potentially clinically useful differences of miR-155-5p, miR-21-5p, and miR-29a plasma expression levels were observed among healthy controls, active pulmonary TB and LTBI, suggesting that these miRNA may serve as potential biomarkers for diagnosis, as well as provide new insights into the human response to tuberculosis infection.

457

Contribution of gut microbial composition to the development of diet-induced metabolic syndrome in BALB/c mice

van den Elsen, L., Jones, A., Plunkett, C., Forbes-Blom, E.

Malaghan Institute of Medical Research, Wellington, New Zealand

The gut microbiota contributes to the metabolic phenotype. Germ-free mice are protected against diet-induced obesity and transfer of gut microbiota from obese to germ-free mice results in fat mass gain. The development of obesity correlates with low *Bacteroidetes* and high *Firmicutes* in the gut. Generally BALB/c are considered resistant to developing metabolic syndrome. We investigated the susceptibility of BALB/c mice to develop diet-induced metabolic syndrome and the role of the gut microbiota in this process by using 2 lines of BALB/c mice with divergent gut microbial compositions (BALB/c A versus B). Mice were fed a control or high fat/high sugar diet (HFHSD) for 15 weeks. BALB/c A had a higher *Firmicutes/Bacteroidetes* ratio at baseline than BALB/c B. The HFHSD increased the ratio for both BALB/c lines, however their microbial signature remained very different with specific bacterial species present. BALB/c A fed the HFHSD gained more body weight than the control group, whereas BALB/c B did not. Fat pad mass was larger in BALB/c A vs B and increased significantly when fed the HFHSD in BALB/c A only. This is in line with increased serum leptin concentrations. HFHSD-fed BALB/c A also showed increased expression of IL-6 and TNF- α mRNA in adipose tissue. However, BALB/c B but not A developed impaired glucose tolerance and insulin sensitivity

when fed HFHSD. This was associated with higher serum LPS levels. In conclusion, the gut microbiota has a differential effect on hallmarks of the metabolic syndrome, which is associated with the abundance of certain bacterial species.

458

Blockade of CB1 cannabinoid receptor attenuates gut microbiota dysbiosis and inflammation in dietary induced obesity

Mehrpouya-Bahrami, P.¹, Ganewatta, M.S.², Tang, C.², Nagarkatti, M.^{1,3}, Nagarkatti, P.¹

¹School of Medicine, University of South Carolina, Pathology Microbiology and Immunology, Columbia, United States,

²University of South Carolina, Department of Chemistry and Biochemistry, Columbia, United States, ³Dorn VA Medical Center, Columbia, United States

Obesity is characterized by chronic low-grade, systemic inflammation, altered gut microbiota and gut barrier disruption. The endocannabinoid system (eCB) plays a major role in the regulation of the inflammation and metabolic disorders associated with obesity. We investigated the effect of treatment of mice with SR141716A, a cannabinoid receptor1 (CB1) antagonist, on Diet Induced Obesity (DIO), specifically addressing whether such a treatment can induce anti-inflammatory state in adipose tissue. We demonstrated that blockade of CB1 receptor reduced plasma LPS level, circulating inflammatory cytokines and the trafficking of M1 macrophages into the adipose tissue. This decreased inflammatory tone was associated with a lower intestinal permeability and improved hyperglycemia and insulin resistance. In order to better understand the beneficial effects of SR141716A in DIO model, we performed 16S rRNA metagenomic sequencing to investigate alterations in the gut microbiome. Analysis of fecal samples revealed that treatment with SR141716A dramatically increased the relative abundance of Akkermansia muciniphila within the Verrucomicrobia phylum. Although an increase in the genus Prevotella also emerged as strong biomarkers of SR141716A treatment, the increase in A. muciniphila was the only strong biomarker consistently detectable across taxonomic levels and sample types. Drastic reduction in immunogenic Lachnospiraceae and Erysipelotrichaceae with SR141716A treatment was beyond its effect on the weight loss and diet intake. High levels of anti-inflammatory propionate and butyrate in cecal content of SR141716A treated group was detected. Our data suggest that blocking of CB1 receptors ameliorates obesity by restoring gut microbiome and consequently their metabolites which modulate macrophage inflammatory mediators.

459

Deletion of CD44 leading to amelioration of experimental autoimmune encephalomyelitis results in altered gut microbiome profile and short-chain fatty acid production

Chitralla, K.N.¹, Guan, H.¹, Busbee, B.¹, Gandy, A.¹, Ganewatta, M.S.², Tang, C.², Nagarkatti, P.¹, Nagarkatti, M.^{1,3}

¹University of South Carolina, School of Medicine, Pathology, Microbiology, and Immunology, Columbia, United States,

²University of South Carolina, Chemistry and Biochemistry, Columbia, United States, ³WJB Dorn VA Medical Center, Columbia, United States

Dysbiosis in gut microbiome has been shown to be prevalent in inflammatory and autoimmune diseases. Previous studies from our lab have demonstrated the pivotal role played by CD44 in experimental autoimmune encephalomyelitis (EAE), a murine model of multiple sclerosis (MS). Specifically, we showed that CD44KO mice were resistant to induction of EAE when compared to CD44WT mice and this was to be due to inhibition in the pro-inflammatory Th1/Th17 and increased anti-inflammatory Th2/Treg cell activity. In the current study, we determined whether these effects resulted from an alteration in gut microbiota and the short-chain fatty acids (SCFAs) produced in CD44WT and KO mice. For this purpose, we have performed high-throughput bacterial 16S rRNA gene sequencing followed by clustering sequences into operational taxonomic units (OTUs) and biochemical analyses. KO mice showed significant diversity, richness and evenness when compared to WT mice at the phylum level with dominant *Bacteroidetes* (70.37%) and low *Firmicutes* (27.43%). Taxonomic analysis showed a significant change ($P < 0.05$) in the genera *Alistipes*, *Bacteroides*, *Hallella*, *Meniscus*, *Odoribacter*, *Parabacteroides*, *Phocaeicola*, *Flavonifractor*, *Syntrophococcus*, *Daeguia*, *Desulfovibrio*, *Dongia*, *Helicobacter*, *Litorimonas*, *Nitrosococcus*, *Thiobacter*, *Vampirovibrio*, *Wolinella* and *Mucispirillum* of KO mice compared to the WT mice. Further, results showed a significant change ($P < 0.05$) in the SCFAs, butyric acid, propionic acid and valeric acid in KO compared to WT mice. In conclusion, our results showed that alterations in gut microbiota and SCFAs can shape the immunological environment in MS. (Supported by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357).

Natural dietary indole, indole-3-carbinol, prevents gut microbiota dysbiosis during murine TNBS colitis induction, effectively alleviating colitis associated symptoms

Busbee, P.¹, Nagarkatti, M.², Nagarkatti, P.³

¹University of South Carolina School of Medicine, Columbia, United States, ²University of South Carolina School of Medicine, Pathology, Microbiology, and Immunology, Columbia, United States,

³University of South Carolina, Vice President of Research, Columbia, United States

Colitis is an autoimmune disease characterized by acute or chronic inflammation of the large intestine. Currently there is no cure for patients suffering from colitis, and most treatments involve the use of immunosuppressive drugs that can have adverse side-effects or increased toxicity. In the current study, we investigated the effects of indole-3-carbinol (I3C), a component found in a number of cruciferous vegetables, on two murine colitis models (DSS and TNBS). Our data shows that administration of I3C alleviates symptoms associated with colitis in both of these models, which includes reversal of weight loss and colon shortening. In addition, mice treated with I3C showed decreased levels of circulating inflammatory

serum cytokines and cellular infiltration into the colon. In order to better understand the beneficial effects of I3C against colitis, we performed 16S rRNA metagenomic sequencing to investigate alterations in the gut microbiome after induction of colitis by TNBS and treatment with I3C. Analysis of cecal flushes revealed that TNBS administration leads to a decrease in several Firmicute species (e.g. *Sedimentibacter hydroxybenzoicus* and *Clostridium frigidis*), while increasing several species belonging to the Phylum Bacteroidetes (e.g. *Bacteroides acidifaciens*, *Dysgonomonas wimpennyi*, and *Bacteroides xylanisolvens*). However, mice that were treated with I3C showed a remarkable reversal in these gut microbial alterations caused by TNBS colitis induction, having gut microbiome similar to that of vehicle-treated control mice. Collectively, these data suggest that I3C is able to ameliorate colitis by preventing pathogenic gut microbial dysbiosis and restoring gut microbiome composition to a more homeostatic state.

Effects of folate on gut microbiome and intestinal immune responses in AA-induced kidney inflammation model

Tang, P.Y., Lin, B.-F.

National Taiwan University, Department of Biochemical Science and Technology, Taipei, Taiwan, Republic of China

Introduction: Aristolochic acid is a common ingredient in Chinese medicine for aiding losing weight, but has been found causing kidney inflammation. Folic acid supplementation has been used as a treatment for the patients to reduce adverse effects in chronic kidney diseases. Gut microbiota has been suggested to modulate immune homeostasis and microbial imbalance has been found in many inflammation diseases, including kidney diseases. Besides kidney, AA is also toxic to intestine, folate supplementation can help maintain gut barrier that might prevent intestinal inflammation. So we want to explore the effects of folate supplementation on intestinal immune responses and microbiome in AA-induced kidney inflammation model.

Materials and methods: Feces from C57BL/6 mice fed with AA and supplemented with or without folic acid were collected and fecal genomic DNA were analyzed. Immune cells from payer's patches or mesenteric lymph nodes will be stimulated with ConA and cytokine levels including IL-2, IFN-g, IL-10 and IL-17 will be analyzed.

Results: Due to the results of CNS inflammation model (EAE) we did before, under folate supplementation conditions, the average level of IL-2 in MLN decreased. The gene fold expression of Lactobacilli is lower than normal folate diet. We will further analyze the association between the microbiome and inflammation in murine model of kidney inflammation.

Conclusion: Intestinal immune responses of AA-induced kidney inflammation animal model might be influenced under folate supplementation. Microbial constitution and intestinal immune responses will be correlated to further clarify the effects of folate on gut microbiome in murine model of kidney inflammation.

High frequency of *Helicobacter pylori* infection in opisthorchiasis and its association with advanced periductal fibrosis in liver fluke endemic areas of Thailand

Deenonpoe, R.¹, Chomvarin, C.², Mairiang, E.³, Rinaldi, G.⁴, Pairojkul, C.⁵, Chamgramol, Y.⁵, Mairiang, P.⁶, Loukas, A.⁷, J. Brindley, P.⁴, Sripa, B.^{5,8}

¹Chulabhorn International College of Medicine Thammasat University, Pathobiology, Pathum Thani, Thailand, ²Khon Kaen University, Microbiology, Khon Kaen, Thailand, ³Khon Kaen University, Radiology, Khon Kaen, Thailand, ⁴George Washington University, Microbiology, Immunology and Tropical Medicine, and Research Center for Neglected Tropical Diseases of Poverty, Washington DC, United States, ⁵Khon Kaen University, Pathology, Khon Kaen, Thailand, ⁶Khon Kaen University, Medicine, Khon Kaen, Thailand, ⁷James Cook University, Australian Institute of Tropical Health & Medicine, Cairns, Australia, ⁸Khon Kaen University, Tropical Disease Research Laboratory, Khon Kaen, Thailand

Objective: To investigate the prevalence of infection with *Helicobacter* spp. and virulence factors in association with advanced periductal fibrosis in people with and without infection with the *Opisthorchis viverrini* in endemic areas of Thailand.

Methods: Five hundred and fifty-four stool samples recruited from case-control Thai people residing in endemic for opisthorchiasis were investigated for infection with species of *Helicobacter*. All *Helicobacter* data were analyzed in association with advanced periductal fibrosis.

Results: Overall prevalence of *H. pylori* infection was significantly higher in *O. viverrini*-infected (69.3%) than uninfected (30.8%) groups (P 0.001). Significantly higher prevalence of infection with *H. bilis*, but not *H. hepaticus*, was also observed in *O. viverrini* infected group (29.3%) compared to non-*O. viverrini* positive participants (5.4%) (P 0.001). Interestingly, participants infected with *O. viverrini* showed significantly higher frequency of *cagA*-positive *H. pylori* than those uninfected (21.1 vs. 5.0%,) (P 0.001) similar to those of *cagE* (10.2 vs. 1.9 % for *O. viverrini*-infected and uninfected groups, respectively)

(P 0.001). Phylogenetic analysis of *CagA* sequences revealed significant higher prevalence of AB type in *O. viverrini*-infected (75.8%) than those uninfected (93.2%) (0.05) whereas the ABC type (typically western *CagA* type) was found only in *O. viverrini*-infected group.

Conclusion: People with opisthorchiasis harbour higher rates of *Helicobacter* than those uninfected in an intensity dependent manner. *H. pylori* and its virulence factors, specifically *CagA* and *CagE* and *H. bilis* may be involved in the pathogenesis of opisthorchiasis-associated hepatobiliary disease and including cholangiocarcinoma.

Keywords: *Helicobacter* spp., *Helicobacter pylori*, *cagA*, *cagE*, opisthorchiasis, periductal fibrosis

463**Altered gut microbiota and resulting immunomodulation is key to alcoholic liver disease pathogenesis: a northeast India based study**

Bose, S.¹, Bose, M.¹, Basumatary, T.K.¹, Begum, R.H.², Baruah, V.¹, Kalita, M.P.², Bujarbaruah, D.¹, Saikia, A.K.³

¹Gauhati University, Biotechnology, Guwahati, India, ²Assam University, Diphu Campus, Lifesciences and Bioinformatics, Diphu, India, ³Central Hospital, NF Railway, Gastroenterology and Medicinal Unit, Guwahati, India

Present study focused on alterations in gut-microbiota and its clinical relevance with alcohol mediated liver disease susceptibility and severity in tribal patients enrolled from northeast India.

Methodology: Cases[ALD=76, alcoholic-without liver disease(AWLD=25)] were enrolled with clinical details and liver stiffness measurement(LSM) score;along with healthy controls(n=180). Decidual aspirations based microbiome load analysis was performed by standard culture methods for ALD and AWLD cases. Serum endotoxin levels were estimated using standard kit (Lonza). Differential sCD14,mCD14,TLR4,TLR2,NK/NKT expression was analyzed by ELISA/flowcytometry. Differential cytokine profile was studied by multiplex ELISA method. Statistical analysis was performed by SPSS software.

Results: Increased total and gram negative bacterial load was significantly associated with ALD compared to AWLD. Serum endotoxin, sCD14 levels increased gradiently: controls< AWLD< CLD< cirrhosis. Monocyte-CD14 expression was significantly higher in cirrhosis cases(73.98±33.46%) compared to controls(44.30±28.84%), AWLD (43.47±17.08%) and alcoholic-CLD(42.28±18.97%). Average TLR4 expression on blood cells was highest in alcoholic-CLD cases(19.04±8.62%) compared to other cohorts which were comparative. Average serum TLR2 expression (in ng/ml) was higher in alcoholic-CLD(6.08±0.763) and cirrhosis cases(6.12±0.78) compared to AWLD(5.39±0.62) and controls(5.43±0.89). TLR4, TLR2 levels significantly positively correlated with higher LSM scores and mCD14 levels; while mCD14 levels also correlated positively with higher LSM score. NK cell expression was higher in cirrhosis. Distinct up-regulation of NFκB, TNF-α combined with significant down-regulation of anti-inflammatory cytokine IL-6, IL-10 at both protein and mRNA level was found to be significantly correlating with ALD pathogenesis, higher LSM score (p< 0.001) and severity.

Conclusion: Higher gut microflora load and resulting altered hyper-immunomodulation is detrimental to ALD susceptibility and severity.

464**A high fibre diet can modulate hallmarks of inflammation and autoimmunity culminating in reduced nephritis in a model of systemic lupus erythematosus**

Gottschalk, T.A., Tsantikos, E., Hibbs, M.L.

Monash University, Department of Immunology and Pathology, Melbourne, Australia

Systemic Lupus Erythematosus (SLE) is a highly complex, heterogeneous autoimmune disease characterized by circulating self-reactive antibodies that deposit in tissues including skin,

kidneys and brain, alongside a chronic inflammatory response that leads to progressive tissue damage and impaired function. Recent evidence suggests that diet and gut microbiota can influence the development of inflammatory and autoimmune diseases through the generation of short chain fatty acids via the fermentation of dietary fibre. Mice deficient in the tyrosine kinase Lyn (Lyn^{-/-}) develop an autoantibody mediated autoimmune disease and age-dependent glomerulonephritis reminiscent of human SLE. To determine whether a high fibre diet could modulate systemic autoimmune and inflammatory pathology, Lyn^{-/-} and C57BL/6/J control mice were weaned and reared on a diet high in both soluble and insoluble fibre (HFD) or a standard control diet until 42 weeks of age. While Lyn^{-/-} mice on a standard diet developed high titer pathogenic IgG anti-dsDNA autoantibodies and plasma cell expansion, as well as splenomegaly and enhanced splenic hematopoiesis, a HFD ameliorated these phenotypes, suggesting that systemic inflammation could be dampened by dietary intervention. Histological analysis of the kidneys revealed that Lyn^{-/-} mice on the HFD had reduced cellular infiltration and glomerular expansion, and indeed, their kidneys resembled those of control mice. These findings indicate a role for diet in modulating autoimmune responses and inhibiting the generation of pathology in an SLE-like environment. Further studies will focus on characterizing the microbiome and the efficacy of high fibre diet as a post-diagnosis lifestyle intervention.

