Eukaryotic cells sequester their DNA in the nucleus and organelles. The presence of DNA in the cytosol indicates a danger of either internal or external origin. In mammalian macrophages cytosolic DNA is recognized by AIM2, leading to inflammasome activation and pyroptosis, rapid lytic death. There is no data about such a system for invertebrates, and AIM2 itself is a mammalian-restricted protein. We hypothesized that defence against cytosolic DNA is a feature of all eukaryotic cells, and fundamental to maintenance of genome integrity as well as recognition of infection. To investigate responses to cytosolic DNA in *Drosophila* or non-mammalian vertebrates which lack AIM2, both fruitfly and chicken cells were transfected with DNA via electroporation and viability was assessed at one hour after transfection. Cytosolic DNA but not double-stranded synthetic RNA was toxic for both *Drosophila* and chicken cells, and elicited lytic cell death between 5 and 15 minutes after introduction of DNA. *Drosophila* and chicken cells were sensitive to both single- and double-stranded DNA in contrast to the mammalian cells where the AIM2 response is mediated by only double-stranded DNA. This programmed necrotic death is not pyroptosis or necroptosis, as *Drosophila* does not have the proteins essential to these pathways. Thus we have demonstrated a novel form of rapid necrotic cell death, likely to be an ancient response rendered redundant in mammalian macrophages by the appearance of the AIM2 inflammasome. The retention of

cytosolic DNA-dependent death through evolution suggests a fundamental importance in cellular defence.

532

CD44 expression and apoptosis of lymphocytes in *in vitro* stimulation by lipopolysaccharide

Slama, P.¹, Sladek, Z.¹, Kabourkova, E.¹, Havlicek, Z.¹, Kwak, J.Y.²

¹Mendel University in Brno, Brno, Czech Republic, ²Ajou University School of Medicine, Suwon, Korea, Republic of

Lipopolysaccharide (LPS) is a toxin released from the cell wall of Gram-negative bacteria that induces the inflammatory response of bovine mammary gland. CD44 is a proteoglycan that is expressed by most cell types including leukocytes. There is known information about expression of the CD44 on bovine neutrophils and macrophages during the inflammatory response. The virgin, clinically healthy, Holstein × Bohemian Red Pied crossbred heifers were used as mammary gland cell donors for *in vitro* study. Intact lymphocytes from the mammary glands were harvested following the phosphate buffered saline intramammary injection. The samples were incubated at 37 °C in a 5% CO₂ atmosphere for 1, 2 and 5 hours with LPS (0.2, 2 and 20 µg/ml). Apoptosis and CD44-positive lymphocytes were analysed by flow cytometry (FACS Calibur apparatus, Becton Dickinson, CA, USA). Results of this study demonstrate that apoptosis of lymphocytes was modulated with LPS. After 2 and 5 hours of *in vitro* incubation with LPS, there was detected delaying of lymphocyte apoptosis with no significant differences among used concentrations. The proportion of CD44-positive lymphocytes was decreased during *in vitro* cultivation. There was found out the positive correlation between the apoptosis of the lymphocytes and the CD44 expression. The results suggest that the cell surface receptor CD44 may play a role in inflammatory response of mammary gland in connection with lymphocyte apoptosis.

Apoptosis of gamma delta T cells during inflammatory response of bovine mammary gland induced by *Staphylococcus aureus*

Slama, P.¹, Sladek, Z.¹, Kabourkova, E.¹, Havlicek, Z.¹, Kwak, J.Y.²

¹Mendel University in Brno, Brno, Czech Republic, ²Ajou University School of Medicine, Suwon, Korea, Republic of

Staphylococcus aureus is one of the most important pathogens causing clinical and subclinical bovine mastitis. This pathogen was used for stimulation of bovine mammary gland inflammatory response. The experiments were carried out on the virgin, clinically healthy, Holstein × Bohemian Red Pied crossbred heifers. Gamma delta T cells and apoptosis of lymphocytes were analysed by flow cytometry (FACS Calibur apparatus, Becton Dickinson, CA, USA) at 24, 48, 72 and 168 hours following the stimulation. The stimulation of mammary gland with *Staphylococcus aureus* resulted in a gradual increase in apoptotic lymphocytes. The portion of gamma delta T cells

was also gradually increased during one week following the stimulation. There was found out the positive correlation between the apoptosis of the lymphocytes and the proportion of gamma delta T cells. The results suggest that gamma delta T cells may play a role in inflammatory response of mammary gland induced by *Staphylococcus aureus* in connection with lymphocyte apoptosis.

Acknowledgement: The study was supported by the project IGA AF MENDELU TP3/2015.

DDX23, an evolutionary conserved dsRNA sensor, pairs with TRIF or MAVS to trigger the antiviral responses

Yuan, S., Ruan, J., Xu, A.

Sun Yat-Sen University, Department of Biochemistry, Guangzhou, China

DExD/H-box helicases play essential roles in RNA metabolism, and emerging data suggest that they have additional functions in antiviral immunity across species. However, little is known about this evolutionary conserved family in antiviral responses in lower species. Here, by isolation of poly(I:C)-binding proteins in amphioxus, an extant basal chordate, we found that DExD/H-box helicases DHX9, DHX15 and DDX23, rather than RLRs to be responsible for cytoplasmic dsRNA detection in amphioxus. Since the antiviral roles of DDX23 have not been characterized in mammals, we performed further poly(I:C)-pull down assays and found human DDX23 to bind poly(I:C) through its N-terminal region, suggesting that DDX23 is an evolutionary conserved dsRNA sensor. Knockdown of human DDX23 via siRNA enhanced replication of VSV and reduced activation of the NF-κB and IRF3. When stimulated with poly(I:C), human DDX23 translocated from nucleus to cytoplasm and formed complexes with TRIF or MAVS for downstream signaling. This comparative immunological study not only provided a new strategy to identify a novel dsRNA sensor in humans, but also revealed that the essential role of the DExD/H helicase family in viral RNA/DNA sensing extends to the basal chordate, to close a major gap in our understanding of antiviral immunity during evolution.

535

Naturally truncated NS gene of H3N8 equine influenza virus attenuates the virulence of the A/Puerto Rico/8/34 virus in mice in mice

Na, W.¹, Yoon, S.-W.², Yeom, M.¹, Song, D.¹

¹Korea University College of Pharmacy, Sejong-si, Korea, Republic of, ²Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of

Equine influenza virus (EIV) causes a highly contagious disease of horses and other equid, and also transmits into dogs. Recently, we isolated H3N8 EIV from vaccinated horse that presented symptoms of respiratory disease in South Korea, and the EIV had truncated NS gene segment showing low viral growth kinetics. In order to elucidate correlation between truncation of NS gene and reduced viral virulence, reverse genetics were

applied to generate different NS recombinant virus utilizing an identical [A/Puerto Rico/8/1934(H1N1), PR8] virus. We have analyzed virulence of recombinant viruses in mice and found that naturally truncated NS gene led to incompetent viral pathogenicity and cytokine production compared to other rescued PR8 containing intact NS genes. This study could suggest that the partially deleted NS gene is responsible for the low pathogenicity and inefficient viral replication of the wild type Korean H3N8 EIV.

The adjuvanticity of seabuckthorn polysaccharide for chicken Newcastle disease vaccine

Zhang, X., Liu, H., Zou, K., Chen, J., Wang, X., Liu, F., Wang, Y.
Inner Mongolia Agricultural University, College of Life Science,
Hohhot, China

The adjuvanticity of Seabuckthorn polysaccharide (SP) was evaluated in vitro and in vivo. In vitro experiment, the effects of SP on chicken peripheral lymphocyte proliferation were measured by Cell Counting Kit-8 assay. The results showed that SP significantly enhanced chicken peripheral lymphocyte proliferation synergistically with ConA. In vivo experiment, 180 one-day-old chickens were randomly assigned into 6 groups. The chickens were vaccinated with 0.2 mL inactivated Newcastle disease (ND) vaccine containing 6.25, 12.50 and 25.00 mg/mL SP as SP low (SP/L), medium (SP/M) and high (SP/H) dose adjuvant group, repeated vaccination on 28th day. Chickens in blank control (BC), non-adjuvant control (NC) and oil-adjuvant control (OC) were injected with equal volume of physiological saline, ND vaccine and ND oil-adjuvant vaccine, respectively. On days 7, 14, 21, 28, 35 and 42 after the first vaccination, the peripheral lymphocytes proliferation, serum ND antibody titers, interferon-gamma (IFN- γ) and interleukin-4 (IL-4) levels were investigated. The results showed that SP could significantly promote chicken peripheral lymphocyte proliferation, enhance serum ND antibody titers and promote the production of IFN- γ and IL-4. Those results indicated that SP act as a novel adjuvant for ND vaccine.

T cell receptor recognition of non peptide-based antigens

Rosjohn, J.

Infection and Immunity Program and Department of Biochemistry and Molecular Biology, Biomedicine Discovery Institute, Faculty of Medicine, Monash University

T-cells determine the specificity of the immune response via the T-cell Receptor (TCR), of which there is a vast array of different TCRs within an individual, encompassing TCRs that encoded by the α and β TCR loci and the γ and δ TCR loci. Most of the studies in the area of TCR recognition have focused on peptides that are presented by molecules encoded by the Major Histocompatibility Complex (MHC). Great inroads have been made in understanding the TCR-peptide-MHC interaction in the context of key immunological questions. Notably, the three-dimensional fold of the MHC molecule is extremely versatile, and a related group of MHC-I-like molecules play critical roles in immunity by binding to Ags that are non-peptidic in nature. For example, the CD1 family is suited to capture lipid Ags for recognition by lipid-reactive T-cells. Moreover the MHC-I like molecule, MR1, captures vitamin B precursors that activate mucosal-associated invariant T-cells (MAITs). While lipid-specific and vitamin B-specific T-cells play a vital role in the immune system, our understanding of lipid- and metabolite-mediated immunity is in its infancy, and any role in aberrant immune function is unclear. My presentation will detail how the TCR can recognize lipids and metabolites.

Imaging Membranes

The functional importance of T cell receptor clustering

Gaus, K.^{1,2}, Pageonn, S.V.^{1,2}, Tabarin T.^{1,2}, Yamamoto, Y.^{1,2}, Ma, Y.^{1,2}
¹EMBL Australia Node in Single Molecule Science, ²ARC Centre of Excellence in Advanced Molecular Imaging, University of New South Wales, Sydney, Australia

Antigen recognition by the T cell receptor (TCR) is a hallmark of the adaptive immune system. When the TCR engages a peptide bound to the restricting major histocompatibility complex molecule (pMHC), it transmits a signal via the associated CD3 complex. How the extracellular antigen recognition event leads to intracellular phosphorylation remains unclear. Here, we used single-molecule localization microscopy to quantify the organization of TCR-CD3 complexes into nanoscale clusters and to distinguish between triggered and non-triggered TCR-CD3 complexes. We found that only TCR-CD3 complexes in dense clusters were phosphorylated and associated with downstream signaling proteins, demonstrating that the molecular density within clusters dictates signal initiation. Both pMHC dose and

TCR-pMHC affinity determined the density of TCR-CD3 clusters, which scaled with overall phosphorylation levels. Thus, TCR-CD3 clustering translates antigen recognition by the TCR into signal initiation by the CD3 complex and the formation of dense signaling-competent clusters is a process of antigen discrimination.

T-B

How the helper T cell repertoire responds to infection

Jenkins, M.

University of Minnesota, Center for Immunology

CD4⁺ helper T lymphocytes play an important role in adaptive immunity to microbes. My laboratory is trying to understand how the CD4⁺ T cells that are specific for a microbial epitope and are present before the relevant infection generate effector and memory cell types with different immune functions. We found that the secondary lymphoid organs of uninfected mice contained about 100 CD4⁺ T cells expressing T cell receptors capable of high affinity binding to an MHCII-bound peptide from the listeriolysin O protein of *Listeria monocytogenes*. About 90% of the cells in this population had the phenotype of conventional naïve T cells (CD44^{low} Foxp3⁻), while 10% of the cells had the phenotype of thymic regulatory T cells (Foxp3⁺ Helios⁺). Each cell in this population expressed a different T cell receptor and was therefore a unique clone. Following systemic infection with attenuated *L. monocytogenes* bacteria, the small pre-immune population generated a large effector cell population consisting of Th1 and follicular helper T cells but few if any regulatory T cells. As the infection was cleared, about 10% of the effector cells survived in the form of Th1 and follicular helper T cell-like memory cells. My lecture will describe our efforts to identify the factors that influence how single listeriolysin O peptide:MHCII-specific CD4⁺ T cells from a diverse pre-immune repertoire produce different types of effector and memory cells.

Distinct Gene Regulatory Pathways for Human Innate versus Adaptive Lymphoid Cells

Collins, P., Koues, O.I., Cella, M., Robinette, M.L., Porter, S.I., Pyfrom, S.C., Payton, J.E., Colonna, M., Oltz, E.M.

Department of Pathology and Immunology, Washington University School of Medicine

Upon sensing pathogens or other alterations to their local microenvironments, innate lymphoid cells (ILCs) respond with rapid and robust secretion of cytokines. In turn, these cytokines promote the release of antimicrobial peptides, minimize damage to surrounding cells, and influence the balance of T helper (Th) lymphocytes. While development kinships, functions, and pathologies involving ILCs have been studied extensively in model organisms, little is known about these first responders in humans. Moreover, while ILC and Th subsets rely on common effector genes, distinct signals and kinetics regulate expression programs in innate and cellular counterparts. Using integrated “-omics” analyses of lymphoid cells from a human mucosal environment (tonsils), we show that expression programs for ILC, Th, and NK cells diverge developmentally, but their regulomes devoted to functional polarization are highly convergent. Genes critical for cell-type identity, as well as autoimmune disease-associated polymorphisms, were located in cell-type specific regions of hyperacetylated chromatin known as “super enhancers.” Our results implicate novel pathways for the regulation of genes involved in ILC and Th functional niches, as well as new connections between autoimmune-associated variants and each of the human lymphoid subsets.

Cancer immunosurveillance by tissue-resident innate lymphoid cells and innate-like T cells

Dadi, S.¹, Chhangawala, S.², Whitlock, B.M.¹, Franklin, R.A.¹, Luo, C.T.¹, Oh, S.A.¹, Toure, A.¹, Pritykin, Y.², Huse, M.¹, Leslie, C.S.², Li, M.O.¹

¹Memorial Sloan Kettering Cancer Center, Immunology, New York, United States, ²Memorial Sloan Kettering Cancer Center, Computational Biology, New York, United States

Malignancy can be suppressed by the immune system in a process termed immunosurveillance. However, to what extent immunosurveillance occurs in spontaneous cancers and the composition of participating cell types remain obscure. Here we show that cell transformation triggers a tissue-resident lymphocyte response in oncogene-induced murine cancer

models. Non-circulating cytotoxic lymphocytes, derived from innate, TCR $\alpha\beta$ and TCR $\gamma\delta$ lineages, expand in early tumors. Characterized by high expression of NK1.1, CD49a and CD103, these cells share a gene expression signature distinct from those of conventional NK cells, T cells and invariant NKT cells. Generation of these lymphocytes is dependent on the cytokine IL-15, but not the transcription factor Nfil3 that is required for the differentiation of tumor-infiltrating NK cells, and IL-15, but not Nfil3, deficiency results in accelerated tumor growth. These findings reveal a tumor-elicited immunosurveillance mechanism that engages unconventional type 1-like innate lymphoid cells and type 1 innate-like T cells.

Regulation of lung immunity by epithelial derived cytokines

Lloyd, C.

Imperial College London, London, UK, NHLI, London, United Kingdom

Maintaining the balance between immune homeostasis and inappropriate immune activation and associated pathology is particularly complex at mucosal sites that are constantly exposed to potentially antigenic particles. Lung epithelial cells orchestrate pulmonary immune homeostasis and defence against pathogens but also play a critical role in the initiation of allergic responses. Cells within the pulmonary epithelium are a rich source of inflammatory cytokines, chemokines and growth factors. Lung epithelial cells are thought to be particularly important in the development of allergic immune reactions. Indeed, several of the genes identified in asthma GWAS studies are expressed by lung epithelial cells. We have shown that IL-33 contributes to the development of allergic pathology in mouse models and paediatric severe asthma. Moreover, IL-33 was shown to be a steroid resistant cytokine able to promote airway remodelling directly. We have recently identified a relationship between IL33 and epithelial derived TGFbeta in mediating acute pulmonary allergic inflammation. We generated inducible bronchial epithelial cell specific knockouts of TGF-beta and exposed them to inhaled allergen or IL-33. Deletion of TGFbeta solely in the bronchial epithelium resulted in diminished airway hyperactivity (AHR), eosinophilia and pulmonary type2 cytokines. Moreover, accumulation IL-13+ innate lymphoid cells (ILC2s) was significantly reduced. This presentation will highlight a novel interaction between IL33 and epithelial derived TGF-beta to promote ILC2 chemoactivity which facilitates development of allergic inflammation. Our data show that resident epithelial cells instruct immune cells reinforcing the central role of the local environmental niche in defining the nature and magnitude of immune reactions.

Antigen Presentation

Antigen presentation and T cell activation by dendritic cells

Amigorena, S.
Institut Curie

Dendritic cells represent a highly specialized hematopoietic lineage, whose main role is to sense infections in tissues and to activate specific T lymphocytes in lymphoid organs to mount immune responses adapted to the threat. To activate T lymphocytes, dendritic cells need to present peptides derived from infectious antigens on MHC molecules on their plasma membrane. There are two main intracellular sites of peptide loading on MHC molecules: the endocytic pathway for class II and the ER for class I MHC molecules. Because of this localization, the former are mainly (not exclusively) loaded with peptides cleaved by lysosomal proteases from internalized antigens. Peptides to be loaded on class I MHC are mainly derived from proteins that are being translated in the cytosol and are cleaved by the proteasome, before translocation into the ER by dedicated TAP1/2 transporters. In most cells types, the interchange of cargo and membranes between the two compartments is very limited. In dendritic cells, however, ER proteins are quite abundant in phagosomes. We showed recently that Sec22b controls the delivery of a subset of ER resident proteins to phagosomes. In the absence of Sec22b, the abundance of several ER residents in phagosomes is reduced, causing a defect in antigen cross presentation. Intriguingly, we also observed a marked acceleration of phago-lysosome fusion in the Sec22b-silenced dendritic cells, suggesting that the presence of ER in phagosomes delays phagosome maturation. Reduced levels of Sec22b also impaired antigen export from endosomes to the cytosol, suggesting a molecular link between export and the presence of ER-derived proteins in phagosomes. Interestingly, activation of dendritic cells by Toll-like receptor ligands modified both their antigen presentation capacities and their phagocytic functions, especially the fusion of phagosomes with lysosomes. Export to the cytosol, in contrast, seems to be regulated independently through other pathways of stress sensing. The contributions of factors that regulate phagosome functions in dendritic cells, and their relevance to antigen cross presentation will be discussed.

Imaging immunity non-invasively

Ploegh, H.
MIT

We have undertaken a systematic effort to produce single domain antibody fragments, derived from the heavy chain-only antibodies of camelid species to produce a new set of tools. We specifically target proteins of immunological interest, such as the checkpoints PD-L1 and CTLA-4. Antibody fragments composed of the variable region of such heavy chain only antibodies are referred to as VHHs or nanobodies. Their small size accounts for improved tissue penetration compared to full sized antibodies, and they are also cleared from the circulation more rapidly than intact antibodies. These are properties that make VHHs ideal for non-invasive imaging applications, such as positron emission tomography (PET)-based imaging, for example to track CD8 T

cells. These same properties also allow the use of VHHs to deliver payloads such as cytokines to the site of a tumor to improve an immune response against it. Finally, VHHs can survive with in the reducing environment of the eukaryotic cytosol with retention of specificity. This has allowed us to configure screens that select for VHHs that target cytosolic proteins and modulate their function. Examples that will be discussed include VHHs that recognize inflammasome components to interfere with the release of IL-1, and VHHs that impede the replication of influenza virus and vesicular stomatitis virus. An added bonus is the ability of VHHs to serve as crystallization chaperones to identify the functionally relevant epitope.

403

TAPBPR associates with UDP-glucose:glycoprotein glucosyltransferase 1 to provide quality control in the MHC class I pathway

Hermann, C.¹, Neerincx, A.¹, Antrobus, R.², van Hateren, A.³, Trautwein, N.⁴, Stevanović, S.⁴, Elliott, T.³, Deane, J.², Boyle, L.¹
¹University of Cambridge, Department of Pathology, UK, United Kingdom, ²University of Cambridge, Cambridge Institute of Medical Research, Cambridge, United Kingdom, ³University of Southampton, Faculty of Medicine and Institute for Life Science, Southampton, United Kingdom, ⁴Eberhard Karls Universität Tübingen, Department of Immunology, Tübingen, Germany

Our understanding of the antigen presentation pathway has recently been enhanced with the identification that the tapasin-related protein TAPBPR is a second MHC class I-specific chaperone. Recently we revealed TAPBPR influences MHC class I peptide presentation by functioning as a peptide exchange catalyst. Therefore, it is now apparent that tapasin and TAPBPR are both intimately involved in selecting peptides for immune recognition. Here we asked whether any other co-factor associated with TAPBPR in cells. We identify an interaction between TAPBPR and UDP-glucose: glycoprotein glucosyltransferase 1 (UGT1), a folding sensor in the calnexin/calreticulin quality control cycle known to reglucosylate MHC class I. The interaction between TAPBPR and UGT1 is dependent on a conserved cysteine at position 94 in TAPBPR. Our results suggest the formation of a multimeric complex between TAPBPR, UGT1 and peptide-receptive MHC class I. The loss of the association between TAPBPR and UGT1 alters the peptide repertoire expressed on cells and increases the surface expression of peptide-receptive MHC class I. These results suggest TAPBPR and UGT1 can work together to provide an important quality control check-point in the MHC class I antigen presentation pathway.

Innate Molecular

Identification of a novel monocyte subset involved in lung fibrosis

Akira, S.

Laboratory of Host Defense, WPI Immunology Frontier Research Center, Osaka University

Macrophages represent a diverse set of phagocytic cells distributed in the whole body. They play a central role in a variety of biological events including host defense against pathogens, tissue remodelling, chronic inflammation, fibrosis and cancer. Accumulating evidence indicates the existence of multiple and distinct subsets that exert different biological functions. We previously showed that JMJD3, one of H3K27trimethyl demethylases is involved in M2 polarization of macrophages in helminth infection. We also found that Trib-1 knockout mice show severe reduction of tissue-resident M2-like macrophages in various organs, resulting in severe lipodystrophy owing to increases lipolysis. Recently we have identified another monocyte subset critical for development of bleomycin-induced lung fibrosis. We named this novel monocyte subset segregated-nucleus containing atypical monocytes (SatM) based on a unique nuclear shape and a hybrid character of monocyte and granulocyte. C/EBP β deficiency results in a complete lack of SatM. These results demonstrate that C/EBP β is a key transcription factor for differentiation of profibrotic SatM from their committed progenitors.

Pore-forming activity and structural autoinhibition of the gasdermin family

Shao, F.¹, Ding, J.^{1,2}, Wang, K.¹, Liu, W.¹, She, Y.^{1,2}, Sun, Q.¹, Shi, J.¹, Sun, H.¹, Wang, D.C.²

¹National Institute of Biological Sciences (NIBS), Beijing, ²Institute of Biophysics, Chinese Academy of Sciences, Beijing

Inflammatory caspases cleave the gasdermin D (GSDMD) protein to trigger pyroptosis, a lytic form of cell death that is crucial for immune defences and diseases. GSDMD contains a functionally important gasdermin-N domain that is shared in the gasdermin family. The functional mechanism of action of gasdermin proteins is unknown. Here we show that the gasdermin-N domains of the gasdermin proteins GSDMD, GSDMA3 and GSDMA can bind membrane lipids, phosphoinositides and cardiolipin, and exhibit membrane-disrupting cytotoxicity in mammalian cells and artificially transformed bacteria. Gasdermin-N moved to the plasma membrane during pyroptosis. Purified gasdermin-N efficiently lysed phosphoinositide/cardiolipin-containing liposomes and formed pores on membranes made of artificial or natural phospholipid mixtures. Most gasdermin pores had an inner diameter of 10–14 nm and contained 16 symmetric protomers. The crystal structure of GSDMA3 showed an autoinhibited two-domain architecture that is conserved in the gasdermin family. Structure-guided mutagenesis demonstrated that the liposome-leakage and pore-forming activities of the gasdermin-N domain are required for pyroptosis. These findings reveal the mechanism for pyroptosis and provide insights into the roles of the gasdermin family in necrosis, immunity and diseases.

Cytosolic DNA, HIN-200 proteins and inflammasome activation

Stacey, K.J., Vajjhala, P.R., Sagulenko, V., Thygesen, S., Vitak, N., Sester, D.P.

School of Chemistry and Molecular Biosciences, The University of Queensland, Brisbane Qld 4072, Australia

Cytosolic DNA can indicate viral or bacterial infection, activity of retroelements, or DNA damage and repair processes. The two major known pathways of response to cytosolic DNA are induction of type I interferon via cGAS/STING, and activation of the AIM2 inflammasome, leading to IL-1 β and IL-18 processing and rapid cell death within 5-10 minutes of DNA introduction. AIM2 is a member of the HIN-200/PYHIN family proteins that contain a DNA-binding HIN domain, and a pyrin domain mediating effector function. AIM2 is the best-studied of this family, and binds to cytosolic DNA eliciting an inflammasome response via recruitment of ASC with subsequent activation of caspase-1. We have also demonstrated the direct recruitment and activation of caspase-8 by inflammasome complexes, leading to apoptotic death. This is mediated by a novel heterotypic interaction between the ASC pyrin domain and caspase-8 death effector domains. This extends the relevance of the inflammasome to cell types not expressing caspase-1. The HIN-200 proteins are restricted to mammals, and have expanded variably and independently in different lineages. Within the family AIM2 is phylogenetically distinct, whereas other family members have no direct orthologues between species, and their function is not well understood. Detection of ASC clustering *in vivo* shows that only AIM2 is competent for direct recruitment of ASC, and the function of the pyrin domain of other family members remains to be determined. Interestingly, some mammalian species have AIM2 pseudogenes and have lost capacity for inflammasome function.

Treg

Regulatory T cells at Barrier Surfaces

Powrie, F.M.

Kennedy Institute of Rheumatology, University of Oxford, UK

The gastrointestinal (GI) tract is home to a large number and vast array of bacteria that play an important role in nutrition, immune system development and host defense. In inflammatory bowel disease (IBD) there is a breakdown in this mutualistic relationship resulting in aberrant inflammatory responses to intestinal bacteria. Studies in model systems indicate that intestinal homeostasis is an active process involving a delicate balance between effector and immune suppressive pathways. In this presentation I will discuss host and bacterial pathways that promote the regulatory T cell response and how these may be harnessed therapeutically.

Aboriginal Australians with acute rheumatic fever have enhanced Th17 responses to group A streptococcus that can be inhibited *in vitro* by repurposed clinical drugs

Martin, W.J.^{1,2}, Minigo, G.^{3,4}, Kim, M.L.⁵, Keeble, J.¹, Pitman, M.C.⁶, Tipping, P.³, Pacini, G.^{1,7}, Smyth, G.K.^{1,7}, Carapetis, J.^{8,9}, Wicks, I.P.^{1,2,10}

¹Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²University of Melbourne, Department of Medical Biology, Parkville, Australia, ³Menzies School of Health Research, Casuarina, Australia, ⁴Charles Darwin University, Casuarina, Australia, ⁵Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, ⁶Royal Darwin Hospital, Casuarina, Australia, ⁷University of Melbourne, Department of Mathematics and Statistics, Parkville, Australia, ⁸Telethon Kids Institute, Subiaco, Australia, ⁹Princess Margaret Hospital for Children, Subiaco, Australia, ¹⁰Royal Melbourne Hospital, Rheumatology Unit, Parkville, Australia

In the Northern Territory of Australia, the rate of rheumatic heart disease (RHD) in Aboriginal and Torres Strait Islanders is 26 times that of the non-Indigenous population. New therapies to reduce RHD and its harbinger, acute rheumatic fever (ARF), have remained out of reach due to a limited understanding of the immunopathogenesis. As ARF/RHD are autoimmune consequences of group A streptococcus (GAS) infection, we evaluated *in vitro* responses of peripheral blood mononuclear cells (PBMC) of ARF patients and healthy individuals to GAS. 19 Aboriginal ARF patients and nine non-ARF controls were recruited to the study. GAS induced Th1 and Th17 CD4 T cell responses in all participants as determined by flow cytometry. ARF patients had elevated Th17 markers in plasma, which rose as CRP levels fell, and also had enhanced Th17 responses to GAS restimulation *in vitro* compared to non-ARF controls. Using an *in vitro* PBMC assay, we assessed a number of drugs used in other autoimmune conditions for the capacity to inhibit T-cell responses to GAS, and to the presumed targets of RHD autoimmunity, streptococcal M protein and cardiac myosin. From a number of positive hits, one drug was of particular interest due to its current cost effectiveness and known safety. This drug was able to inhibit GAS-induced antigen presenting cell function and inhibited IFN γ and IL-23 signalling pathways as assessed by RNAseq analysis. These results demonstrate that ARF patients have elevated Th17 responses to GAS and we propose this drug that could be trialled for RHD prevention.

T cell up-regulation of CD127 is associated with reductions in the homeostatic set point of the peripheral T cell pool during malnourishment

Gubbels Bupp, M., Murphy, S., Patrick, K., Thoner, T., Edwards, R.W., Litvin, S.

Randolph-Macon College, Biology, Ashland, United States

The following study was undertaken to better understand the impact of short-term malnutrition on T cell homeostasis, with particular attention focused on the CD127/IL-7 signaling dynamic of peripheral T cells in mice. We report that the total number of peripheral naive and memory CD4⁺ and CD8⁺ T cells notably declined after one week of mild malnourishment a time period too short to be entirely due to malnutrition-induced thymic involution. Peripheral malnourished T cells expressed higher levels of the IL-7 receptor component, CD127, and were less sensitive to death-by-neglect as compared to control T cells. Adoptive transfer studies revealed that CD127 expression did not correlate with increased survival *in vivo* and that all naive CD8⁺ T cells upregulated CD127, regardless of initial expression levels. Corticosterone levels were elevated in malnourished mice and this correlated in time with peripheral T cell up-regulation of CD127 and the diminishment of the peripheral T cell pool. Overall, these data suggest a model in which CD127 levels are up-regulated quickly during malnourishment, thereby increasing the scavenge rate of IL-7, and providing a mechanism to quickly adjust the total number of T cells during malnutrition.

406

IL-33-dependent endothelial activation contributes to apoptosis and renal injury in *Orientia tsutsugamushi*-infected mice

Soong, L.¹, Shelite, T.¹, Liang, Y.¹, Trent, B.², Hu, H.¹, Sun, J.¹

¹University of Texas Medical Branch, Microbiology and Immunology, Galveston, United States, ²University of Texas Medical Branch, Pathology, Galveston, United States

Endothelial cells (EC) are the main target for *Orientia tsutsugamushi* infection and EC dysfunction is a hallmark of severe scrub typhus in patients. However, the molecular basis of EC dysfunction and its impact on infection outcome are poorly understood. We found that C57BL/6 mice receiving a lethal-dose *O. tsutsugamushi* infection had a significant increase in gene expression of IL-33 and its receptor ST2L in the kidneys and liver, but a rapid reduction of IL-33 in the lungs. We also found exacerbated EC stress and activation in infected kidneys, as evidenced by elevated angiopoietin (Ang) 2/Ang1 ratio, increased endothelin 1 and endothelial nitric oxide synthase expression. Such responses were significantly attenuated in IL-33^{-/-} mice. Infected IL-33^{-/-} mice also had markedly attenuated disease due to reduced EC stress and cellular apoptosis. Moreover, we challenged wild-type mice with a sub-lethal dose of *O. tsutsugamushi* and gave mice rIL-33 every 2 days for 10 days. Exogenous IL-33 significantly increased disease severity and lethality, which correlated with increased EC stress and activation, increased CXCL1 and CXCL2 chemokines, but decreased anti-apoptotic gene BCL-2 in the kidneys. To validate EC stress, we infected human umbilical vein endothelial cells

(HUVEC) *in vitro*. We found an infection dose-dependent increase in the expression of IL-33, ST2L soluble ST2 (sST2), and the Ang2/Ang1 ratio at 24 and 48 hours post-infection. This study indicates a pathogenic role of alarmin IL-33 in a murine model of scrub typhus and highlights infection-triggered EC damage and IL-33-mediated pathological changes during the course of *Orientia* infection.

Understanding sepsis-induced lymphopenia

Puthalakath, H.¹, Doerflinger, M.², Pellegrini, M.³, Hotchkiss, R.⁴, Nedeva, C.²

¹La Trobe University, Biochemistry and Genetics, Melbourne, Australia, ²La Trobe University, Melbourne, Australia, ³Walter & Eliza Hall Institute, Melbourne, Australia, ⁴Washington University School of Medicine, St Louis, United States

Sepsis-induced lymphopenia is a major cause of morbidities in intensive care units and in populations with chronic conditions such as renal failure, diabetes, HIV and alcohol abuse. Currently, other than supportive care and antibiotics, there are no treatments for this condition. We developed an *in vitro* assay to understand the role of the ER-stress-mediated apoptosis process in lymphocyte death during polymicrobial sepsis, which was reproducible in *in vivo* mouse models. Modulating ER stress with clinically used chemical chaperones improved survival of mice undergoing polymicrobial sepsis four-fold.

Furthermore, to understand the molecular mechanism of, we biochemically purified the factor released by activated macrophages that leads to lymphocyte apoptosis (Immunoglobulin-binding protein or BiP). Using genome-wide CRISPR knockout, we also identified a new receptor that mediates lymphocyte death known as "Function Unknown Membrane Receptor" or FUMR. Genetic ablation of this receptor results in apoptosis resistance of lymphocyte in mice undergoing polymicrobial sepsis. Administration of a soluble form of the receptor also protected mice from lymphopenia. There have been over fifty clinical trials targeting the inflammatory phase of sepsis without success. It is now thought by many investigators that the immunosuppressive phase (caused by apoptosis) has by far the greatest pathophysiological significance in determining the patient's survival. Our findings open new therapeutic opportunities for treating sepsis.

Development of a MVA-based vaccine against Crimean-Congo Haemorrhagic Fever virus

Graham, V., Dowall, S., Hewson, R.

PHE, Virology and Pathogenesis, Salisbury, United Kingdom

Crimean-Congo Haemorrhagic Fever (CCHF) is a severe tick-borne disease, endemic in many countries in Africa, the Middle East, Eastern Europe and Asia. Between 15-70% of reported cases are fatal. Handling of live virus requires biosafety level 4 facilities, which has restricted work on developing interventions against infection. There is no approved vaccine available, and preclinical protection by an experimental vaccine has not been

demonstrated previously. In the present study, the attenuated poxvirus vector, Modified Vaccinia virus Ankara, was used to develop a recombinant candidate vaccine expressing the CCHF virus glycoproteins. Cellular and humoral immunogenicity was confirmed in two mouse strains, including type I interferon receptor knockout mice, which are susceptible to CCHF disease. The vaccine generated strong humoral and cellular immunity against CCHF viral antigens. This vaccine protected all recipient animals from lethal disease in a challenge model adapted to represent infection via a tick bite. Histopathology and viral load analysis of protected animals confirmed that they had been exposed to challenge virus, even though they did not exhibit clinical signs. Subsequent analysis using passive and adoptive transfer of sera and CD3+ T-cells, respectively, demonstrated that both arms of the immune system were required to exert protective effects against lethal infection. This is the first demonstration of efficacy of a CCHF vaccine that is suitable for development for human use and can meet international regulatory approval.

Andrographolide, a therapeutic agent for chikungunya and other inflammatory diseases

Gupta, S.¹, Mishra, K.P.¹, Ganju, L.¹, Singh, S.B.²

¹Defence Institute of Physiology and Allied Sciences, Immunomodulation, Delhi, India, ²Defence Institute of Physiology and Allied Sciences, Delhi, India

Aim: To study the anti-inflammatory and anti-chikungunya virus (CHIKV) potential of andrographolide (AND).

Method: Anti-inflammatory, anti-arthritic and anti-CHIKV properties of the major bioactive compound of plant *Andrographis paniculata* i.e. AND has been tested both *in vitro* and *in vivo*. Mouse peritoneal macrophages (PM) were used to measure COX-2, iNOS and NF-κB expression by immunoblotting and TNF-α and IL-6 by ELISA. However, *in vivo* studies were carried out in Complete Freund's Adjuvant (CFA) induced arthritis in Sprague Dawley rats. Paw edema in rats was treated by intraperitoneal AND treatment and measured for paw swelling.

In vitro anti-CHIKV studies were performed in THP-1 cell line and intracellular viral load was measured by flow cytometry and immunoblotting. For *in vivo* studies, Balb/c mouse neonates were used as CHIKV animal model. AND treatment was given intraperitoneally to CHIKV infected neonates and tested for CHIKV RNA by qPCR.

Results: *In vitro* studies in PM showed that AND exhibit anti-inflammatory properties by reducing COX2, iNOS and NF-κB expression along with TNF-α and IL-6. A further, *in vivo* study revealed that AND efficiently reduces paw edema formation. The *in vitro* anti-CHIKV study found that AND inhibits CHIKV protein expression in THP-1 cells. Moreover, *in vivo* study suggests that AND reduces CHIKV RNA copy number and percent mortality in Balb/c mouse neonates.

Conclusion: Andrographolide is a potent anti-inflammatory and anti-CHIKV agent and therefore, it can be used as a therapeutic agent for the treatment of virus induced arthritis which sustains for years after CHIKV infection.

Cutaneous manifestations of an emerging viral infection: chikungunya fever*Inamadar, A.**BLDE University, Dermatology, Vijaypur, India*

Chikungunya fever is a viral illness caused by an Arbo virus (CHIKV), transmitted by *Aedes sp.* of mosquitoes. The clinical features include high grade fever, arthralgia, myalgia, headache and morbilliform rash. In a recent outbreak of chikungunya fever in India, several new cutaneous features have been documented.

During the earlier epidemics of chikungunya fever in various parts of the world, facial flush, generalized exanthema and purpura were reported as cutaneous features. In the recent outbreak of the disease in south-India, the dermatological manifestations recorded were various patterns of hyperpigmentation (centro-facial freckle like, flagellate and diffuse), vesiculo-bullous (VB) lesions, aphthous-like ulcers in the intertriginous areas, lymphedema, lichenoid eruptions and ecchymosis. The VB lesions were seen among infants and aphthous-like ulcers among adult males. Oral mucosal ulcers, pigmentation of pinna and nails and subungual hemorrhage are the other features noted. Exacerbation of existing dermatoses, such as psoriasis, and unmasking of undiagnosed leprosy were observed.

Skin biopsy from the ulcers showed features suggestive of lymphocytic vasculopathy which might have been viral antigen induced. Evidence of vertical transmission from mothers with acute infection was noted in newborns, which developed diffuse pigmentation present at birth or soon thereafter. Serum IgM antibody for CHIKV was positive in these newborns.

The current outbreak of chikungunya fever in India is due to the African genotype of the virus, in contrast to the Asian genotype on previous occasions. The atypical / newer cutaneous features observed may be attributed to infection due to this different strain of the virus.

Use of the rapid urine lipoarabinomannan antigen-antibody test for bovine tuberculosis diagnosis*Balada-Llasat, J.-M.¹, Sidiki, S.¹, Gebreyes, W.¹, Hunt, W.G.¹, Pan, X.¹, Arcos, J.¹, Hengesbach, J.², Baer, S.³, Smith, R.³, Averill, J.³, Wang, S.-H.¹, Torrelles, J.¹**¹Ohio State University, Columbus, United States, ²Michigan State University, Lansing, United States, ³Michigan Department of Agriculture and Rural Development, Lansing Charter Township, United States*

Bovine-Tuberculosis (BTB) is one of the World Health Organization's seven neglected endemic zoonotic diseases. Currently, there is no rapid-point-of-care, easy-to-use diagnostic test. Therefore, there is an urgent need worldwide for the development and implementation of a BTB point-of-care diagnostic test. The purpose of this study was to assess the accuracy of the lipoarabinomannan antigen-antibody (LAM-Ag-Ab) test to detect BTB. Urine collected from cattle (n=32) suspected of BTB disease in an outbreak in Michigan were tested with the LAM-Ag-Ab test and lipids were removed

from urine to increase test sensitivity. Results were compared to the USDA BTB-standard culture (n=29), gross pathology (n=21), histopathology (n=32) and the IFN- γ blood test (n=21). Ninety percent of the cattle suspected of BTB tested positive by the urine LAM-Ag test. These results were obtained in only 25 minutes, without the requirement of specialized personnel or equipment. Eighty-six percent were positive by gross pathology, 90% positive by histopathology, 57% positive by IFN- γ blood test, and 90% positive for culture. In conclusion, detection of LAM-Ag-Ab in urine offers the potential to diagnose BTB in cattle in a more rapid, accurate, and less expensive fashion than current methods.

Changes in the effector and regulatory functions of CD8⁺ T cells in visceral leishmaniasis patients*Singh, B.¹, Kumar, R.^{2,3}, Engwerda, C.³, Sundar, S.¹**¹Institute of Medical Sciences, Banaras Hindu University, Department of Medicine, Varanasi, India, ²Netaji Subhas Institute of Technology (University of Delhi), New Delhi, India, ³QIMR Berghofer Medical Research Institute, Brisbane, Australia*

Visceral leishmaniasis (VL) is a major neglected tropical disease caused by *Leishmania donovani* in the Indian sub-continent. Following infection, CD8⁺ T cell activation can result in the generation of effector mechanisms allowing killing of target cells. In addition, CD8⁺ T cells can also develop regulatory functions, especially during chronic infection. However, the factors influencing these different fates of CD8⁺ T cells remain poorly understood. We hypothesized that CD8⁺ cell effector functions are compromised in VL patients, and instead CD8⁺ T cells develop immunoregulatory functions that suppress inflammation. To test this hypothesis, we purified CD8⁺ T cells from VL patients on presentation to clinic and after 30 days of drug treatment from blood. CD8⁺ T cells were isolated from the blood of healthy endemic controls and RNA was used to measure the abundance of 130 different mRNA species encoding gene products involved in T cell development, activation, function and regulation using nanostring technology. The results revealed significant differences in mRNA level in VL patients before and after treatment, as well as between cases and controls. CD8⁺ T cells from patients had elevated levels of mRNA encoding genes involved in cytolytic T cell function, including granzymes A, B, H, and perforin. However, these cells also displayed a dominant regulatory phenotype, including high levels of mRNA encoding IL-10, CTLA-4 and CD38 genes. These results will provide new insights into the functions of CD8⁺ T cells during chronic infection diseases and identify potential new strategies to manipulate this

T cell subset for therapeutic advantage.

Lymph node stromal cells derive from a distinct embryonic FAP+ progenitor

Denton, A.^{1,2}, Magiera, L.², Watts, A.², Fearon, D.^{2,3}

¹*Babraham Institute, Lymphocyte Signalling and Development ISP, Cambridge, United Kingdom,* ²*University of Cambridge, CRUK Cambridge Institute, Cambridge, United Kingdom,* ³*Weill Cornell Medical College and Cold Spring Harbor Laboratories, Cold Spring Harbor, United States*

Lymph node stromal cells (LNSCs) are critical regulators of LN structure and function and are indispensable for adaptive immune responses. The relationship between different LNSCs is poorly defined, as is their developmental origin. In this study, we aimed to understand the origin of stromal cells in the inguinal (i)LN based on expression of fibroblast activation protein- α (FAP). We generated a novel transgenic mouse strain in which the murine FAP transgene drives expression of the Tet-Off tetracycline transactivator. Cross-breeding with tetO-cre and ROSA-lox-stop-lox-tdTomato mice generated a strain in which FAP expression is indelibly marked in a manner that can be inhibited by administration of doxycycline. We show that all gp38+ LNSCs (i.e., fibroblastic reticular cells, FRCs; follicular dendritic cells, FDCs; and marginal reticular cells, MRCs) in adult mice derive from embryonic FAP-expressing cells, whilst endothelial cells - both blood and lymphatic - do not. Doxycycline-regulated fate-mapping revealed that all adult gp38+ LNSCs in the iLN derive from FAP+ cells that arise at e14.5-15.5. 20-25% of gp38+ LNSCs derive from a FAP+ cell present at e14.5, and microscopy analysis demonstrated that FAP+ cells give rise to adult FRCs, FDCs and MRCs in discrete patches that are localised throughout the iLN. Surprisingly, the FAP+ cells that give rise to LNSCs are distinct from the FAP+ progenitors that give rise to bone, muscle and fat tissue. We conclude that a distinct embryonic progenitor, identified by FAP expression, gives rise to adult LNSCs and is thus essential to the generation of adaptive immune responses.

Host genetic polymorphisms affect p24 Gag epitope presentation and T-cell engagement in HIV-1 infection

Josephs, T.M.¹, McLaren, J.E.², Ladell, K.², Geldmacher, C.³, Rossjohn, J.^{1,2}, Price, D.A.², Gras, S.¹

¹*Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia,* ²*Cardiff University School of Medicine, Institute of Infection and Immunity, Cardiff, United Kingdom,* ³*Medical Centre of the University of Munich, German Centre for Infection Research, Munich, Germany*

Genetic association studies have consistently linked disease progression rates to particular HLA class I alleles in HIV-1 infection, leading to a consensus in the field that viral epitope presentation and CD8 T-cell targeting patterns are key mechanistic determinants of biological outcome. However, the attractive simplicity of this paradigm is challenged by observations of peptide binding promiscuity, a phenomenon

that enables specific epitope cross-presentation in the context of different HLA class I molecules. The highly conserved p24 Gag-derived epitope TL9 (TPQDLNTML, residues 180-188) elicits protective CD8 T-cell responses restricted by members of the B7 superfamily, most notably HLA-B*4201 and HLA-B*8101. Despite their close molecular homology, the HLA-B*8101 allele is associated with comparatively slower rates of disease progression. To investigate this dichotomy, we examined the functional, biophysical and structural characteristics of TL9 epitope presentation and T-cell receptor (TCR) recognition in HLA-B*4201+ and/or HLA-B*8101+ individuals with chronic HIV-1 clade C infection. The data reveal that clonotype selection from the peripheral TCR repertoire is governed by the presenting HLA class I molecule. This process differentially regulates the mobilization of particular TL9-specific clonotypes defined by a unique mode of antigen engagement, thereby modulating immune escape pathways that influence the course of infection.

Bringing veterinary immunology up to speed using the Babraham pig model of influenza A infection/vaccination

Tungatt, K.¹, Dolton, G.¹, Attaf, M.¹, Hemmink, H.², Morgan, S.B.², Hammond, J.A.², Porter, E.³, Miles, J.J.^{1,4}, Montoya, M.², Bailey, M.³, Tchilian, E.Z.², Charleston, B.², Sewell, A.K.¹

¹Cardiff University, Division of Infection and Immunity, Cardiff, United Kingdom, ²The Pirbright Institute, Pirbright, United Kingdom, ³University of Bristol, School of Veterinary Sciences, Bristol, United Kingdom, ⁴QIMR Berghofer, Brisbane, Australia

Cross-species jumps by viruses such as HIV, ebola and influenza can exploit gaps in existing immune coverage and represent significant threats to both public health and economic stability. Livestock-derived zoonoses represent a particular menace as these animals live in close proximity with humans and can act as mixing vessels for the generation of new and highly pathogenic viral species. Human/avian influenza A viruses typically sit at the apex of such threats because blending of viral strains within their common vector, the pig, fabricates highly dangerous novel fusions. Thus, it is imperative that we develop veterinary vaccines against this peril, however the immunology “toolbox” available for swine lacks routine culture and assay of T-cells, easy definition of dominant T-cell epitopes, robust MHC-binding motifs and effective peptide-MHC tetramers. Here we have studied T-cell responses to influenza A following vaccination of the Babraham inbred pig line and developed novel methods for immunological profiling including:

- i) Defining 3 immunodominant MHC class I restricted peptide epitopes from the pandemic H1N1 nucleoprotein;
- (ii) Large-scale culturing of T-cell clones; and,
- (iii) Routine manufacture and use of porcine-derived peptide-MHC tetramers.

These tools have enabled us to study protective porcine T-cell responses. We are currently in the process of determining Babraham MHC class I crystal structures and will establish peptide-binding motifs through peptide combinatorics and other means. Overall, we expect that these breakthroughs will help establish the Babraham pig as a powerful research platform for both basic and applied infectious disease research that has direct relevance for human health.

Deregulated expression of MiRNAs in purified disease relevant blood cell populations in patients with spondyloarthritis

Miceli-Richard, C.^{1,2}, Bugge Tinggaard, A.³, Wang-Renault, S.-F.³, Busato, F.³, Dougados, M.¹, Tost, J.³

¹Université Paris Descartes (Paris V), Rheumatology - Hôpital Cochin, Paris, France, ²Pasteur Institute of Paris, Immunoregulation, Paris, France, ³Institut de Génomique - Centre National de Génotypage - CEA, Epigenetics, Evry, France

Background: No systematic studies in specific cell populations have been reported so far in Spondyloarthritis (SpA). A recently published computational analysis (Farh et al. Nature 2015) showed a large overlap of active gene regulatory regions with genetic variation associated with SpA for CD4 T cells and CD14

monocytes.

Objective: To analyze the miRNA expression pattern in two disease relevant cell populations of purified CD4 T cells and CD14 monocytes from Spondyloarthritis (SpA) patients and controls.

Methods: We analyzed the expression of 360 MiRNAs in cell-sorted (MACS) monocytes and CD4 T-lymphocyte populations from 24 SpA patients and 16 age and sex-matched controls by qPCR using the Exiqon MicroRNA Ready-to-Use Human Panel I on the miRNA-enriched fraction from both CD4+ and CD14+ cell populations.

Results: In CD4 cells 6 miRNAs were found to be differentially expressed including miR-491-3p, recently reported to be downregulated in ulcerative colitis, and miRNA-26a, a well known inflammation associated miRNA implicated in both allergic inflammation and autoimmune diseases. In monocytes, 25 miRNAs were found to be differentially expressed including the paradigmatic anti-inflammatory miRNA miR-146a and as the most significantly expressed miRNA, a miRNA involved in the degradation of TNF α .

Conclusions: The study is the first to analyze miRNA expression in purified disease-relevant blood cell populations in SpA bringing into evidence a number of interesting miRNAs whose deregulation might contribute to the pathogenesis of the disease.

Acknowledgements: This work was funded by a SIRIUS Research Grant from UCB Pharmaceuticals S.A.

Dissecting the IL-21/IL-21R system in human monocytes and macrophages: cell signaling events during phagocytosis adhesion

Vallières, F., Girard, D.

INRS-Institut Armand-Frappier, Laval, Canada

The biological significance of the IL-21/IL-21R system in human myeloid cells, especially in monocytes/macrophages, is not well documented. Previously, we demonstrated that IL-21 enhances the ability of human monocytes and macrophages to phagocytose opsonized sheep erythrocytes by a Syk dependent mechanism. In the present study, we showed that IL-21 enhances FcR-mediated phagocytosis in human monocyte-like THP-1 cells and in GM-CSF monocyte-derived macrophages (HMDM). The ability of IL-21 to enhance FcR-mediated phagocytosis was not associated with an increased expression of CD16 (Fc γ RIII), CD32 (Fc γ RIIA) and CD64 (Fc γ RI) at the cell surface. IL-21 was found to activate ERK-1/2 and p38, Akt and Jak/STAT pathways in THP-1 cells and HMDM, as evidenced by its ability to increase phosphorylation levels of these proteins. Using a pharmacological approach, we demonstrated the importance of ERK-1/2, Akt and Jak/STAT activation in IL-21-induced phagocytosis. Moreover, IL-21 was found to induce phagocytosis of zymosan by a ERK-1/2, Akt and Jak/STAT dependent mechanism. We also investigate the role of IL-21 in regulating other monocyte/macrophage functions, including cellular adhesion and protease secretion and found that it can induce adhesion of THP-1 cells onto the human endothelial hybrid cell line EA.hy 926. The importance of the different cell signaling

pathways are currently under investigation in our laboratory. We conclude that IL-21 possesses important biological effects in mononuclear phagocyte cells. Therefore, future development of therapeutic strategies targeting the IL-21/IL-21R system should consider that monocyte and macrophage cell physiology could be affected by this system.