465**Plasmodium berghei ANKA infection induces intestinal dysbiosis**

Taniguchi, T.^{1,2}, Miyauchi, E.³, Nakamura, S.⁴, Hirai, M.⁵, Suzue, K.¹, Imai, T.¹, Nomura, T.⁶, Okada, H.¹, Shimokawa, C.¹, Onishi, R.¹, Ochiai, A.¹, Hirata, J.¹, Tomita, H.⁶, Ohno, H.³, Horii, T.⁷, Hiseada, H.¹

¹Gunma University, Department of Parasitology, Maebashi, Japan, ²Gunma University, Center for Medical Education, Maebashi, Japan, ³RIKEN Center for Integrative Medical Sciences (IMS), Laboratory for Intestinal Ecosystem, Yokohama, Japan, ⁴Research Institute for Microbial Diseases, Osaka University, Department of Genome Informatics, Suita, Japan, ⁵Juntendo University School of Medicine, Department of Molecular and Cellular Parasitology, Bunkyo, Japan, ⁶Gunma University, Department of Bacteriology and Laboratory of Bacterial Drug Resistance, Maebashi, Japan, ⁷Research Institute for Microbial Diseases, Osaka University, Department of Molecular Protozoology, Suita, Japan

Malaria caused by protozoa of the genus *Plasmodium* is the most prevalent infectious disease in tropical and subtropical regions. Gastrointestinal symptoms, such as abdominal pain, vomiting and diarrhea, are frequently observed in patients with *P. falciparum* in addition to the malarial triad of fever, anemia, and splenomegaly. The pathogenesis of malaria which depends on parasite growth and host immunity to malaria parasites is very complicated. However, it remains unknown whether intestinal microbiota are involved in host-parasite interactions during malaria including intestinal pathology. Here we show that infection of C57BL/6 mice with *P. berghei* ANKA, experimental cerebral malaria (ECM), cause intestinal pathological changes such as epithelial detachment and bleeding in the small

intestines, and an apparent dysbiosis characterized by a reduction of Firmicutes and an increase in Proteobacteria. Furthermore, some genera of microbiota correlate with parasite growth and/or ECM development. By contrast, BALB/c mice that are resistant to ECM exhibit milder intestinal pathology and dysbiosis. These results indicate that the severity of cerebral and intestinal pathology coincides with the degree of alteration in microbiota. Further investigations of the relationship between dysbiosis and intestinal pathogenesis during *P. berghei* ANKA will add to our understanding of the mechanisms involved in intestinal pathology in malaria patients.

TRAIL regulates egg-allergen induced eosinophilic oesophagitis

Collison, A.¹, Sokulsky, L.A.¹, Starkey, M.R.^{1,2}, Nightingale, S.^{1,3}, Le Fevre, A.³, Percival, E.^{1,3}, Hansbro, P.M.², Foster, P.S.², Mattes, J.^{1,4}

¹University of Newcastle & Hunter Medical Research Institute, Priority Research Centre GrowUpWell, Callaghan, Australia, ²University of Newcastle & Hunter Medical Research Institute, Priority Research Centre Lung Health, Newcastle, Australia, ³John Hunter Children's Hospital, Department of Gastroenterology, Newcastle, Australia, ⁴John Hunter Children's Hospital, Department of Respiratory and Sleep Medicine, Newcastle, Australia

Introduction: Food antigens are common inflammatory triggers in paediatric eosinophilic oesophagitis (EoE), with food elimination often effective in treating the disease. TNF-related apoptosis-inducing ligand (TRAIL) is a key inducer of eosinophilic inflammation in inflammatory disorders such as house dust mite-induced allergic airways disease and Aspergillus-induced experimental EoE through the upregulation of Midline (MID)-1 and subsequent downregulation of Protein Phosphatase 2A (PP2A).

Methods: Oesophageal biopsies collected from paediatric EoE patients and healthy controls were assessed for TRAIL and MID-1 protein and mRNA transcript levels. To investigate the role of TRAIL in vivo, wild type (TRAIL+/+) and TRAIL deficient (TRAIL-/-) mice were administered subcutaneous chicken egg ovalbumin (OVA) followed by an oral challenge of OVA. Oesophageal samples were collected for histological, protein and gene analyses.

Results: TRAIL and MID-1 protein levels were significantly increased in EoE biopsy samples derived from paediatric EoE patients. TRAIL+/+ mice were found to have a significant upregulation of TRAIL and MID-1 in the oesophagus, with eosinophilic inflammation, fibrosis and elevation of EoE associated cytokines TSLP, IL-5, IL-13 and CCL11. This inflammatory phenotype was significantly attenuated in TRAIL-/- mice.

Conclusion: TRAIL and its associated downstream molecules are upregulated in EoE patients and are key inducers of inflammation in OVA-driven EoE. We propose that TRAIL is a key cytokine involved in the perpetuation of EoE and a potential therapeutic target.

Micro-RNA-125a/b target A20 and MAVS to promote inflammatory and impair antiviral responses in chronic obstructive pulmonary disease

Hsu, A.^{1,2}, Starkey, M.^{1,2}, Hansbro, P.^{1,2}, Wark, P.^{1,2,3}

¹University of Newcastle, Newcastle, Australia, ²Hunter Medical Research Institute, Newcastle, Australia, ³John Hunter Hospital, Newcastle, Australia

Chronic obstructive pulmonary disease (COPD) is characterized by exaggerated airway inflammatory responses and heightened susceptibility to influenza virus infections with increased mortality. The mechanisms of which are unknown.

In this study we infected primary bronchial epithelial cells (pBECs) from COPD and healthy subjects with human influenza H3N2 or H1N1.

Infection led to significantly higher activation of NF-κB and inflammatory cytokines production

(IL-6/-8/-1β), but resulted in impaired induction of antiviral type I interferon (IFN)-β/-I in COPD, leading to higher viral replication.

A20, an important negative regulator of NF-κB, was not induced by infection in COPD. Ectopic expression of A20 decreased NF-κB phosphorylation but minimally affected IFN-β induction.

This reduced level of A20 was the result of increased induction of miR-125a/b. miR-125a/b antagomiRs increased A20 expression and decreased NF-κB phosphorylation, but IFN-β was markedly increased. TargetScan analysis also showed the antiviral adaptor protein MAVS is a potential target of miR-125a/b. By using MAVS-3' UTR-luciferase reporter constructs and miR-125a/b mimetics and immunoprecipitation, enhanced miR-125a/b targeted the putative binding region on 3' UTR, leading to reduced MAVS expression and IFN-β induction in COPD.

In conclusion, influenza virus infection led to enhanced inflammatory but reduced antiviral responses in COPD. miR-125a/b targets A20 and MAVS, leading to enhanced NF-κB activation and impaired IFN response in COPD. miR-125a/b antagomiRs suppressed NF-κB activation and increased IFN-β induction via increased A20 and MAVS, respectively.

468

Nasal tissue resident memory CD8+ T cells are highly protective against influenza A infection

Pizzolla, A., Reading, P., Wakim, L.

University of Melbourne, Microbiology and Immunology, Melbourne, Australia

CD8+ tissue resident memory T cells (Trm) develop after viral infection and persist in the tissue after viral clearance without recirculating.

Influenza A virus is a common pathogen infecting mainly the upper respiratory tract and in severe cases the lower respiratory tract (lung). Influenza virus specific CD8+ Trm have been described in the lung following influenza infection. Whether these cells are also deposited in the upper respiratory tract and if they assist in controlling secondary influenza virus infections is currently unknown.

We find influenza specific CD8 Trm persist within the upper respiratory tract (URT) following influenza infection. URT Trm

were capable of producing cytokines upon re-stimulation and were highly effective at reducing virus growth within the nasal tissue upon re-infection. Importantly, we show that following influenza virus infection CD8⁺ Trm in the URT prevented the migration of influenza virus from the upper respiratory tract to the lungs and the development of severe pulmonary influenza infection.

Deeper understanding of acquired memory in the URT, the predominant site of influenza virus infection, will assist in the development of better vaccination regimes.

469

CXCR6 deficiency alters the kinetics of acute inflammatory responses to influenza virus and control of chronic *Mycobacterium tuberculosis* infection

Ashhurst, A.¹, Flórido, M.¹, Lin, L.¹, Stambas, J.², Britton, W.J.^{1,3}

¹Centenary Institute, Tuberculosis Research Program, Camperdown, Australia, ²Deakin University, School of Medicine, Geelong, Australia,

³University of Sydney, Medical School, Sydney, Australia

Respiratory infections cause a significant burden on global health. Understanding the inflammatory response to pathogens, such as influenza and *Mycobacterium tuberculosis* (*Mtb*), may assist in the development of more effective vaccines or treatments. Previous studies have suggested a link between CXCR6⁺ CD8⁺ T-cells and protection against *Mtb* at early stages of infection (Lee et al., *Infect Immun.*, 2011). However the role of CXCR6 during pulmonary infection has not been fully elucidated. We assessed vaccine-induced CD4⁺ T-cell responses in CXCR6^{-/-} mice, using a recombinant influenza virus expressing the *Mtb* p25 epitope (rIAV-p25), that is protective against *Mtb* in mice (Flórido et al., *EJI*, 2015, 45:780). Interestingly, CXCR6^{-/-} mice lost less weight and returned to their initial weight earlier after acute rIAV-p25 infection, when compared to WT counterparts. At 3 weeks post infection, CXCR6^{-/-} mice had elevated activated T-cells in the lungs, however there was reduced Th1-cytokine production and increased KLRG-1 expression on parenchymal T-cells. By 6 weeks this was comparable to WT mice. In an aerosol model of *M. tuberculosis* infection, we demonstrated that CXCR6 was redundant for early recruitment of T-cells and control of bacterial growth. Interestingly at late time points, 6 and 12 weeks, CXCR6^{-/-} mice showed a reduction in bacterial counts in the lungs, associated with a decrease in Th1-cytokines and KLRG-1 expression. While CXCR6 deficiency has minimal impact on CD4⁺ T-cell recruitment to the lungs, it may modulate inflammatory kinetics in mice infected with influenza or *Mtb*, which can be beneficial to the clearance of pathogens.

470

Immune regulation in the gastrointestinal tract during persistent virus infection

MacLeod, B.L., Elsaesser, H.J., Snell, L.M., Brooks, D.G.

University Health Network, Princess Margaret Cancer Centre, Toronto, Canada

The sustained antigen load during persistent virus infection creates an immunosuppressive environment that results in the

functional alteration of multiple immune subsets, including CD4 and CD8 T cells, B cells, dendritic cells and macrophages. Persistent infection of mice with LCMV Clone-13 results in profound T cell exhaustion in both lymphoid organs and peripheral tissues. However, the extent to which virally exhausted cells are able to persist and function in the intestinal mucosa is poorly understood. Therefore, we compared and contrasted the composition and functionality of mucosal immune cells following infection with the acutely cleared LCMV-Armstrong and the persistent LCMV Clone-13 virus. These studies provide novel insight into the unique gastrointestinal environment in the context of persistent virus infection.

471

CCR7 in periodontal lymphoid-like structures formation

Alvarez Rivas, C., Rojas, L., Monasterio, G., García, K., Pujol, M.,

Carvajal, P., Vernal, R.

Universidad de Chile, Periodontal Biology Laboratory, Santiago, Chile

Periodontal lymphoid-like clusters formation has been postulated in chronic periodontitis patients, where dendritic cells may locally present microbial antigens to naïve T-cells and thus promote alveolar bone resorption in a periodontal site-specific manner. CCR7, CCL19, CCL21, and CXCL12 have been widely associated with ectopic lymphoid-like structures formation in other inflammatory diseases. This study aimed to analyze the CCR7, CXCR4, CXCL12, CCL19, and CCL21 production, as well as the CCR7⁺ naïve T-helper lymphocyte detection, in periodontal tissues from healthy or periodontitis-diseased individuals.

Methods: From gingival samples of healthy or moderate-to-severe chronic periodontitis individuals, total cells were obtained using enzymatic digestion and then analyzed by flow cytometry using the following monoclonal-antibodies: anti-CD4, CD25, CD45RA, CD45RO, RORC2, Foxp3, and CD197. In addition, the mRNA expression for CCR7, CXCR4, CXCL12, CCL19, and CCL21 was quantified by qRT-PCR. Correspondingly, CCL19, CCL21, and CXCL12 secretion was quantified from gingival crevicular fluid samples by ELISA. Finally, CCR7 was detected by western-blot and localized by immuno-fluorescence.

Results: Higher levels of CCR7, CXCR4, CCL19, CCL21, and CXCL12 were detected in periodontitis compared with healthy individuals. In addition, the number of CCR7⁺ naïve T-cells and CCR7⁺ RORC2⁺ memory T-cells were greater in periodontitis patients. CCR7 was localized broadly in the gingival connective tissue, and particularly clustered around blood vessels.

Conclusions: Higher levels of CCR7⁺ naïve T-cells were detected in periodontal tissues from periodontitis versus healthy individuals and this increment was associated with local CCL19, CCL21, and CXCL12 production. Therefore, CCR7 could play a role in periodontal lymphoid-like structures formation.

472

Investigating the role of Th1 cells in response to infection with the enteric pathogen *Citrobacter rodentium**Kennedy, C.L.¹, Burke, Z.¹, Alison, E.¹, Brown, A.S.^{1,2}, Fung, K.Y.¹, van Driel, I.R.², Hartland, E.L.¹*¹*Peter Doherty Institute for Infection and Immunity, University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ²The Bio21 Molecular Science and Biotechnology Institute, Department of Biochemistry and Molecular Biology, Parkville, Australia*

Citrobacter rodentium is a mouse pathogen that mimics many virulence behaviours of the human pathogen enteropathogenic *E. coli* and is commonly used as a model organism in the investigation of the enteric mucosal immune response. *C. rodentium* is commonly described in the literature as eliciting a Th1-, Th17-, ILC3-mediated immune response where IL-22 is critical for maintaining epithelial integrity and promoting the production of antimicrobial peptides. However a recent paper by Aycheh, et al, (2015) indicates that Th1 cells may, in fact, be detrimental in the host response to *C. rodentium* infection.

This study aims to clarify the role of Th1 cells in the intestinal immune response. The differentiation of naïve T cells into pro-inflammatory Th1 cells is dependent on the heterodimeric cytokine IL-12, which is expressed by dendritic cells and macrophages. IL-12 is made up of two subunits, IL-12p35 which is unique to IL-12, and IL-12p40 which is shared with IL-23. To date, all studies into IL-12 in the *C. rodentium* immune response have utilised IL-12p40^{-/-} mice, which will also be deficient in IL-23. Our study shows that IL-12p35^{-/-} mice, deficient in IL-12 and, consequently, Th1 cells, are able to contain and clear *C. rodentium* infection as well as C57BL/6 mice. Histologically, there was increased inflammation observed in the lamina propria of infected IL-12p35^{-/-} mice compared C57BL/6 mice and increased penetration of the bacteria into the crypts. Overall, however, these data suggest that IL-12 and Th1 cells are largely dispensable in the host response to *C. rodentium* infection.

473

Characterisation of CD4⁺ T cells in healthy and diseased koalas (*Phascolarctos cinereus*) using cell-type-specific monoclonal antibodies*Mangar, C.¹, Armitage, C.W.¹, Timms, P.², Corcoran, L.M.³, Beagley, K.W.¹*¹*Queensland University of Technology, Brisbane, Australia, ²University of Sunshine Coast, Sunshine Coast, Australia, ³Walter and Eliza Hall Institute of Medical Research (WEHI), Melbourne, Australia*

The koala (*Phascolarctos cinereus*) is an arboreal herbivorous marsupial that is an Australian icon. *Chlamydia pecorum* and *C. pneumoniae* are obligate intracellular Gram-negative bacteria that infect koalas and can cause, infertility, arthritis, conjunctivitis, respiratory disease, and in some cases death. Due to a lack of koala-specific immune reagents and assays there is currently no way to adequately analyse the immune response in diseased, healthy or vaccinated animals. Using the extracellular domain of koala CD4⁺ this paper reports the production and characterisation of the first anti-koala CD4 monoclonal antibody

(mAb). Fluorochrome-conjugated anti-CD4 mAb was used to investigate the levels of CD4⁺ T helper cells collected from koala spleens, lymph nodes and peripheral blood by flow cytometry. Biotin-conjugated anti-CD4 mAb was also used for Western Blot and immunohistochemistry to identify CD4⁺ T helper cells in the lymph node. The results indicate that CD4⁺ specific T cells could be identified using flow cytometry of cells from both tissues and peripheral blood as well as visualised using immunohistochemistry techniques. Further analysis of the results also showed an increased level of CD4⁺ cells in animals with current signs of chlamydial infection/disease as opposed to those showing no signs of infection or clinical disease. Since CD4⁺ T cells have been shown to play a pivotal role in clearing chlamydial infection in both human and mouse infections, using this novel antibody will help determine the role CD4⁺ T cells play in protection against chlamydial infection in koalas.