The complement C3a receptor contributes to melanoma tumorigenesis by regulating neutrophil and CD4⁺ T cell responses

Nabizadeh, J.¹, Manthey, H.¹, Boyle, G.², Steyn, F.^{3,4}, Woodruff, T.³, Rolfe, B.¹

¹The University of Queensland, Australian Institute for Bioengineering and Nanotechnology, Brisbane, Australia, ²QIMR Berghofer Medical Research Institute, Brisbane, Australia, ³The University of Queensland, School of Biomedical Sciences, Brisbane, Australia, ⁴The University of Queensland, The University of Queensland Centre for Clinical Research, Brisbane, Australia

The complement peptide C3a is a key component of the innate immune system, and a major fragment produced following complement activation. We utilised a murine model of melanoma (B16-F0) to identify a hitherto unknown role for C3a-C3a receptor (C3aR) signalling in tumour growth. The results show that the development and growth of B16-F0 melanomas is retarded in mice lacking C3aR, while growth of established melanomas can be arrested by C3aR antagonism. Flow cytometric analysis showed alterations in tumour-infiltrating leukocytes in the absence of C3aR. Specifically, neutrophils and CD4⁺ T lymphocyte sub-populations were increased, whereas macrophages were reduced. The central role of neutrophils was confirmed by depletion experiments which reversed the tumour inhibitory effects observed in C3aR-deficient mice, and returned tumour infiltrating CD4⁺ T cells to control levels. Analysis of the tumour microenvironment showed up-regulation of inflammatory genes which may contribute to the enhanced anti-tumour response observed in C3aR-deficient mice. C3aR deficiency/inhibition was also protective in murine models of BRAF^{V600E} mutant melanoma, colon and breast cancer, suggesting a tumour-promoting role for C3aR signalling in a range of tumour types. We propose that C3aR activation regulates the tumour inflammatory milieu, thereby promoting tumour growth.

Therapeutic inhibition of C3aR may therefore be an effective way to trigger an anti-tumour response in melanoma and other cancers.

An evolutionary balance between immune protection to pathogen challenge and maintenance of self-tolerance may be permissive to autoimmunity and tumor formation, respectively. How tissue immune homeostasis is achieved on a programmatic level is unknown, as are the consequences for tumor immune surveillance and progression. Dendritic cells (DC) are professional antigen-presenting cells, which direct both tolerance and immunity in T cells. DC arriving in lymph node (LN) from peripheral tissue such as skin regulate tolerance to self antigens and have a newly described role in dampening ongoing immunity. Here we show DC and other monophagocytes share a species-conserved homeostatic differentiation program, heightened upon tissue entry and exit. We find this signature associates closely with early melanoma progression, stratifies melanoma survival, and is enriched across multiple human tumors. In particular, loss of the highest species-conserved gene in this signature, expands DC-based priming and adaptive anti-tumor immunity, indicating a critical regulatory role. These findings indicate adaptive immune resistance is closely linked to peripheral immune homeostasis and may be commonly conditioned by cues shared during development and in the tumor microenvironment.

Adaptive NK cells with low TIGIT expression are inherently resistant to myeloid-derived suppressor cell inhibitory activities

Sarhan, D.^{1,2}, Cichocki, F.³, Zhang, B.³, Yingst, A.³, Spellman, S.R.⁴, Cooley, S.³, Verneris, M.R.³, Blazar, B.R.³, Miller, J.S.³

¹University of Minnesota, Masonic Cancer Center, Minneapolis, United States, ²Karolinska Institute, Oncology-Pathology, Stockholm, Sweden, ³University of Minnesota, Adult and Pediatric Blood and Marrow Transplant Program, Minneapolis, United States, ⁴University of Minnesota, Center for International Blood and Marrow Transplant Research, Minneapolis, United States

Human cytomegalovirus (CMV)-induced adaptive natural killer (NK) cells characterized by distinct phenotypic and functional characteristics, including properties of immune memory. We hypothesized that adaptive NK cells are more resistant to suppression mediated by regulatory cell subsets, making them an attractive candidate for cancer therapy. Indeed, we found that relative to conventional NK cells, adaptive NK cells express significantly lower levels of the inhibitory receptor T cell Ig and ITIM domain (TIGIT). Consequently, adaptive NK cells are inherently resistant to suppression mediated by myeloid-derived suppressor cells (MDSCs). In contrast, conventional NK cells were potently suppressed by MDSCs ($p \leq 0.001$), an effect completely abrogated by TIGIT blockade ($p \leq 0.001$). TIGIT signaling in NK cells following co-culture with MDSCs resulted

in a decrease in the phosphorylation of ZAP70/Syk and ERK1/2 ($p \leq 0.003$), which could be reversed by blocking TIGIT on NK cells or by inhibiting reactive oxygen species (ROS) production by MDSCs ($p \leq 0.02$). TIGIT ligand CD155 was highly expressed on MDSCs compared to no/low expression on monocytes. CD155 increased expression was dependent on ROS production in MDSCs or induced by H_2O_2 treatment in monocytes. Thus, NK cells co-cultured with MDSCs in the presence of anti-TIGIT or ROS-inhibitor have normal cytotoxicity against K562 cells. Our results demonstrate that adaptive NK cells arising in response to CMV infection are resistant to MDSC-mediated functional suppression. Furthermore, TIGIT may represent a key checkpoint inhibitor for conventional NK cells that can be neutralized to enhance NK cell-mediated responses against cancer and infection.

The role of CD8 T-cells during anti-PD1 treatment of viral infection-induced secondary bacterial pneumonia

Brown, A.C.¹, Essilfie, A.T.¹, Beckett, E.L.², Thorburn, A.N.¹, Hansbro, N.G.¹, Jarnicki, A.G.³, Yagita, H.⁴, Foster, P.S.¹, Horvat, J.C.¹, Wark, P.A.B.^{1,5}, Hansbro, P.M.¹

¹The University of Newcastle, Centre for Asthma and Respiratory Disease, Callaghan, Australia, ²The University of Newcastle, Callaghan, Australia, ³University of Melbourne, Department of Pharmacology and Therapeutics, Melbourne, Australia, ⁴Juntendo University, Department of Immunology, Tokyo, Japan, ⁵John Hunter Hospital, Department of Respiratory and Sleep Medicine, Newcastle, Australia

Introduction and aim: Secondary bacterial pneumonia frequently occurs following respiratory viral infections with many components of the immune response being dysfunctional. Anti-inflammatory processes such as the PD-1/PD-Ligand (PD-1/PD-L) pathway may be elevated following primary infection and suppress protective immunity to subsequent bacterial exposure. We determined whether primary viral infection increased the PD-1/PD-L pathway. We also assessed the role of this pathway and whether it could be targeted to improve responses to secondary infections.

Methods: We developed a mouse model of respiratory viral infection followed by secondary bacterial infection. Mice were infected with pneumonia virus of mice (PVM), then at viral clearance, they were infected with *Streptococcus pneumoniae*. The levels of PD-1/PD-L on different immune cells were assessed by flow cytometry. The role of PD-1/PD-L was determined by administration of a PD-1 blocking antibody and mediating immune responses determined by flow cytometry. The role of CD8 T-cells during PD-1 blocking treatment was determined by depletion antibodies at the end of viral clearance.

Results: Primary infection with PVM increased bacterial titres and PD-1/PD-L1 expressing cells in secondary *S. pneumoniae* infections compared to controls. Upon blocking PD-1 signalling, bacterial titres were reduced. Respiratory cellular profiles demonstrated increases in activated CD8 T-cells. Depleting CD8 T-cells during this treatment, prevented the suppressive effects

of blocking PD-1 signalling on bacterial titres.

Conclusion: These findings suggest that blocking PD-1 during viral infection-induced secondary bacterial pneumonia improves clearance of bacterial infection, which may be mediated by CD8 T-cells. This may be a potential new therapeutic approach for at risk patients.

Intestine lamina propria CD4⁺T cells promote the bactericidal activity of macrophages via galectin-9 and Tim-3 interaction during *Salmonella typhimurium* infection

Zhang, C., Zhang, H., Zuo, Z., Han, Q., Zhang, J.

Institute of Immunopharmacology & Immunotherapy, School of Pharmaceutical Sciences, Shandong University, Jinan, China

The intestinal immune system is crucial for protection the host from pathogenic infection and maintenance of mucosal homeostasis. The intestine lamina propria macrophages are main effector cells in innate resistance to *intracellular* microbial pathogens. In the present study, we found that *Salmonella typhimurium* infection augmented the Tim-3 expression on intestinal lamina propria CD4⁺T cells and enhanced galectin-9 expression on F4/80⁺CD11c⁺macrophages. Moreover, CD4⁺T cells promote the activation and bactericidal activity of F4/80⁺CD11c⁺macrophages via galectin-9 and Tim-3 interaction during *Salmonella typhimurium* infection. Blockade the interaction of Tim-3 and galectin-9 with α -Lactose significantly attenuated the killing of intracellular bacteria by macrophages. Furthermore, the interaction of Tim-3 and galectin-9 also promoted the formation and activation of inflammasome, which leads to the cleavage of caspase-1 and IL-1 β . The secretion of active IL-1 β further improved bactericidal activity of macrophages and expression of galectin-9 on macrophages. These results demonstrated the critical role of the cross-talk between CD4⁺T cell and macrophage, in particularly the interaction of Tim-3 and galectin-9, in antimicrobial immunity and control intestinal pathogen infection.

There is no conflict of interest.

Human CD8⁺ T-cells recognizing peptides from *Mycobacterium tuberculosis* presented by HLA-E have an unorthodox Th2-like, multifunctional, *Mtb*-inhibitory phenotype and represent a novel human T-cell subset

Ottenhoff, T.¹, van Meijgaarden, K.E.¹, Haks, M.C.¹, Caccamo, N.², Dieli, F.², Joosten, S.A.¹

¹Leiden University Medical Center, Department of Infectious Diseases, Leiden, Netherlands, ²Central Laboratory for Advanced Diagnostic and Biomedical Research (CLADIBIOR), Dipartimento di Biopatologia e Biotecnologie Mediche e Forensi, Università di Palermo, Palermo, Italy

Mycobacterial antigens are not only presented to T-cells by classical HLA-class Ia and HLA-class II molecules, but also through alternative antigen presentation molecules such as CD1a/b/c, MR1 and HLA-E. We recently described mycobacterial peptides that are presented in HLA-E and recognized by CD8⁺ T-cells.

Using T-cell cloning, phenotyping, microbiological, functional and RNA-expression analyses, we found that these T-cells can exert cytolytic or suppressive functions, inhibit mycobacterial growth, yet express GATA3, produce Th2 cytokines (IL-4,-5,-10,-13) and activate B-cells via IL-4. In TB patients, Mtb specific cells were detectable by peptide-HLA-E tetramers, and IL-4 and IL-13 were produced following peptide stimulation. The frequencies were highest in untreated TB patients and declined following successful treatment. These results identify a novel human T-cell subset with an unorthodox, multifunctional Th2 like phenotype and cytolytic or regulatory capacities, which is involved in the human immune response to mycobacteria and demonstrable in active TB patients' blood. The results challenge the current dogma that only Th1 cells are able to inhibit Mtb growth and clearly show that Th2 like cells can strongly inhibit outgrowth of Mtb from human macrophages. These insights significantly expand our understanding of the immune response in infectious disease.

PKC- δ (delta), a host factor critical for macrophage killing effector functions during *Mycobacterium tuberculosis* in mice

Parihar, S.P.¹, Ozturk, M.¹, Hurdayal, R.¹, Zak, D.E.², Penn-Nicholson, A.³, Scriba, T.³, Guler, R.¹, Brombacher, F.¹

¹University of Cape Town/Institute of Infectious Disease and Molecular Medicine (IDM), Cape Town, South Africa, ²Center for Infectious Disease Research, Seattle, United States, ³South African Tuberculosis Vaccine Initiative (SATVI), Institute of Infectious Disease and Molecular Medicine (IDM) and School of Child and Adolescent Health, University of Cape Town, Cape Town, South Africa

We demonstrated previously that Protein Kinase C delta (PKC- δ), a critical host factor is involved in controlling *Listeria monocytogenes*, *Leishmania major* and *Candida albicans* infection in mice. Here, we aim to demonstrate the role of PKC- δ in *Mycobacterium tuberculosis* (Mtb) infection. Mice deficient for PKC- δ are highly susceptible to tuberculosis infection when compared to wild type mice. Decreased survival of PKC- δ ^{-/-} mice was associated with a rapid weight loss, exaggerated lung pathology and increased mycobacterial burdens in lungs and spleen. Exaggerated lung pathology is reflected by uncontrolled pro-inflammatory cytokine response such as IFN- γ , TNF- α , IL-6, IL-1 β and IFN- β in PKC- δ ^{-/-} mice. Interestingly, PKC- δ ^{-/-} mice exhibited no major differences in the recruiting immune cell populations at the site of infection. However, absence PKC- δ resulted in decreased accumulation of neutral lipid bodies in lungs and in isolated macrophages following Mtb infection. Moreover, the expression of PKC- δ increases following infection in wild-type macrophages however other PKC isoforms remains largely unaffected. *In vitro*, infection of isolated macrophages from PKC- δ mice increased bacterial growth with concomitant decrease in the production of nitric oxide and hydrogen peroxide. Furthermore, PKC- δ is highly expressed in active tuberculosis patients versus healthy adolescent control subjects, which rapidly decreases on the onset of anti-tuberculosis therapy. Thus, we demonstrated

that PKC- δ is required for efficient macrophage killing effector functions and host protection during tuberculosis infection.

Inhibition of IL-1 β expression by anthrax lethal toxin through HDAC8 and enhancer RNAs

Kim, S.O.

Western University, London, Canada

Many pathogenic microbes often release toxins that subvert the host immune responses to render the environment suitable for their survival and proliferation. LeTx is one of the toxins causing immune paralysis through cleaving and inactivating the mitogen-activated protein kinase (MAPK) kinases (MEKs). Here, we show that inhibition of the histone deacetylase 8 (HDAC8) by either the HDAC8-specific inhibitor PCI-34051 or small interference (si)RNAs rendered LeTx-exposed murine macrophages responsive to LPS in pro-IL-1 β production. LeTx induced HDAC8 expression and nuclear localization, in part through inhibiting p38 MAPK, which resulted in a decrease of H3K27Ac levels, and inhibition of recruitment of NF- κ B to IL-1 β enhancer/promoter regions. Inhibition of HDAC8 increased H3K27Ac levels and enhanced NF- κ B-mediated pro-IL-1 β enhancer and messenger RNA production in LeTx-exposed macrophages. Collectively, this study demonstrates a novel role of HDAC8 in LeTx immunotoxicity and regulation of pro-IL-1 β production likely through HDAC8. Targeting HDAC8 could be a strategy for enhancing immune responses in macrophages exposed to LeTx or other toxins that inhibits MAPKs.

Dynamics of phagocytic cells early after mycobacterial lung infection

Ryder, B.M., Manners, K., Kirman, J.R.

University of Otago, Department of Microbiology & Immunology, Dunedin, New Zealand

Dendritic Cells (DC) are essential for instigating adaptive immune responses to mycobacterial infection, however the roles that specific lung DC subsets play in the first two weeks of lung mycobacterial infection are unclear. We used fluorescent *Mycobacterium bovis* Bacillus Calmette-Guérin (BCG) in a murine infection model with multi-parametric flow cytometry to track early phagocytic innate immune cell subsets and examine the ability of different lung DC subsets to activate T cells. Our model revealed a rapidly evolving, dynamic range of innate cell association with BCG during the first 14 days of infection, beginning with rapid accumulation of neutrophils in the lung. In contrast with the prevailing dogma, alveolar macrophages remained uninfected during the first two weeks of BCG infection. Although CD103⁺ DC were also uninfected, CD11b⁺ conventional and plasmacytoid DC subsets became associated with BCG as infection progressed. Distinct CD11b^{high} and GR-1^{high} conventional DC subsets and a CD11c^{high} population of plasmacytoid DC were more frequently associated with BCG than CD11b⁺, GR-1^{int} and CD11c^{int} DC populations. Additionally, DC activation states differed between uninfected cells and

those associated with BCG. Collectively, these data demonstrate a highly dynamic early immune response to mycobacterial infection, and the importance of understanding distinct roles played by innate cell subsets to inform development of improved anti-mycobacterial therapies and vaccines against tuberculosis.

Cooperation between monocyte-derived dendritic cells and lymphoid cells in the acute response to a bacterial lung pathogen

Brown, A.S.^{1,2}, Yang, C.^{1,2}, Fung, K.Y.², Bachem, A.², Bourges, D.¹, Bedoui, S.², Hartland, E.L.², van Driel, I.R.¹

¹University of Melbourne, Department of Biochemistry and Molecular Biology, Bio21 Molecular Science and Biotechnology Institute, Melbourne, Australia, ²University of Melbourne, Department of Microbiology and Immunology at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia

Legionella pneumophila is the causative agent of Legionnaires' disease, a potentially fatal lung infection. Alveolar macrophages support intracellular replication of *L. pneumophila*, however the contributions of other immune cell types to bacterial killing during infection are unclear. Here, we observed that during acute respiratory infection of mice, reduced numbers of alveolar macrophages coincided with rapid infiltration of the lung by monocyte-derived dendritic cells (moDC), which, together with neutrophils, became the dominant inflammatory cells associated with the bacteria. moDC were required for bacterial clearance and provided the IL-12 needed to induce IFN γ production by lymphoid cells including NK cells, NKT cells and memory T cells that responded in an antigen-independent fashion. In turn, IFN γ was necessary for bacterial killing by moDC, but not neutrophils. This work has revealed a cooperative innate immune circuit between lymphoid cells and moDC that combats acute *L. pneumophila* infection and defines a specific role for IFN γ .

Galectin-3 negatively regulates CR3-mediated neutrophil anti-*Candida albicans* functions

Wu, S.-Y., Huang, J.-H., Wu-Hsieh, B.

National Taiwan University, Graduate Institute of Immunology, Taipei, Taiwan, Republic of China

Galectin-3 (gal3) a chimera type of galectin that binds to the N-acetyllactosamine motif of glycoproteins through its carbohydrate-recognition domain and polymerizes through its N-terminal domain. Neutrophils are among the immune cells that express gal3. Published studies employing recombinant gal3 demonstrated that gal3 enhances dectin-1 and TLR2-dependent macrophage cytokine response to *Candida albicans*. Here we show that intracellular gal3 suppressed killing of engulfed opsonized *C. albicans* by neutrophils through complement receptor 3 (CR3)-mediated ROS production. Using live cell imaging to track the movement of cytosolic gal3 after phagocytosis of *C. albicans*, we found that cytosolic gal3 moved

towards but did not interact with engulfed *C. albicans* nor membrane CR3. However, both immunofluorescence staining and co-immunoprecipitation assay reveal that cytosolic gal3 physically interacted with Syk after stimulation by *C. albicans* and inhibited the phosphorylation of Syk and PKC β 2 thereby modulated neutrophil ROS production. Moreover, gal3^{-/-} mice were more resistant to systemic *C. albicans* infection than gal3^{+/+} mice with lower mortality. Our results reveal the molecular mechanism of how cell intrinsic gal3 modulates neutrophil anti-*C. albicans* function and demonstrate that neutrophil intrinsic gal3 dampens host defense against candidiasis.

Calcineurin-NFAT signaling control of the innate response

Fric, J.^{1,2}, Zelante, T.^{2,3}, Wong, A.², Mencarelli, A.², Lee, B.², Poidinger, M.², Ricciardi-Castagnoli, P.²

¹International Clinical Research Center (ICRC), Center for Translational Medicine (CTM), Brno, Czech Republic, ²Agency for Science, Technology and Research (A*STAR), Singapore Immunology Network (SIgN), Singapore, Singapore, ³University of Perugia, Department of Experimental Medicine, Perugia, Italy

Treatment of patients with immunosuppressive drugs as Cyclosporine A or Tacrolimus targets calcineurin-NFAT pathway. This treatment often results in different types of immune disorders and higher incidence of different types of infection. Interestingly, although these drugs have an anti-fungal potential, in the clinical setting, the therapeutic usage may also lead to systemic fungal infections as a side effect. The susceptibility to infections cannot be sufficiently explained only through the suppression of T cell function, recent discoveries highlight the importance of the calcineurin-NFAT in innate immune cells and especially in dendritic cells (DCs). Knowing that beta glucan is triggering NFAT translocation in DCs, here we address the question whether NFAT in DCs might have a specific control on innate response to fungal spores, in particular to *Aspergillus fumigatus* conidia. Conditional transgenic mice lacking calcineurin specifically in CD11c expressing cells were screened in order to evaluate calcineurin-NFAT dependent genes induced upon fungal infections. Knockout mice display higher susceptibility to *A. fumigatus* infection. Global expression profiling identified calcineurin-regulated processes in immune response to infection and revealed calcineurin dependent changes in expression of important anti-fungal defense proteins. This result suggests that immunosuppressive drugs based on calcineurin inhibition directly impair important immune defense functions of myeloid cells, this directly resolve in higher susceptibility in models of systemic aspergillosis and invasive pulmonary aspergillosis after allogeneic transplantation of calcineurin knockout bone marrow. These findings are important in context of severity of aspergillus infections in immunosuppressed patients.

Adoptive Cell Therapy

High-affinity PD-1/CD28 chimeric switch receptors improve the potency of CAR-T cells

Salter, A.^{1,2}, Cabanov, A.¹, Balakrishnan, A.¹, Srivastava, S.¹, Riddell, S.^{1,3}

¹Fred Hutchinson Cancer Research Center, Program in Immunology, Seattle, United States, ²University of Washington, Medical Scientist Training Program, Seattle, United States, ³University of Washington, Department of Medicine, Seattle, United States

The adoptive transfer of chimeric antigen receptor-modified T (CAR-T) cells targeting CD19 has produced robust antitumor responses in a subset of patients with B cell malignancies. However, CAR-T cell trials targeting solid epithelial cancers have been less successful. One major obstacle to CAR-T cell therapy in the solid tumor setting is PD-1-mediated immunosuppression. After antigen engagement, CAR-T cells rapidly upregulate PD-1 *in vitro* and *in vivo* and are functionally inhibited by PD-L1, which is commonly expressed on solid tumors. To endow CAR-T cells with an intrinsic ability to resist PD-1-mediated immunosuppression in the tumor microenvironment, we engineered chimeric switch receptors that link the PD-1 ectodomain to the CD28 signaling endodomain and convert negative PD-1 signals into positive costimulatory signals. Previous attempts to develop PD-1/CD28 receptors using the wild type PD-1 ectodomain failed to significantly improve the function of transgenic mouse and human T cells. As interactions between PD-1 and PD-L1/L2 are of low affinity, we hypothesized that these early receptors may have failed to outcompete endogenous PD-1 on the T cell surface or be recruited to the CAR-T cell synapse. We constructed high-affinity PD-1/CD28 chimeric switch receptors using mutated PD-1 ectodomains and show that the high-affinity, but not wild-type, PD-1/CD28 receptors significantly improve activation, cytokine production, and proliferation of ROR1-specific CAR-T cells *in vitro*. These receptors are now being tested in tumor xenograft models. Our results demonstrate that receptor affinity is critical for optimal PD-1/CD28 receptors and provide a strategy for improving CAR-T cell therapy of PD-L1⁺ tumors.

System analysis of the functional fate of tumor infiltrating lymphocytes

Hod Marco, M.¹, Pickman, Y.², Shen-Orr, S.², Besser, M.³, Reiter, Y.⁴

¹Technion, Biology, Haifa, Israel, ²Technion, Immunology, Haifa, Israel, ³Sheba Medical Center, Tel-Hashomer, Ella Institute for Melanoma Research and Treatment, Ramat Gan, Israel, ⁴Technion, Haifa, Israel

Tumor infiltrating lymphocytes (TIL) is a heterogeneous population with potential anti-tumor reactivity. TIL recognition and reactivity with autologous tumor is associated with increased secretion of IFN- γ . Despite the encouraging results obtained from the use of adoptive cell transfer, in stage IV metastatic melanoma patients, and despite extensive research efforts, little is known about the cellular interactions and the mechanisms

determine TIL reactivity. Using multiparametric flow cytometry, computational tools and IFN- γ release assays, we determined the influence of the expansion process on specific subpopulation frequencies, subpopulation signatures, and tumor reactivity of pre- and post-REP Young-TILs. Furthermore, using RNA-seq we defined gene expression signatures for reactive vs. non-reactive post-REP TILs. Analysis of pre-REP Young-TILs discovered distinctive subpopulation signatures which significantly correlate with reactivity and non-reactivity. Importantly, we revealed that pre-REP Young-TIL signatures share similarity, in subpopulation composition and correlation with reactivity, to signatures obtained in previous study for pre-REP Selected-TILs. Further analysis of Pre- vs. post-REP Young-TILs revealed that REP induces alternations in subpopulation composition and thus, alterations in TIL reactivity and TIL subpopulation signatures. Unexpectedly, we obtained that Pre- and post-REP Young-TILs possess similar signature for non-reactivity, but differ in the signatures for reactivity. Interestingly, we found common features of post-REP reactive Young-TILs which are determined in their pre-REP state. The gene expression analysis revealed distinct mechanisms involved in reactivity vs. non-reactivity of TILs. Our studies may shed light on the molecular mechanisms that control TIL reactivity, improve the clinical efficacy of TILs and assist with selecting TILs with potential reactivity.

Dendritic cells electroporated with mRNA encoding the Wilms' tumor protein (WT1) have major effects as adjuvant treatment in cancer patients

Berneman, Z.^{1,2}, Van de Velde, A.¹, Anguille, S.¹, Willemsen, Y.², Huizing, M.^{1,2}, Germonpré, P.², Saevels, K.¹, Cools, N.^{1,2}, Nijs, G.¹, Stein, B.¹, Van Driessche, A.¹, De Reu, H.², Schroyens, W.^{1,2}, Gadsisseur, A.^{1,2}, Verlinden, A.¹, Vermeulen, K.^{1,2}, Maes, M.-B.¹, Goossens, H.^{1,2}, Lammens, M.^{1,2}, Peeters, M.^{1,2}, Van Tendeloo, V.², Smits, E.^{1,2}

¹Antwerp University Hospital, Edegem, Belgium, ²University of Antwerp, Antwerp, Belgium

Previously we reported on vaccination with WT1 mRNA-electroporated dendritic cells (WT1/DC) as a post-remission treatment in 10 patients with acute myeloid leukemia (AML) (Van Tendeloo et al. PNAS 2010). In the present study, we expanded on the initial results and investigated WT1/DC as an adjuvant treatment in 60 high-risk cancer patients.

In AML, there was an antileukemic response in 13/30 patients; 5-yr relative survival was 46.7%, compared to 26.2% in the SEER data. Long-term clinical response was correlated with an increase in poly-epitope WT1-specific tetramer+ CD8 T-cells, long-term survival with WT1-specific IFN- γ + and/or TNF- α + CD8 T-cells from delayed type hypersensitivity sites.

In metastatic breast cancer (n=11), 5 patients had stable disease and 1 partial remission 2 months after starting WT1/DC; and 3 patients had stable disease after 6 months. Median overall survival (OS) was 43.8 months from the time of first documented metastasis, compared to a median OS of 21.7 months in the literature.

In glioblastoma multiforme (n=9), there were 4 patients with stable disease after 2 months; and 1 patient with partial

remission and 2 patients with stable disease after 6 months. Median OS was 30.5 months from time of diagnosis, compared to 14.7 months in the literature.

In non-resectable epithelial-type malignant pleural mesothelioma (n=10), 7 patients showed a stable disease. Median OS was 35.7 months post-start chemotherapy, compared to 22 months in the literature.

These results show that adjuvant WT1/DC-based immunotherapy provides a demonstrable clinical effect in part of these cancer patients and strongly suggest a survival benefit.

The CARPETS trial: GD2-specific CAR T cell therapy for advanced metastatic melanoma

Gargett, T.^{1,2}, Yu, W.², Dotti, G.³, Yvon, E.⁴, Christo, S.⁵, Hayball, J.⁵, Lewis, I.², Brenner, M.⁶, Brown, M.^{1,2}

¹Royal Adelaide Hospital, Translational Oncology Laboratory, Hanson Institute, Adelaide, Australia, ²University of South Australia, Centre for Cancer Biology, Adelaide, Australia, ³University of North Carolina, Department of Microbiology and Immunology and Lineberger Comprehensive Cancer Center, Chapel Hill, United States, ⁴University of Texas MD Anderson Cancer Center, Houston, United States, ⁵University of South Australia, Experimental Therapeutics Laboratory, Adelaide, Australia, ⁶Baylor College of Medicine, Houston, United States

Chimeric Antigen Receptor (CAR) T cells have shown great promise in the treatment of hematologic malignancies but more variable results in the treatment of solid tumors, and the persistence and expansion of CAR T cells within patients has been identified as a key correlate of anti-tumor efficacy. Lack of immunological 'space', functional exhaustion, suppression due to immune or tumour microenvironments and deletion have all been proposed as mechanisms that hamper CAR T-cell persistence. The world first CARPETS trial (ACTRN12613000198729) investigates third-generation CD3ζ/CD28/OX40 CAR T cells specific for the tumor-associated antigen GD2 in patients with advanced metastatic melanoma. This trial has given us the opportunity to study third-generation CAR signalling and factors effecting CAR T cell persistence. We have performed a detailed analysis of the events following CAR engagement and have identified potent activation followed by significant activation-induced cell death (AICD) *in vitro*, which is in part mediated by PD-1/PD-L1 interactions. PD-1 blockade enhanced both CAR T-cell cytokine production and survival, and promoted killing of PD-L1⁺ tumor lines. We also found PD-L1 expression on CAR T cells was sufficient to ligate PD-1 and cause AICD in the absence of PD-L1⁺ tumor cells. Finally, we have related our *in vitro* findings to CAR T-cell persistence and immune phenotype data from four patients enrolled in the ongoing CARPETS phase 1 clinical trial. Together, these results suggest that CAR T cell activation and deletion also occurs *in vivo* and that combination therapy approaches will be useful to augment CAR T-cell efficacy in patients.

Expanding the scope of TCR gene therapy for the treatment of AML and other cancers

Perret, R.¹, Valliant-Saunders, K.¹, Cao, J.¹, Greenberg, P.^{1,2}

¹Fred Hutchinson Cancer Research Center, Clinical Research Division, Seattle, United States, ²University of Washington, Seattle, United States

TCR gene therapy hastens the reproducible generation of tumor-specific T cells from patients, creating a promising avenue for treating hematological and solid tumors. Several hurdles remain to making this a broadly effective modality, including variable target antigen expression, risk of tumor antigenic escape, and current therapies limited almost exclusively to HLA-A0201⁺ patients. We previously characterized WT1 and cyclin A1 as favorable T cell immunotherapy targets, based on high expression in malignant versus normal cells and roles in oncogenesis, reducing likelihood of loss variants. We currently have a high-affinity HLA-A0201/WT1-specific TCR in Phase I trials for the treatment of AML and NSCLC, and are now focused on developing WT1- and cyclin A1-specific TCRs for ~7 common HLA types, aiming to cover >90% of patients. T cell lines were generated by stimulating donor cells with overlapping peptide libraries to identify new epitopes, and the highest affinity T-cell clones for each HLA/antigen combination identified by tetramer binding strength. TCRs were then cloned into lentiviral vectors for expression in CD8 T cells. We are currently selecting the best HLA-A0201/cyclin A1-specific TCR to advance to clinical development. We are also optimizing our epitope discovery protocol to improve selection of TCRs for other HLA alleles. Safety and efficacy of selected TCRs are rigorously tested using bioinformatics screens, *in vitro* assays, and humanized MHC-I mice. Our goal is to create a molecular toolbox of off-the-shelf TCR reagents to facilitate rapid treatment of patients, using T cell immunotherapies targeted to each particular tumor antigenic profile and HLA type.

847

Of mice and men: HSC transplantation fails to fully regenerate the immune system

Ghosn, E.¹, Waters, J.¹, Phillips, M.¹, Yamamoto, R.^{2,3}, Long, B.⁴, Yang, Y.¹, Gerstein, R.⁵, Stoddart, C.⁴, Nakauchi, H.^{2,3}, Herzenberg, L.¹

¹Stanford University, Genetics and Immunology Program, Stanford, United States, ²Stanford University, Institute for Stem Cell Biology and Regenerative Medicine, Stanford, United States, ³University of Tokyo, Institute of Medical Science, Center for Stem Cell Biology and Regenerative Medicine, Division of Stem Cell Therapy, Tokyo, Japan, ⁴University of California, Department of Medicine, Division of Experimental Medicine, San Francisco, United States, ⁵University of Massachusetts Medical School, Department of Microbiology and Physiological Systems, Worcester, United States

The accepted paradigm has been that a single hematopoietic stem cell (HSC) can regenerate all components of the immune system, including B and T lymphocytes, NK cells, myeloid cells, granulocytes, erythrocytes, and platelets. However, our *in vivo* single-cell transplantation study shows that long-term (LT)-HSC, sorted from adult bone marrow, selectively fails to regenerate

B-1a lymphocytes, a subset of tissue B-cells required for protection against Pneumonia, Influenza, and other infections. Here, continuing with this study, we show that LT-HSCs transplants harvested from mouse fetal liver similarly fail to regenerate B-1a cells in otherwise fully reconstituted host (i.e., fetal liver LT-HSCs fully regenerate follicular B and T lymphocytes, NK cells, myeloid cells, granulocytes, erythrocytes, but do not detectably regenerate B-1a lymphocytes). Thus, our studies establish B-1a as a separate B-cell lineage that develops independently of LT-HSCs and overtly challenge the current paradigm that LT-HSCs regenerate all components of the immune system.

Important from a clinical standpoint, we also show that, in humanized mice, human fetal liver reconstitutes tissue B cells that are phenotypically similar to murine B-1a, raising the question of whether human HSC transplantation, widely used in human regenerative therapies to restore immunity in irradiated or otherwise immune-compromised patients, is sufficient to regenerate human tissue B-1a.

396

Optimizing adoptive cell therapy by genetic engineering of T cells for improved homing to tumor site

Idorn, M.¹, Olofsson, G.H.¹, Olsen, M.¹, Larsen, H.L.², van der Berg, J.¹, Met, Ö.¹, Thor Straten, P.^{1,3}

¹Center for Cancer Immune Therapy, Herlev University Hospital, Herlev, Denmark, ²The Danish Stem Cell Center (DanStem), University of Copenhagen, Copenhagen, Denmark, ³University of Copenhagen, Department of Immunology and Microbiology, Copenhagen, Denmark

Adoptive cell therapy (ACT) using *in vitro* expanded tumor infiltrating T lymphocytes (TILs) from biopsy material represents a highly promising treatment of disseminated cancer. A crucial prerequisite for successful ACT is sufficient recruitment of transferred lymphocytes to the tumor site; however, despite transfer of billions of lymphocytes, T-cell infiltration into the tumor post ACT is limited. By PCR and ELISA analyses we found that a majority of malignant melanoma (MM) cell lines expressed chemokines CXCL8/IL-8, CXCL12/SDF-1 and CCL2. Taking advantage of lentiviral transduction, successful transduction of TILs and peripheral blood T cells significantly increased receptor expression of the corresponding chemokine receptors CXCR2, CXCR4 and CCR2. All three chemokine receptors are functional *in vitro* and show ligand specific transwell migration of engineered T cells as well as increased migration towards MM conditioned medium. *In vivo* homing was assessed in a xenograft NOG mouse model. Mice with subcutaneous human melanoma were treated with ACT of tumor specific T cells transduced with either CXCR2 or GFP. Transducing T cells with CXCR2 increased tumor infiltration. In comparison mock transfected T cells appeared to be allocated to other organ-compartments. In conclusion, our CXCR2, CXCR4 and CCR2 transduced T cells are functional *in vitro*, and transduction with CXCR2 improve *in vivo* homing of T cells to tumor site, setting the stage for mixing and matching chemokine-receptor expression to tumor microenvironments. Longitudinal studies assessing cell trafficking and tumor control using *in vivo* imaging are currently ongoing, and results will be presented at the meeting.

Vdelta1 T cells expressing natural cytotoxicity receptors for adoptive cell therapy of leukemia

Silva-Santos, B.¹, Correia, D.V.¹, Almeida, A.², Anjos, D.R.², Silva, M.G.d.³

¹Instituto de Medicina Molecular, Lisbon, Portugal, ²Lymphact SA, Coimbra, Portugal, ³Instituto Português de Oncologia de Lisboa, Lisbon, Portugal

Adoptive transfer of chimeric antigen receptor (CAR)-expressing T-cells constitutes a promising immunotherapy for leukemia. However, antigens targeted by CARs are often expressed by healthy leukocytes or progenitors, thus leading to significant on-target effects. Here we characterize a cellular immunotherapy product composed of genetically unmanipulated gamma-delta T-cells that selectively recognizes malignant (but not normal) leukocytes *in vitro* and *in vivo*. This subset expresses the Vdelta1 TCR and a broad repertoire of natural killer receptors, including NKG2D and the natural cytotoxicity receptors (NCRs), NKp30 and NKp44. Critically, NCR expression is absent in freshly-isolated gamma-delta T-cells but is selectively induced on Vdelta1 T-cells by a cocktail of cytokines and TCR agonists. NCR expression endows these lymphocytes, termed Delta One T (DOT-) cells[®], with enhanced cytotoxicity against lymphoid and myeloid leukemia cells *in vitro*. Importantly, DOT-cells[®] combined TCR and NCR mechanisms to recognize transformation-induced ligands on leukemic (but not healthy) cells. To test DOT-cells[®] *in vivo*, we employed xenograft models of human chronic lymphocytic leukemia and acute myeloid leukemia in NOD-SCID *gc*^{-/-} (NSG) mice. Upon two DOT-cell[®] transfers, we observed a significant reduction in tumor load compared to control animals. DOT-Cells[®] showed an activated and proliferative profile and produced TNF-alpha and IFN-gamma but no interleukins (IL)-17 or IL-10. Most strikingly, DOT-Cells[®] were capable of preventing tumor dissemination to secondary organs and prolonged mouse survival, with no evidence of treatment-associated toxicity (as inferred from blood biochemistry and histology). These data provide the seminal proof-of-concept for pioneering the application of DOT-Cells[®] in leukemia clinical trials.

Immunotherapy by using rejuvenated antigen-specific T cells

Nishimura, T.¹, Ando, M.², Nakauchi, H.^{1,2}

¹Stanford University School of Medicine, Institute for Stem Cell Biology and Regenerative Medicine, Stanford, United States, ²University of Tokyo, Institute of Medical Science, Tokyo, Japan

Adoptive immunotherapy is a promising approach to fight cancers or chronic viral infections with cytotoxic T cells expressing antigen-specific TCRs. However, its effectiveness is diminished by the exhaustion of antigen-specific T cells during *ex vivo* expansion.

The discovery of induced pluripotent stem cells (iPSCs) has created promising new avenues for therapies in regenerative medicine. Recently, we developed a novel system in which a single antigen-specific T cell can be reprogrammed into an iPSC, expanded and redifferentiated back to the original cell type. Redifferentiated CD8⁺ T cells express the same TCR and exert cytotoxic T cell functions in the same antigen-specific manner

as the original T cell. Rejuvenation via iPSC-reprogramming is highlighted in the redifferentiated CD8⁺ T cells through their characteristic longer telomeres, higher proliferative capacity and younger memory phenotype compared to the original T cells. However, the actual *in vivo* efficacy of rejuvenated T cells has not been tested formally. Here we demonstrate that rejuvenated T cells are effective against EBV-mediated tumors *in vivo* using the tumor-burden mouse model. This unique technique was deployed *in vivo* with inducible Caspase-9 (iC9), a safeguard system which evokes apoptosis via the caspase signaling cascade upon administration of a specific chemical compound. Furthermore, now it becomes possible to obtain abundant CD8αβ⁺ type, CD8αα⁺ type, and CD4⁺ T cells from iPSCs. Although several biological and technical challenges still lie ahead, the application of iPSC-mediated T cell rejuvenation technology could represent a breakthrough in the field of adoptive immunotherapy.

¹European Molecular Biology Laboratory, European Bioinformatics Institute, Hinxton, United Kingdom, ²Wellcome Trust Sanger Institute, Hinxton, United Kingdom, ³QIMR Berghofer Medical Research Institute, Herston, Australia, ⁴Peter Doherty Institute, University of Melbourne, Melbourne, Australia

Differentiation of naïve CD4⁺ T cells into functionally distinct T helper subsets is crucial for the orchestration of immune responses. Due to multiple levels of heterogeneity and overlap in differentiating

T cell populations, this process has remained a challenge for systematic dissection *in vivo*. Single-cell RNA-sequencing has provided a powerful tool for identifying such transitional cellular states and elucidating their developmental relationships. Using an antigen-specific transgenic TCR mouse strain, we have dissected the CD4⁺ T cell response to blood-stage *Plasmodium chabaudi* infection, during which both Th1 and Tfh populations emerge and contribute to the successful resolution of the infection. By using a novel computational approach based on overlapping mixtures of Gaussian processes, we have reconstructed the developmental trajectories of Th1 and Tfh cell populations at single-cell resolution in an unbiased way. On a genomic scale, these cell fates emerged from a common, highly proliferative and metabolically active precursor. Moreover, by tracking clonality from T cell receptor sequences, we infer that sibling cells derived from the same naïve CD4⁺ T cell can concurrently populate both Th1 and Tfh subsets. We further found that precursor T cells were coached towards a Th1 but not a Tfh fate by monocytes. Importantly, our integrated genomic and computational methodology is applicable for analysis of any cellular system characterized by differentiation towards multiple fates.

The features that define autoreactive T_H cell pathogenicity remain obscure. We have previously shown that T_H cells require the basic helix-loop-helix transcription factor Bhlhe40 to mediate experimental autoimmune encephalomyelitis (EAE), a mouse model of multiple sclerosis. Bhlhe40 regulates the production of specific cytokines by T_H cells, such that *in vitro*-polarized Bhlhe40-deficient T_H1 and T_H17 cells show reduced production of GM-CSF and increased production of IL-10. Here, using novel *Bhlhe40*^{GFP} reporter mice and analyzing both polyclonal and TCR transgenic T_H cells, we found that Bhlhe40 expression by activated T_H cells was heterogeneous after EAE induction. Bhlhe40-expressing T_H cells displayed marked production of IFN-γ, IL-17A, and GM-CSF, while exhibiting reduced expression of both IL-10 and the regulatory T cell transcription factor Foxp3. In adoptive transfer EAE models, Bhlhe40-deficient T_H1 and T_H17 cells were both nonencephalitogenic. Pertussis toxin (PTX), a classical adjuvant for actively induced EAE, promoted IL-1β production by myeloid cells in the draining lymph node and served as a strong stimulus for Bhlhe40 expression in T_H cells. Furthermore, PTX adjuvant activity was Bhlhe40 dependent. IL-1β induced Bhlhe40 expression in polarized T_H17 cells, and Bhlhe40-expressing cells exhibited an encephalitogenic transcriptional signature. *In vivo*, IL-1R signaling was required for full Bhlhe40 expression by T_H cells after immunization. Overall, we demonstrate that Bhlhe40 expression identifies encephalitogenic T_H cells and we define a PTX-IL-1-Bhlhe40 pathway active in EAE.

CD4⁺ T cells undergo sequential phases of differentiation and maturation to become mature *bona fide* germinal center (GC) T follicular helper (Tfh) cells, which support the GC reaction and promote the production of high-affinity antibodies. ICOS plays a critical role in Tfh cell development and the only protein so far known to interact with the cytoplasmic tail of ICOS is PI3K. Indeed, PI3K signaling was found to play an important role in Tfh cell differentiation and functions. However, independent studies demonstrated that several events associated with Tfh differentiation are independent of ICOS-mediated PI3K signaling, implying additional, undefined ICOS signaling pathways. Here, we have unraveled a novel signaling pathway emanating from ICOS, which is critical for the full maturation of GC-residing Tfh cells. Specifically, we have:

- i) identified a previously unknown, evolutionarily conserved membrane proximal ICOS motif, IProx, that is required for Tfh development and function;
- ii) identified TBK1 as an activation-induced interacting partner of this motif;
- iii) demonstrated that the recruitment of TBK1 to ICOS is required for the development of fully mature GC Tfh cells while being dispensable for the differentiation of early, nascent Tfh cells; and
- iv) identified the canonical TBK1-binding consensus sequence that is shared between the IProx motif and TRAF2/3 molecules. Therefore, our findings reveal a novel ICOS-TBK1 signaling pathway that specifies Tfh cell commitment to GC reactions. Strategic manipulations of these ICOS-dependent pathways could lead to better vaccine design and treatment of autoimmune diseases.

Peroxisome proliferator activated receptor gamma promotes type 2 immune responses

Coquet, J.

Karolinska, MTC, Stockholm, Sweden

T helper (Th) 2 cells are central to the development of asthma and for immunity to nematode infection. Fully differentiated Th2 cells are marked by their expression of the IL-33 receptor (IL-33R), which promptly induces IL-5 and IL-13 production when ligated. In this study, we report that Th2 cells expressed high levels of the nuclear receptor peroxisome proliferator activated receptor gamma (PPAR-gamma) in models of asthma and following infection with *Heligmosomoides polygyrus*. Mice lacking PPAR-gamma in T cells failed to effectively differentiate into IL-5- and IL-13-secreting cells and as such, did not develop Th2 cell-associated pathologies including goblet cell metaplasia and eosinophilia in response to allergen challenge. Nor did these mice mount protective immune responses to nematode infection. Furthermore, in visceral adipose tissue where PPAR-gamma is important for Treg cell maintenance, we demonstrate that PPAR-gamma also promoted resident Th2 cells and type 2 innate lymphoid cells. Mechanistically, activation of PPAR-gamma was able to induce the expression of surface ST2 *in vivo* and *in vitro* on Th2 cells and ILC2. This study conclusively demonstrates that PPAR-gamma promotes type 2 immune responses and suggests that antagonists of this factor may prevent unwanted allergic immune responses.

Follicular helper T cells (T_{FH}) are a CD4⁺T helper subset specialized in helping B cells. T_{FH} cells are critical for humoral immunity, including the generation of long-lived and high affinity plasma cells and memory B cells. Alteration of T_{FH}-specific genes leads to defects in germinal centers (GCs) formation, with consequent autoimmune or immunodeficiency disorders. The molecular mechanisms underlying human T_{FH} cells differentiation are poorly understood. MicroRNAs (miRNAs) are highly conserved non-coding single-stranded small RNA molecules that control gene expression post-transcriptionally by binding the 3' untranslated region of target mRNA. To investigate the role of miRNAs in T_{FH} cells biology we performed RT-qPCR and deep sequencing analysis on T_{FH} and Naive CD4⁺ T cells sorted from secondary lymphoid organs (SLO). We defined a T_{FH}-specific signature of 17 miRNAs that are up or down-regulated in T_{FH} cells compared to other CD4⁺ effector T cells. We showed that miR-31-5p (miR-31) displayed the strongest down-modulation in T_{FH} cells, and found that miR-31 gene promoter is bound by Bcl6, the master transcription factor of T_{FH}, suggesting that that Bcl6 can repress miR-31 expression by binding to regulatory regions in its locus. We combined target prediction with gene-expression analysis and identified CD40L, BTLA and SAP (i.e., key molecules in T_{FH} biology) as predicted miR-31 targets. Modulation of miR-31 expression in T_{FH} cells proved that miR-31 directly regulates the expression of these genes and that increased levels of miR-31 impair B-helper activity of T_{FH} cells suggesting that miR-31 contribute to the modulation of their functional activity.

A dominant function of transcription factor Foxo1 in the development of Th9 and IL-9-producing T cells

Malik, S., Sadhu, S., Awasthi, A.

Translational Health Science and Technology Institute, Faridabad, India

Interleukin 9 (IL-9), a pleiotropic cytokine of common γ -chain cytokine receptor family, plays a crucial role in allergic inflammation, autoimmunity and immunity to extracellular pathogens. Recent identification of anti-tumor function of IL-9 makes it an attractive target for anti-tumor therapy. Although Th2, Th17 cells and Foxp3⁺ Treg cells were shown to produce IL-9, more specialized IL-9-producing Th9 cells were identified as a distinct subset of Th cells that are proinflammatory *in vivo*. The master transcription factors that regulates IL-9 production in Th2, Th9 and Th17 cells has not been identified, although IRF-4, PU.1, Batf and IRF1 were shown to be essential for IL-9 induction in Th9 cells. Here we have identified Foxo1, a forkhead family transcription factor, predominantly required for the induction

of IL-9 in Th9 and Th17 cells. We further identified AKT, an upstream kinase that regulates IL-9 induction in Th1, Th9 and Th17 cells via Foxo1. In addition, c-Jun N-terminal kinase (JNK), a MAPK (Mitogen Activated Protein kinase) enhanced IL-9 induction in Th9 cells via Foxo1. Chromatin Immunoprecipitation identified a direct physical association of Foxo1 with IL-9 and IRF4 promoters. In addition, Foxo1 transactivates both IL-9 and IRF4 genes in Th9 and Tc9 cells, and together with IRF-4 synergistically enhanced IL-9 induction. Furthermore, loss of Foxo1 suppressed IL-9 production in Th9 and Th17 cells. In Th9 mediated asthma model, Foxo1 inhibition substantially ameliorated allergic inflammation and IL-9 induction. Our findings thus identify Foxo1 is the key transcription factor in controlling the development of Th9 and IL-9-producing Th cells.

Tumor suppressor death-associated protein kinase inhibits Th17 by targeting cytoplasmic HIF-1 α for degradation

Chou, T.-F.^{1,2}, Chuang, Y.-T.³, Hsieh, W.-C.¹, Chang, P.-Y.¹, Hsu, T.-S.¹, Miaw, S.-C.⁴, Chen, R.-H.⁵, Kimchi, A.⁶, Lai, M.-Z.¹

¹Academia Sinica, Institute of Molecular Biology, Taipei, Taiwan, Republic of China, ²National Defense Medical College, Institute of Life Sciences, Taipei, Taiwan, Republic of China, ³National Taiwan University Hospital, Department of Medical Research, Taipei, Taiwan, Republic of China, ⁴National Taiwan University, Institute of Immunology, Taipei, Taiwan, Republic of China, ⁵Academia Sinica, Institute of Biological Chemistry, Taipei, Taiwan, Republic of China, ⁶Weizmann Institute of Science, Department of Molecular Genetics, Rehovot, Israel

Death-associated protein kinase (DAPK) is known for its tumor suppressor function, while hypoxia-inducible factor 1 α (HIF-1 α) plays a prominent role in tumorigenesis. Here we report an antagonism between DAPK and HIF-1 α in T helper 17 (Th17) differentiation. HIF-1 α is known to promote Th17 development. We show that DAPK inhibits Th17 and prevents Th17-mediated autoimmune diseases. We identified that DAPK specifically downregulates HIF-1 α in a novel process. In contrast to the predominant nuclear localization of HIF-1 α in many cancer cells, HIF-1 α is located in both cytosol and nucleus in T cells, allowing a cytosolic interaction between DAPK and HIF-1 α . DAPK also binds prolyl hydroxylase domain protein 2 (PHD2) and increases HIF-1 α -PHD2 association. DAPK thereby promotes the proline hydroxylation and proteasome degradation of HIF-1 α . Consequently, DAPK-deficiency led to excess HIF-1 α accumulation, enhanced IL-17 expression, and exacerbated experimental autoimmune encephalomyelitis (EAE). Transgenic DAPK expression suppresses Th17 differentiation and prevents EAE generation. Our results demonstrate a new process involving DAPK-mediated degradation of cytoplasmic HIF-1 α , and suggest that a potential therapy for Th17-associated inflammatory diseases by targeting to DAPK.