474

Increased Langerhan cell counts and elevated chemokine gene expression in foreskins from young men with asymptomatic sexually transmitted infections (STIs)*Gray, C.M.¹, Olivier, A.J.¹, Amu, S.², Jaspán, H.B.¹, Harryparsad, R.¹, Wilson, D.³, Dietrich, J.⁴, Martinson, N.⁴, Mukudu, H.⁴, Mkhize, N.⁵, Morris, L.⁵, Cianci, G.C.⁶, Dinh, M.H.⁶, Hope, T.J.⁶, Passmore, J.S.¹, Chiodi, F.²*¹*University of Cape Town, Immunology, Cape Town, South Africa,*²*Karolinska Institutet, Stockholm, Sweden, ³Edendale Hospital, Pietermaritzburg, South Africa, ⁴Perinatal HIV Research Unit, Johannesburg, South Africa, ⁵National Institute for Communicable Disease, Johannesburg, South Africa, ⁶Northwestern University Feinberg School of Medicine, Chicago, United States*

Medical Male Circumcision (MMC) has been shown to reduce HIV acquisition by up to 60%, and additionally decrease the incidence of other sexually transmitted infections (STIs). We hypothesize that the underlying mechanisms for this protection is that MMC results in the removal of potential target cells for HIV infection, and alters levels of keratinisation. In a longitudinal study involving 14-24 year-old HIV-negative men undergoing MMC, we compared the numbers of CD4⁺ T cells, expression of langerin, Ki67, and chemokine genes. Participants were tested for asymptomatic STIs using multiplex PCR (*C. trachomatis*, *N. gonorrhoea*, *M. genitalium*, *T. vaginalis*, HSV-1/2). We found elevated numbers of CD207⁺ Langerhans cells (LCs) in the foreskin of men with asymptomatic STIs (n=28) compared to age-matched STI-negative men (n=28) (median 1 vs 4 cells/mm³, p=0.0005). There were no significant differences in CD4⁺ T cell and Ki67 cell counts as a function of STI status. The outer foreskin had higher keratin thickness compared to the inner foreskin (median difference = 1.712um; p=0.0058), but no difference due to STI status. There was a positive correlation between CD207 and elevated CCL27 gene expression in the inner foreskin (r=0.498; p=0.016). STI-induced inflammation and recruitment of immune cells via chemokines to the foreskin may be elevating the risk of HIV acquisition in uncircumcised men with an asymptomatic STI. MMC may thus reduce HIV acquisition risk in this highly susceptible group of men by removing potential HIV target cells in foreskins. Treatment

of asymptomatic STIs in uncircumcised men would lower HIV acquisition risks.

475

Regulation of intestinal immune homeostasis by the retinoic acid-responsive transcriptional factor hypermethylated in cancer 1

Burrows, K.¹, Antignano, F.¹, Chenery, A.¹, Underhill, T.M.¹, Zaph, C.^{1,2}

¹University of British Columbia, The Biomedical Research Centre, Vancouver, Canada, ²Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia

Retinoic acid (RA) has critical functions in the intestinal immune system. RA licenses CD4 T helper (Th) cells to express gut-tropic homing receptors and is important in determining the balance between regulatory T (Treg) cells and Th17 cells in the intestinal microenvironment. However, the molecular mechanisms linking RA to intestinal immune homeostasis are unknown. Here, we identify the POK/ZBTB family zinc finger transcription factor Hypermethylated in cancer 1 (Hic1) as a critical RA-responsive transcriptional determinant that controls intestinal T cell function. *In vivo*, Hic1 expression within the hematopoietic compartment is restricted to the small intestine. Strikingly, mice fed a vitamin A deficient diet exhibit notably diminished expression of Hic1 in intestinal immune cells. Mice with a specific deletion of Hic1 in T cells (*Hic1^{ΔT}* mice) have reduced frequencies of T cells in the lamina propria of the small intestine at steady state but display increased levels of interleukin (IL)-17A. Following induction of small intestinal inflammation, *Hic1^{ΔT}* mice displayed significantly less signs of pathology, associated with heightened levels of IL-17A and IL-10 at the site of inflammation. *In vitro*, *Hic1*-deficient Th17 cells also displayed increased levels of IL-17A and IL-10. Mechanistically we found that Hic1 and Stat3 interact in Th17 cells, and in the absence of Hic1 there are higher levels of Stat3 binding to both the *Il17a* and *Il10* loci. Taken together, these results demonstrate that Hic1 is a novel intestinally-restricted transcription factor that regulates Th17 cell differentiation and may be a target for therapeutics in treating intestinal inflammation.

Galectin-9 regulate epithelial innate immunity and is essential for intestinal and inflammation

Lu, D.H.H., Liu, F.T., Shui, J.W.

Academia Sinica, IBMS, Taipei, Taiwan, Republic of China

Galectin-9 (Gal-9), a β -galactosides binding animal lectin, has been recently reported as a risk gene for inflammatory-bowel-disease (IBD) in a genome-wide-association-study (GWAS). However, it remains unclear how Gal-9 is involved in innate immune regulation in gut, particularly mucosal host defense and inflammatory pathogenesis.

To reveal functions of Gal-9 in the mucosa, we first determined Gal-9 expression levels in different segments and compartments of intestine. Interestingly, Gal-9 is predominantly expressed in colonic and ileal crypts, where stem cells and anti-microbial Paneth cells are located. Further analysis indicated that Gal-9^{-/-}

mice had reduced crypt numbers in ileum and colon at steady state. Based on this finding, we hypothesized that Gal-9 might be essential for epithelial cell homeostasis and as such, Gal-9 could be involved in colitis pathogenesis via regulating epithelial innate immunity and barrier integrity. We find that after dextran-sulfate-sodium (DSS)-induced colitis, Gal-9 expression level in epithelial cell were increased and Gal-9^{-/-} mice showed 100% mortality with more severely inflammation and lower IL-22 production (important to epithelial repair and anti-microbial-peptide induction). Also, Gal-9^{-/-} mice were highly susceptible to *Yersinia*, with increased bacterial burden and translocation. Correlated to *in vivo* findings, freshly isolated Gal-9^{-/-} epithelial cells (crypts) showed impaired *Yersinia* killing ability and Gal-9^{-/-} crypts and fragment had defective innate response after *Yersinia* infection.

Our results indicate that galectin-9 not only plays an essential role in mucosal immunity during host defense, but also regulate intestinal inflammation during colitis pathogenesis. Our findings therefore provide evidences that polymorphism of galectin-9 gene might contribute to dysfunction of epithelial barrier, leading to intestinal inflammation.

The role of host IL-1 α and the microbiome in acute colitis

Nunberg, M.¹, Werbner, N.², Bersudsky, M.¹, Apte, R.N.¹, Koren, O.², Voronov, E.¹

¹Ben Gurion University of the Negev, Beer Sheva, Israel, ²Bar Ilan University, Safed, Israel

Interleukin-1 α (IL1 α) is a pleiotropic cytokine, which acts as an alarmin during inflammation. It is expressed in intestinal epithelial cells (IECs) under homeostatic conditions and is released from damaged IECs and initiates inflammation. The effect of IL-1 α on acute colon inflammation was assessed in DSS-induced colitis model, using complete IL-1 α mice KO mice and mice with a specific deletion of IL-1 α in IECs, we observed a very mild form of colitis with significantly better repair compared to control mice. Thus, various possible mechanisms involved in IL-1 α -induced colon inflammation were studied. Changes in the microbiome could explain how deficiency of IL-1 α leads to reduced DSS-induced damage of intestinal mucosal barrier, as well as high expression of tight junction proteins, preservation of goblet cells or retained epithelial barrier functions. Thus IL-1 α , which induces exacerbated colon inflammation, may be critical in driving the pathologic breakdown of barrier integrity. Co-housing experiments combined with metagenomic analysis confirmed the role of the specific microbiota in IL-1 α KO mice as compared to control mice. After DSS administration, IL-1 α KO co-housed mice developed a disease phenotype similar to DSS-treated control mice rather than to DSS-treated control IL-1 α KO mice. Goblet cells in co-housed mice were also similar to their distribution to control mice. Metagenomic analysis, obtained from fecal samples, revealed a significant shift in β -diversity towards control and co-housed mice. These results confirmed that IL-1 α is a key molecule in acute colon inflammation and affects barrier functions and colon microbiota.

Dendritic cells from ankylosing spondylitis patients show reduced activation in response to stimulation with gut bacteria

Peyroux, E.¹, Gray, A.², Mc Connell, M.³, Highton, J.⁴, Young, S.¹

¹University of Otago, Pathology, Dunedin, New Zealand, ²University of Otago, Preventative and Social Medicine, Dunedin, New Zealand, ³University of Otago, Microbiology and Immunology, Dunedin, New Zealand, ⁴University of Otago, Medicine, Dunedin School of Medicine, Dunedin, New Zealand

Ankylosing Spondylitis (AS) is a chronic inflammatory arthritis of spine and sacroiliac joints with further peripheral manifestations affecting 0.1- 1.4% of the population. Susceptibility genes identified include HLA-B27 and ERAP1, both essential components in antigen processing for initiation of immune responses. Numerous lines of evidence indicate that bacterial contact at mucosal surfaces is the driving force behind inflammation in AS. We generated monocyte-derived dendritic cells (MoDCs) from the venous blood of AS patients (n= 24) and control group (n= 15) and stimulated them with a range of heat-killed gut bacteria with known associations to Reactive arthritis and inflammation - *Bacteroides fragilis*, *Yersinia enterocolitica*, *Campylobacter jejuni* and *Helicobacter pylori*. We measured expression of MoDC activation markers- MHC-I, MHC-II, CD40, CD80 and CD83 by flow cytometry. Analysis of cytokine secretion in supernatants was assessed by Bioplex immunoassay. Our results indicated the level of CD40 and CD80 costimulatory marker up-regulation was significantly reduced in many of the bacterial treatments in the AS group compared to control group. Reduced MHC-II up-regulation was also observed in two treatments- Polyinosinic-polycytidylic acid and *C. jejuni*. CD83, a MoDC maturation marker, was expressed at similar levels for all treatments. Cytokine analysis showed altered TNF α secretion to *Y. enterocolitica* treatment and IL-23 production to *C. jejuni*. From these results we hypothesize that abnormal signaling through innate pattern recognition receptor signaling pathways induces aberrant activation of MoDCs in AS patients. These MoDCs in turn may direct cells of the immune system toward an inappropriate or misdirected immune response.

479

Specification of peripheral Treg cells particular to a commensal bacterium that regulates intestinal homeostasis

O. E.^{1,2}, Hong, S.-W.^{1,2}, Lee, J.^{1,2}, Surh, C.D.^{1,2,3}

¹POSTECH, Department of Integrative Biosciences and Biotechnology, Pohang, Korea, Republic of, ²Institute for Basic Science, Academy of Immunology and Microbiology, Pohang, Korea, Republic of, ³La Jolla Institute for Allergy and Immunology, Division of Developmental Immunology, La Jolla, CA, United States

The establishment and the maintenance of intestinal homeostasis requires generation of peripheral regulatory T (pTreg) cells specific to the commensal microbiota in the colon. However, how microbiota-specific pTreg cells initially develop and maintain is not clearly demonstrated, including the identity of the microbial antigens that induce generation of pTreg cells and how such microbial antigens initiate activation

and differentiation of conventional T cells into pTreg cells. To understand these issues, we have begun to define the specificity of a TCR transgenic (Tg) line, CT6, that was shown to be specific to an uncharacterized *Clostridium* species of commensal bacterium. We recently identify CT6 Tg T cells to react to *Clostridium.symbiosum* and proliferated strongly to *C.symbiosum* when its extract was presented *in vitro* by splenic antigen presenting cells whereas control polyclonal C57BL/6 T cells did not. CT6 Tg T cells also responded to *C.symbiosum in vivo* when CT6 cells were adoptively transferred into specific pathogen-free (SPF) B6 mice that were then i.p injected with live *C.symbiosum*. However, CT6 cells did not respond to *C.symbiosum* when the bacterium was introduced orally in SPF or germ-free (GF) B6 host. These findings suggest that the mucosal immunity in SPF and GF mice prevents unopposed presentation of *C.symbiosum* antigens to peripheral immune system. We are currently in the process of defining factors that form the intestinal barrier to prevent *C.symbiosum* translocation under normal conditions and also determine how this barrier establishes and maintains intestinal homeostasis by generating effector and pTreg cells to *C.symbiosum*.

Synergetic damaging effect of factors decreasing the respiratory epithelial barrier

Waltl, E.E.¹, Selb, R.¹, Eckl-Dorna, J.¹, Valenta, R.², Niederberger, V.¹

¹Medical University of Vienna, Austria, Otorhinolaryngology, Vienna, Austria, ²Medical University of Vienna, Austria, Division of Immunopathology, Department of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria

The respiratory epithelial barrier plays an important role in protecting humans against various exogenous factors (e.g. allergens, pathogens, toxic substances). Here we aimed to establish different damaging models in order to enable us to investigate protective factors for the epithelium. Furthermore we performed experiments testing the synergetic effect of barrier-decreasing substances.

A bronchial epithelial cell line (16HBE14o-) was cultured in monolayers in the xCELLigence DP system. This system allows continuous real-time measurement of impedance-based cell responses. The epithelial integrity was impaired by the following damaging conditions: i) Physical damage by scratching the cell layer, ii) infection with human rhinovirus (RV), iii) incubation with standardised cigarette smoke extract (CSE) and iv) exposure to the pro-inflammatory TH1 cytokine interferon-gamma and v) exposure to house dust mite (HDM) extract.

Barrier function decreased in a time- and dose-dependent manner after treatment of cells with all above-mentioned substances. However, the various conditions induced different damaging patterns to the respiratory epithelium. The maximal barrier decreasing effects were observed after 36 hours of RV infection, after 12 hours of exposure to CSE, after 4-5 days of treatment with interferon-gamma and after 3-4 days of exposure to HDM extract. Especially, experiments testing the synergetic effect of HDM and CSE showed a significantly amplified damaging effect of the cells when substances were added in combination, in contrast to application of the substances alone. Our results visualise the synergetic damaging effect of CSE and

HDM extract indicating that smoking may facilitate allergic sensitisation and increase allergic symptoms in patients.

481

The polysaccharide maltodextrin exacerbates intestinal inflammation

Laudisi, F.¹, Di Fusco, D.¹, Dinallo, V.¹, Vezza, T.², Marafini, I.¹, Alfredo, C.¹, Ortenzi, A.¹, Monteleone, I.¹, Pallone, F.¹, Monteleone, G.¹

¹University of Rome 'Tor Vergata', Rome, Italy, ²IBS Granada, CIBM, University of Granada, Granada, Spain

In the last decades, there has been an increased incidence of Inflammatory Bowel Diseases (IBD), particularly in previously low incidence areas, mainly due to changes in environmental and lifestyle factors. Food additives commonly used as emulsifiers, stabilizers or bulking agents are frequently present in Western diet. Preliminary evidences indicate that daily consumption of some of these compounds could alter the intestinal homeostasis in mice, by promoting dysbiosis and inflammatory response.

In this study, we evaluated whether a diet rich in Maltodextrin (MDX), a polysaccharide used as food additive, energy supplement and coating agent, can increase the susceptibility of mice to develop intestinal inflammation.

Wild-type mice were exposed to drinking water containing MDX and then challenged with dextran-sulfate sodium (DSS) to induce colitis. Mice were sacrificed and colons harvested for RNA/protein analysis and histopathology.

Mice receiving MDX-enriched diet did not exhibit macroscopic signs of intestinal inflammation. Instead, they showed hyperplasia of mucus-producing cells and altered intestinal microbiota composition with high levels of Dual oxidase-2, an epithelial-specific NADPH oxidase that correlates with mucosal dysbiosis. Once challenged with DSS, MDX-treated mice exhibited significant weight loss, destruction of intestinal epithelium, higher inflammatory cell infiltration and increased expression of pro-inflammatory cytokines compared with mice treated with DSS alone.

In conclusion, a diet rich in MDX may alter the interaction between luminal flora and mucosal cells, thus leading to altered intestinal homeostasis and exacerbated tissue-damaging pathogenic responses.

Altogether, data suggest that daily consumption of MDX may contribute to enhance host's susceptibility to IBD.

482

Triggering receptor expressed on myeloid cells-1 plays a crucial role in regulating intestinal barrier in an experimental colitis model

Yang, F.-C., Chen, N.-J.

National Yang-Ming University/Institute of Microbiology and Immunology, School of Life Sciences, Taipei, Taiwan, Republic of China

TREM-1 expression is induced mostly on monocytes, macrophages and neutrophils by various stimuli such as toll-like receptor (TLR) ligands. It contributes to the exacerbation of inflammatory disorders by enhancing the secretion of

pro-inflammatory cytokines. Ulcerative colitis (UC) is one of inflammatory bowel disease (IBD) that majorly causing colonic inflammation associated with type 2 inflammatory mediators induction. It was recently demonstrated that a substantial accumulation of TREM-1 expressing macrophages could be obtained in the inflamed colonic tissue of patients with IBD and of mice with experimental colitis. However, the underlying mechanism contributed by TREM-1 is still unknown. To elucidate the precise role of TREM-1 in intestinal inflammation by using an independent TREM-1 knockout mouse line in DSS-induced mouse colitis model, which can mimic patient with UC. We found TREM-1 is involved in enhanced pro-inflammatory mediators expression, and increased macrophages and neutrophils infiltration in affected colons. Ablation of TREM-1 did not protect mice from DSS-induced colitis. Oppositely, an exacerbated tissue damage resulted from impaired intestinal epithelium integrity was obtained in DSS-treated mice lacking TREM-1, implicating a protective role of TREM-1 in modulating the intestinal barrier integrity during DSS-induced colitis. Furthermore, TREM-1 deficiency associates with a drastic reduction of IL-22 that involves in epithelial repair and regeneration, in line with a significant decrease of group 3 innate lymphoid cell (ILC3s), a well known innate source of IL-22 and IL-17. Thus, our results implicate a unique role of TREM-1-expressing macrophages on attenuating DSS-induced colitis through promoting intestinal barrier reconstitution.