Early growth response gene (Egr) 2 and 3 control Th1 differentiation by directly inhibiting T-bet

Miao, T.¹, Li, S.², Symonds, A.¹, Wang, P.¹

¹BICMS, Queen Mary University of London, Immunology, London, United Kingdom, ²Brunel University, Immunology, London, United Kingdom

Egr2 and 3 are inducible transcription factors in T cells that are essential to maintain self-tolerance. In the absence of Egr2 and 3, effector phenotype T cells are hyper-inflammatory resulting in autoimmune diseases. We have now discovered that Egr2 and 3 control Th1 differentiation. Egr2 and 3 deficiency in T cells not only results in excessive Th1 differentiation in unpolarized or Th1 polarized conditions, but a substantial fraction of Egr2 and 3 deficient CD4 cells produced IFN γ under Th2 and Th17 conditions. Significantly, the IFN γ producing cells in Th2 and Th17 conditions did not co-produce IL4 and IL17, indicating Egr2 and 3 inhibit Th1 differentiation in Th2 and Th17 conditions rather than re-directing Th2 or Th17 programmes to Th1. Egr2 and 3 are co-induced with T-bet in Th2 and Th17 conditions. However, in Th1 conditions, T-bet positive cells express low levels of Egr2 and 3. We found that Egr2 and 3 physically interact with T-bet in CD4 T cells, which potently inhibits T-bet mediated IFN γ expression and Th1 differentiation. Egr2 and 3 are induced by antigen stimulation in naive T cells, but this induction is inhibited by Th1 cytokines such as IFN γ and IL12, but not by Th2 and Th17 cytokines. The inhibition of Egr2 and 3 expression by Th1 cytokines is essential for efficient Th1 differentiation. Our findings reveal a novel mechanism of Egr2 and 3 function in controlling Th differentiation.

PU.1 expressing Th9 cells promote colitis-associated cancer (CAC)

Gerlach, K.¹, Wirtz, S.¹, McKenzie, A.², Neurath, M.F.¹, Weigmann, B.¹

¹Medical Clinic 1, Erlangen, Germany, ²MRC Laboratory of Molecular Biology, Cambridge, United Kingdom

Inflammatory bowel disease (IBD) is linked to an increased risk of developing colitis-associated colorectal cancer (CAC). In IBD especially T cells are critical mediators playing important roles in colorectal cancer. Recently, we have identified Th9 cells as IL-9 producing cells inducing colitis. The pro inflammatory cytokine IL-9 is important in inflammatory disease, but the involvement of IL-9 in CAC is not revealed yet.

IL-9 KO mice were treated with AOM/DSS to induce colon cancer. Miniendoscopic analysis was done to monitor number and size of tumors. For restoration of the IL-9 deficient phenotype an IL-9 expressing minicircle DNA vector was injected into IL-9 deficient mice and the model of AOM/DSS has been investigated. Colonic tumors have been isolated, histological sections were taken out and immunofluorescent analysis was done.

IL-9 deficiency led to significant less inflammation consequently followed with a significant reduction of tumors in the experimental model of AOM/DSS. Furthermore, we explored the effect of IL-9 on tumor growth by overexpression of IL-9 via mini-circle DNA and AOM/DSS treatment, which led to the

development of tumors when IL-9 is absent. Additionally, in cryosections of tumorigenic colon tissue more PU.1+ T-cells were found, pointing out the important relevance for Th9 cells in colon cancer.

Our findings uncover a crucial role of IL-9 in the development of colitis-associated neoplasias as IL-9 led to tumor growth in the model of CAC. The presence of PU.1+ CD4+ -expressing cells in tumorigenic tissue suggests that these cells belong to the recently described Th9 T cell subset.

The anti-viral CD8⁺ T-cell response is drawn from the naïve T-cell repertoire. Selective recruitment and expansion from the available naïve T cell set can significantly shape the characteristics of the responding immune CD8⁺ T cell population. During influenza A virus (IAV) infection, for example, the CD8⁺ T-cell response to an MHC class I H2-D^b-restricted nucleoprotein epitope (NP₃₆₆) is characterized by the preferential expansion of cells that express the T cell receptor beta chain variable region gene (TRBV) 13-1 from the naïve repertoire. In contrast, the TRBV17⁺ set, despite comprising around 25% of all naïve H2-D^bNP₃₆₆-specific cells, is almost completely avoided in the immune response (< 1%). To define the structural basis of this suboptimal recruitment, we examined the docking mode of two TRBV17⁺ TCRs and, strikingly, found that they bound H2-D^bNP₃₆₆ with a 180° reversed polarity in comparison to the canonical TCR-peptide+MHCI (pMHCI) docking mode. The TRBV17⁺ TCR beta chains dominated the interaction, mediating contacts at the C-terminal end of the peptide-binding cleft. Despite this reversed docking mode, the TRBV17⁺ TCRs showed exquisite specificity but a moderate affinity for H-2D^bNP₃₆₆ corresponding to a limited profile of cytokine production after IAV infection. Thus, naturally occurring T-cells in the naïve pool express TCRs with reversed polarity pMHC-I docking modes that confer antigen specificity and functionality, but limit their ability to contribute to the immune response. These data challenge the concept of a germline bias for TCR recognition of pMHC.

Links between specificity and function in CD4 T cell immunity to influenza virus

Sant, A.¹, Treanor, J.², Nayak, J.³, Richards, K.¹, Knowlden, Z.¹, Dipiazza, A.¹

¹University of Rochester Medical Center, Microbiology and Immunology, Rochester, United States, ²University of Rochester Medical Center, Infectious Diseases, Rochester, United States, ³University of Rochester Medical Center, Pediatrics, Rochester, United States

Memory CD4 T cells contribute a multiplicity of functions and at discreet sites in vivo to protective immunity to influenza virus. Our studies have revealed that in both humans and in animal models of infection and vaccination, the specificity of CD4 T cells is exceptionally broad and includes CD4 T cells specific for virtually all viral proteins, including the most genetically conserved proteins such as NP and M1. However, we have found that some functions of CD4 T cells are selectively conveyed by cells of limited specificity. For example, HA- but not NP-specific CD4 T cells can promote neutralizing antibody responses to influenza and are selectively enriched in expression of CXCR5 in human circulation. This restriction in function is likely in part responsible for the relatively poor neutralizing antibody responses to avian and potentially pandemic influenza viruses and vaccines. Other functions, such as cytotoxicity, are selectively conveyed by CD4 T cells specific for internal virion proteins. Thus, although the circulating memory CD4 repertoire specific for influenza virus is typically abundant and diverse, these complexities in functional potential pose a formidable obstacle to predicting protective immune response to potentially pandemic strains of influenza and in devising strategies to potentiate these responses. Our results suggest that more precise efforts to identify and enumerate both the positive and negative contributors within the CD4 T cell compartment will aid significantly in the achievement of these goals.

A systems approach to understanding the role of MAVS in Ebola pathogenesis in murine models of infection

Dutta, M.¹, Robertson, S.², Okumura, A.², Rasmussen, A.¹, Chang, J.¹, Weiss, J.M.¹, Katze, M.G.¹, Best, S.²

¹University of Washington, Department of Microbiology, Seattle, United States, ²Rocky Mountain Laboratories, NIAID, NIH, Hamilton, United States

Ebola virus causes lethal hemorrhagic fever in humans and is a threat to biosecurity and public health. Wild-type Ebola virus (WT-EBOV) is not lethal in immunocompetent mice, although virus adaptation to mice is associated with mutations that facilitate replication and increase virulence. In the mouse model, type I interferon is required for resistance to WT-EBOV, but little is known regarding the signaling pathways that coordinate this response in vivo. EBOV infection is detected by RIG-I-like receptors (RLR) that signal through the adapter molecule, mitochondrial antiviral signaling protein (MAVS) to induce innate immunity. To elucidate how MAVS signaling determines cellular

responses to EBOV, we infected MAVS knockout mice (MAVS KO) with WT- or mouse adapted (MA)- EBOV. Compared to C57BL/6 mice, MAVS KO mice showed increased susceptibility to MA-EBOV and succumbed to infection by 5-6 days post-infection (dpi). Analysis of virus replication demonstrated that WT-EBOV replicated in spleen and liver to higher titers than MA-EBOV at 3 dpi in MAVS KO mice. Despite this, replication of WT-EBOV was controlled by 5 dpi whereas MA-EBOV replication increased. Differential expression analysis demonstrated significant differences in host responses when comparing WT- and MA-EBOV, or MAVS KO and C57BL/6 mice. Using a deconvolution approach with digital cell quantification, we demonstrated that pDCs drive MAVS-independent resistance to WT-EBOV in C57BL/6 mice, whereas macrophages have a dominant role in MAVS-dependent resistance to EBOV. These findings suggest that cell-specific responses determine pathogenic outcome. Therapeutic targeting of these cells with RLR agonists may improve clinical outcomes in EBOV-infected humans.

Deep profiling of the murine myelopoietic system: signaling and cell cycle responses to neurotropic viral infection profiled by flow and mass cytometry (CyTOF)

Ashhurst, T.^{1,2}, Niewold, P.¹, Cox, D.¹, Smith, A.^{2,3}, King, N.^{1,2,3}

¹The University of Sydney, Pathology, Sydney, Australia, ²The University of Sydney and the Centenary Institute, The Ramaciotti Facility for Human Systems Biology (RFHSB), Sydney, Australia, ³The University of Sydney and the Centenary Institute, Sydney Cytometry Facility, Sydney, Australia

Viral infection of the central nervous system (CNS) results in a rapid influx of bone marrow (BM)-derived monocytes/macrophages, that ultimately induce fatal pathology in the mouse. Whilst these cells are derived from the BM, little is known about the kinetic and migratory events that mobilise BM monocytes and their progenitors in response to CNS infection. In this study we conducted comprehensive mapping of the murine haemopoietic system in the BM using high-dimensional single cell flow and mass cytometry (CyTOF). Initially, we used this approach to refine the identification of myeloid developmental intermediates involved in monopoiesis and granulopoiesis, during steady state and inflammation. Additionally we examined the expression of the transcription factor IRF8 across the haematopoietic system and its role in instructing myeloid developmental trajectories. During viral encephalitis, we found a reorganisation of cellular outputs to favour monocyte production, resulting in activation and expansion of monocytes and monocyte progenitors, with increased proliferation of mature and progenitor populations. In addition, we observed compensatory downregulation of B-cell lymphopoiesis, and modification of granulopoiesis in the BM, favouring monocyte expansion. The upregulation of the interferon (IFN)-inducible marker SCA-1 on specific lineages suggested a role for IFN signalling, and implicates IFN-gamma (IFN-g) producing NK and T-cells in the BM in this process. As such, antibody blockade of IFN-g resulted in a reduction of monocyte proliferation, associated with improved clinical outcomes. In this study we have used high-dimensional cytometry approaches, and have

characterized modifications to the haematopoietic lineage during viral encephalitis that favour production of pathogenic monocytes.

733

Type I interferon preferentially induces GITRL on inflammatory APC compared to classical DC to establish early viral control during chronic LCMV infection

Chang, Y.-H., Clouthier, D.L., Zhou, A., Abdul-Sater, A., Watts, T.H.
University of Toronto, Department of Immunology, Toronto, Canada

Disease outcome in chronic viral infections correlates with early viral set-point, established by the initial T cell response. Previous studies showed that GITR, an NFκB-activating TNFR family member, sustains CD4 T cell accumulation and help for CD8 T cells early during chronic LCMV infection. While the endogenous effect of GITR on CD8 T cells is largely attributed to enhanced early CD4 T cell help, CD8 T cells are directly responsive to exogenous GITR agonist. How endogenous GITR co-stimulation selectively impacts CD4 T cells early during LCMV infection, however, remains elusive. We hypothesize that CD4 and CD8 T cells interact with distinct APC and that the availability of GITRL underscores the regulation of GITR co-stimulation. Here we identified inflammatory monocyte-derived DC and macrophages (infMΦ) as the dominant GITRL-expressing APC with almost 5 times higher GITRL compared to classical DC during LCMV infection. A preliminary experiment showed that deleting exon 2 of GITRL with Lys-M-Cre recapitulates the marked reduction in Th1 response against LCMV observed in the global GITR knockout. During LCMV infection, GITRL expression peaks just after type I IFN expression. Consistently, type I IFN is a potent inducer of GITRL *ex vivo* and blockade of the type I IFN receptor abrogates up-regulation of GITRL on macrophages during LCMV infection. Together, the current study suggests a critical role for infMΦ in GITR-dependent CD4 T cell immunity to LCMV and identifies type I IFN as a key regulator of GITRL on infMΦ *in vivo*. Supported by the Canadian Institutes of Health Research.

NADPH Oxidase 1 (NOX1) is associated with altered host survival and T cell phenotypes after influenza A virus infection in mice

Hofstetter, A.¹, De La Cruz, J.¹, Cao, W.¹, Patel, J.¹, Belser, J.¹, Liepkalns, J.¹, Amoah, S.¹, McCoy, J.², Cheng, G.², Diebold, B.², Shieh, W.-J.³, Zaki, S.³, Katz, J.¹, Sambhara, S.¹, Lambeth, J.D.², Gangappa, S.¹

¹Centers for Disease Control and Prevention, Influenza Division, Atlanta, United States, ²Emory University, Pathology and Laboratory Medicine, Atlanta, United States, ³Centers for Disease Control and Prevention, Infectious Disease Pathology Branch, Atlanta, United States

The role of the reactive oxygen species-producing NADPH-oxidase (NOX) family of enzymes in the pathology of influenza A virus infection remains enigmatic. Previous reports implicated NOX2 in influenza A virus-induced inflammation. In contrast,

NOX1 was reported to decrease inflammation in mice within 7 days post influenza A virus infection. However, the effect of NOX1 on lethality and adaptive immunity after influenza A virus challenge has not been explored. Here we report improved survival and decreased morbidity in NOX1-deficient mice compared with controls after challenge with A/PR/8/34 influenza A virus. While changes in lung inflammation were not obvious between NOX1-deficient and control mice, we observed alterations in the T cell response to influenza A virus by day 15 post-infection, including increased interleukin-7 receptor-expressing virus-specific CD8⁺ T cells in lungs and draining lymph nodes of NOX1-deficient mice, and increased cytokine-producing T cells in lungs and spleen. Furthermore, a greater percentage of conventional and interstitial dendritic cells from NOX1-deficient draining lymph nodes expressed the co-stimulatory ligand CD40 within 6 days post-infection. Results indicate that NOX1 modulates the innate and adaptive cellular immune response to influenza virus infection, while also playing a role in host survival. Results suggest that NOX1 inhibitors may be beneficial as adjunct therapeutics during acute influenza infection.

Towards identification of immune and genetic correlates of severe influenza disease in Indigenous Australians

Clemens, E.B.¹, Grant, E.J.², Wang, Z.¹, Gras, S.^{3,4}, Mifsud, N.³, Illing, P.³, Tipping, P.⁵, Purcell, A.W.³, Rossjohn, J.^{2,3,4}, Miller, A.⁶, Tong, S.Y.C.⁵, Kedzierska, K.¹

¹The University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ²Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom, ³Infection and Immunity Program, Monash Biomedicine Discovery Institute and Department of Biochemistry and Molecular Biology, Monash University, Clayton, Australia, ⁴Australian Research Council Centre of Excellence for Advanced Molecular Imaging, Monash University, Clayton, Australia, ⁵Menzies School of Health Research, Casuarina, Australia, ⁶Indigenous Research Network, Griffith University, Nathan, Australia

We have investigated immune and genetic factors that could predispose Indigenous Australians to severe influenza disease. We surveyed HLA allelic frequencies in a cohort of Indigenous Australians (n=82), which confirmed previous studies showing predominant usage of HLA-A*02:01, 11:01, 24:02, 34:01 and HLA-B*13:01, 15:21, 40:01/02, 56:01/02. We also identified two novel HLA alleles (HLA-A*02:new and HLA-B*56:new), with homology modelling suggesting that variations within HLA-A*02:new will affect peptide binding. There is a paucity of known influenza epitopes for the majority of these HLAs, with the exception of a universal HLA-A*02:01-M1₅₈ epitope and proposed epitopes presented by HLA-A*11:01/HLA-A*24:02. To dissect universal CD8⁺ T-cell responses, we analysed the magnitude, function and T-cell receptor (TCR) clonality of HLA-A*02:01-M1₅₈⁺CD8⁺ T-cells. We found comparable IFN- γ , TNF and CD107a and TCR α characteristics in Indigenous and non-Indigenous Australians, suggesting that the ~15% of Indigenous people that express HLA-A*02:01 have universal influenza-

specific CD8⁺ T-cell immunity. Furthermore, the frequency of a polymorphic host risk factor, IFITM3-C/C, was comparable between Indigenous Australians and Europeans, suggesting that expression of this allele does not explain increased influenza severity. This suggests that failure of the predominant HLA allomorphs maintained within Indigenous populations to generate a diverse antiviral response may predispose them to more severe influenza disease. Therefore, we undertook peptide presentation studies that identified novel influenza epitopes restricted by HLA-A*24:02, an allele expressed by ~25% of Indigenous Australians. Characterisation of such novel influenza-specific CD8⁺ T-cell epitopes restricted by HLA alleles prevalent in Indigenous populations will inform future rational design of universal T-cell vaccines.

Protective monotherapy against lethal ebola virus infection: structural and molecular basis of potent neutralization

Sullivan, N.J.

NIAID, National Institutes of Health, Vaccine Research Center, Bethesda, United States

Ebola virus disease in humans is highly lethal, with case fatality rates ranging from 25-90%. There is no licensed treatment or vaccine against the virus, underscoring the need for efficacious countermeasures. Here, we demonstrate that a human survivor of the 1995 Kikwit Ebola virus disease outbreak maintained circulating antibodies against the Ebola virus surface glycoprotein for more than a decade after infection. From this survivor we isolated monoclonal antibodies (mAb) that neutralize recent and previous outbreak strains of Ebola virus, and mediate antibody-dependent cell-mediated cytotoxicity *in vitro*. Strikingly, monotherapy with mAb114 protected macaques when given as late as five days after challenge. We defined the mAb binding epitope on Ebola GP and show that blocking a single functional domain in Ebola GP by mAb114 is sufficient for complete protection of primates. These results define a basis of neutralization for protective mAbs, and demonstrate that treatment with a single human mAb as a therapeutic strategy for human Ebola infection may be possible.

Harnessing innate immune responses to inhibit influenza H1N1 infection

Poux, C.¹, Dondalska, A.¹, Järver, P.¹, Contreras, V.², Le Grand, R.², Spetz, A.-L.¹

¹Stockholm University, Department of Molecular Biosciences The Wenner-Gren Institute, Stockholm, Sweden, ²Commissariat à l'Énergie Atomique, UMR 1184, IDMIT Center, Institute for Emerging Diseases and Innovative Therapies, DSV, Fontenay-aux-Roses, France

Influenza viral infection leads to the activation of pattern recognition receptors responding to dsRNA with subsequent pro-inflammatory cytokine and interferon responses. Influenza viruses are often sensitive to interferons but extensive pro-

inflammatory responses contribute to lethal pathology. This is exemplified in TLR3 knock out mice, which have been shown to have increased survival compared with wild-type mice upon influenza infection. To further address the role of dsRNA-induced signaling during influenza infection, we treated influenza H1N1 (IAV) infected human monocyte-derived DCs (MoDCs) with an inhibitor of TLR3 (a single stranded oligonucleotide (ssON)) and/or the synthetic dsRNA analogue, poly I:C. Flow cytometry was used to measure the frequency of IAV nucleoprotein positive cells and the expression of co-stimulatory molecules. The IAV infected cells did not upregulate CD80 and CD86, while the neighboring nucleoprotein negative cells upregulated both co-stimulatory molecules. The impeded MoDC maturation, in IAV infected cells, could not be overcome with polyI:C stimulation. Although the TLR3 inhibitor ssON was able to prevent poly I:C-induced MoDC maturation, it was incapable of blocking MoDC maturation in IAV exposed but non-infected cells. The IAV loads in the cultures were approximately 1×10^5 vp/ml, as measured by real-time PCR, and the combined stimulation of both polyI:C and ssON resulted in a significant reduction in IAV production and/or release (to under 100 vp/ml). Moreover, intradermal injection of macaques with both polyI:C and ssON led to induction of multiple viral restriction factors, but without concomitant pro-inflammatory response. These findings suggest that harnessing innate immunity engaged by oligonucleotides can inhibit IAV infection.

Antigen Processing & Presentation

MHC class II antigen-processing chaperone H2-O regulates thymic selection in vivo

Sadegh-Nasseri, S., Welsh, R., Song, N.

Johns Hopkins University, Pathology, Baltimore, United States

HLA-DO or H2-O (DO) in mice is a non-classical, non-polymorphic MHC II molecule primarily expressed in the thymic medulla and B cells. While the common belief is that DO inhibits the activity of DM, controversial data opposes that point of view. Physicochemical studies with purified DO, DM and HLA-DR1 demonstrated that DO interacts directly with HLA-DR1 molecules in a peptide-receptive-conformation, augmenting binding of 'DM-resistant' peptides, while inhibiting binding of 'DM-sensitive' peptides to HLA-DR1. We hypothesized that by optimizing presentation of self-epitopes in thymic medulla, thus increasing the density of presented epitopes, DO might ensure full execution of negative selection. We tested this hypothesis in H2-O-Knockout (DO-KO) mice in two ways:

A) a novel 'Prime-Restim' strategy, and

B) by monitoring disease development and severity in a murine model of experimental autoimmune encephalomyelitis (EAE).

In the former, CD4 T cells from DO-WT were immunized and restimulated repeatedly with antigen presenting cells from the DO-KO mice. The results demonstrated that in DO-KO mice, the peptide repertoire of MHC II is different from that of the DO-WT mice. In the latter approach, we found that DO-KO mice develop EAE considerably faster than DO-WT mice. This enhancement in disease onset correlated with

increased numbers of MOG-tetramer-specific-CD4 T cells collected from the CNS of DO-KO mice during the disease, or from periphery in naïve DO-KO mice. Thus, loss of DO correlates with poor deletion of self-reactive T cells leading to larger numbers of MOG-specific T cells, as well as varied epitope selection for presentation by MHCII.

Antigen presentation by Major Histocompatibility Complex (MHC) and MHC-I like molecules is central to the cellular arm of adaptive immunity. While the cellular pathways of peptide and lipid antigen presentation by MHC and CD1 molecules are well established, our understanding of the presentation of small molecule metabolites is unclear. MR1 is an MHC-I like molecule that presents vitamin B metabolites to MAIT cells, and while diverse cell types ubiquitously express MR1, it only egresses to the cell surface in the presence of antigen(s). We show that, unlike other antigen-presenting molecules, human MR1 does not appear to constitutively present self-ligands, but accumulates in the endoplasmic reticulum (ER) in a ligand-receptive conformation. Here, a lysine residue within MR1 forms a Schiff base with vitamin B metabolites, thereby acting as a "molecular switch" that allows folding and egress of MR1 molecules. Newly formed MR1-antigen complexes follow the secretory pathway, whereupon the half-life of MR1-antigen complexes expressed on the plasma membrane was several hours and not significantly different when ligand was bound. After exposure on the plasma membrane, MR1-antigen complexes underwent endocytosis and degradation, however some recycling back to the cell surface and ligand exchange could be detected. Thus MR1 presentation is characterised by an off-on-off mechanism, where in the steady state the majority of MR1 molecules reside in the ER until they encounter extracellular metabolites. Accordingly the MR1-mediated metabolite presentation is distinct from that of the constitutive presentation of peptides and lipids.

Immunology by numbers: quantitation of antigen presentation completes the quantitative milieu of systems immunology

Purcell, A.

Monash University, Biochemistry, Clayton, Australia

The classic quantitative tools of immunology have provided critical insights into immune outcome, recent advances have

now taken this to a cell specific and in some circumstances even single cell level of resolution. For example MHC tetramers have allowed the enumeration and characterisation of epitope specific lymphocytes. More recently, the development of mass spectrometry based approaches have provided new avenues to investigate the specificity of the immune response and to address the missing gap of systems wide epitope quantitation on the surface of antigen presenting cells. I will present recent data that highlights the discovery and quantitation of anti-viral epitopes, self epitopes and neoepitopes using next generation mass spectrometric approaches including multiple reaction monitoring and data independent acquisition (SWATH) - mass spectrometry. Within this context we have developed several novel workflows that allow simultaneous measurement of antigen expression and epitope presentation, the identification of post-translationally modified T cell epitopes and differential antigen processing that promotes T cell heterogeneity and immune evasion. Incorporation of this information into system based models facilitates the study of infectious immunity, autoimmunity and allergy at a system wide level.

Highly efficient cross-priming of CD8+ T cells by splenic CD169 macrophages employing a unique endosomal processing pathway

Mauvais, F.-X.¹, Hamel, Y.², Garfa, M.³, Diana, J.¹, van Endert, P.¹
¹INSERM U 1151, Paris, France, ²INSERM U 1163, Paris, France,
³INSERM US 24, Paris, France

Splenic CD169+ marginal zone macrophages (MZM) are strategically located for uptake of soluble and particulate blood-borne antigens. However their role in T cell priming is commonly considered limited to antigen capture and transfer to adjacent dendritic cells (DC). To critically evaluate this concept, we developed a novel protocol allowing for the first time to purify these cells and examine their function in vitro. Purified CD169+ MZM are clearly distinct from dendritic cells by size and morphology and by expression of key genes and of a vast panel of surface receptors. In contrast to current concepts, we demonstrate that purified CD169+ MZM cross-present receptor-targeted antigen as well as CD8+ DCs, and soluble and particulate antigen with greater efficacy. Consistent with this, antigen targeting to CD169+ and DEC205 in vivo induce T cell proliferation with equivalent efficiency. Intravital biphoton live imaging reveals rapid T cell arrest on CD169+ MZM upon antigen targeting.