483

Investigating the immune composition of the human anorectal tract

Baharlou, H.^{1,2}, Bertram, K.¹, Botting, R.¹, Sandgren, K.¹, Kim, M.¹, Cunningham, A.¹, Harman, A.¹

¹Westmead Institute for Medical Research, Centre for Virus Research, Sydney, Australia, ²Sydney University, School of Medicine, Sydney, Australia

Little is known about the immune cells present in the human anorectal tract; instead information is inferred from genital and intestinal tissues. However, caution should be applied to such inferences as differences in immune cell distribution and function have been observed in other mucosal tissues such as the respiratory tract. This represents a critical gap in our knowledge as the anorectal tract is a key site of transmission for many pathogens, especially HIV.

Therefore, we have gained access to human anorectal tissue from colorectal surgery and defined the immune cell subsets that make up these tissues and compared them to those found in genital and intestinal tissue. We have made several novel observations.

1) In anal and rectal tissue the predominant myeloid populations are macrophages whereas in genital tissue dendritic cells predominate.

2) Nevertheless we have identified 4 separate anal epithelial dendritic cell subsets, two of which are negative for CD1a and differ significantly to those found in genital epithelium.

3) We have observed that rectal tissue contains a high frequency of lymphoid aggregates that are rich in both B and T lymphocytes, occupying discrete zones. Interestingly, the

specific subsets of these lymphocytes differ significantly from those found in the colon and small intestine.

For example the rectum contains fewer numbers of central memory CD4 T cells.

Thus the anorectal tract contains a unique immune environment which may reflect differences in the microbiota. Future studies should lead to preventative treatment strategies to block the transmission of pathogens across this surface.

484

Dietary iron and transcription factor Spi-C regulate gut homeostasis through maintenance of CX₃CR1^{high} CD11b⁺ CD11c⁺ cells

Kayama, H.¹, Kohyama, M.², Arase, H.², Takeda, K.¹

¹Osaka University Graduate School of Medicine, Suita, Japan,

²Osaka University, Suita, Japan

Intestinal innate immune cells contribute to maintenance of gut homeostasis. In particular, CX₃CR1^{high} CD11b⁺ CD11c⁺ cells are involved in preventing intestinal inflammation through several mechanisms. Recent studies identified transcription factors and environment factors controlling development of several tissue resident macrophages. However, how CX₃CR1^{high} CD11b⁺ CD11c⁺ cells are maintained in the intestine remains poorly understood. In this study, we show that CX₃CR1^{high} CD11b⁺ CD11c⁺ cells highly expressed the transcription factor Spi-C, which is shown to be induced by heme in red pulp macrophages, and iron metabolism-related genes including *Hmox1*, *Blvrb*, and *Slc40a1*. Iron deficient diet-fed mice showed decreased number of CX₃CR1^{high} CD11b⁺ CD11c⁺ cells in the colon and high sensitivity to dextran sulfate sodium (DSS)-induced colitis. Transfer of CX₃CR1^{high} CD11b⁺ CD11c⁺ cells from control diet-fed mice ameliorated DSS-induced colitis in mice given iron deficient diet. Furthermore, *LysM-cre; Spi-C^{flox/flox}* mice, in which *Spi-C* expression was abrogated in CX₃CR1^{high} CD11b⁺ CD11c⁺ cells, but not in red pulp macrophages, were highly sensitive to DSS colitis. These results indicate that dietary iron and transcription factor Spi-C are required for functional properties and survival of CX₃CR1^{high} CD11b⁺ CD11c⁺ cells and prevention of intestinal inflammation.

485

Uncoupling of the pDC-Treg crosstalk during early-life Pneumovirus infection underlies long-lived Treg dysfunction and asthma development

Lynch, J.P.¹, Werder, R.B.¹, Loh, Z.¹, Lane, K.¹, Rogers, M.¹, Diener, K.², Hayball, J.², Hill, G.³, Haque, A.³, Spann, K.⁴, Mazzone, S.¹, Upham, J.W.⁵, Sly, P.⁶, Phipps, S.¹

¹University of Queensland, School of Biomedical Sciences, Brisbane, Australia, ²University of South Australia, School of Pharmacy and Medical Sciences, Adelaide, Australia, ³QIMR Berghofer Medical Research Institute, Brisbane, Australia, ⁴Queensland University of Technology, Brisbane, Australia, ⁵University of Queensland, Lung and Allergy Research Centre, School of Medicine, Brisbane, Australia, ⁶University of Queensland, Queensland Children's Medical Research Institute, Brisbane, Australia

Severe viral bronchiolitis is a major risk factor for asthma, a disease associated regulatory T cell (Treg) dysfunction. Plasmacytoid dendritic cells (pDC) produce type-I IFN and induce Treg cell responses to regulate virus infections. Here we addressed whether inducible depletion of pDC in early-life alone increases the severity of viral bronchiolitis and predisposes toward asthma. Neonatal pDC-diphtheria toxin receptor (pDC-DTR) knock-in mice and wild-type (WT) littermates were infected with low-dose pneumonia virus of mice (PVM, 10pfu/i.n.), and challenged with 100pfu 6 weeks later. DT (3ng/g body weight/i.p.) was administered -1, +1, +3, and +5 days post infection and pathologic features of bronchiolitis or asthma assessed. Temporary pDC depletion reduced antiviral cytokine production, increased viral load and induced severe bronchiolitis (airway epithelial cell sloughing, neutrophilic inflammation). This phenotype was associated with diminished IL-10 production and a failure to expand neuropilin-1+ Tregs. Ligation of neuropilin-1 was necessary for pDC-mediated proliferation of Tregs ex vivo. Viral challenge of pDC-DTR but not WT mice induced the hallmark features of asthma and was associated with lower numbers of antigen-experienced Tregs. Adoptive transfer of antigen-experienced WT Tregs (3x10⁴, i.v. route) during primary infection or prior to viral challenge of pDC-depleted mice prevented the development of both severe bronchiolitis and postviral asthma. In contrast, Tregs from 'asthmatic' pDC-DTR mice were insufficient. pDCs mediate the expansion of Tregs to protect against severe bronchiolitis in early-life. Dysregulation of this crosstalk leads to the generation of aberrant and long-lived Tregs that are insufficient to protect against virus-associated asthma in later-life.

486

Absence of interferon-β promoter stimulator-1 (IPS1) induces bronchiolitis and asthma-like pathology in response to pneumoviral infection

Simpson, J.¹, Loh, Z.¹, Zhang, V.¹, Spann, K.², Upham, J.³, Phipps, S.¹

¹University of Queensland, School of Biomedical Science, Brisbane, Australia, ²Queensland University of Technology, School of Biomedical Science, Brisbane, Australia, ³University of Queensland, School of Medicine, Brisbane, Australia

Pneumovirus-induced bronchiolitis causes ~200,000 deaths per year and is a risk factor for subsequent asthma. Impaired antiviral responses may underlie susceptibility to bronchiolitis and subsequent asthma. Interferon (IFN)-β promoter stimulator-1 (IPS1, also known as MAVs) is an adaptor protein involved in IFN and inflammatory cytokine production following cytosolic viral detection. Here, we determined the role of IPS1 in pneumonia virus of mice (PVM)-induced bronchiolitis and asthma. Wild-type (WT) and IPS1-deficient mice were inoculated with PVM (2 pfu), at 7 days of age. Pathologies associated with bronchiolitis were evaluated at 4, 7, 10 and 14 days post infection (dpi). To assess susceptibility to asthma, mice were challenged with PVM (100 pfu) at 42 dpi, and euthanised 7 days later. Infection of WT mice induced IFN production and plasmacytoid dendritic cell (pDC) recruitment. The absence of IPS1 impaired IFN production and decreased pDC numbers in the lungs, accompanied by an elevated viral load in the airway epithelium and the release

of epithelial cell-derived alarmins IL-33 and high-mobility group box 1. Bronchiolitic IPS1-deficient mice also exhibited increased airway smooth muscle growth and mucous secretion. Reinfection of IPS1-deficient mice induced the cardinal features of asthma including airway hyperreactivity, mucous hypersecretion and airway smooth muscle remodelling, but failed to induce a significant type-2 inflammatory response. The absence of IPS1 increased the severity of bronchiolitis and predisposed to the development of asthma following viral challenge in later life. Notably, airway remodelling commenced early in life and occurred in the absence of type 2 inflammation.

487

Dietary fiber promotes oral tolerance by modulating vitamin A metabolism in mucosal dendritic cells

Tan, J.¹, Mackay, C.¹, Macia, L.²

¹Monash University, Melbourne, Australia, ²University of Sydney, Sydney, Australia

Food allergy is a potentially fatal disease and its incidence has increased dramatically in recent decades. Diet and the gut microbiota have been implicated in attenuating allergic responses, but the exact mechanisms remain elusive. We show that high-fiber diet feeding in mice establishes an anti-inflammatory mucosal environment, enhances oral tolerance and protected from severe food allergy. Mucosal CD103⁺ dendritic cells (DCs) are critical for establishing oral tolerance by their capacity to induce Treg differentiation as well as imprinting gut homing receptor CCR9 on responding naïve T cells. These effects are dependent on their production of retinoic acid from Vitamin A by the enzyme retinaldehyde dehydrogenase (RALDH). High-fiber feeding promoted oral tolerance by upregulating RALDH activity in CD103⁺ DCs, promoting Treg differentiation *in vitro* and *in vivo* as well as suppressing antigen-specific CD4⁺ T cell proliferation *in vivo*. Inhibition of retinoic acid signaling by retinoic acid receptor antagonist LE540 abrogated the ability of mesenteric lymph node derived CD103⁺ DCs from high-fiber fed mice to promote Treg differentiation as well as induce CCR9 expression. Furthermore, high-fiber feeding under Vitamin A deficient condition abrogated the beneficial effects of dietary fiber on oral tolerance. Thus, dietary elements including fiber and Vitamin A regulate tolerogenic pathways in the gastrointestinal tract upstream of Treg cells, necessary for immune non-responsiveness towards food antigens.

488

Dietary macromolecules regulate differentiation of small intestine resident memory T cells in IEL compartment

Jung, J.^{1,2}, Kim, K.S.¹, Surh, C.^{1,2,3}

¹Academy of Immunology and Microbiology (AIM), Institute for Basic Science (IBS), Pohang, Korea, Republic of, ²Pohang University of Science and Technology (POSTECH), Department of Integrative Biosciences and Biotechnology (IBB), Pohang, Korea, Republic of, ³La Jolla Institute for Allergy and Immunology (LIAI), San Diego, United States

Intestinal tissue-resident memory CD8⁺ T (T_{RM}) cells are mostly

located within intraepithelial lymphocyte (IEL) compartment. They are abundantly present in the small intestine and serve as the first line of defense against invading pathogens and to maintain homeostasis of the intestinal epithelial cells. Although small intestine is constitutively exposed to both microbial and dietary antigens (Ags), more attention has been focused on the influences of commensal microbiota. To investigate the role of both microbiota and diet in intestinal T_{RM} cells, we compared IELs in the offspring of germ-free (GF) B6 mice raised with a chemically defined elemental diet. In such "Ag-free" (AF) mice, we found a severe reduction in the development of induced IELs, i.e., TCRαβ⁺CD4⁺, TCRαβ⁺ CD8αβ⁺, TCRαβ⁺ CD4⁺CD8α⁺ IELs, and a partial depletion of natural TCRαβ⁺CD8α⁺ IELs. The TCRγδ⁺CD8α⁺ IEL population was relatively unaffected in AF mice. Furthermore, using our GF and AF mice, we directly demonstrate a larger role of diet than microbiota in inducing development of T_{RM} cells. More importantly, we found that the residual T_{RM} cells in the small intestine of AF mice, unlike those in SPF and GF mice, do not display constitutive effector function. Taken together, our results indicate that consumption of diet is important for normal generation and function of effector memory T_{RM} cells in IEL compartment.

489

Aeroallergen sampling in an experimental animal model of respiratory allergy

Leffler, J.¹, Mincham, K.T.¹, Mok, D.¹, Holt, P.G.¹, Stumbles, P.A.^{1,2,3}, Strickland, D.H.¹

¹Telethon Kids Institute, University of Western Australia, Subiaco, Australia, ²School of Veterinary and Life Sciences, Murdoch University, Murdoch, Australia, ³School of Paediatrics and Child Health, University of Western Australia, Crawley, Australia

The prevalence of respiratory allergic sensitisation has increased the last decades yet there is only limited understanding of the immunological processes involved. Our previous studies show that a deficient regulatory T cell response, crucial to prevent sensitisation, is linked to reduced allergen uptake in the respiratory mucosa. To provide insights into the immunological processes, modulating development of tolerance versus sensitization during natural respiratory aeroallergen exposure, we used an experimental animal model employing sensitisation of resistant and susceptible rat strains to mimic clinical observations in humans.

During repeated intra-nasal, adjuvant-free ovalbumin exposures, naïve male rats from the susceptible strain develop antigen-specific IgE sensitisation and airway eosinophil infiltration. This was further associated with skewed T-effector to T-regulatory cell ratio in the airways. In the resistant strain, exposure did not induce IgE but rather IgG and the T-effector:regulatory ratio remained constant. Higher levels of initial allergen uptake by respiratory dendritic cells were observed in the resistant strain, that together with subsequent lymph node delivery, increased following exposure in both strains although to lesser extent in the susceptible strain. To identify if increased antigen uptake could alter the course of sensitisation, we exposed the susceptible strain to an elevated ovalbumin dose. This induced T-regulatory cell proliferation and IL-10 production but did not

alter antigen-specific IgE levels. Current analysis is addressing how antigen dose modulates long-term tolerance in this strain. Given these results, this model may provide a platform for developing future therapeutic regimes based on manipulating allergen exposure to prevent allergic sensitisation.

490

Role of regulatory T cells in bacterial induced colitis

Fung, K.Y.¹, Rahman, T.², Kennedy, C.¹, van Driel, I.², Hartland, E.L.¹

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Parkville, Australia,

²University of Melbourne, Bio21 Molecular Science and Biotechnology Institute, Department of Biochemistry and Molecular Biology, Parkville, Australia

CD4⁺CD25⁺Foxp3⁺ Regulatory T cells (Treg) contribute to the maintenance of immune homeostasis in large intestine and as such, are implicated in the development of inflammatory bowel disease (IBD). To determine the role of Treg cells during colonic inflammation, we examined the course and outcome of *Citrobacter rodentium* infection in mice depleted of Treg cells. We found that mice depleted of Treg cells are more susceptible to mucosal *C.rodentium* infection than non-depleted mice. Treg-depleted mice exhibited exacerbated weight loss, significantly higher bacterial burden in the colon, increased dissemination to systemic tissue, increased epithelial permeability and colonic pathology. Compared to non-depleted mice, at 5 days after infection depleted mice showed altered expression of inflammatory cytokines and antimicrobial peptides in the colon, which have been shown to be protective against *C.rodentium* infection and important for maintaining epithelial integrity. In addition, there is reduced number of B cells infiltrating the colon and less anti-*Citrobacter* IgG in serum of Treg-depleted mice at 10 days post infection. These data suggest that Treg cells are important in supporting the host immune response and maintaining the immune epithelial barrier which is vital for healthy gut homeostasis. More importantly, we have revealed a possible role for Treg cells in regulating or cooperating with B cells to combat bacterial infection or possible involvement of B cells in epithelial barrier maintenance.

491

dLac and FOS reverse antibiotic-induced lung defense impairment in a ventilator model through increasing intestinal reactive oxygen species

Chen, L.-W.¹, Chen, P.-H.², Hsu, C.-M.³

¹Kaohsiung Veterans General Hospital, Surgery, Kaohsiung, Taiwan, Republic of China, ²Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, Republic of China, ³National Sun Yat-Sen University, Department of Biological Sciences, Kaohsiung, Taiwan, Republic of China

Prior antibiotic exposure is associated with increased mortality in gram-negative bacteremia complicated by sepsis or septic shock. This study was to determine effect and mechanisms of antibiotic treatment on lung defense mechanism in a mechanical ventilation (MV) model. C57BL/6 (WT) mice received ventilation

for 3 h at 6 days after intramuscular antibiotic treatment. The effects of dead *L. salivarius* and fructo-oligosaccharides (FOS) feeding on reactive oxygen species (ROS) of intestinal mucosa and *Pseudomonas aeruginosa* (PA) killing activity of alveolar macrophages (AMs) were examined. ROS scavenger, NAC, was used to investigate the involvement of intestinal ROS. Antibiotic treatment decreased ROS production of the intestinal mucosa and PA killing activity of AMs. Dead *L. salivarius* or fructo-oligosaccharides (FOS) feeding reversed the inhibitory effects of antibiotic on PA killing activity of AMs and protein expression of Reg3b as well as TLR4 in intestinal mucosa. Ablation of dead *L. salivarius* or fructo-oligosaccharides (FOS)-induced intestinal ROS with N-Acetylcysteine (NAC) decreased dihydrorhodamine (DHR) production and PA killing activity of AMs. Taken together with the inhibition of the stimulatory effect of FOS on lung defense mechanisms in MyD88 knockout (MyD88^{-/-}) mice, we concluded that antibiotic induces the inhibitory effect of lung defense mechanisms through the decrease of intestinal ROS and DHR production of AMs. Dead *L. salivarius* or fructo-oligosaccharides (FOS) feeding reverses antibiotic-induced lung defense impairment through intestinal TLR4/MyD88 pathway.

Free neutrophil elastase activity in airways of young children with cystic fibrosis prior to, during and post-Pseudomonas infection

Garratt, L.¹, Kicic, A.^{1,2,3,4}, Ranganathan, S.^{5,6,7}, Stick, S.^{1,2,3,4}, on behalf of AREST CF

¹Telethon Kids Institute, Subiaco, Australia, ²University of Western Australia, School of Paediatric and Child Health, Nedlands, Australia, ³University of Western Australia, Centre for Cell Therapy and Regenerative Medicine, Nedlands, Australia, ⁴Princess Margaret Hospital for Children, Department of Respiratory Medicine, Subiaco, Australia, ⁵Royal Children's Hospital Melbourne, Department of Respiratory Medicine, Parkville, Australia, ⁶Murdoch Childrens Research Institute, The Royal Children's Hospital, Parkville, Australia, ⁷University of Melbourne, Department of Paediatrics, Parkville, Australia

Introduction: Early acquisition of *Pseudomonas aeruginosa* (Psa) by children with cystic fibrosis (CF) is associated with worse prognosis. Neutrophil elastase (NE) activity is also abnormally present in CF airways. We examined NE activity to investigate whether Psa eradication also successfully reduced NE activity and inflammation.

Methods: Bronchoalveolar lavage fluid (BALf) was obtained through the AREST CF longitudinal cohort study for standard clinical microbiology. Children positive for Psa underwent a program-specific eradication regimen. Additional BALf was collected three months later to confirm eradication. All BALf were assessed for inflammation including leukocyte counts, IL-8 and NE activity.

Results: Eighty-one episodes of Psa infection in 74 children (0.27-6.63 years) were assessed. Of those, free NE activity was detected in 46. Mean NE activity (137.80 nM ±385.60) was significantly higher than prior annual BALf (35.31 nM ±84.49, p=0.0444) and peers who never cultured Psa (33.58 nM ±86.93, p< 0.0001). After eradication therapy, Psa was still detected

in 12 cases. Free NE prevalence was lower in 26 patients post-eradication, however mean activity was not significantly different ($124.30 \text{ nM} \pm 614.70$, $p=0.0645$). At following annual assessment ($n=67$), prevalence ($n=23$, 34.33%) and mean activity ($60.60 \text{ nM} \pm 181.10$, $p=0.0334$) remained significantly lower than Psa infection. No significant changes were observed in IL-8 or neutrophil cell count.

Conclusion: Prevalence and activity of NE were associated with Psa infection that was not always resolved following eradication. The treatment of residual protease activity during Psa eradication regimens should also be investigated for potential to prevent additional lung damage.

NKT cells mediate the recruitment of neutrophils by stimulating epithelial CXCL secretion during colitis

Huang, E.¹, Liu, R.¹, Lu, Z.¹, Liu, X.¹, Chu, Y.^{1,2}

¹Fudan University, Department of Immunology, Shanghai, China,

²Fudan University, Biotherapy Research Center, Shanghai, China

CD1d is a member of the major histocompatibility complex class I (MHC I)-like molecule family and has been proved to present glycolipid or glycerol lipid antigens to NKT cells. NKT cells are cells that express both NK cell markers and semi-invariant CD1d-restricted TCRs, and upon activation, can regulate immune responses via secreting a variety of cytokines. Ulcerative colitis (UC) is a kind of inflammatory bowel diseases characterized by inflammation and ulcer in colon, and its course is usually chronic and recurrent. UC patients have increased risk of getting colorectal cancer. In our research, we adopted the DSS-induced colitis mouse model, which is widely used to simulate UC, to investigate the role of CD1d and NKT cells in the progression of the disease. We found that in CD1d knocked-out (CD1dKO) mice, colitis was relieved. Further investigations revealed that when CD1d is knocked-out, colon epithelium express less chemokines that attract neutrophils (CXCL1, 2 and 3), and this may lead to fewer neutrophil infiltration. Infiltrated neutrophils also produce less reactive oxygen species (ROS) and TNF-alpha, this indicates they may cause less severe epithelial damage in CD1dKO mice. During colitis, NKT cells strongly express TNF-alpha, and TNF-alpha, can stimulate the expression of CXCL 1, 2, 3 by the epithelium. This can partially explain the mechanism of relieved neutrophil infiltration in CD1dKO mice with colitis.

494

Regulatory role of IL-22-dependent microRNAs in homeostasis and inflammation in the intestinal epithelium

Sadio, M., Tourneur, E., Bens, M., Vandewalle, A., Chassin, C.
INSERM, U 1149, Paris, France

The intestinal mucosa is constantly exposed to microbes, and the mechanisms implicated in the control of tolerance by intestinal epithelial cells (IECs) to avoid an inappropriate activation of the inflammation are unclear. The stimulation of IECs by Interleukine 22 (IL-22) induces the production of antimicrobial peptides, the reinforcement of the mucus barrier

and of IECs regeneration. Several studies showed the protective role of IL-22 during pathologies such as inflammatory bowel diseases or infections, but the mechanisms implicated in IECs remain not clear. Our group identified a specific panel of small non coding microRNAs (miRs), key regulators of physiological and pathological processes, induced by IL-22 in IECs. The results show that the panel of miRs induced by IL-22 is able to modulate the inflammation by targeting important proteins involved in inflammatory signaling pathway, correlated with a modulation of inflammatory-induced cytokine and of the bacterial load. Results were confirmed in a mouse model of intestinal inflammation. We also showed that the TLR4 expression is modulated by the induction of a miRs specifically targeting TLR4 induced by IL-22 in IECs. This modulation can be reversed with the injection of an antagomiR in our mouse model of intestinal inflammation. This finding could explain the IL-22 induced mechanisms regulating the inflammatory signaling pathway in IECs and highlight the possible use of microRNAs as therapeutic tool to prevent the intestinal inflammation.

Macrophages regulate steroid resistant airway inflammation in a mouse model of respiratory syncytial virus-induced asthma exacerbation

Nguyen, T.H.¹, Maltby, S.¹, Simpson, J.L.¹, Evers, F.¹, Gibson, P.G.², Foster, P.S.¹, Yang, M.¹

¹Priority Research Centre for Asthma and Respiratory Diseases, Department of Immunology and Microbiology, School of Biomedical Sciences & Pharmacy, Faculty of Health and Medicine and Hunter Medical Research Institute, University of Newcastle, Newcastle, Australia, ²Department of Respiratory and Sleep Medicine, Hunter New England Area Health Service, Newcastle, Australia

Background: About 5-10% of asthma patients with severe disease poorly respond to corticosteroid therapy and account for >50% of asthma-associated healthcare costs. Viral respiratory infections are one of the main factors responsible for exacerbations of asthma. However, the mechanisms how viral-induced asthma exacerbations are poorly understood.

Objectives: The aim of the study was to establish a mouse model of respiratory syncytial virus (RSV)-induced exacerbation of airway hyperresponsiveness (AHR) and airway inflammation to study the underlying mechanisms.

Methods: BALB/c mice were sensitised with OVA (or PBS control) in alum and later exposed to OVA aerosol to establish allergic airways disease. After the final OVA aerosol challenge, some groups were inoculated with either RSV or UV-inactivated RSV and lung function and airway inflammation were assessed.

Results: Infection of OVA-sensitised/challenged mice with RSV significantly increased AHR, macrophage and neutrophil lung infiltration. Exacerbations were accompanied by increased levels of inflammatory cytokines (including TNF α , MCP-1, and KC), compared to OVA-treated mice or OVA/UV-RSV-treated mice. Interestingly, we also observed increased TNF α levels in sputum samples from neutrophilic asthmatic patients. Dexamethasone treatment completely inhibited AHR and eosinophil infiltration in OVA-treated mice. Dexamethasone

treatment in OVA/RSV-treated mice partially suppressed AHR, but failed to dampen macrophage and neutrophil infiltration or inflammatory cytokine production. Furthermore, inhibition of TNF α , MCP-1 or macrophage depletion effectively suppressed features of disease, including AHR and macrophage infiltration.

Conclusions: Our findings highlight critical roles for macrophages and inflammatory cytokines (including TNF α and MCP-1) in viral-induced asthma exacerbations and suggest these as novel therapeutic pathways.

Structural prediction of receptor binding to IgM and IgA

Agostino, M.^{1,2,3}, Mancera, R.¹, Fernandez-Recio, J.², Ramsland, P.^{3,4,5,6}

¹Curtin University, School of Biomedical Sciences, CHIRI Biosciences and Curtin Institute for Computation, Perth, Australia, ²Barcelona Supercomputing Centre, Life Sciences Department, Barcelona, Spain, ³Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ⁴RMIT, School of Science, Bundoora, Australia, ⁵University of Melbourne, Department of Surgery Austin Health, Heidelberg, Australia, ⁶Monash University, Department of Immunology, Melbourne, Australia

Receptor binding to the antibody Fc region is a crucial step in the immune response to pathogens, as well as facilitating antibody transport and protection. Although IgM and IgA occupy important niches in host defence, structural knowledge of receptor binding to these immunoglobulins is currently limited. In particular, the large size and flexibility of the IgM pentamer precludes the application of high resolution experimental techniques for structural investigation of protein binding.

In this work, computational molecular docking is applied to predict the structures of pIgR, the pIgR-related receptors Fc α / μ R and Fc γ R, and TRIM21 in complex with IgA and IgM. The docking strategy employed has been specifically optimized for use in predicting Fc-protein interactions. Further analysis of the top 20 ranked poses, using molecular dynamics simulations combined with molecular mechanics generalized Born/surface area calculations, reveals the most likely binding modes of pIgR and TRIM21 in complex with both IgA and IgM. The identified binding modes of pIgR with IgA and IgM are then used to infer the binding modes of Fc α / μ R, based on the fold similarity between the binding domains of these receptors. Structural insight into the selectivity of Fc γ R for IgM over IgA is also revealed.

497

Differential cellular expression of the melatonin synthesizing enzyme, Arylalkylamine N-acetyltransferase (AANAT), in the mouse gut E-cadherin-immunolabeled resident enterocytes versus trafficking CD3⁺ and CD117⁺ immune cells

Fazal, N.¹, Al-Ghoul, W.², Royan, A.¹

¹Chicago State University, Pharmaceutical Sciences, Chicago, United States, ²Chicago State University, Biological Sciences, Chicago, United States

Our previous work has demonstrated anti-inflammatory

actions of melatonin in the gut alongside increased *de novo* endogenous melatonin synthesis in the gut in a mouse model of major thermal injury. Here, we investigated the distribution and dynamic changes of AANAT synthesis in the E-cadherin-immunolabeled resident enterocytes versus trafficking CD3⁺ and CD117⁺ immunocytes. Towards this end, AANAT levels were compared in E-cadherin, CD3, and CD117 immunopositive cells as assessed by flow cytometry and/or EasySep magnetic bead purification performed on ileum, colon, spleen, and mesenteric lymph node tissue preparations from control mice versus mice subjected to hot water scald (90°C for 10 seconds) over 20-25% total-body-surface on the back while under anesthesia in the presence or absence of melatonin treatment in accordance with IACUC approved protocols by Chicago State University. Our results suggest differential *de novo* gastrointestinal cell melatonin production and regulation in the resident E-cadherin positive mucosa cells versus and trafficking CD3⁺ and CD117⁺ cells depending on the tissue examined with highest levels being consistently in CD117⁺ cells from unmedicated injury group.

498

Lypd8 maintains gut homeostasis by segregating flagellated bacteria and colonic epithelia

Okumura, R., Takeda, K.

Osaka University Graduate School of Medicine, Department of Microbiology and Immunology, Suita, Japan

The intestinal mucosa is protected from commensal and pathogenic microorganisms by several types of barriers. In the large intestine where tremendous numbers of microbiota exist, epithelial cells are covered by thick mucus composed of two layers, the inner firm mucus layer and outer loose mucus layer. Many commensal bacteria are present in the outer mucus layer, whereas none is present in the inner mucus layer. However, the precise mechanisms for the segregation of bacteria and colonic epithelia by the inner mucus layer remain unclear. We found a molecule named Ly6/PLAUR domain containing 8 (Lydp8), which is a highly glycosylated GPI-anchored protein, is highly and selectively expressed in epithelial cells on the uppermost layer of the colonic gland and shed into the intestinal lumen. Bacterial free space in the inner mucus layer disappeared and many flagellated bacteria such as *Escherichia*, *Helicobacter* and *Proteus* invaded colonic epithelia in *Lydp8*^{-/-} mice. In addition, *Lydp8*^{-/-} mice were highly sensitive to dextran sulfate sodium (DSS)-induced colitis. Elimination of intestinal Gram-negative flagellated bacteria by the oral treatment of gentamicin restored colonic bacterial free space and ameliorated DSS colitis in *Lydp8*^{-/-} mice. Lydp8 preferentially bound to flagellated bacteria in the colon. In vitro analysis showed that Lydp8 bound to the flagella of *Proteus mirabilis* and *Escherichia coli*, thereby suppressing their swarming motility. These findings demonstrate that Lydp8 is essential for segregation of flagellated bacteria and colonic epithelial cells through the binding to bacterial flagella and subsequent suppression of their motility.

Influence of commensal microbiota and dietary antigens on the development and function of antigen presenting cells in intestinal homeostasis

Ko, S.H.-J.^{1,2}, Kim, K.S.^{1,2}, Hong, S.-W.^{1,2}, Jung, J.^{1,2}, Lee, M.J.^{1,2}, Surh, C.D.^{1,2,3}

¹Institute for Basic Science, Academy of Immunology and Microbiology, Pohang-si, Korea, Republic of, ²POSTECH (Pohang University of Science and Technology), Department of Integrative Biosciences and Biotechnology, Pohang-si, Korea, Republic of, ³La Jolla Institute for Allergy & Immunology, Division of Developmental Immunology, La Jolla, United States

Antigen presenting cells (APCs), such as dendritic cells (DCs) and macrophages, are the key immune cells that regulate function of lymphoid populations of immune cells by delivering self or foreign antigens in either steady state or inflammatory state. Intestinal APCs acquire the distinct roles by its constant exposure to commensal microbiota, pathogens, and food antigens. However, it is not elucidated yet how commensal microbiota and dietary antigens influence the development of intestinal APCs and how these cells are involved in establishing and maintaining intestinal homeostasis. To investigate this, we established the unique system that experimental mice are free from commensal microbiota (germ-free (GF mice)) and free from solid food diet (antigen-free (AF)). We examined the phenotypic differences of intestinal APCs from SPF, GF, and AF mice. We found that the number of CD103⁺DCs from AF mice is significantly lower than those from SPF and GF mice while the number of CD103⁺DCs is comparable between SPF and GF mice. When we further distinguished CD103⁺DCs with CD11b, there was more CD103⁺CD11b⁺DCs in AF mice that is similar with those in neonatal GF and SPF mice, indicating that food antigens may be involved in DC differentiation. We speculate that the components in the diet affect immune system without being triggering the Ag-specific receptors of the adaptive immune system. Defining the mechanisms how commensal microbiota and/or dietary antigens influence such a key immune cells in the gut will insight into the understanding of intestinal immunity.

Can aerosolised bacteriophage preparations against *Pseudomonas aeruginosa* protect against endotoxin-mediated inflammation in the lungs of people with cystic fibrosis?

Trend, S.^{1,2}, Chang, B.³, Kicic, A.^{1,2,4,5}, Stick, S.M.^{1,2,4,5}

¹Telethon Kids Institute, Centre for Health Research, Perth, Australia, ²University of Western Australia, School of Paediatrics and Child Health, Perth, Australia, ³University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia, ⁴Princess Margaret Hospital for Children, Department of Respiratory Medicine, Perth, Australia, ⁵University of Western Australia, Centre for Cell Therapy and Regenerative Medicine, School of Medicine and Pharmacology, Perth, Australia

Cystic fibrosis (CF) is a heritable disease caused by mutations to the CFTR gene. Chronic lung infections with bacterial pathogens including *Pseudomonas aeruginosa* are very common in CF,

and cause inflammation and lung destruction that contribute to early mortality. Current therapies for these lung infections include extensive intravenous or inhaled antibiotics, which are burdensome, and do not always eradicate infection. Bacteriophages are viruses that infect bacteria killing their host through replication. Endotoxin-binding bacteriophages are of particular interest to treat infections in CF since they have been shown to exhibit prophylactic anti-inflammatory properties *in vitro* by the reducing the production of reactive oxygen species (Miedzybrodzki *et al.* 2008). We hypothesise that an endotoxin-binding bacteriophage under investigation in our laboratory will have both anti-bacterial and anti-inflammatory properties in CF epithelial cells through hindrance of the interaction of endotoxin with TLR-4. Preliminary results indicate that an endotoxin-binding bacteriophage has broad antibacterial activity against *P. aeruginosa* isolates from children with CF (19 of 21 isolates susceptible). We will use dose-controlled deposition of a bacteriophage preparation on CF primary airway epithelial cells cultured at the air-liquid interface \pm endotoxin to test this hypothesis *in vitro*. RNA will be extracted from stimulated and control cells for analysis of gene expression changes in inflammatory pathways downstream of TLR-4 activation (NF-kappaB, MAPK/AP-1; IL-1beta, IL-6, IL-8, TNF-alpha). This research will explore the potential of bacteriophages to have anti-inflammatory effects in the host human during lung infections in CF using a clinically relevant model, and will inform our future research.

501

Dietary N- and O-glycans from cow milk and TLR modulation

Figueroa, S.^{1,2}, Dijkhuizen, L.², Valk, R.², van Leeuwen, S.², de Vos, P.¹

¹University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands, ²University of Groningen, Microbial Physiology, Groningen, Netherlands

Diseases such as type 1 diabetes, food allergies or atopic disorders have been linked with the precocious contact of food components such as glycoproteins from cow milk with the immature intestinal mucosa. The exact mechanism by which food components contribute to food allergy or induce tolerance is still not completely clear. The immune tolerance is lost in MyD88-knockout mice, which made us hypothesize that some food components might signal via TLR-dependent pathways.