We also examined the intracellular cross-presentation pathway employed by CD169+ MZM. Although, in the case of DCs, strictly endosomal ("vacuolar") cross-presentation is considered inefficient, we find that, in CD169+ MZM, endosomal processing and presentation of internalized antigen is highly efficient, possibly due to a unique MHC class I recycling pathway. Thus, CD169+ MZM belong together with CD8+ DCs to a small group of professional antigen-presenting cells capable of highly efficient cross-priming. The effector functions primed by CD169+ MZM and the quality of ensuing anti-infectious immune responses are under investigation and will be presented.

In vivo biosensors for pathogen physiological functions reveal distinct effector T cell - APC interaction dynamics depending on intracellular pathogen proliferation

Heyde, S.¹, Formaglio, P.¹, Bousoo, P.², Müller, A.^{1,3}

¹Otto-von-Guericke University, Institute for Molecular and Clinical Immunology, Magdeburg, Germany, ²Institut Pasteur, Immunology Department, Paris, France, ³Helmholtz Centre for Infection Research, Braunschweig, Germany

Pathogen physiology has a profound impact on the outcome of infections: Growth rate and metabolic activity within the pathogen population are important for persistence during chronic infections, but can also have dramatic effects on the deployment of immune responses. How immune cells can distinguish pathogens according to their physiological state, or impact pathogen physiology on a cellular level, is unclear. This is mainly due to difficulties in analyzing at the same time the dynamics of immune cells and pathogen physiology *in vivo*.

To overcome this limitation, we have developed genetically encoded fluorescent reporter systems which permit probing pathogen physiology by intravital 2-photon microscopy. Consequently, we could determine on a single cell level, and longitudinally over the course of an infection, the proliferation and cell death of the intracellular parasite *Leishmania major*. Furthermore, we were able to characterize the cellular niche of high proliferating versus low proliferating pathogens, and could show that pathogen-specific effector

T cells interact preferentially with APCs infected with high proliferating parasites.

Our approach thus provides for the first time an insight into how cells of the immune system recognize and influence distinct pathogen physiological states in the on-going infection.

The modulation of cellular protease activities by HIV protease inhibitors alters the processing, direct and cross-presentation of pathogens

Kourjian, G., Rucevic, M., Berberich, M.J., Boucau, J., Le Gall, S.
 Ragon Institute of MGH, MIT and Harvard, Cambridge, United States

Immune recognition by T cells relies on the presentation of pathogen-derived peptides by infected cells but the persistence of chronic infections calls for new approaches to modulate immune recognition. Pathogen uptake in phagosomes initiates infection of macrophages and leads to the priming of T cell responses by dendritic cells (DC) whereas viruses like HIV fuses at the plasma membrane of CD4+ cells to access the cytosol. The original degradation of antigens is performed by cytosolic proteases or by pH-dependent endolysosomal cathepsins. We show that HIV protease inhibitors (PIs) prescribed to HIV-infected persons modulate proteasome, aminopeptidases and cathepsin hydrolytic activities in human antigen presenting cells (APCs), DC and macrophages, and CD4 T cells. While they modulate aminopeptidase activities in a residue-specific manner, HIV PIs acted in two complementary ways on cathepsin activities: They directly enhanced procathepsin maturation

and increased cathepsin hydrolytic activities. They indirectly altered regulators of cathepsin functions by inhibiting Akt kinase activities, reducing NADPH oxidase 2 (NOX2) activation, lowering phagolysosomal ROS production and pH, which altogether led to enhanced cathepsin activities. HIV PIs modified endolysosomal degradation and epitope production of proteins from HIV and other pathogens in a sequence-dependent manner. They altered cross-presentation of antigens by DC and epitope-specific T cell-mediated killing. HIV PI-induced modulation of antigen processing partly changed the self MHC-peptidome displayed by primary human cells. This first identification of prescription drugs modifying cellular peptidase activities and the MHC-peptidome may provide an alternate therapeutic approach to modulate immune recognition in immune disease beyond HIV.

MARCH E3 ligases and ubiquitination events that shape immunity

Mintern, J.D.¹, Liu, H.¹, Ching, A.¹, Huang, P.¹, Ishido, S.², Villadangos, J.A.^{1,3}

¹University of Melbourne, Biochemistry and Molecular Biology, Parkville, Australia, ²Showa Pharmaceutical University, Machida, Japan, ³University of Melbourne, Microbiology and Immunology, Parkville, Australia

Membrane associated RING-CH (MARCH) E3 ligases promote the ubiquitination of membrane associated substrates. Here, we have undertaken a comprehensive analysis of the role of MARCH E3 ligase in the ubiquitination of major histocompatibility complex II (MHC II). Our studies use primary immune cells to monitor ubiquitination in endogenous settings. First, we detect distinct patterns of MHC II ubiquitination in different cell types. In brief, the length of the ubiquitin chain and the ubiquitin chain linkages, as identified by mass spectrometry, associated with MHC II differs in B cells versus dendritic cells, while in both cell types, MARCH 1 is the E3 ligase responsible. This implicates the cell-type specific participation of E2 ligases and/or deubiquitinases that are currently under investigation with CRISPR/cas-9 screening. Second, utilising mice deficient in specific MARCH E3 ligases, we have identified different MARCH family members that are responsible for the ubiquitination of MHC II in haemopoietic versus non haemopoietic cell types. Third, by undertaking proteomic screens of plasma membrane fractions isolated from primary MARCH-deficient dendritic cells and B cells, we have discovered novel substrates for MARCH-mediated ubiquitination. This analysis has identified a surprising role for MARCH 1-mediated ubiquitination in the deposition of complement component 3. In summary, we have undertaken in depth analysis of the role of MARCH E3 ligases in primary immune cells. Our findings uncover cell-type specific ubiquitination events and implicate MARCH and/or ubiquitination in playing unexpected roles in immune pathways.

1982

GILT-mediated antigen processing in thymic epithelial cells diminishes T cell-mediated protection from melanoma through promoting thymic deletion and regulatory T cells

Rausch, M.¹, Metzger, T.², Waterfield, M.², Cortez, J.², Anderson, M.², Hastings, K.¹

¹University of Arizona College of Medicine, Basic Medical Sciences, Phoenix, United States, ²University of California (UCSF), San Francisco, United States

Central tolerance is critical to prevent autoimmunity, but limits T cell responses to tumor Ags that are self Ags. Gamma-interferon-inducible lysosomal thiol reductase (GILT) is required for thymic deletion of CD4⁺ T cells specific for self and melanoma Ag, tyrosinase-related protein 1 (TRP1). GILT expression was enriched in thymic APCs capable of mediating deletion, medullary thymic epithelial cells (mTECs) and DCs. TRP1 expression was restricted to mTECs. GILT facilitated MHC class II-restricted presentation of endogenous TRP1 by pooled thymic APCs. Bone marrow (BM) chimeras demonstrated that GILT expression in TECs is necessary and sufficient for efficient deletion of TRP1-specific thymocytes. Diminished MHC class II expression on mTECs had no effect on thymic deletion or the percentage or activation of peripheral TRP1-specific T cells, suggesting that TRP1 is processed by GILT in mTECs and transferred to DCs to mediate deletion. In chimeras that express GILT in TECs TRP1-specific thymocytes underwent deletion, and chimeras were not protected from melanoma. Although an intermediate level of TRP1-specific T cells developed in chimeras in which GILT expression was limited to BM-derived cells, only chimeras lacking GILT in both populations were protected from melanoma. Chimeras that expressed GILT in TECs or in which GILT was limited to BM-derived cells had a substantially higher percentage of TRP1-specific Treg cells and lower effector:Treg cell ratio. These findings suggest that GILT operates in mTECs to facilitate the processing of tissue-restricted Ags and promote thymic deletion and development of Treg cells, resulting in diminished T cell-mediated protection from melanoma.

The efficiency of antigen presentation in vitro correlates with the capacity to induce protection in vivo

Gil-Torregrosa, B.¹, Johnstone, C.¹, Rodríguez-Castro, M.¹, Prados, F.¹, Schlicht, H.-J.², Koszinowski, U.H.², Castaño, A.R.¹, Del Val, M.³

¹Instituto de Salud Carlos III, Centro Nacional de Microbiología, Majadahonda, Spain, ²University of Ulm, Virology, Ulm, Germany, ³Centro de Biología Molecular Severo Ochoa (CSIC-UAM), Madrid, Spain

The influence of the flanking sequences of an antigenic epitope on its presentation by MHC class I is established. The efficiency of antigen presentation in vitro has been shown sometimes to parallel the degree of protection conferred in vivo to a lethal challenge infection. However, to be able to predict vaccine potency in vivo these observations had to be extended. To this end, several chimerical proteins encoded in recombinant vaccinia virus (rVACV) and containing the same epitope were produced. All rVACV express the immunogenic nonapeptide

9pp89 (¹⁶⁸YPHFMPNTL¹⁷⁶) of murine CMV inserted in different positions of different carrier proteins. When two different cell lines were infected, all constructions were recognized by specific CTL. The differences in the level of presentation to CTL shown by the different chimeras did not correlate with differences in the total synthesized protein analyzed in the stationary state in the infected cells. Protection induced by 9pp89 is mediated by CD8⁺ T lymphocytes *in vivo*. Therefore, the capacity of the rVACV to protect against a lethal infection by murine CMV was studied. A good correlation was found between *in vitro* antigen presentation and *in vivo* protection capacity induced by the chimerical proteins. In addition, the fact that all the chimeras with the epitope bi-terminally flanked by 5 Ala conferred high presentation and high protection values indicates the beneficial effect of flanking Ala. In conclusion, the differences in the antigenic presentation obtained *in vitro* significantly correlate with the capacity of the different rVACV to induce protection *in vivo*.

Natural IgG is innate immune responsive

Ding, J.L.¹, Panda, S.²

¹National University of Singapore, Biological Sciences, Singapore, Singapore, ²Skirball Institute of Biomolecular Medicine, NYU School of Medicine, New York, United States

Discovered ~50 years ago, natural IgG (nIgG) has been perceived to be inactive and belong to the adaptive immune system. nIgG exists in neonates and uninfected individuals, but it has been deemed non-functional due to its lack of antigen-specificity and low affinity for pathogens, when studied in isolation. Recently, we discovered that nIgG plays a vital and instant defense role by collaborating with plasma lectins (e.g. ficolin). We demonstrated how nIgG collaborates with ficolin-bound pathogens to kill and clear the invading pathogen through phagocytosis. This nIgG-mediated innate immune response is non-specific to antigens, operates independently of the complement system, and evokes a rapid pro-inflammatory response. Knockout mice lacking nIgG showed increased mortality during *Pseudomonas* infection, but are protected by reconstitution with nIgG. We have defined the contact points of interaction between nIgG:ficolin, revealing that infection-induced local acidosis and hypocalcemia conditions stimulate their interaction. Bioactive peptides derived from nIgG and ficolin could be developed into therapeutic immunomodulators, tunable to pH shifts in the infection-inflammation microenvironment.

The NLRP3 inflammasome controls IL-1 β maturation in antigen presenting and other innate immune cells but a direct role in

human adaptive immune cells for canonical NLRP3 activity has not been described. This study demonstrates that NLRP3 inflammasome assembles in human CD4⁺ T cells and initiates caspase-1-dependent IL-1 β secretion, thereby promoting IFN- γ production and Th1 differentiation in an autocrine fashion. Importantly, aside from T cell receptor engagement, NLRP3 activation requires intracellular C5 activation and stimulation of C5a receptor 1 (C5aR1) which leads to subsequent ROS generation. This process is negatively controlled by surface-expressed C5aR2: either C5aR2 agonism or NLRP3 inhibition with MCC950 significantly reduce Th1 response *in vitro*, while inhibition of C5aR2 is accompanied by increased IL-1 β and IFN- γ secretion. Dysregulation of NLRP3 activity in T cells affects inflammatory responses in autoimmune disease or infection: Firstly, CD4⁺ T cells from patients with cryopyrin-associated periodic syndromes (CAPS), who have constitutively-active NLRP3, exhibit overactive Th1 responses that are normalized by treatment with a specific NLRP3 inhibitor. Secondly, IFN- γ production is impaired in T cells from Nlrp3^{-/-} or Il1a/Il1b^{-/-} mice upon viral infection. Our results demonstrate that NLRP3 inflammasome activity is not confined to 'innate immune cells' but occurs in adaptive cells and that its crosstalk with the (intracellular) complement system is an integral component of normal adaptive Th1 responses.

Sid2 transports extracellular dsRNA into the cytoplasm for innate immune recognition

Nguyen, T.¹, Smith, B.¹, Weissman, A.², Elgass, K.³, Belz, G.¹, Masters, S.¹, Hunter, C.², Pang, K.¹

¹Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²Harvard University, Cambridge, United States, ³Monash Micro Imaging, Clayton, Australia

During viral infection, extracellular double stranded RNA (dsRNA) acts as a potent trigger of innate immunity via the production of type I interferons (IFNs). The detection of extracellular dsRNA involves different host cell sensors such as Toll-like receptor 3 (TLR3) and the RIG-I-like receptors (RLRs), RIG-I and MDA-5. TLR3 is located within endo-lysosomes, and is therefore well situated to detect dsRNA that has been taken up from the environment. Internalised dsRNA also activates the cytoplasmic RLRs, implying the existence of a mechanism to transport dsRNA across the endosomal membrane. Interestingly, the RLRs are functionally dominant over TLR-3 in the response to extracellular dsRNA and are critical for immunity to multiple viruses, but how dsRNA escapes from the endosome is unknown. Here we report that Sid2, a mammalian orthologue of the *C. elegans* SID-1 dsRNA transporter, is present within the endosomal compartment and co-localises with internalised poly(I:C), a synthetic analogue of dsRNA. Sid2-deficient mice show impaired production of type I IFNs in response to extracellular poly(I:C) *in vivo*. These observations suggest a role for Sid2 in transporting dsRNA from the endosome into the cytoplasm. In support of this, we found that loss of Sid2 does not affect dsRNA internalization, but instead results in the accumulation of poly(I:C) within the endosomal compartment. Sid2-deficient mice produce less type I IFNs and have increased mortality in response to infection

with herpes simplex virus. Our findings demonstrate a key role for Sid2 in the endosomal escape of dsRNA and the subsequent induction of innate immunity.

1289

Inflammatory response sculpting by neutrophil inflammasomes

Chen, K.¹, Gross, C.², Wall, A.¹, Stacey, K.¹, Stow, J.¹, Sweet, M.¹, Schroder, K.¹
¹The University of Queensland, Brisbane, Australia, ²Technische Universität München, Munich, Germany

Macrophage and dendritic cell inflammasomes drive potent innate immune responses against intracellular pathogens, by eliciting rapid caspase-1-dependent pro-inflammatory cytokine production (e.g. interleukins (IL)-1 β and -18 and pyroptotic cell death, as well as caspase-8-directed apoptotic cell death. The contribution of other cell types to inflammasome-mediated host defence had not been examined in detail. Here we demonstrate that neutrophils, typically viewed as cellular targets of IL-1 β themselves activate the NLRC4 inflammasome during acute *Salmonella* infection, and are a major cell compartment for IL-1 β production during acute peritoneal challenge *in vivo*. Importantly, unlike macrophages, neutrophils do not undergo pyroptosis upon *in vitro* or *in vivo* NLRC4, NLRP3 or AIM2 inflammasome activation. Furthermore, neutrophils also resisted inflammasome/caspase-8-directed apoptotic cell death. The ability of neutrophils to resist inflammasome-mediated death is unique amongst inflammasome-signalling cells so far described. Their continued viability allows neutrophils to sustain IL-1 β production at a site of infection, and exert their crucial inflammasome-independent antimicrobial effector functions to clear infection. Additionally, we have found that neutrophils possess a unique specialisation of the NLRP3 pathway that allows these cells to co-ordinate a neutrophil-dominated response only when it is appropriate to do so. This work reveals neutrophils as a surprising new cellular player in shaping inflammasome-mediated inflammatory responses *in vivo*, and highlights the major impact of myeloid cell identity on innate immune signalling pathways.

1600

Differential contribution of the Inflammasome to *L. pneumophila* clearance independently of cell death

Caution, K.¹, Gavrilin, M.², Tazi, M.¹, Kanneganti, A.¹, Layman, D.¹, Hoque, S.¹, Krause, K.¹, Amer, A.¹

¹Ohio State University, Microbial Infection & Immunity, Columbus, United States, ²Ohio State University, Internal Medicine, Columbus, United States

Trafficking and fusion of the phagosome with the lysosome is a key host defense against pathogens. Regulation of the actin cytoskeleton is crucial for proper vesicle trafficking. Inflammasomes are large, multiprotein complexes that promote inflammation and cell death in response to pathogenic microorganisms and sterile stressors. Recently, prominent members of the inflammasome, caspase-1 and caspase-11, were implicated in the fusion of vacuoles harboring intracellular

microbes with lysosomes. However, the molecular mechanisms of caspase-mediated intracellular trafficking are unknown. It is this study's objective to decipher the effects of caspase-1 and -11 on actin dynamics to promote phagolysosomal fusion and restriction. Using single knockout mice lacking caspase-1 or -11, we determined that during *Legionella pneumophila* (*L. pneumophila*) infection, *Casp-1*^{-/-} and *Casp-11*^{-/-} macrophages exhibited diminished F/G-actin ratios compared to WT counterparts. In addition, the absence of caspase-1 or -11 prevented the colocalization of F-actin around the bacterium. We also identified the signaling pathway linking caspase-1 and -11 with actin. We demonstrate that caspase-1 and caspase-11 exert contrasting effects on cofilin phosphorylation state upon intracellular infection. The absence of either caspase maintains actin in the polymerized or depolymerized form, respectively and averts the fusion of pathogen-containing vacuole with lysosomes, allowing bacterial persistence. However, non-pathogenic bacteria were delivered to the lysosome independently of caspase-1 and caspase-11. Notably, caspase-11 targets cofilin via the RhoA GTPase, whereas caspase-1 engages the Slingshot phosphatase. These data establish that inflammasome caspases differentially regulate actin polymerization during infection by modulating F-actin assembly via the activation of cofilin.

32

Rhbdd3 controls innate inflammatory diseases via negatively regulating TLR signaling

Liu, J.¹, Han, C.¹, Liu, S.¹, Xia, M.², Chen, K.³, Cao, X.²

¹National Key Laboratory of Medical Immunology & Institute of Immunology, Second Military Medical University, Shanghai, China, ²National Key Laboratory of Medical Molecular Biology & Department of Immunology, Chinese Academy of Medical Sciences, Beijing, China, ³Institute of Immunology, Zhejiang University School of Medicine, Hangzhou, China

Rhomboid domain-containing protein 3 (Rhbdd3), which belongs to a family of proteins with rhomboid domain, is widely expressed in immune cells; however, the roles of Rhbdd3 in immunity remain largely unknown. Using Rhbdd3-deficient mice, we reveal that Rhbdd3-deficient mice spontaneously developed autoimmune diseases due to increased IL-6 production, and developed more severe inducible autoinflammatory colitis and acute hepatic injury. Rhbdd3 negatively regulates Toll like receptor (TLR)-mediated NK cell and DC activation. Rhbdd3 inhibits TLR3-triggered IFN- γ and granzyme B expression of NK cells in cell-cell contact dependence of accessory cells such as dendritic cells and Kupffer cells. Rhbdd3 interacts with DAP12 and promotes its degradation, inhibiting MAPK activation in TLR3-triggered NK cells. Furthermore, Rhbdd3 directly binds to K27-linked polyubiquitin chains on NEMO via its UBA domain, and recruits the deubiquitinase A20 to induce K63-linked deubiquitination of NEMO and thus inhibits activation of the transcription factor NF- κ B in DCs. Our study identify provide a new mechanistic explanation for the post-translational regulation of TLR triggered activation of MAPK and NF- κ B, indicative of potential intervention strategies for autoimmune or chronic inflammatory diseases.

2029

Anti-phosphorylcholine antibodies decrease the interaction of house dust mite with antigen-presenting cells in the lung through CD36 and platelet activating factor receptor (PAFR)

Patel, P., Kearney, J.

University of Alabama at Birmingham, Microbiology, Birmingham, United States

There is an alarmingly high rate of asthma that occurs among children born in developed countries. Approximately 89% of these asthmatic children demonstrate sensitivity to house dust mite (HDM) allergen. HDM is composed of LPS, chitin, and β -glucan, and studies have shown that blocking the receptors of these PAMPS such as TLR4, Dectin-2, and PAR2 can significantly inhibit both the innate and adaptive immune response to HDM. However, these findings have not lead to the generation of any viable therapeutics. We, and others, have published that HDM contains phosphorylcholine (PC) epitopes. PC receptors such as CD36 and platelet activating factor receptor (PAFR) have been shown to modulate disease states involving oxidized lipids like atherosclerosis, but not much is known about the role of these receptors in allergies and asthma. Our findings demonstrate that mice deficient in CD36, PAFR, or both receptors develop a significantly attenuated form of HDM-induced allergic disease compared to C57BL/6 mice. We further demonstrate that anti-PC IgM antibodies bound to HDM prevent the interaction of the allergen with CD36 and PAFR on APCs in the lung and suppress the development of allergic disease. Additionally, elevated levels of anti-PC IgM antibodies are associated with a decreased incidence of asthma in a local pediatric cohort. Thus, we have indicated that engagement of CD36 and PAFR by HDM plays a critical role in the initiation of allergic disease, and inhibiting the engagement of HDM with these receptors via treatment with anti-PC antibodies can significantly attenuate the development of allergic disease.

The NLRP3 specific inhibitor CP-456,773 potently attenuates crystal-induced kidney fibrosis in vivo

Ludwig-Portugall, I.¹, Bartok, E.², Dhana, E.¹, Evers, B.G.¹, Franklin, B.S.³, Hall, P.⁴, Primiano, M.J.⁴, Hornung, V.⁵, Hartmann, G.², Boor, P.⁶, Latz, E.³, Kurts, C.¹

¹Institute of Experimental Immunology, University Hospital of the Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany, ²Institute of Clinical Chemistry and Clinical Pharmacology, University Hospital of the Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany, ³Institute of Innate Immunity, University Hospital of the Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany, ⁴Inflammation and Immunology Research Unit, Pfizer Inc., Cambridge, United States, ⁵Institute of Molecular Medicine, University Hospital of the Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany, ⁶University of Aachen, Dept. of Nephrology, Aachen, Germany

The Nlrp3 inflammasome in myeloid cells triggers profound inflammatory reaction in response to a variety of stimuli. Mice genetically deficient in inflammasome components have been shown to be protected against inflammation in acute and chronic crystal nephropathy. Here we demonstrate that

a specific inhibitor of the Nlrp3 inflammasome (CP-456,773), potently attenuated the course of a murine model of crystal nephropathy. IL-1 β and IL-18 production, parameters of renal failure, kidney injury and fibrosis were markedly improved after CP-456,773 treatment. In contrast, the crystal burden remained unaltered and the adaptive immune response was not compromised as previously reported for the global inhibition of IL-1 signaling. Using iGLuc, a proteolytic luciferase-based reporter for inflammasome activation, we established an *in vivo* imaging assay making use of iGLuc-transduced bone-marrow cells in order to directly visualize renal inflammasome activation and its inhibition by CP-456,773 *in vivo*. In summary, our study demonstrates the efficacy of NLRP3 inhibition by CP-456,773 for the treatment of crystal nephropathy and introduces a novel imaging technique for *in vivo* inflammasome activation.

E3 ubiquitin ligase TRIM31 negatively regulates NLRP3 inflammasome activation by promoting proteasomal degradation of NLRP3

Huai, W., Song, H., Liu, B., Han, L., Zhang, L., Gao, C., Zhao, W.
Shandong University School of Medicine, Department of Immunology, Jinan, China

NLRP3 inflammasome plays fundamental roles in host defense against microbial pathogens and its deregulation may cause diverse inflammatory diseases. NLRP3 protein expression is considered as a rate-limiting step for inflammasome activation, thus its expression must be tightly controlled to maintain immune homeostasis and avoid detrimental effects. However, how NLRP3 expression is regulated, remains largely unknown. In the present study, we identified E3 ubiquitin ligase TRIM31 as a feedback suppressor of NLRP3 inflammasome. TRIM31 binds to NLRP3, promotes K48-linked polyubiquitination and proteasomal degradation of NLRP3 in both resting and activated macrophages. Our research described a new mechanism by which TRIM31 negatively regulated NLRP3 inflammasome activity and provided an explanation on the limitation of NLRP3 inflammasome activation under physiological conditions.

Gut microbial metabolites regulate autoimmune T cell responses and protect against type 1 diabetes

Marino, E., Richards, J.L., McLeod, K.H., Yap, Y.A., Stanley, D., Mackay, C.R.

Monash University, Infection and Immunity Program, Monash Biomedicine Discovery Institute, Biochemistry and Molecular Biology, Melbourne, Australia

Diet and gut microbial ecology may underlie the increasing incidence of certain inflammatory diseases. Here, we found that key features of autoimmune diabetes in NOD mice, such as gender differences and protection in *MyD88*^{-/-} NOD mice correlated closely with fecal concentrations of the short chain fatty acids (SCFAs) acetate and butyrate. We then used specialised

diets to deliver high concentrations of acetate and butyrate to the colon and hepatic portal vein of NOD mice, when tolerance to islet antigens has already been broken. High acetate- or butyrate-yielding diets significantly reduced progression to diabetes, through effects on the colonic microbiota, improved gut epithelial integrity and reduced concentrations of pro-inflammatory cytokines. Both acetate and butyrate diets led to dramatically decreased numbers of autoreactive T cells. A high butyrate-yielding diet promoted conversion of naive Foxp3⁻ T cells into Foxp3⁺ Treg cells *in vivo*, through histone modification at the *Foxp3* promoter that led to increased numbers of Treg cells. In contrast, an acetate-yielding diet inhibited histone deacetylase 3 (HDAC3) transcription in B cells, through histone modification at the *CD40*, *b2m* and *Blimp1* promoters, which led to markedly reduced expression of CD86 and MHC1 and reduced their capacity to expand autoreactive CD8⁺ T cells *in vivo*. Control of autoimmune T cell frequencies, and protection from diabetes relied in part on the metabolite-sensor GPR43, a receptor for both acetate and butyrate. Specialised diets that yield high acetate or butyrate may represent an effective non-pharmacologic means to limit autoreactive T cell numbers, and prevent autoimmune disease progression.