In this study cow milk preparations were enzymatically modified to N- and O-glycans. These preparations were exposed to reporter cell lines expressing TLR-receptors. We compared the effect of modified glycans against their intact counterparts and against the original intact glycoprotein. Unlike the original molecule, modified fractions showed an average 3-fold ($p < 0.05$) change in its inhibitory effects on TLR-4. At the same time, the original molecule displayed stimulatory activity on the same receptor. Among modified glycan fractions i.e. glycans with and without sialic acid units, we observed a 2-fold ($p < 0.05$) inhibitory effect on TLR-9.

Our findings suggest a function-structure relationship influence on the inhibition of the signaling cascade for the production of NF-KB mediated by TLR.

502

Live but not heat-inactivated *Aquaphilus dolomiae*, a bacteria from aquifer water, inhibit inflammation and ameliorate TNBS-induced colitis in IBD rat's model

Nguyen, T.¹, Helffer, K.¹, Maître, M.¹, Rousset, P.², Vergnole, N.², Libon, C.¹

¹Institut de Recherche Pierre Fabre, Biotechnology, Toulouse, France, ²INSERM U 1220, CHU Purpan, Toulouse, France

Recently, numerous publications have strongly supported the crucial role of Microbiota in immunomodulation of both innate and adaptive mucosal immunity. Many probiotics have showed beneficial effects in immune homeostasis and contributed to human health by complex regulations pathways. *Aquaphilus dolomiae* (ADLM), a non-pathogenic beta-proteobacteria, isolated from a thermal spring water (South of France), was evaluated in inflammatory bowel disease (IBD) experimental model.

Methods: Different doses of live or heat-killed ADLM were daily administered per os for 7 days to Wistar rats prior colitis induction by rectal injection of TNBS, and compared to vehicle controls and to reference drugs (Prednisolone and Remicade™). Development of colitis was assessed daily by checking body weight change, stool consistency and detection of blood in stools. Seven days after TNBS administration, rats were sacrificed. The whole colon was excised to determine macroscopic and microscopic damages and then cut into pieces for myeloperoxidase activity (MPO), proteins and cytokines profile quantification, and histological analysis.

Results: Live ADLM dose-dependently (109 > 108 bacteria/day/rat) protected rats from TNBS colitis. This effect was correlated with reduced inflammation as assessed by MPO activity and inflammatory cytokines (IL-1beta, IL-1RA, MIP-1alpha, IL-6, GRO/KC and TNF-alpha). These effects were at least comparable or better as compared to Prednisolone and Remicade™ treatments. In contrast, heat-inactivated ADLM were less protective, and most of the inflammatory parameters were not modified.

Conclusion: Oral administration of live ADLM is able to prevent colitis development and reduces inflammation. Thus, this probiotic therapy strategy is very promising to alleviate human IBD.

503

Long lasting effect of mucosal topical applied microbicides on the subsequent rectal SIV infection and survival by regulating SIV-specific T cell immune responses

Ren, Y., Wan, Y., Wang, J., Xu, J., Zhang, X.

Fudan University, Shanghai Public Health Clinical Center and Institutes of Biomedical Sciences, Shanghai, China

Most previous studies of candidate microbicides focused on the efficacy for the prevention from HIV/SIV infection, few on their potential influences on mucosal immune system and later on the disease progression during subsequent SIV infection. We designed a two-phase study: to mimic microbicide efficacy studies and determine the disease progression in a productive infection model. During the first phase, monkeys were intrarectally pre-treated with tenofovir (TFV), sifuvirtide (SFT) or maroviroc (MVC) formulated microbicides and then

challenged with low-dose SHIV-1157ipd3N4. Secondly, all monkeys were re-challenged with a single high dose SIVmac239 to generate productive infections. The survival rate, viral loads, CD4+ T-cell counts and SIV-specific T-cell responses were determined during the 104-week following up. Repeated rectal challenges resulted in infection in all groups, evidenced by the recurrent viral blips during the first phase of this study. All monkeys were productively infected after the high-dose re-challenge with SIVmac239. Two groups, including MVC- and TFV-treated groups, experienced 100% death during the 104-week following up; In contrast, SFT-treated group survived significantly better ($p=0.0169$ for SFT vs TFV, and $p=0.0067$ for SFT vs MVC), and only 25% (one monkey) dies at week 95. Interestingly, SIV-specific T cell responses were also significantly higher in SFT group comparing to MVC and TFV groups. This study informs a preliminary but important observation on the influence of previously applied microbicides on the disease progression of subsequent SIV infection, and suggests that the long-term immune safety concern for microbicides should be also considered in the effort to develop effective microbicides.

504

MAIT cell activation and accumulation after *in vivo* infection depends on microbial riboflavin synthesis and co-stimulatory signals

Chen, Z.¹, Wang, H.¹, D'Souza, C.¹, Sun, S.¹, Kostenko, L.¹, Eckle, S.¹, Meehan, B.¹, Jackson, D.¹, Strugnelli, R.¹, Cao, H.¹, Wang, N.¹, Fairlie, D.², Liu, L.², Godfrey, D.¹, Rossjohn, J.³, McCluskey, J.¹, Corbett, A.¹

¹University of Melbourne, Melbourne, Australia, ²University of Queensland, Brisbane, Australia, ³Monash University, Melbourne, Australia

Despite recent breakthroughs in identifying MAIT cell antigens, the precise requirements for *in vivo* MAIT responses to infection remain unclear. Using MR1 tetramers, the MAIT cell response was investigated in a model of bacterial lung infection employing *rib* gene-competent and deficient bacteria. MAIT cells were rapidly enriched in the lungs of C57BL/6 mice infected with *Salmonella* Typhimurium, comprising up to 50% of ab-T cells after one week. MAIT cell accumulation was MR1-dependent, required antigen derived from the microbial riboflavin synthesis pathway and did not occur in response to synthetic antigen, unless accompanied by a TLR2/6 agonist or by co-infection with riboflavin pathway-deficient *S. Typhimurium*. MAIT cell accumulation involved proliferation in the lungs and regional LN, and was associated with their long-term retention in the lungs. Lung MAIT cells from infected mice were mainly CD4⁺ CD8⁻ double negative (DN) or CD8⁺, displayed an activated/memory phenotype, and most expressed the transcription factor ROR γ t. T-bet expression increased following infection. The majority produced IL-17 while smaller subsets produced IFN γ or TNF, detected directly *ex vivo*. Thus, the activation and expansion of MAIT cells coupled with their pro-inflammatory cytokine production, occurred in response to antigens derived from microbial riboflavin synthesis and was augmented by co-stimulatory signals.

Transforming Growth Factor $\beta 1$ (TGF- $\beta 1$) is increased in the sera of postmenopausal osteoporotic women: a case-control study

Samsami-Dehaghani, A.¹, Faraji, A.², Ghaderi, A.³

¹Shiraz University of Medical Sciences, Ob/Gyn, Shiraz, Iran, Islamic Republic of, ²Sadoughi University of Medical Sciences, Ob/Gyn, Shiraz, Iran, Islamic Republic of, ³Shiraz University of Medical Sciences, Shiraz Institute for Cancer Research, Shiraz, Iran, Islamic Republic of

Objectives: TGF- $\beta 1$ and IL-18 play complex roles in normal bone metabolism, and in pathophysiology of postmenopausal osteoporosis. A case-control study was conducted in order to further clarify the role of TGF- $\beta 1$ and IL-18 in osteoporosis of post-menopausal women.

Materials and methods: 65 postmenopausal women with osteoporosis (T score < -2.5 in the lumbar spine or femoral neck) and 69 postmenopausal normal women (T score \geq -1) were enrolled. Serum levels of TGF- $\beta 1$ and IL-18 were measured in both groups.

Results: Serum TGF- $\beta 1$ levels were significantly higher in osteoporotic postmenopausal women than non-osteoporotic individuals (23.80 vs. 15.77 ng/ml; p value=0.009). There was no difference between IL-18 levels in the sera of osteoporotic and non-osteoporotic post menopausal women in this study. There was a positive correlation between body mass index (BMI) and serum level of TGF- $\beta 1$ (p value=0.04).

Conclusion: Aberrant increase in TGF- $\beta 1$ serum levels in postmenopausal ages can result in uncoupled bone resorption and formation, leading to osteoporosis. Screening the levels of TGF- $\beta 1$ in the sera of postmenopausal women can have a predictive value for osteoporosis.

506

Immunological modes of pregnancy loss: similarity in hepatitis E infected and non-infected pregnancy cases

Bose, P.D.¹, Tiwari, D.², Bose, M.², Sultana, R.², Begum, A.², Datta, R.³, Das, C.R.⁴, Bose, S.²

¹Cotton College State University, Molecular Biology & Biotechnology, Guwahati, India, ²Gauhati University, Biotechnology, Guwahati, India, ³Gauhati University, Guwahati, India, ⁴Guwahati Medical College, Guwahati, India

We aimed to evaluate the role of alterations in progesterone receptor pathway and altered cytokine profile in deciding the outcome of Hepatitis E virus(HEV) infected pregnancies.

Methods: Blood, placental tissue samples were collected from pregnant cases [term-delivery-cases(TC=30),preterm-cases(TC=50)] and HEV infected PC[HEV-PC,n=22]. Progesterone receptor(PR) polymorphism(PROGINS) was studied by PCR. Differential placental PR expression was studied by IHC. Differential mRNA profile of PR and PIBF expression was analyzed by RT-PCR. Differential cytokine expression at protein and mRNA level was studied by multiplex ELISA (TNF α ,IFN γ ,IL12,IL10,IL6,IL2,IL4,IL8) and RT-PCR, and correlated with PR expression and pregnancy outcome.

Results: Prevalance of PROGINS polymorphism was higher in PC(p=0.216),HEV-PC(p=0.342) compared to TC. PR- expression was down-regulated in both PC and HEV-PC compared to TC;and in IUD/fetal-death PC compared to PC with successful pregnancy outcome. PIBF expression was also down-regulated in both HEV-PC and PC; and PC with negative pregnancy outcome cases compared to TC, and PC with successful outcome respectively. Placental NF κ B expression was significantly higher in PC(0.348 \pm 0.126 μ g/ml)(p=0.032) and HEV-PC (0.329 \pm 0.182 μ g/ml)(p=0.047) compared to term cases(0.289 \pm 0.169 μ g/ml). Cytokine profile clearly indicated significant changes in inflammatory cytokines TNF α ,IL6 and IL8 in both HEV-PC and PC, and correlated with pregnancy outcome; while IFN γ expression was also significantly higher in HEV-PC compared to TC(p< 0.001) and PC(p=0.004). NF κ Bp65,TNF α placental expression was higher in HEV-PC and PC compared to TC,and positively correlated with pregnancy outcome. TNF α mRNA expression significantly negatively correlated with PR-mRNA expression.

Conclusion: Alteration in PR pathway and resulting altered Th1-modulation is detrimental to both HEV-PC and PC; and thus have both prognostic and therapeutic importance.

507

Regulatory T cell abundance and phenotype in pregnancy - a novel role for progesterone potentially independent of nuclear progesterone receptor

Green, E.S.¹, Moldenhauer, L.M.¹, Kara, E.E.², Chin, P.Y.¹, Robker, R.L.¹, McColl, S.R.², Robertson, S.A.¹

¹Robinson Research Institute, University of Adelaide, Discipline of Obstetrics & Gynaecology, Adelaide, Australia, ²University of Adelaide, Department of Molecular & Cellular Biology, Adelaide, Australia

Fetal-maternal tolerance is primarily mediated by maternal CD4⁺Foxp3⁺ regulatory T (Treg) cells, with both thymus-derived (tTreg) and peripherally derived (pTreg) cells contributing. Absence or reduced function of Treg cells at embryo implantation causes infertility in mice and is implicated as a cause of reproductive disorders in women. The importance of adequate Treg cell responses during pregnancy is well recognised, however, the factors which control the strength and quality of this response are not defined. Progesterone (P4) has potent immunosuppressive actions. We previously demonstrated that administration of ovarian steroid hormones estrogen and P4 to female ovariectomised mice increases Treg cell numbers in vivo. To further investigate the effects of P4 on Treg cells, mated female mice were administered low doses of the progesterone antagonist RU486 in the peri-implantation period. Flow cytometry analyses showed RU486 treatment resulted in decreased proportions of total Treg cells and increased proportions of IFN γ -producing tTreg and pTreg cells in the uterus-draining para-aortic lymph nodes. In vitro, P4 repressed IFN γ expression in Treg and T effector cells cultured under Th1-, Th17- and non-polarising conditions. Treg cells from mice with a null mutation in the nuclear progesterone receptor (PR) also responded to P4 with attenuated IFN γ production, indicating the P4 effect was not mediated by the nuclear PR and suggesting a non-classical mechanism for progesterone action

on Treg cell phenotype. Collectively, this work demonstrates that P4 can regulate Treg cell abundance and cytokine production, which may be important in the establishment and maintenance of competent maternal tolerance during pregnancy.

508

Immune suppression by human semen is mediated by soluble CD52

Harrison, L.C.^{1,2}, Stone, N.L.^{1,2}, Bandala-Sanchez, E.^{1,2}, McLachlan, R.I.³, Merriner, D.J.³, O'Bryan, M.K.³

¹Walter and Eliza Hall Institute of Medical Research, Population Health and Immunity Division, Parkville, Australia, ²The University of Melbourne Victoria 3010, Australia., Medical Biology, Parkville, Australia, ³Monash University, Anatomy and Developmental Biology, Clayton, Australia

Male seminal vesicular fluid or semen not only provides for the carriage and nutritional maintenance of sperm but has immunomodulatory properties that protect against allojection of sperm. Immune modulation by semen has been attributed to several of its components, namely prostaglandins, spermine and transforming growth factor-beta, and to induction of regulatory T cells in the female, but whether these fully account for suppression of lymphocyte activation-proliferation by semen is unclear.

A major 'antigen' in semen, the target of anti-sperm antibodies in some infertile women, is CD52, secreted by the epithelial cells of the distal epididymis and vas deferens, which becomes incorporated into the sperm cell membrane. CD52 is also present as a small GPI-anchored glycoprotein on lymphoid cells. We reported that CD52 is released by activated T cells and suppresses T cells by binding of its glycan to the inhibitory receptor Siglec-10 (1).

Here we show that human semen contains high concentrations of soluble CD52, blockade or depletion of which abrogates suppression of T or B cell function by semen. Blocking by antibodies or by recombinant soluble Siglec-Fc proteins revealed that semen CD52 bound to Siglec-7, which was expressed predominantly by Sertoli cells in the testis. Ligation of Siglec-7 inhibits natural killer cells in the female, which are known to target sperm. In conclusion, the suppression of lymphocyte function by human semen can be accounted for by the Siglec ligand, CD52.

HLA-G, KIR2DL4 and LILRB1 gene polymorphisms in spontaneous abortion in Poles

Nowak, I.¹, Malinowski, A.², Barcz, E.³, Wilczyński, J.R.⁴, Wagner, M.¹, Majorczyk, E.^{1,5}, Motak-Pochrzęst, H.⁶, Kuśnierczyk, P.⁷

¹Ludwik Hirszfild Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Laboratory of Immunogenetics and Tissue Immunology, Wrocław, Poland,

²Mothers' Memorial Hospital - Research Institute, Surgical, Endoscopic and Oncologic Gynecology, Łódź, Poland, ³Medical University of Warsaw, Poland, First Chair and Clinic of Obstetrics and Gynecology, Warsaw, Poland, ⁴Mothers' Memorial Hospital -

Research Institute, Department of Gynecology and Gynecologic Oncology, Łódź, Poland, ⁵Opole University of Technology, Faculty of Physical Education and Physiotherapy, Opole, Poland, ⁶District Hospital, Strzelce Opolskie, Poland, ⁷Ludwik Hirszfild Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Laboratory of Immunogenetics and Tissue Immunology, Wrocław, Poland

The KIR2DL4 receptor and its ligand HLA-G are considered important for fetal-maternal immune tolerance and successful pregnancy. The absence of a particular variant of KIR2DL4 might be a bad prognostic factor for pregnancy outcome. However, it could be compensated by the presence of the respective LILRB1 allele. Therefore, we investigated the *KIR2DL4*, *LILRB1* and *HLA-G* polymorphisms in 277 couples with spontaneous abortion and 219 control couples by HRM, PCR-SSP and RFLP methods. We found a protective effect of women's heterozygosity in -716 T>G *HLA-G* ($p = 0.0206$) and 5651 G>A *LILRB1* ($p = 0.0131$) against spontaneous abortion. Surprisingly, we observed higher frequency of 9A/10A heterozygotes of *KIR2DL4* gene in the group of male partners from the miscarriage group in comparison to the men from the control group ($p = 0.0288$). Furthermore, there was no association of women's *KIR2DL4* polymorphism with susceptibility to spontaneous abortion. Multivariate analysis indicated that female *HLA-G* -716 T>G and *LILRB1* 5651 G>A and male *KIR2DL4* 9A/10A are important in terms of the protection or susceptibility to miscarriage, respectively ($p = 0.00968$).

In conclusion, a woman's heterozygosity in *HLA-G* and *LILRB1* might be advantageous for a success of reproduction, but the partner's heterozygosity in 9A/10A *KIR2DL4* alleles might be a rather bad predictor.

510

Up-regulation of autophagy by sera from women with preeclampsia is associated with pro-inflammatory cytokines

Matias, M.L.¹, Peracoli, M.T.¹, Kanninen, T.², Sisti, G.², Romão-Veiga, M.¹, Peracoli, J.C.¹, Bongiovanni, A.M.², Witkin, S.²

¹UNESP, Botucatu, Brazil, ²Weill Cornell Medical College, New York, United States

Preeclampsia (PE) is a clinical complication of pregnancy associated with elevated levels of inflammatory cytokines and uric acid. Autophagy, an intracellular catabolic process, seems to maintain the cellular homeostasis and can control the inflammasomes activation. Monocytes stimulation with monosodium urate (MSU) demonstrates that uric acid plays a role in inflammasome activation. This study compared the ability of sera from pregnant women with or without PE to induce autophagy in peripheral blood mononuclear cells (PBMC) from healthy non-pregnant women. PBMC from 20 non-pregnant women were incubated with sera from 45 pregnant women, being 23 normotensive (NT) and 22 with PE in the presence or absence of the autophagy inducer, rapamycin. Autophagy induction was evaluated by the expression of p62 by RT-qPCR and ELISA. Higher p62 gene expression was observed in PBMCs

cultured with PE and NT sera or MSU compared to the control cultures. Moreover, gene expression of p62 is increased in PBMCs cultured with PE sera than in culture stimulated with NT sera. Protein levels of p62 in PBMC cultured without rapamycin and treated with sera from NT group were significantly higher when compared to cultures with PE sera. Sera of preeclamptic women showed association between autophagy induction and higher concentrations of IL-1 β and TNF- α . Association between autophagy induction and higher levels of inflammatory cytokines in sera from patients with PE suggests that the enhanced pro-inflammatory state characteristic of PE may result in the up-regulation of autophagy induction in these women.

511

Immunoregulation of the decidualization program

Grasso, E.¹, Gallino, L.¹, Soczewski, E.¹, Gori, S.², Salamone, G.², Pérez-Leirós, C.¹, Ramhorst, R.¹

¹University of Buenos Aires, School of Sciences, CONICET, Immunopharmacology Lab. IQUBICEN-CONICET, Buenos Aires, Argentina, ²National Academy of Sciences, IMEX, Buenos Aires, Argentina

Decidualization process involves phenotype and functional changes on endometrial cells and the modulation of different mediators such as cytokines, chemokines and the selective recruitment of immune cells. Particularly, the vasoactive intestinal peptide (VIP) is a neuropeptide produced by endometrial stromal cells that displays multiple target circuits allowing immunetolerance.

To investigate VIP contribution to the decidualization program, we used an in vitro implantation model based in the co-culture of blastocyst-like spheroids (BLS) from trophoblast cells cultured on Human endometrial stromal cell line monolayer (HESC) decidualized with or with medroxyprogesterone and dbcAMP (+control).

Decidualization increased VIP expression and secretion on HESC cells ($p < 0.05$ ANOVA). The decidualization induced by VIP increased differentiation markers as IGFBP1, PRL, KLF13/KLF9 ratio

($p < 0.05$, ANOVA). When BLS from first trimester trophoblast cells (Swan71 cell line) were cultured on HESC monolayer, BLS were able to invade HESC decidualized with VIP or MPA+dbcAMP. In fact, the condition media from developmentally impaired human blastocyst decrease the invasion of on HESC cells decidualized under both treatments. Decidualized HESC CM induced a semi-mature profile on DC preventing CD83 and CD86 induction and increasing IL-10 secretion ($p < 0.05$ Student Ttest), while did not modulate monocytes activation profile. Decidualized cells selective recruit Foxp3+ cells, among monocytes and effector Tcells, associated with and increase CXCL12 expression.

In conclusion, VIP may have an important role during decidualization by allowing BLS invasion contributing to control the immune micro-environment associated with the condition of DC to a tolerogenic profile and to the selective recruitment of maternal Tregs to the uterus.

512

The influence of viral infection on the innate immune system during pregnancy

Moore, S.^{1,2}, Garcia Valtanen, P.¹, Robertson, S.², Hayball, J.¹, Diener, K.^{1,2}

¹University of South Australia, Experimental Therapeutics Laboratory, Hanson Institute & Sansom Institute, School of Pharmacy and Medical Science, Adelaide, Australia, ²University of Adelaide, Robinson Research Institute, School of Medicine, Adelaide, Australia

Successful pregnancy is dependent on the establishment of maternal immune tolerance which is predominantly facilitated by the adaptive arm of the immune system. The presence of infection has however the potential to alter pregnancy outcomes, which can be attributed to alterations in tolerance induction. The innate immune system is the first defence against pathogenic invasion and is often considered to educate subsequent adaptive immune responses; however viral-induced changes to the activation and function of innate immune cells during maternal infection and how this may affect reproductive outcomes has largely remained unexplored. Recent evidence suggests that the innate immune system possesses a degree of 'memory' in response to infection, and may therefore be detrimental to pregnancy upon challenge with an unrelated secondary infection. In this study, mated female mice received an infection with murine cytomegalovirus (MCMV) prior to embryo implantation and subsequently challenged with lipopolysaccharide (LPS) later during gestation to assess whether prior innate immune stimulation alters the response to a secondary challenge and what effect this may have on fetal rejection. This was combined with a novel mouse triply-deficient in the innate immune molecules (TLR7, TLR9 and ASC) necessary for MCMV control, which we show results in abrogated natural killer (NK) cell activity. We propose that NK cells alongside monocytes hold the key to differences in pregnancy outcomes between primary and secondary innate immune recognition. These results demonstrate for the first time the innate immune system obtaining memory of infectious challenge and how this may impact on reproductive outcomes.

513

Association of IL-17A and IL-17 F gene polymorphisms with recurrent pregnancy loss in Iranian women

Najafi, S.¹, Hadinedoushan, H.², Eslami, G.²

¹Tehran University of Medical Sciences, School of Public Health, Dept. of Pathobiology, Tehran, Iran, Islamic Republic of, ²Yazd University of Medical Sciences, Yazd, Iran, Islamic Republic of

Purpose: Recurrent pregnancy loss (RPL) is defined as the occurrence of two or more miscarriages before the 20th week of pregnancy. T helper17 cells are a novel subset of T cells, which secrete IL (Interleukin)-17 and are known to be involved in inflammation, autoimmunity and rejection of nonself tissues. Herein, we studied the association between IL-17A rs2275913 and IL-17F rs763780 gene polymorphisms with RPL in Iranian women.

Methods: A case-controlled study was performed on two groups

consisting of 85 healthy women with at least one delivery and 85 women with the history of two or more RPLs. The frequency of IL-17A rs2275913 and IL-17 F rs763780 polymorphisms were determined by PCR-RFLP.

Results: In the RPL group, the genotypes frequencies of rs2275913 polymorphism were GG (8.2 %), AG (30.6 %), and AA (61.2 %) and in the control group, were GG (3.5 %), AG (42.4 %) and AA (54.1 %). Statistical analysis showed no significant difference between the genotypes of AA, AG and GG in the two groups ($p=0.1$). The genotypes frequencies of rs763780 polymorphism were TT (43.5 %), TC (49.4 %) and CC (7.1 %) in the RPL group; whereas the frequencies were TT (25.9 %), TC (70.6 %) and CC (3.5 %) in the control group. Statistical analysis revealed a significant difference in the TT, TC, and CC genotypes frequencies between the case and the control groups ($p=0.01$).

Conclusions: Our findings indicate that IL-17F polymorphism, rs763780, might be associated with a high risk of RPL in Iranian women.

514

Short and long term effects of pregnancy on memory T cells

Kieffer, T.E.C.¹, Faas, M.M.², Scherjon, S.A.¹, Prins, J.R.¹

¹University Medical Center Groningen, University of Groningen, Department of Obstetrics and Gynecology, Groningen, Netherlands, ²University Medical Center Groningen, University of Groningen, Division of Medical Biology, Department of Pathology and Medical Biology, Groningen, Netherlands

Non-optimal induction of immune tolerance towards paternal antigens during pregnancy is associated with pregnancy complications. Studies have shown that the maternal immune system memorizes paternal antigens and with that possibly reduces the risk of pregnancy complications. This study aims to analyze the short and long term effects of pregnancy on memory T-lymphocytes. Effector memory (EM) and central memory (CM) T-lymphocytes and their activation status were analyzed using flow cytometry in peripheral blood of 14 women that had never been pregnant (nulligravid), 12 women that were pregnant for the first time (primigravid), and 15 women with an uncomplicated pregnancy that were at least 6 months post partum (parous). Populations were compared using one-way ANOVA and Tukey's post hoc test; $p < 0.05$. The short term effects were shown by the significantly higher CD4+ EM cell ($p < 0.05$) and activated CD4+ memory cell ($p < 0.001$) proportions in primigravid women compared to nulligravid women. The long term effects found in this study were the significantly higher proportions of CD4+ EM ($p < 0.05$), CD4+ CM ($p < 0.001$) and activated memory T cells ($p < 0.05$) in parous women compared to nulligravid women. In contrast to CD4+ cells, activation status of CD8+ memory cells did not differ between the groups. Possibly, a shift from CD4+ CM to EM cells occurs during pregnancy followed by an increase of both subsets postpartum. These findings support the hypothesis that memory cells are involved in memorizing paternal antigens.

515

The improvement of abnormal pregnancy by IL-10 treatment in *T. gondii*-infected mice

Hu, X.¹, Zhang, H.², Zhao, M.³, Liu, X.², Jiang, Y.²

¹Binzhou Medical University, Department of Immunology, Binzhou, China, ²Binzhou Medical University, Department of Immunology, Yantai, China, ³Binzhou Medical University, Department of Medicine & Pharmacy Research Center, Yantai, China

Aims: To investigate the role of IL-10 on abnormal pregnancy outcomes following *T. gondii* infection.

Methods: C57BL/6 pregnant mice were randomly divided into control group, infected group and rIL-10-treated group. The infected group and rIL-10-treated group were infected with 400 *T. gondii* on gestational day (gd) 7. On gd 6 and 8, rIL-10-treated group was administrated with 1 μ g rIL-10 via a tail vein injection. The mice were sacrificed on gd 12 and their pregnancy outcomes were observed. The expression of NKG2A, an NK cell inhibiting receptor, and NKG2D, an NK cell activating receptor, on NK cells were analyzed by flow cytometry; the level of IFN- γ inside NK cells as well as the total level of IFN- γ in placental tissue extract was measured by flow cytometry and ELISA respectively.

Results: rIL-10-treated group showed significantly alleviated adverse pregnancy outcomes compared with infected group. The expression of NKG2D on NK cells was up-regulated in infected group compared to controls, but was down-regulated in rIL-10-treated group compared to infected group. Conversely, NKG2A was elevated in the infected group, and further increased in rIL-10-treated group. The IFN- γ level inside NK cells as well as in placental tissue extract was up-regulated in infected group compared to controls, but were down-regulated in rIL-10-treated group compared to infected group.

Conclusion: IL-10 may play an immunoprotective role in abnormal pregnancy following *T. gondii* infection through regulating the function of decidual NK cells.

Keywords: IL-10, decidual NK cells, NKG2D, NKG2A, abnormal pregnancy outcomes, *Toxoplasma gondii*.

Critical differences in the fc receptors of humans and non-human primates with implications for the analysis of antibody effector functions *in vivo*

Chenoweth, A.M.^{1,2}, Trist, H.¹, Tan, P.S.¹, Esparon, S.¹, Anania, J.C.^{1,2}, Munro, J.¹, Wines, B.^{1,2,3}, Hogarth, P.M.^{1,2,3}

¹Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ²Monash University, Department of Immunology, Melbourne, Australia, ³University of Melbourne, Department of Pathology, Melbourne, Australia

The spectacular success of monoclonal antibodies as therapeutic modalities and of vaccines in preventative medicine, together with the increasing emphasis on translational research, have focused attention on the drive for new therapeutic targets, understanding of the human immune system, and development of appropriate animal models of human immunity, including non-human primates (NHP).

Antibodies, and their Fc receptor (FcR)-based effector functions, are major contributors to the effectiveness of therapeutic antibodies, vaccines, and the regulation of immunity. However, despite the use of NHP as models of human immunity, little is known of their FcR genetics, function, and interaction with immunoglobulins.

We have undertaken a comparative analysis of the interaction of eight high- and low-affinity macaque and human FcγRs with IgG subclasses. We discovered marked differences between macaque FcγR and their human counterparts in their specificity for, and interaction with, human IgG subclasses. Moreover, FcγR sequence analysis revealed surprisingly extensive genetic polymorphisms in macaque, especially in FcγRIIIa, which profoundly affects receptor function as demonstrated by flow cytometry. The molecular basis for these interspecies differences was investigated by engineering 50 IgG subclass mutants, with mutations throughout the IgG Fc region and several "hotspots" of interspecies difference in receptor binding were identified.

Our studies suggest that responses expected in humans may not be faithfully reproduced in NHP due to differences in their FcγRs. This has implications for their use as a model of human adaptive and innate immunity to infection and for their use in preclinical evaluation of human monoclonal antibodies.

Analysis of toll-like receptor responses in the endangered Tasmanian devil

Patchett, A.¹, Kalodimos, G.¹, Tovar, C.¹, Lyons, A.B.², Woods, G.^{1,2}

¹Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, ²School of Medicine, University of Tasmania, Hobart, Australia

Devil facial tumour disease (DFTD) is a fatal transmissible cancer threatening Tasmania's largest marsupial carnivore, the Tasmanian devil (*Sarcophilus harrisi*). Development of a vaccine against DFTD is fundamental to the conservation of this unique species. For this vaccine to be effective, a strong adjuvant will likely be required. Toll-like receptors (TLRs) are expressed by immune cells and promote potent immune responses after binding to specific microbial molecules. We have previously shown that TLRs are functional in the Tasmanian devil and, as with human and mouse, we hypothesise that their ligands will act as effective vaccine adjuvants. To analyse TLR responses in the Tasmanian devil, we isolated mononuclear cells (MNCs) from peripheral blood and stimulated these in culture with TLR ligands. Quantitative PCR was performed to measure inflammatory gene expression after TLR stimulation. To assess the response *in vivo*, Tasmanian devils were vaccinated with the model antigen KLH with or without TLR ligands. Blood and serum samples were collected at intervals post-vaccination and the anti-KLH response was measured. Our *in vitro* data showed that a combination of the TLR3 ligand poly(IC) and the TLR7 ligand imiquimod consistently up-regulated inflammatory gene expression in MNCs. These ligands also significantly increased the magnitude of the specific immune response to KLH in Tasmanian devils. Our data provide the first *in vivo* evidence that TLR signaling activates effective immune responses in Tasmanian devils upon vaccination. Furthermore, these findings

could improve the efficacy of candidate DFTD vaccines for enhanced protection against disease transmission.

518

Identification and characterization of chicken IFIT5

Rohringer, A.^{1,2}, Lowenthal, B.W.^{1,2}, Butler, J.M.³, Williams, D.T.³, Ward, A.C.², Bean, A.G.D.¹

¹CSIRO AAHL, Immunology, Geelong, Australia, ²Deakin University, School of Medicine, Geelong, Australia, ³CSIRO AAHL, Avian Virology, Geelong, Australia

The comprehensive characterization of antiviral immune pathways is essential for understanding host pathogen mechanisms to underpin improved molecular therapies for both human and livestock use. The interferon pathway impacts the expression of a myriad of interferon stimulated genes (ISGs) that reduce viral replication and infection. One of these, Interferon-Induced protein with Tetratricopeptide repeats 5 (IFIT5), has been shown to be important in the antiviral response in mammals. In this study we identify and characterize chicken IFIT5. This gene shows synteny with the human IFIT genes and encodes a 470 amino acid (AA) protein with strong conservation to mammalian IFITs. IFIT5 expression was induced in chicken splenocytes stimulated with type I interferon or TLR ligand *in vivo*. *In vivo* experiments demonstrated a 400-fold increase in IFIT5 expression in the lungs of chickens following infection with a highly pathogenic avian influenza virus. These data highlight the conserved role of IFIT5 in the response to viral infection and provide information on the chicken immune response to highly pathogenic avian influenza.

519

Comparison of immune responses and transmissibility between Korean and Chinese canine influenza viruses in Guinea pigs

Kang, A.¹, Xie, X.², Yuk, H.¹, Yeom, M.¹, Na, W.¹, Song, D.¹

¹Korea University College of Pharmacy, Sejong, Korea, Republic of, ²Nanjing Agricultural University, College of Veterinary Medicine, Nanjing, China

Canine influenza virus (CIV) is a disease that can cause cough, pneumonia even death in dog populations. H3N2 CIV has been circulating in dogs in both Korea and China since 2007. Previous studies showed that guinea pigs have been successfully used as models to evaluate the pathogenicity and transmissibility of different species of influenza in mammalian hosts. But till now, few studies have reported pathogenicity and transmissibility of H3N2 CIV in guinea pigs. Here, we firstly make a comparison about the pathogenicity and transmissibility in same place and time condition of 4 influenza virus, which are Chinese CIV, Korean CIV, CIV/H3N2 mv and pandemic H1N1 virus, respectively. Except for nasal swab collected until days post infection (d.p.i) 10, we collected lung, trachea, nasal terminate, soft palate and rectal from different virus groups for virus load test and histopathology examination. Results showed that four virus strains in infected and contact group (extra guinea pigs put in 4 groups in d.p.i 1) all induce lesions, guinea pigs infected CIV/H3N2 mv and H1N1 showed more severe lesions compared

to CIV strains, lungs in contact group being extracted RNA and amplified to compare with original CIV strains to find mutation point, CIV only replicated in some tissues without production of obvious clinical signs, but was transmissible among guinea pigs. Therefore, the continued evaluation of the pathogenicity and transmissibility of CIVs is critical to the understanding of the evolutionary characteristics of CIVs and emergence of potential pandemic strains.