4459

cIAP1/2 inhibition downregulates IL-17A and synergizes with TNF- α blockade for sustained suppression of joint inflammation

Kawalkowska, J., Venables, P., Williams, R.

University of Oxford, Kennedy Institute, NDORMS, Oxford, United Kingdom

Cellular inhibitors of apoptosis proteins 1 and 2 (cIAP1/2) are ubiquitin E3 ligases which regulate apoptosis and NF- κ B and MAPK signalling pathways. As cIAP2 may also play a role in regulating TCR signals, by the ubiquitination of BCL10, the aim of this study was to assess the effects of cIAP1/2 inhibition on T cell cytokine secretion, survival, and differentiation using a specific inhibitor (GT13072). Here we show that GT13072 dramatically reduced IL-17A secretion by activated CD4⁺ T cells with little effect on other cytokines, including TNF- α and IFN- γ . Thus, the addition of GT13072 to naive T cell cultures led to a complete abrogation of T_H17 differentiation *in vitro*. We also evaluated the therapeutic potential of GT13072 in collagen-induced arthritis (CIA), a mouse model of rheumatoid arthritis, in which IL-17A plays a pathogenic role. GT13072 profoundly decreased the number of IL-17⁺ cells in joints and lymph nodes resulting in abrogation of joint inflammation. Furthermore, when combined with the TNF- α inhibitor etanercept, GT13072 treatment led to an increase in immunosuppressive Treg numbers and a prolonged therapeutic effect that was sustained after therapy retraction. GT13072 also inhibited the increase in T_H17 cells that has been reported in mice and man after TNF- α blockade. Thus, in summary, cIAP1/2 regulate IL-17A expression by modulating TCR signals and therefore control the balance between Tregs and IL-17A⁺ cells during inflammation. More importantly, we demonstrate that cIAP1/2 antagonism has therapeutic potential and should be further explored for the treatment of inflammatory diseases in which IL-17A plays a role.

1588**Increased frequency of circulating microparticles forming immune complexes, and their putative receptors in monocytes subsets in patients with systemic lupus erythematosus**Burbano, C.^{1,2}, Rojas, M.^{1,2}, Gloria, V.¹, Orejuela, J.¹, Muñoz, C.³, Vanegas, A.³, Castaño, D.¹¹Universidad de Antioquia, Facultad de Medicina, Instituto de Investigaciones Médicas, Grupo de Inmunología Celular e Inmunogenética, Medellín, Colombia, ²Universidad de Antioquia, Unidad de Citometría de Flujo, Sede de Investigación Universitaria, Medellín, Colombia, ³Hospital Universitario de San Vicente Fundación, Sección de Reumatología, Medellín, Colombia

Microparticles (MP) play a critical role in immune responses, due to their ability to transfer and modulate a variety of cellular components. Circulating MP can be recognized by monocytes affecting their functions. Because this interaction could be determinant in Systemic Lupus Erythematosus (SLE) immunopathology, monocytes and MP were studied in the peripheral blood from SLE patients and healthy controls (HC) by multiparametric flow cytometry.

Inactive (i, SLEDAI < 4) and active (a, SLEDAI ≥ 4) SLE patients had elevated percentages of MP IgG+, IgM+, IgM+IgG+, and C1q+; however, iSLE has more MP-IgM+ and aSLE more MP-IgG+. Only aSLE had elevated HMGB1+, and DNA+ MP. We did not observed differences in the MP number, size, neither in the content of RNA and phosphatidylserine compared to HC. To understand the possible pathways by which MP interact with monocytes, we evaluated their putative receptors. The aSLE patients have significantly increased expression of FcγR CD64 in intermediate and non-classical monocytes, and decreased of CD16 in non-classical, respect to HC. There were not differences regarding CD32, complement receptors (CR) 3 and CR4, and FcμR.

These evidences suggest that the interaction of circulating MP with monocytes in iSLE could be through C1qR, FcμR and CD36, favoring their silent clearance. However, in aSLE the recognition of MP could be through FcγR potentially affecting their activation pattern, migration, contact with the endothelium, and induction of tissue damage in SLE patients. The identification of the modulatory effect of MP forming immune complexes in monocytes will provide new immunopathogenic mechanisms in SLE patients.

3078**TCR affinity and bond lifetime for antigen combine to determine avoidance of tolerance and induction of demyelinating disease**

Blanchfield, L., Liu, B., Evavold, B.

Emory University, Microbiology and Immunology, Atlanta, United States

A fundamental question for autoimmunity is how T cells evade tolerance mechanisms in the thymus yet become activated to attack self in the periphery. Ligand discrimination by TCR is often characterized by affinity for peptide:MHC (pMHC), yet T cells also generate dynamic forces during antigen recognition that can limit or enhance TCR-pMHC bond lifetimes. Using an

experimental autoimmune encephalomyelitis (EAE) mouse model, we have analyzed tetramer positive and negative myelin oligodendrocyte glycoprotein (MOG)₃₅₋₅₅-specific TCRs that correspond to high and low affinity TCRs respectively and defined their binding kinetics as they progress through thymocyte development to induction of disease. We report that the bond lifetime of MOG specific T cells under applied force on naïve and activated

T cells are much longer (up to 100 fold) than those on thymocytes, suggesting physiological regulation of TCR kinetics within single T cell clones. Therefore, these data identify unique kinetic properties of autoimmune TCRs where weak interactions in the thymus potentially allow avoidance of negative selection yet in the periphery bind with sufficiently long lifetime to promote autoimmunity. Our work supports a model of T cell activation linking antigen discrimination with actin remodeling and availability of intracellular chemical signaling molecules where with time, high and low affinity T cells are essentially equipotent contributors to autoimmune disease.

3760**Down-regulation of autoreactive T and B lymphocytes by selective therapy in humanized murine SCID model of Systemic lupus erythematosus**Mihaylova, N.¹, Bradyanova, S.¹, Kerekov, N.¹, Chipinski, P.¹, Nikolova-Ganeva, K.¹, Velikova, T.², Ivanova-Todorova, E.², Kyurkchiev, D.², Kalinova, D.³, Herbáth, M.⁴, Prechl, J.⁴, Tchobanov, A.¹¹Institute of Microbiology, Bulgarian Academy of Sciences, Laboratory of Experimental Immunology, Sofia, Bulgaria,²University Hospital 'St. Ivan Rilski'; Laboratory of Clinical³University Hospital 'St. Ivan Rilski'; Clinic of Rheumatology, Sofia, Bulgaria, ⁴Hungarian Academy of Sciences, Immunology Research Group, Budapest, Hungary

Self-specific B and T cells play a main role in pathogenesis of SLE and are a logical target for a selective therapy. The complement receptor type 1 (CR1) on human B-lymphocytes has suppressive activity and the co-crosslinking of this receptor with BCR inhibits B cell activation.

The protein Annexin A1 (ANXA1), is a modulator of the immune system and abnormal expression was found on activated B and T cells in human autoimmunity.

We hypothesize that it may be possible to down-modulate the activity of autoreactive T and B cells from SLE patients in humanized SCID mouse model by treating them with a neutralizing antibody against ANXA1 or by protein engineered molecules, which co-crosslink the BCR and CR1.

The protein chimeric molecules were constructed by coupling an DNA-mimotope peptide to an anti-CR1 antibody. Immunodeficient SCID mice have been used for cell transfer with human PBMC from SLE patients for evaluating the pathogenesis of SLE. The immunomodulatory activities of the therapeutic monoclonal or engineered antibodies were tested *in vitro* and *in vivo*. The levels of anti-dsDNA antibodies and cytokines in the mice sera as well as the apoptosis and the number of dsDNA producing plasma cells were quantified by ELISA, FACS, ELISpot and protein array. Reconstituted SCID mice showed presence of auto-antibodies, as well as immunoglobulin deposition in the

renal glomeruli. Treatment of the transferred SCID mice either with DNA-like chimera and anti-ANXA1 antibody prevented appearance of anti-DNA antibodies and proteinuria, while the PBS-injected animals had high levels after the transfer.

Self-reactive IgE exacerbates interferon responses associated with autoimmunity

Sanjuan, M.

Medimmune, Gaithersburg, United States

The discovery of Immunoglobulin E (IgE) nearly 40 years ago was a breakthrough in the field of allergy research. IgE directed against parasitic worms and allergens binds mast cells and basophils, triggering an inflammatory response that is characterized by the release of histamine and Th2 cytokines. Here we report that double-stranded DNA (dsDNA)-specific IgE autoantibodies complexed to DNA activate plasmacytoid dendritic cells (pDC), an immune cell type linked to viral defense, leading to the secretion of substantial amounts of IFN- α . Although typical IgE mediated responses are not a hallmark of systemic lupus erythematosus (SLE), IFN- α producing pDCs are a key driver for loss of immune tolerance to host DNA in SLE. We, therefore, investigated this apparent paradox and found that even the small concentrations of circulating dsDNA-specific IgE found in SLE patients greatly potentiated pDC secretion of IFN- α by triggering phagocytosis via the Fc-epsilon receptor 1 (Fc ϵ RI) and TLR9-mediated DNA sensing in the phagolysosome. Consequently, this potent pDC signaling mechanism reduces the threshold of pDC activation, which has the potential to expand anti-DNA responses and greatly exacerbate self-inflicted damage. These findings expand the known pathogenic mechanisms of IgE mediated inflammation beyond those found in allergies and demonstrate that, in addition to recognizing exogenous allergens, IgE can also bind to autoantigens and drive an aberrant self-destructive response. This previously unrecognized link between IgE and the interferon pathway provides additional insights into the pathological mechanisms underlying autoimmunity and may be useful in the rational design of therapies for the treatment of autoimmunity.

Preferential internalization of antioxidant carbon nanoparticles by T lymphocytes to treat autoimmune diseases

Huq, R.¹, Samuel, E.L.G.², Sikkema, W.K.A.², Lee, T.¹, Tanner, M.R.¹, Khan, F.S.¹, Porter, P.C.³, Tajhya, R.B.¹, Patel, R.S.¹, Inoue, T.¹, Pautler, R.G.¹, Corry, D.B.³, Tour, J.M.², Beeton, C.¹

¹Baylor College of Medicine, Molecular Physiology and Biophysics, Houston, United States, ²Rice University, Chemistry, Houston, United States, ³Baylor College of Medicine, Medicine, Houston, United States

The intracellular production of superoxide (O₂⁻) by the mitochondria in T lymphocytes is an integral part of signaling downstream of the T cell receptor as O₂⁻ are required for the translocation of NFAT from the cytosol to the nucleus.

Scavenging O₂⁻ has proven beneficial in reducing the severity animal models of autoimmune diseases. However, dietary antioxidants require the administration of high doses and have not proven effective in the clinic, likely because of their low potency and rapid inactivation. In addition, high doses or long-term use of broad antioxidants, such as Vitamin E, is toxic.

Antioxidant carbon nanoparticles can scavenge reactive oxygen species (ROS) with higher efficacy than dietary and endogenous antioxidants. Furthermore, the affinity of carbon nanoparticles for specific cell types represents an emerging tactic for targeted therapy. Here, we report that nontoxic poly(ethylene glycol)-functionalized hydrophilic carbon clusters (PEG-HCCs), which are selective antioxidants for O₂⁻ and its derivative hydroxyl radical, are preferentially and rapidly internalized by T lymphocytes over other splenic immune cells and localize in T cell mitochondria. We use this selectivity to inhibit T cell function without affecting major functions of macrophages. We also demonstrate the effectiveness of PEG-HCCs in reducing T lymphocyte-mediated inflammation in delayed-type hypersensitivity (DTH) and experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis. Our results suggest that the preferential targeting of PEG-HCCs to T lymphocytes is a new and attractive route for treating

T cell-mediated autoimmune diseases without affecting other immune cells and therefore inducing broad-spectrum immunosuppression.

Synovitis in Juvenile idiopathic arthritis is mediated by TCR-independent CD31-IL17 axis of inflammation

Ferguson, I.^{1,2}, Griffin, P.¹, Yano, H.³, Michel, J.¹, Gaffen, S.^{3,4}, Piganelli, J.^{3,5}, Dvergsten, J.⁶, Rosenkranz, M.^{1,2}, Kietz, D.^{1,2}, Vallejo, A.^{1,2,3}

¹University of Pittsburgh School of Medicine, Department of Pediatrics, Pittsburgh, United States, ²UPMC Children's Hospital of Pittsburgh, Division of Rheumatology, Pittsburgh, United States, ³University of Pittsburgh School of Medicine, Department of Immunology, Pittsburgh, United States, ⁴University of Pittsburgh School of Medicine, Department of Medicine, Pittsburgh, United States, ⁵University of Pittsburgh School of Medicine, Department of Surgery, Pittsburgh, United States, ⁶Duke University Medical Center, Department of Pediatrics, Durham, United States

Juvenile idiopathic arthritis (JIA) is the most prevalent autoimmune, rheumatic disease of childhood. T cells are considered autoimmune effectors, but the autoantigenic basis of JIA pathology remains unknown. Our analyses of joint aspirates from children with oligoarticular and polyarticular JIA showed preponderance of CD28^{null}CD31⁺ $\alpha\beta$ T cells that are deficient in the expression of CD4 and CD8, herein called DN T cells. Along with similar CD28^{null}CD31⁺ CD8 T cells that we reported previously, we hypothesized that CD31 triggering shapes the inflammatory milieu within the inflamed joint. Humoral profiling of synovial fluid (SF) samples showed dominance of IL6, IL10, IL17, IFN γ , and TNF α . Bioassays using primary synovial T cells showed CD31 ligation alone was sufficient to drive production of these cytokines. Moreover, CD31 ligation led to the upregulation ROR γ T transcription factor, and to direct transactivation of *IL17A* gene promoter,

providing a first evidence for TCR-independent production of IL17 by T cells. Cellular analyses of SF also showed high numbers of fibrocyte-like cells (FLC) that expressed procollagen, IL17 receptor A, and CD38, the natural ligand of CD31. FLC exposed to IL17 expressed high levels of IL6, TNF α , and MMPs. Bioassays in the presence of a novel small molecule inhibitor effectively suppressed CD31-driven IL17 production by T cells, as well as the downstream IL17-dependent activation of FLC. Collectively, these data indicate a CD31-IL17A axis of T cell-FLC interaction that likely perpetuates synovitis in JIA. Targeted interruption of CD31-IL17A cell activation cascades may provide new avenue(s) towards alternative therapies for JIA.

Human iPSC-derived neural stem cells modulate adaptive and innate immune responses to protein against autoimmune-mediated demyelination

Payne, N.¹, Shu, R.¹, Sun, G.¹, Sylvain, A.¹, Zhang, Z.¹, Morey, R.², Laurent, L.², Yu, D.³, Bernard, C.¹

¹Monash University, Australian Regenerative Medicine Institute, Clayton, Australia, ²University of California San Diego, Department of Reproductive Medicine, San Diego, United States, ³Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia

Neural stem cell (NSC) transplantation reduces neuroinflammation and promotes endogenous repair processes in mouse models of multiple sclerosis (MS). We have generated induced pluripotent stem cells (iPSCs) from a set of monozygotic twins discordant for MS, termed patients 6 and 7, using two reprogramming strategies. In the current study, we investigated the immune modulatory activity of iPSC-derived NSCs from patients 6 and 7 using *in vitro* assays and a model of autoimmune-mediated demyelination. Gene expression profiling by RNA-seq and qPCR revealed that genes encoding secreted proteins known to regulate neuroinflammation, such as CX3CL1, LIF, IL-10, and TGF β 2, were upregulated upon neural differentiation of iPSCs. NSC conditioned media reduced the proliferation of human T-cells and regulated the activation state of macrophages *in vitro*, confirming that secreted factors likely play a role in the immune modulatory activity of NSCs. Transplantation of NSCs into the cerebrospinal fluid, but not into the bloodstream, of mice with experimental autoimmune encephalomyelitis (EAE) significantly reduced clinical signs of disease in a preventative treatment protocol. This therapeutic effect was not associated with an expansion of FoxP3+ T regulatory cells, but rather an increase in IL-4+ CD4 T-cells both in the CNS and periphery, as well as a reduction in tissue-invading myeloid cells that mediate demyelination. Our work provides the first evidence that human iPSC-derived NSCs can exert a bystander immune modulatory effect that improves clinical outcomes in a mouse model of MS.

²University of Massachusetts Medical School, Medicine, Worcester, United States, ³Lund University, Clinical Sciences, Lund, Sweden

Streptococcus pyogenes, also known as group A streptococcus (GAS) is an important bacterial pathogen that causes disease in humans. This gram-positive bacterium has developed several strategies to evade the human immune system that enables GAS to survive in the host. These include binding of IgG via Fc domains that results in recruitment of soluble complement inhibitors, C4b-binding protein (C4BP) and Factor H (FH) to the surface of GAS, that hinders complement dependent opsonisation and clearance. Protein H is a GAS surface bound virulence factor that, in turn, binds both C4BP and IgG. We characterized IgG's influence on C4BP binding to protein H and the resultant effect of IgG-C4BP interactions on *S. pyogenes* pathogenesis. Human IgG enhanced C4BP binding to GAS protein H over 20-fold. IgG did not augment binding of other protein H ligands such as factor H and did not increase binding of C4BP to streptococcal M protein (another ligand for both C4BP and IgG). Fc fragments derived from human IgG, but not other species were sufficient to increase C4BP binding to protein H. Using a novel humanized C4BP transgenic animal model, we found that mice treated with human Fc and infected with GAS had more severe disease manifestations and higher mortality compared to PBS treated control animals that effectively cleared the infection and survived. Taken together, we have identified a novel virulence mechanism whereby the Fc region of human IgG enhances C4BP binding to GAS and accentuates disease in a novel mouse model.

The ubiquitin ligase MARCH 1 regulates complement C3 deposition on professional antigen presenting cells

Villadangos, J.^{1,2}, *Ching, A.*², *Infusini, G.*³, *Moffat, J.*¹, *Ishido, S.*⁴, *Mintern, J.*²

¹The University of Melbourne, Microbiology and Immunology at the Doherty Institute of Infection and Immunity, Melbourne, Australia, ²The University of Melbourne, Biochemistry and Molecular Biology at the Bio21 Institute, Parkville, Australia, ³The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ⁴Showa Pharmaceutical University, Tokyo, Japan

Membrane-Associated Ring-CH1 (MARCH 1) is the best studied of the mammalian MARCHs, a family of E3 ubiquitin ligases specialised in regulation of immunoreceptor expression,

trafficking and turn-over. MARCH 1 ubiquitinates MHC class II and CD86 in professional antigen presenting cells, thereby regulating CD4 T cell antigen recognition and immunity (1). Whether MARCH 1 regulates other immunoregulatory proteins *in vivo* remains unknown.

We have undertaken label-free, comparative proteomic screens of plasma membrane fractions isolated from primary wild-type and MARCH I-deficient dendritic cells (DC) and B cells, and discovered novel substrates for MARCH I-mediated ubiquitination. We have also uncovered an unexpected role for MARCH 1 in deposition and/or removal of complement component 3 (C3) on the plasma membrane of DC and B cells in the steady-state. In the absence of MARCH 1, both cell types accumulated large amounts of C3 on their surface, which was not produced by the cells themselves but captured from the extracellular environment. We will present our studies characterizing how MARCH 1 regulates C3 abundance on professional antigen presenting cells and the functional implications of this novel mechanism of Complement regulation. (1) J. M. Moffat, J. D. Mintern and J. A. Villadangos. 2013. Control of MHC II antigen presentation by ubiquitination. *Curr. Opin. Immunol.* **25**: 109-114.

1985

Collectin-11 recognises stress-induced epithelial cell pattern of L-fucose and triggers the innate immune system

*Zhou, W.*¹, *Farrar, C.A.*¹, *Tran, D.*¹, *Li, K.*², *Wu, W.*¹, *Peng, Q.*¹, *Schwaeble, W.*³, *Sacks, S.H.*¹

¹King's College London, Department of Innate Immunity, Medical Research Council (MRC) Centre for Transplantation, London, United Kingdom, ²Xi'an Jiaotong University, Core Research Laboratory, The Second Affiliated Hospital, School of Medicine, Xi'an, China, ³University of Leicester, Department of Infection, Immunity and Inflammation, Leicester, United Kingdom

The mechanism by which physiochemical stress induces tissue injury involves detection of abnormal molecular patterns by sensory molecules of the innate immune system. In this study, we describe how the recently discovered soluble C-type lectin known as collectin-11 (CL-11) recognises an abnormal pattern of L-fucose on post-ischaemic renal tissue and activates the innate immune response. Rapid local increase in CL-11 expression was associated with post-ischaemic renal damage. Mice with generalised deficiency or specific intrarenal deficiency of CL-11 were strongly protected against loss of renal function and tubule injury due to complement. Detection of the stable complement metabolite (C3d) mapped to proximal tubules, where CL-11 and potential ligand (L-fucose) were co-expressed. *Ex vivo* study of isolated renal tubule cells showed marked capacity for CL-11 binding that was induced by cell culture in hypoxic or hypothermic conditions and prevented after specific removal of L-fucose. Further analysis showed that cell-bound CL-11 required the serine protease MASP-2 to initiate complement deposition on the cell surface. We conclude that lectin complement pathway activation triggered by ligand-CL-11 interaction in post-ischaemic tissue is a potent source of acute kidney injury and is amenable to sugar-specific blockade.

Scabies mites give mite associated bacterial pathogens a helping handSwe, P.M., Christian, L., Sriprakash, K.S., Fischer, K.
QIMR Berghofer Medical Research Institute, Brisbane, Australia

On a global scale scabies is one of the three commonest dermatological conditions, imposing a considerable economic burden on individuals, communities and health systems. Substantial epidemiological evidence shows that in tropical regions scabies is often linked to pyoderma. Patients can develop serious illness due to invasion by opportunistic bacteria such as cellulitis, heart and kidney diseases, bacteraemia and sepsis. The health burden due to complicated scabies in resource-poor Australian Aboriginal and Torres Strait Islander communities is extreme.

The molecular mechanisms that underpin the link between scabies and bacterial pathogens were unknown. We proposed that scabies mites play a role in the establishment, proliferation and transmission of opportunistic pathogens. We investigate here the impact of a scabies mite complement inhibitors on the growth of the two most recognised mite associated pathogens *Streptococcus pyogenes* and *Staphylococcus aureus*.

Scabies mites secrete several classes of complement inhibiting proteins into the mite gut and excrete them into the epidermal mite burrows. These inhibitors promoted the growth of bacteria *in vitro* in whole blood bactericidal assays. We tested specifically the mite complement inhibitor Serpin SMSB4 on various *S. pyogenes* clinical isolates. Recombinant SMSB4 was produced and purified from *Pichia pastoris*. The complement inhibitory function of SMSB4 was confirmed by haemolytic assays. SMSB4 reduced the opsonisation of the bacteria surface as well as the phagocytosis of bacteria by neutrophils. Investigation of the tripartite interactions between host, parasite and microbial pathogens could serve as a basis to develop novel intervention strategies targeting scabies and associated bacterial infections.

528

Complement C5 regulates TGF- β and response gene to complement -32 expression in experimental autoimmune encephalomyelitisTatomir, A.¹, Boodhoo, D.¹, Tegla, C.¹, Cudrici, C.¹, Weerth, S.², Rus, V.³, Rus, H.^{3,4,5}

¹University of Maryland, School of Medicine, Neurology, Baltimore, United States, ²Albert Einstein College of Medicine, Pathology, New York, United States, ³University of Maryland, School of Medicine, Medicine, Baltimore, United States, ⁴Veterans Administration Maryland Health Care System, Research Service, Baltimore, United States, ⁵Veterans Administration, Multiple Sclerosis Center of Excellence, Baltimore, United States

Complement activation plays a central role in autoimmune demyelination. We have analyzed the role of complement C5 in experimental autoimmune encephalomyelitis (EAE) using C5-deficient (C5-d) and C5-sufficient mice and found that the absence of C5 resulted in fiber loss and extensive scarring. We now show that TGF- β and Response Gene to Complement (RGC)-32 were significantly increased during EAE in C5-d mice.

Since TGF- β profibrotic effects are mediated in part by RGC-32 we investigated its expression during EAE. RGC-32 level was higher in C5-d mice paralleling the pattern seen for TGF- β during acute and chronic EAE. RGC-32 was found to be expressed by CD4⁺ T cells, monocyte/macrophages and astrocytes. To further investigate the role of RGC-32 in mediation of extracellular matrix production we stimulated astrocytes in culture with TGF- β and used siRNA to silence RGC-32 expression and then we determined whether TGF- β was still able to induce collagens I-V and α smooth muscle actin (α SMA). RGC-32 silencing resulted in a significant reduction in TGF- β - induced collagens I, IV and V and α SMA expression. Using astrocytes isolated from RGC-32 knockout (KO) mouse, we found that TGF- β - induced collagen I, IV and α SMA expression was significantly reduced in RGC-32 KO when compared with wild type mouse. These data suggests that TGF- β might be responsible for the gliosis seen in C5-d during chronic EAE and its effects are at least in part mediated by RGC-32. Therefore, RGC-32 may represent a new target for therapeutic intervention in progressive multiple sclerosis.

The complement modulator SALSA in placentaReichhardt, M.P.¹, Jarva, H.^{2,3}, Lokki, A.I.^{2,4}, Laivuori, H.^{4,5,6}, Vuorela, P.^{6,7}, Loimaranta, V.⁸, Siwetz, M.⁹, Huppertz, B.^{9,10}, Meri, S.^{2,3}

¹University of Oxford, Sir William Dunn School of Pathology, Oxford, United Kingdom, ²University of Helsinki, Immunobiology Research Program, Research Programs Unit, and Department of Bacteriology & Immunology, Medical Faculty, Helsinki, Finland, ³Helsinki University Hospital Laboratory (HUSLAB), Helsinki, Finland, ⁴University of Helsinki and Helsinki University Hospital, Medical Genetics, Helsinki, Finland, ⁵University of Helsinki, Institute for Molecular Medicine Finland, Helsinki, Finland, ⁶University of Helsinki and Helsinki University Hospital, Obstetrics and Gynecology, Helsinki, Finland, ⁷Porvoo Hospital, Obstetrics and Gynecology, Porvoo, Finland, ⁸University of Turku, Department of Medical Biochemistry and Genetics, Turku, Finland, ⁹Medical University of Graz, Institute of Cell Biology, Histology and Embryology, Graz, Austria, ¹⁰Medical University of Graz, Biobank Graz, Organizational Unit of Research Infrastructure, Graz, Austria

Background: The salivary scavenger and agglutinin (SALSA) has known functions in the antimicrobial defense at the mucosal surfaces. We have previously shown that SALSA also modulates the activation of the complement system, both in solution and on surfaces. Furthermore, we recently described the presence of SALSA in amniotic fluid. Strict regulation of the maternal immune response to the fetus is essential for a healthy pregnancy, and complications are often accompanied by immune attack towards components of placenta or the fetus itself. In the placenta this involves activation of the complement system.