520

Functional and molecular characterization of an invertebrate model immune system reveals evolutionary precursors of vertebrate's hematopoietic lineage

Rosental, B.^{1,2}, *Kowarsky, M.A.*³, *Corey, D.M.*¹, *Ishizuka, K.J.*^{1,2}, *Palmeri, K.J.*^{1,2}, *Chen, S.-Y.*⁴, *Sinha, R.*¹, *Newman, A.M.*¹, *Seita, J.*¹, *Weissman, I.L.*^{1,2}, *Voskoboynik, A.*^{1,5}

The colonial tunicate, *Botryllus schlosseri*, undergoes natural self-nonsel self recognition, resulting in an immune response controlled by a single, highly polymorphic histocompatibility locus we call BHF. Lack of a match in this locus results in a cytotoxic immune rejection that prevents formation of vascular anastomoses between adjacent colonies. Histocompatible colonies form vascular anastomoses that allow circulating germline and somatic stem cells to compete for dominance in the chimeric tissues. Circulating somatic and germ stem cells of one partner can take over the tissues of the chimera. Simultaneously one of the chimeric partners undergoes partial or complete resorption (i.e., morphologically showing death and disappearance of tissue). This resorption may be an immune cell based rejection that operates within BHF histocompatible pairs. Here, using FACS, RNAseq, and diverse functional essays, we have characterized the cells of the *Botryllus* blood and immune system. We have isolated 34 *Botryllus* cell populations, sequenced their transcriptome and analyzed their gene expression. This analysis revealed a cell population resembling hematopoietic stem cells, which upon transplantation, migrated to known stem cell niches and differentiated into other cell lineages. Using functional immunological assays for cytotoxicity and phagocytosis we identified phagocytic cell-type that resemble myeloid cells in vertebrates. Furthermore, we identified a *B. schlosseri* cytotoxic cell population originating from large granular lymphocyte-like cells, which upon allogeneic challenge differentiated into morula cells. Our data suggests that the common ancestor of tunicates and vertebrates had a true hematopoietic myeloid lineage, while the cytotoxic cells may result from a convergent evolutionary mechanism.

521

Tamoxifen as a new therapeutic approach for airway inflammation

*Henriquez, C.*¹, *Borlone, C.*², *Morales, N.*¹, *Folch, H.*³, *Uberti, B.*⁴, *Moran, G.*¹
¹Universidad Austral de Chile, Farmacología y Morfofisiología, Valdivia, Chile, ²Universidad Austral de Chile, Graduate Department, Valdivia, Chile, ³Universidad Austral de Chile, Immunología, Valdivia, Chile, ⁴Universidad Austral de Chile, Ciencias Clínicas Veterinarias, Valdivia, Chile

Neutrophils play a central role in innate immunity, acting as the first line of host defense against microorganism. However, this cytotoxic defense machinery has the potential of becoming harmful to surrounding tissues. Dysregulation of apoptosis has been implicated in a range of diseases including allergic asthma and chronic obstructive pulmonary disease in humans and recurrent airway obstruction (RAO) in horses. Tamoxifen (TX) is a non-steroidal estrogen receptor modulator, which has been used for the treatment of breast cancer in women. The efficacy of TX has been attributed to both cell growth arrest and induction of apoptosis. Previous preliminary studies showed that TX improves the clinical status of RAO-affected horses. Therefore, the aim of this study was to evaluate the in vitro effect of TX on chemotaxis, respiratory burst production and phosphatidylserine exposure in equine peripheral blood neutrophils.

We found that IL-8 stimulated cells decrease their chemotactic index when treated with TX (1 and 10µM). Also, respiratory burst production was dampened after treatment with TX. Finally, a significant increase of early apoptotic (Anexin-V positive) cells was observed after treatment with TX (2.5 and 5µM).

These results suggest that tamoxifen has a direct action in equine peripheral blood neutrophils. However, more in vivo and in vitro studies are required to fully understand the mechanisms of action of TX on neutrophils, in order to elucidate if it can be use as treatment in disorders such as allergic asthma in humans and RAO in horses.

Role of overexpressed *mce4A* gene in pathogenesis of murine tuberculosis

Ahmad, F.^{1,2}, *Gupta, P.*¹, *Owais, M.*², *Bose, M.*³, *Gupta, U.D.*¹
¹National JALMA Institute for Leprosy & OMD, BSL-3 Experimental Animal Facility, Agra, India, ²Aligarh Muslim University, Interdisciplinary Biotechnology Unit, Aligarh, India, ³V.P. Patel Chest Institute, Microbiology, New Delhi, India

The incidence of TB, particularly pulmonary TB is the greatest among those with impaired immunity. The *mce4* is one among the four homologues of mammalian cell entry (*mce*) operons of *M. tuberculosis* involved in steroid transport across the cell. The transport function of the *mce4* system is consistent with proposed role of cholesterol and its metabolism in the pathogenesis of Mtb. Mtb *mce4A* (Rv3499c) deletion mutant shows growth defect and reduced survival in C57BL/6 mice. The *mce4A* gene within this operon is homologous to *mce1A* (Rv0169) that has a role in host cell invasion by Mtb. The

expression of Mce4A protein in non-pathogenic *E. coli* enables it to enter and survive within HeLa cells and the macrophages. As Mce4A protein is expressed during later phase of mycobacterial growth, it is presumed that it may have crucial role in promoting the persistence of the Mtb inside the macrophages. We therefore, decipher the role of *mce4A* gene in pathogenesis of Mtb in Balb/c mice. Mice were infected through aerosol route of infection with overexpressed *mce4A* strain of Mtb and their growth pattern in lungs & spleen were compared with animals infected with standard H₃₇Rv. Animals infected with *mce4A* over expressing strain demonstrated an accelerated growth pattern when compared to animals infected with H₃₇Rv. Log phase of growth was appeared within 10-12 days of infection in mice infected with *mce4A* overexpressed strain while in H₃₇Rv infected animals it was appeared only after standard period of incubation, 21-28 days at 37 °C.

³Porto Conte Ricerche S.r.l., R&D - Proteomics Lab, Porto Conte, Italy, ⁴University of Milan, VESPA, Milan, Italy

Dairy cattle are exposed to risk for disease during periparturient period with a peak incidence of production problems, metabolic disorders, infectious diseases, metritis and mastitis.

This study aim was to compare the milk's microbiota during the periparturient period to assess the possible implication on animal health and milk quality.

Milk samples were collected from six Holstein cows at T1=dry off, T2=day after calving (dac), T3=7-10 dac, T4=30 dac and T5=60 dac.

The udder health status was monitored by bacteriological analysis and SCC.

The bacterial DNA was extracted from milk and the 16S rRNA gene was analyzed by Miseq.

Milk proteins were evaluated by SDS-PAGE and densitometric analysis for assessment of total protein profiles. The presence of cathelicidin, S100A9 and lysozyme was estimated. The expression of CD45, KRT5, IL-1b and TNFa messengers in isolated milk cells was analyzed. Finally, the expression of PTX3 and IL-1R8 transcripts in milk fat globules was analyzed to evaluate their modulation and check the activation of the mammary epithelial cells.

Bacteriological analysis showed the absence of contagious bacteria. An interesting modification of the leukocyte/exfoliated epithelial cell ratio, a down regulation of cytokine expression and a pick of lysozyme and other inflammatory markers production were observed around T2 and T3. Moreover, this study describes the relative changes in milk protein abundance along lactation and according to composition of the microbial flora.

524

DPO system based multiplex PCR for detection of viral and bacterial agents causing canine infectious respiratory diseases

Yuk, H., Na, W., Yeom, M., Kang, A., Song, D.

Korea University, Sejongsi, Korea, Republic of

There are several viral and bacterial pathogens related to canine infectious respiratory diseases ; As relevant virus, there are canine influenza virus (CIV) H3N8, H3N2, novel H1N1, canine distemper virus (CDV) and bacterial agents include *Streptococcus zooepidemicus*, *Bordetella bronchiseptica*. These pathogens recently occurs and are regarded as representative cause of canine respiratory diseases. Especially, influenza virus are epidemiologically important and are needed for continuous surveillance because of their enzootic and contagious properties. Such pathogens are easily transmitted in shelters crowded with dogs and cause secondary and complex infection by multi species. In case of multi infection, it is hard to choose appropriate treatment for specific target. Even, there are some reports identifying some pathogens enhance mutual pathogenicity and cause bad prognosis. Therefore, for proper remedy of canine respiratory disease, fast and exact diagnosis of causal agents is required. However, there are no method detecting those agents at once. Thus, in this study, we firstly designed multiplex PCR for detecting those virus and bacteria simultaneously. This multiplex PCR uses dual-priming-oligonucleotide (DPO) system that consists of stabilizing and determining priming region and polydeoxyinosine linker, which can enhance the sensitivity and specificity by reducing nonspecific amplification. Therefore, this multiplex PCR can be useful diagnostic tool for respiratory diseases of dog population.

525

Porphyromonas gulae activates M1 macrophages via TLR2, TLR4 and NOD2

Holden, J.^{1,2}, Lenzo, J.^{1,2}, Orth, R.^{1,2}, O'Brien-Simpson, N.M.^{1,2}, Reynolds, E.C.^{1,2}

¹The University of Melbourne, Melbourne Dental School, Melbourne, Australia, ²Oral Health CRC, Melbourne, Australia

Porphyromonas gulae is an anaerobic, Gram-negative coccobacillus that is frequently isolated from the gingival sulcus of companion animals with periodontal. The aims of this study were to analyse the ligation of pattern recognition receptors by *P. gulae* and to determine how this ligation activated macrophages. Exposure of HEK cells transfected with Toll-like receptors or NOD-like receptors to *P. gulae* resulted in the ligation of TLR2, TLR4 and NOD2 but not NOD1, TLR7, TLR8 or TLR9. The subsequent activation of WT, TLR2^{-/-} or TLR4^{-/-} macrophages was determined by measuring the synthesis of nitric oxide, the expression of CD86 and the production of inflammatory cytokines. The addition of *P. gulae* to naive, unprimed macrophages generated little surface expression of CD86 or nitric oxide production. However, priming macrophages with IFN-γ to generate M1 macrophages resulted in the production of nitric oxide and expression CD86, IL-1β, IL-6 and TNFa in response to *P. gulae*. Nitric oxide and CD86 expression

was abolished in TLR2^{-/-} and reduced in TLR4^{-/-} macrophages, indicating the main TLR ligand of *P. gultae* is lipoprotein and the LPS of *P. gultae* is potentially deacylated and dephosphorylated as in other Porphyromonas spp. These results suggest that inflammatory M1 macrophages responding to *P. gultae* may be important in establishing chronic inflammation in the gingiva of companion animals.

³University of Melbourne, Pathology, Melbourne, Australia

Non-human primates, particularly macaques, are widely used as models of human immunity. Leukocyte Fc receptors (FcR) provide effector cell resistance to infection, however also induce destructive inflammatory processes. Importantly FcR are essential to the success of many therapeutic mAbs. We have defined the function of a newly discovered leukocyte FcR for IgG (designated FcγRIIa3), which is found on circulating leukocytes of humans and macaques. This receptor is abundant on neutrophils¹.

A comparative analysis of genes, proteins and function has revealed remarkable differences between FcγRIIa1 and FcγRIIa3. (i) In both humans and macaques, FcγRIIa3 arises by alternative splicing of the *FCGR2A* gene. The encoded receptor contains a 19 amino acid insertion in the cytoplasmic tail that is absent from the conventional FcγRIIa1.

(ii) Specificity for human IgG was identical for both human and macaque FcγRIIa3 and FcγRIIa1 splice variants, and the expected differences between human and macaque FcR binding of IgG were also observed via flow cytometry.

(iii) Remarkably, confocal microscopy indicates cell localisation of the receptors is distinct, with FcγRIIa3 remaining at the cell surface and FcγRIIa1 being rapidly internalized, potentially altering the receptors signalling potential.

(iv) Indeed ITAM-dependent signalling induced by IgG clustering of FcγRIIa3 is distinctly different in magnitude and kinetics compared to the conventional FcγRIIa1.

Thus the altered functions of FcγRIIa3 may be linked to its increased prevalence in human inflammatory disease¹ and has implications for the analysis of human mAbs in both humans and macaques.

Introduction: Papillon-Lefevre Syndrome (PLS) it's a rare autosomic recessive disorder characterized by palmoplantar hyperkeratosis and early onset aggressive periodontitis, it's been associated with Cathepsin C gene mutations witch enzyme its involve in inflammation and phagocytosis. Over 20 cases have been diagnosed in Sinaloa, yielding a high incidence in the region. We previously reported the presence of two loss of function mutations (p.Leu68Arg and p.Thr153Ile). In this study we evaluate PLS patient's mutation founder effect and leukocytes response to infections and in vitro stimuli.

Methodology: STR analysis of CTSC gene region from leukocytes DNA, Flow Cytometry immunophenotyping of leukocytes populations, proliferation, ROS and NOS production of PMN cells infected for 30 and 60 min with *S. aureus*, PMN and Mononuclear cells (Mn) cytokine release stimulated with LPS, ConA and PMA. T-student (p 0.05) comparisons were made for quantitative measures.

Results: Leukocytes subpopulations were among normal range for both patient's and healthy individuals, bactericidal activity was similar in both groups at 30 min (p = 0.270), eliminating 80±9% and 70±11% respectably of the bacterial load. At 60 min both groups eliminate around 50% of the bacteria (p = 0.064). ROS and NOS production had no statistical significance. PMN IL-8 production was higher in patients and IL-1β, IL-10, IL-12p70 and TNF-α was lower in Mn. 50% of patients had a common CTSC haplotype.

Conclusion: Sinaloa's PLS patients with p.Leu68Arg mutation share a common ancestor, such mutation do not affect peripheral leukocytes proportions or response. Further research is needed to better grasp the disease pathogenesis.

Humoral immune responses against tetanus neurotoxin in human and mouse

Yousefi, M.¹, Shokri, F.²

¹Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, ²Tehran University of Medical Science, Tehran, Iran, Islamic Republic of

Tetanus is a highly fatal disease caused by tetanus neurotoxin (TeNT) and remains one of the major threats to human and animal health despite preventive strategies.

TeNT composed of heavy and light chains linked by a disulfide bond. The catalytic domain of the toxin resides in the light chain while the non toxic carboxy terminal fragment of the tetanus toxin heavy chain (fragment C) is responsible for neurospecific binding and retrograde transport of TeNT.

In this study, we generated 22 murine and 50 lymphoblastoid cell lines secreting monoclonal antibodies against TeNT. In the next step we determined specificity of these mAbs using different fragments of tetanus toxin. Moreover, we investigate in vitro inhibitory activity neutralizing of these mAbs by ganglioside GT1b assay.

Our results showed that tetanus toxoid immunization in human and mice vigorously induced humoral immune response against

fragment C and antibodies against fragment C potentially neutralize toxin in vitro.

These results propose fragment C as a good candidates for the development of epitope-based vaccines and therapeutic antibodies against tetanus.

Porcine reproductive and respiratory syndrome Virus (PRRSV) was first discovered in the United States in 1987. Since its discovery, PRRSV has been spreading worldwide, and nowadays PRRSV is one of the most economically influential infectious diseases in the industry of swine. It is characterized by reproductive failure in pregnant sows and respiratory disorder in growing swine. In northern Vietnam, highly pathogenic PRRS (HP-PRRS) was first recognized in March 2007. The virus isolated from Vietnam showed 99% identity at the genomic level with China. The isolated virus was passaged serially through Marc-145 cells for developing live attenuated vaccine strain candidate. Every 10th passaged samples were collected for identification of nucleotide changes. Three genes (NSP-2, GP5 and GP7) were sequenced and analyzed. Initial passaged virus (5th passage) and attenuated virus (110th passage) were used to compare pathogenicity. A total of 10 healthy 4-week-old PRRSV-free pigs were randomly assigned to 2 challenge groups (4 pigs per group) and one negative group (2 pigs per group). For infection, 2ml of each passaged PRRSV strain (10^{5.5} TCID₅₀/mL) was administered intranasal route. Negative control group were similarly inoculated with the medium. All pigs were monitored daily for clinical signs post-infection until the end of the study. Blood samples were collected from all pigs for serological testing and virus shedding titration. All pigs were euthanized and lung tissue samples were collected at DIP-28 for macroscopic and microscopic test. The pathogenicity was considerably different between wild type and attenuated live vaccine candidate (110th passage).

Introduction: Bats are a major source of zoonotic viruses worldwide, including those causing lethal infections in humans.

However, they might show not apparent clinical signs, even if they are persistently infected. The only virus causing disease is rabies. To elucidate how bats control a high number of infectious agents, the AIM of this work was to study the bats immune response by analyzing the lymphocytes cell proliferation and cytokines production.

Material and methods: Bats (*Artibeus* sp) were captured and handled under bioethical protocols. Mononuclear cells were obtained by Ficoll-paque density gradient centrifugation of 2-3 mL of peripheral blood, 5X10⁶ mononuclear cells were seeded on cover slips in 8 wells lab teck chambers and activated with Concanavaleine-A or PMA/IONOMYCINE per 5 days and proliferation was assessed with 5uM of carboxyfluorescein (CFSE) by flow cytometry. For cytokines production in cells of human and bats, 2X10⁵ mononuclear cells were cultured in a 96 wells plate in DMEM medium, 100 ug/mL of LPS were added to the cells and supernatant was collected at 6,12,24,48 and 72 Hrs for cytokines detection by using de CBA kit from BD.

Results showed that proliferation of lymphocytes for bats is similar to the humans, and only the IL-8 and IL-6 cytokines is slightly increased at 6 hr post LPS activation for bats, no significant change in the concentration of TNF- α , IL-12P70, IL-1b or IL-10 was observed.