Methods: In this study we investigated the potential role of SALSA in pregnancy by analyzing its presence in amniotic fluid and placental tissue during healthy and complicated pregnancies. SALSA levels in amniotic fluid were investigated using ELISA, and the expression in placenta was analyzed by fluorescence immunohistochemistry.

Results: SALSA levels in amniotic fluid increased during

pregnancy. Before 20 weeks of gestation the levels were slightly higher in patients who later developed pre-eclampsia than in gestation age-matched controls. In the placenta syncytial damage is often followed by the formation of fibrinoid structures. SALSA was found clustered into these fibrinoid structures in partial co-localization with complement C1q and fibronectin. In vitro analysis showed direct protein binding of SALSA to fibronectin.

Conclusion: In addition to antimicrobial defense, the data presented here suggest that SALSA, together with fibronectin and C1q, play a role in immunological regulation during pregnancy and may be involved in the containment of injured placental structures into fibrinoids.

⁴Aarhus University, Medical Microbiology and Immunology, Aarhus, Denmark

Thousands of leprosy patients in Brazil and India, not only suffer of physical deformities, but also either have or had HBV (hepatitis B virus) coinfection. Polymorphisms of the complement system modulate susceptibility to leprosy, but genetic susceptibility to coinfection is unknown. We used sequencing and multiplex sequence-specific PCR to genotype 55 functional/tag-SNPs of six genes encoding proteins of the lectin pathway (*MBL2*, *FCN1*, *FCN2*, *FCN3*, *MASP1*, *MASP2*) and two encoding complement receptors (*CR1*, *VSIG4-CR1g*) in up to 190 patients, 74 co-infected (positive for HBsAg and/or HBc) and 116 lepromatous. We also measured serum concentrations of mannan-binding lectin (MBL), MBL-associated proteins (MASP), H-ficolin (FCN-3), soluble complement receptor 1 (sCR1) and MBL mediated C4 activation (MBL-C4) in up to 167 patients. Polymorphisms lowering MBL, FCN-2, FCN-3, MASP-1 and MASP-2 concentrations increased susceptibility: *MBL2*LYQC* (OR=3.5, p=0.03), *FCN2*GGGCAC* (OR=3.6, p=0.01), *FCN3+1637delC* (OR=19.3, p=0.01), *MASP1*ACCA* (OR=4.4, p=0.001), *MASP2*p.126L+p.377A* (OR=4.6, p=0.013), respectively. *VSIG4* genotypes most probably producing a short form of the CR1g receptor, also increased susceptibility (OR=18.8, p=0.01), as well as *MASP2*2B1-i*, causing intermediate MASP-2 levels (OR=6.1, p=0.01) and *CR1*p.1208Arg*, associated with CR1 expression (OR=2.5, p=0.02). Except for *FCN2*, associations were independent of age, gender, ethnicity, institutionalization and lepromatous state, and did not increase susceptibility to leprosy *per se*. Associations for *FCN3*, *MASP1*, *MASP2* and *VSIG4* were also independent of each other. In conclusion, polymorphisms compromising activation of the lectin pathway of complement, as well as modulating the abundance of phagocytic receptors, increase susceptibility to leprosy-HBV coinfection.

The epidermal growth factor receptor regulates complement activation in the local environment of epithelial tumors

Abu-Humaidan, A., Mohanty, T., Schmidtchen, A., Ekblad, L., Sonesson, A., Sørensen, O.E.

Lund University, Clinical Sciences, Lund, Sweden

The Epidermal growth factor receptor (EGFR) is a tyrosine kinase receptor overexpressed in several epithelial tumors, and has proven to be an effective target for cancer treatment. EGFR controls diverse growth and immune functions, and its inhibition commonly leads to inflammatory skin lesions. Previously, we found that EGFR inhibition significantly enhanced the induction of complement components in keratinocytes and epidermis following stimulation with proinflammatory cytokines. Currently, Using Head and neck squamous cell carcinomas (HNSCC) cell lines, we found that EGFR inhibition decreased the expression of membrane complement regulatory proteins (mCRPs) and promoted activation of the complement system after incubation with serum in a C1q dependent manner in Cetuximab sensitive cell lines but not resistant cell lines. These data demonstrate an important role for EGFR in regulating the expression of complement components and complement activation in human epidermis and epithelial cancers and, to our knowledge, identify for the first time a pathway important for the epidermal regulation of complement activation. We hypothesize that tumors manipulate expression of membrane complement regulatory proteins (mCRPs) and other complement components to make use of complement's growth promoting or immune modulatory potential when faced with growth inhibition.

Association of CR1 gene polymorphisms with severe forms of falciparum malaria

Das, N.^{1,2}, Madhukar, M.^{1,2}, Aggarwal, P.^{1,2}, Samantray, J.^{1,2}

¹Nayati Multi Superspecialty Hospital, Lab Medicine, Mathura,

²All India Institute of Medical Sciences ND, Biochemistry, New Delhi, India

We conducted a case-control study to elucidate the association of two exonic (*exon19*, G3093T, molecular weight and Knop's blood group polymorphisms) and one intronic (*intron27* (A-T), polymorphisms of CR1 with severe *falciparum* malaria. Two hundred healthy subjects, 88 patients with non-severe and 59 patients with severe malaria from the National Capital Region of India were enrolled for the study. Gene analysis was done by PCR-RFLP. frequency distribution of genotypes and alleles of CR1 density and structural polymorphisms were determined by gene counting method and related with disease severity. Regarding *exon19*, G3093T polymorphism, Odd's ratio (OR) of GG genotype was 5.27 (95% CI=2.677-10.78, p< 0.05), 5.139 (95% CI=1.945-15.89, p< 0.05) and 5.243 (95% CI=2.82-9.98, p< 0.05) to develop complicated form of the disease as compared to GT, TT and T allele carriers (GT + TT), respectively. Regarding *intron27* (A-T), *HindIII* density polymorphism, OR for AA genotype was 6.428 (95% CI=3.193-13.61, p< 0.05), 6.779 (95%

CI=2.393-23.81, $p < 0.05$) and 6.525 (95% CI=3.44-12.79, $p < 0.05$) to develop complicated form of the disease as compared to AT', T'T' and T' allele carriers (AT'+T'T'), respectively.

The alleles of these two polymorphisms were in linkage equilibrium, the haplotypes of risk alleles imposed further risk of developing severe complications of the disease.

A population screening for these two risk alleles in the malaria endemic region or epidemic may help identify people at higher risk of malarial complication and save lives. Knops group mutants were absent. Molecular weight polymorphism did not relate to the disease.

Genetic variations of complement factors in schizophrenia

Ghazaryan, H.^{1,2}, Zakharyan, R.¹, Stepanyan, A.¹, Petrek, M.², Arakelyan, A.¹

¹Institute of Molecular Biology NAS RA, Laboratory of Human Genomics and Immunomics, Yerevan, Armenia, ²Palacky University, Laboratory of Immunogenomics, Olomouc, Czech Republic

Alterations in the immune response are involved in pathogenesis of schizophrenia - multifactor complex psychiatric disorder with heterogeneous clinical phenotype. Previous studies, including our own findings, indicated systemic hyperactivation of the alternative complement cascade in schizophrenia. However, molecular pathomechanisms of detected alterations are still unclear.

In the present study, we evaluated the potential association of schizophrenia with single nucleotide polymorphisms (SNPs) in genes encoding the complement factor B (*CFB*), complement factor H (*CFH*) and complement factor I (*CFI*) in Armenian population. Factor B is an essential component of the complement alternative pathway. Factors H and I are negative regulators of alternative pathway. In total, 310 patients with schizophrenia and 310 healthy subjects (controls) were enrolled in this study. Genomic DNA samples of schizophrenia patients and controls were genotyped for SNPs using polymerase chain reaction with sequence specific primers (PCR-SSP). Data were analyzed by Fisher's exact test. We measured also mRNA expression levels of these genes in peripheral blood (n=66 schizophrenia, n=99 controls).

According to the results obtained, *CFH* rs424535, *CFH* rs1061170 and *CFI* rs10033900 SNPs were positively associated with schizophrenia, while *CFB* rs12614 was negatively associated with schizophrenia. *CFH* rs800292, *CFI* rs1000954, *CFI* rs4469075 and *CFB* rs1048709 SNPs were not associated with schizophrenia. No differences in gene expression pattern were found.

In summary, our findings nominated *CFH* rs424535*A, *CFH* rs1061170*C and *CFI* rs10033900*C minor alleles as risk factors for schizophrenia, whereas the *CFB* rs12614 minor allele can be considered as a protective factor against this disease.

Understanding the role of Interleukin-6 in human immune system

Ono, R.¹, Tomizawa-Murasawa, M.¹, Sato, K.¹, Matsuda, M.², Hasegawa, T.², Yoshida, H.³, Ohara, O.^{4,5}, Amagai, M.^{6,7}, Koseki, H.², Ishikawa, F.¹

¹RIKEN Center for Integrative Medical Sciences, Laboratory for Human Disease Models, Yokohama, Japan, ²RIKEN Center for Integrative Medical Sciences, Laboratory for Developmental Genetics, Yokohama, Japan, ³RIKEN Center for Integrative Medical Sciences, Laboratory for Immunogenetics, Yokohama, Japan, ⁴RIKEN Center for Integrative Medical Sciences, Laboratory for Integrative Genomics, Yokohama, Japan, ⁵Kazusa DNA Research Institute, Department of Human Genome Research, Kisarazu, Japan, ⁶RIKEN Center for Integrative Medical Sciences, Laboratory for Skin Homeostasis, Yokohama, Japan, ⁷Keio University, Department of Dermatology, Tokyo, Japan

Interleukin-6 (IL-6) is a pleiotropic cytokine and important to the maintenance of immune homeostasis. Over-expression of IL-6 in mice results in anemia, splenomegaly and lymphadenopathy as well as local inflammation in skin and lung. In human, aberrant expression of IL-6 may be related with autoimmune diseases or chronic inflammatory diseases such as rheumatoid arthritis or Castleman's disease.

To study the function of human IL-6 in human immunity, we have developed NOD/SCID/IL2rgKO (NSG) mice expressing human IL-6 (hIL-6 TG NSG mice). By transplanting human hematopoietic stem cells to these mice, we confirmed differentiation of human T cells, B cells, and myeloid cells in the recipient organs. During longer-term observation, hIL-6 TG NSG recipients showed lethargy and skin inflammation. Histological examination demonstrated epidermal thickening and interface dermatitis. In the recipient lung, mice showed perivascularitis and narrowed or obstructed bronchioles. Human CD3+ T cells were detected in the skin and lung of these mice. These observations in hIL-6 TG NSG humanized mice are consistent with chronic GVHD. We found increased human CD4+ T cells producing interferon gamma and Interleukin-17 and decreased regulatory T cells in the recipient spleen.

Our experiments suggest that hIL-6 TG NSG mice may serve as an in vivo model to understand the role of human IL-6 in the pathogenesis of chronic GVHD.

Analysis of sites, kinetics and mechanisms of liver-graft-mediated depletion of alloreactive CD8 T cells reveals a critical role for liver tissue in liver transplant tolerance

Sierro, F.¹, Lu, B.D.², Tay, S.S.¹, Benseler, V.¹, McGuffog, C.¹, Bishop, A.G.³, Cowan, P.J.², Dwyer, K.M.², McCaughan, G.W.⁴, Bowen, D.G.⁴, Bertolino, P.¹

¹Centenary Institute, Liver Immunology, Camperdown, Australia, ²St Vincent's Hospital, Immunology Research Center, Melbourne, Australia, ³University of Sydney, Camperdown, Australia, ⁴Centenary Institute and AW Morrow Gastroenterology and Liver Centre, Camperdown, Australia

Unlike most solid organs, liver transplants are accepted across MHC incompatible barriers and induce donor-specific tolerance. The mechanisms, sites and kinetics of tolerance induction after transplantation remain unclear. Although donor passenger leukocytes (PL) are known to induce abortive activation of alloreactive T cells in recipient lymphoid tissues (RLT), some reports suggest that the liver tissue is a more important contributor to tolerance. We have developed a mouse liver transplantation model in which it is possible to trace the fate of PL, recipient leucocytes and of a reporter liver-reactive transgenic CD8 T cells expressing an H-2K^b-specific TCR. In this model, Ly5.2⁺C57BL/6 livers were transplanted into allogeneic Ly5.1⁺B10.BR recipients adoptively transferred following or prior transplantation with CFSE- or radio-labeled naïve alloreactive Tg T cells. Most liver-reactive CD8 T cells died within RLT within 48hrs following activation by PL. Although rare CD8 T cells surviving deletion, proliferated, recirculated in the blood and accumulated in the transplant, they were unable to reject the liver transplant or donor skin transplanted 100d post-liver transplantation. This tolerance effect was associated with clearance of donor CD8 T cells within the liver tissue following invasion and degradation in hepatocyte lysosomes. Thus, although most liver-reactive CD8 T cells were deleted in RLT within the first 48h post-transplantation, the liver plays a critical role in clearing surviving T cells. These results reveal a novel and unexpected sequence of events in which both RLT and liver tissue contribute to deletion of alloreactive T cells and to the induction of donor-specific tolerance.

Sterile inflammation is an understudied consequence of surgery which contributes to intra-graft inflammation. In this study, we

took a step towards modelling sterile inflammation using a syngenic murine heart transplantation model where native and grafted hearts were studied at Day 0 (n=5), Day 1 (n=3) and Day 7 (n=3) by RNAseq transcriptomic analysis. Mapping 75Gb of raw data to the reference genome, assembly, quantification and differential expression analysis of transcripts both longitudinally (T₀>T₁>T₇) and conditionally (native vs graft) identified genes with significant p-values which were then entered into Pathways Studio 11.0.5 for identification of significant curated inflammation pathways. Results reveal that pathways involving Anti-Inflammatory Function of Macrophage M2 Lineage, Vascular Endothelial Cell Permeability Activation and CR3-Mediated Phagocytosis in Neutrophils and Macrophages were dominantly up-regulated in both graft and native hearts throughout Days 1-7. Additionally, Eosinophil Activation, CC Chemokine Receptor Signalling and CXC Chemokine Receptor Signalling pathways were also significantly up-regulated but in only the native heart at Day 7. A key finding of transcriptomic analysis was the reversal of the regulation pattern at T₁ for above six pathways in the native heart relative to the graft heart. However, by T₇ three of these pathways had become up-regulated relative to T₁ akin to what was observed in the graft hearts at this later stage. Cellular characterisation of the infiltrates by flow cytometry and the impact of mismatched grafts are now being assessed as an aid to identify the underlying functional nodules at the interface between innate and adaptive immunity governing these pathways.

IL-28 Is a critical cytoprotectant in transplantation

Henden, A.^{1,2}, Robb, R.¹, Clouston, A.³, Kuns, R.¹, Lane, S.¹, Gartlan, K.¹, Hill, G.¹

¹QIMR Berghofer Medical Research Institute, Bone Marrow Transplantation Laboratory, Herston, Australia, ²University of Queensland, School of Medicine, Herston, Australia, ³Envoi Pathology, Brisbane, Australia

Aims: We have demonstrated a protective role for type I Interferons (IFN) through inhibition of Th1 differentiation invoked by recipient CD8neg dendritic cells after experimental bone marrow transplantation. Recently described Type III IFNs (IFNλ/IL-28) signal through the unique IL-28R primarily expressed in epithelial tissues and implicated in mucosal pathogen defence. Clinical use of type I IFN is associated with adverse neurological, haematological and constitutional symptoms where IL-28 is better tolerated, yet still demonstrates potent anti-viral effects.

Methods: We used IL-28R^{-/-} and IFNαR1^{-/-} donors and recipients in murine models of GVHD and GVL to develop logical therapeutic strategies to improve transplant outcomes.

Results: IL-28R^{-/-} donors invoked similar GVHD and GVL to WT. However IL-28R^{-/-} recipients had accelerated acute GVHD (aGVHD) mortality and disease relative to WT with a phenotype intermediate to that and the hyperacute aGVHD seen in IFNαR1^{-/-} recipients (median survival WT 42 vs. IL28R^{-/-} 26 vs. IFNαR^{-/-} 6.5 days, p< 0.0001). IL28R^{-/-} recipients have augmented colonic GVHD histopathology early (d 7) after BMT (WT 7.111±0.6550 vs. IL28R^{-/-}12.33±0.7993, p=0.0004) and

exaggerated inflammatory cytokine generation (d4 IFN γ WT 331 \pm 41.47pg/mL vs. IL28R $^{-/-}$ 667 \pm 48.79 pg/mL, $p < 0.0001$ and IL-6 WT 61.25 \pm 10.91pg/mL vs. IL28R $^{-/-}$ 91.99 \pm 11.23pg/mL, $p = 0.024$). Re-transplantation of chimeras with WT or IL28R $^{-/-}$ haematopoietic, non-haematopoietic tissue or combinations thereof demonstrated that IL-28 mediated protection required signalling through both compartments, putatively recipient antigen presenting cells and colonic epithelia.

Conclusion: IL-28 represents an attractive therapeutic to mediate cytoprotection within the GI tract and attenuate to GVHD in the peri-transplant period.

Revealing a critical cross-talk between beta islet cells and the vasculature in diabetes

Bonder, C.¹, Myo Min, K.K.¹, Parham, K.¹, Rojas-Canales, D.², Penko, D.², Drogemuller, C.², Coates, P.T.²

¹Centre for Cancer Biology, University of South Australia & SA Pathology, Adelaide, Australia, ²Centre for Clinical and Experimental Transplantation, Royal Adelaide Hospital & University of Adelaide, Adelaide, Australia

Pancreatic islet transplantation is a promising cellular therapy for Type 1 Diabetes; however, success rates are limited due to suboptimal revascularization of the islet graft once transplanted. Co-culture of endothelial cells with the insulin producing beta islet cells has been shown to improve beta cell survival and function *in vivo*. In light of this novel interaction between endothelial cells and beta islet cells, our study investigates the role of the surface cadherin desmoglein-2 (DSG2) as a novel and important cell adhesion molecule that mediates this cross-talk. We recently discovered that DSG2 is expressed by both endothelial and beta cells, and that beta cells from patients with diabetes have reduced gene expression of DSG2. Therefore, investigation of DSG2's cell-cell adhesion properties will aid in the understanding of the mechanisms of co-dependency between endothelial and beta cells. We generated, and then interrogated, *Dsg2*^{-/-} mice which revealed that *Dsg2* is important for blood vessel formation and that these mice are more susceptible to streptozotocin-induced diabetes. Immunofluorescence has also identified altered morphology of pancreatic vasculature in the *Dsg2*^{-/-} mice, suggesting a previously unrecognized role for this cadherin in the pancreas. Our investigation into the function of *Dsg2* suggests an important role in intercellular communication as well as possibly cell survival and proliferation. These novel findings suggest that DSG2 may be an important target in the fight against a debilitating metabolic disease that affects over 1 million Australians, diabetes.

3915

Understand the role of allo-HLA cross-reactive CD8+ T cells in a transplant setting

Rowntree, L.¹, Van der Heuvel, H.², Claas, F.², Kotsimbos, T.^{1,3}, Purcell, A.⁴, Mifsud, N.⁴

¹Monash University, Department of Medicine, Melbourne, Australia, ²Leiden University Medical Centre, Department of Immunohaematology and Blood Transfusion, Leiden, Netherlands, ³The Alfred Hospital, Department of Allergy, Immunology and Respiratory Medicine, Melbourne, Australia, ⁴Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia

Following solid organ transplantation with HLA-mismatched allografts, a proportion of the alloresponse can be attributed to anti-viral T cells which cross-react with the allograft and potentially mediate immunopathology. In addition, infection with or reactivation of latent DNA viruses such as Epstein Barr virus (EBV) have been associated with poor clinical outcomes post-transplantation. We have demonstrated that CD8+ T cells specific for HLA-B*07:02-restricted EBV peptide RPPFIRRL (B7/RPP) cross-recognise HLA-B*40:02, but only minimally recognise HLA-B*40:01. Cross-reactivity was identified when B7/RPP-specific CD8+ T cells were stimulated with allogenic (allo) PBMCs or transfected K562 cell lines (SALs) expressing alternate HLA molecules. Immune reactivity was then measured using proliferation or cytokine production. The T cell receptor (TCR) signature of two cross-reactive B7/RPP T cell clones from the same healthy donor was found to be TRAV14/DV14TRAJ9_TRBV19TRBJ2-7. Subsequent investigations in four HLA-B7+ lung transplant recipients (LTR) who received a HLA-B40 mismatched allograft were screened for cross-reactive B7/RPP-specific CD8+ T cells across a minimum of two time points ranging from pre- to 12 months post-transplant. Cross-reactive T cells were identified in two LTR; present at pre-, 6 and 11 months post-transplant for LTR117 (TCR signature TRAV38-1TRVJ43_TRBV4-1TRBJ2-3) and at 6 and 12 months post-transplant for LTR54 (TCR signature to be determined). Neither patient experienced EBV reactivation during the first 12 months post-transplant, as such LTR117 TCR usage remained static with no adverse clinical events affecting allograft function. This data corroborates our hypothesis that a clinically significant viral reactivation event is necessary to trigger immunopathology driven by cross-reactive T cells.

Characterising the immune response to allogeneic limbal stem cell transplantation

Sagoo, P.¹, Stauss, H.¹, Morris, E.¹, Shortt, A.J.^{1,2}

¹University College London, Institute of Immunity & Transplantation, London, United Kingdom, ²Moorfields Eye Hospital, Biomedical Research Centre for Ophthalmology, London, United Kingdom

Transplantation of *ex vivo* cultivated limbal stem cell (LSC) allografts is a promising approach for the treatment of clinical bilateral corneal disease caused by limbal stem cell deficiency (LSCD). The use of cultivated LSC from donor tissue would provide a bank of tissue-derived stem cell products for the estimated

10 million patients in need worldwide. However, allogeneic transplantation of LSC has a significantly higher rate of clinical graft failure than autologous LSC. Our current understanding of the immunological processes that lead to stem cell graft failure in the eye is limited and further compounded by the lack of model systems of this unique transplantation setting.

To study the immune mechanisms leading to LSC graft rejection, we have established a murine experimental model of LSCD and therapeutic LSC transplantation. LSCD induced through chemical burn injury is established within several days, with characteristic clinical features of corneal opacity, neovascularisation and epithelial defects. In parallel, LSCD induces a profound lymphocytic corneal infiltrate, composed primarily of inflammatory monocytes, NK, neutrophils and T cells. Corneal composite cell layers also respond to injury through the dramatic and sustained upregulation of MHC molecules, not only providing a potential source of donor alloantigen *in vivo*, but also the capacity to stimulate T cells through the direct pathway of allorecognition. Using a combination of traceable stem cell grafts and effector components of the immune response, with real-time imaging techniques, we are performing a detailed longitudinal analysis of the engraftment, survival and fate of LSC allografts in the eye.

2181

Combined blockade of VEGFR- and VEGFR-3 promotes high-risk corneal transplant survival 2

Wen, Y., Zhang, L., Kang, G.J., Chen, L.

University of California at Berkeley, Center for Eye Disease and Development, Program in Vision Science and School of Optometry, Berkeley, United States

Purpose: Though corneal transplantation enjoys a low rejection rate of 10% in uninflamed corneas or "low-risk" setting, the rejection rate in inflamed and vascularized corneas or "high-risk" setting can be as high as 50-90%. This study was designed to investigate the effect of combined blockade of VEGFR-2 and VEGFR-3 on "high-risk" corneal transplant survival.

Methods: High-risk corneal transplantation was performed between normal C57BL/6 (donor) and inflamed BALB/c (recipient) mice. The recipients were randomized to receive intraperitoneal injections of VEGFR-2 and VEGFR-3 neutralizing antibodies (provided by Eli Lilly and Company) or control twice a week for 8 weeks. Corneal grafts were evaluated by ophthalmic slit-lamp biomicroscopy and analyzed by Kaplan-Meier survival curve.

Results: Compared to the control group, the transplants in the treatment group demonstrated a greater degree of transparency and a higher rate of survival as well.

Conclusion: Combined blockade of VEGFR-2 and VEGFR-3 may offer a new and effective strategy to promote high-risk corneal transplant survival.

Sustained mixed chimerism and regulatory t-cell subsets reconstitution in patients with sickle cell disease after allogeneic hematopoietic stem cell transplantation

de Azevedo, J.T.C.^{1,2}, Palma, P.V.B.¹, Marques, A.¹, Simões, B.P.³, Covas, D.T.^{1,3}, Donadi, E.A.^{2,3}, Malmegrim, K.C.R.^{1,4}

¹National Institute of Science and Technology in Stem Cells and Cell Therapy, Regional Hemotherapy Center of the School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil,

²Department of Biochemistry and Immunology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil,

³Department of Clinical Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ⁴Department

of Clinical Analysis, Toxicological and Bromatological, School of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Introduction: Currently, allogeneic hematopoietic stem cell transplantation (HSCT) is a curative therapeutic option for patients with sickle cell disease (SCD). Nevertheless, hematologic and immune mechanisms involved with immune tolerance achievement after HSCT in SCD patients are not entirely elucidated. Therefore, to study the immune reconstitution dynamics and role of different cells after transplantation in SCD is of great relevance.

Methods and results: Chimerism analysis after HSCT was carried out by short tandem repeats sequencing of peripheral blood mononuclear cells from fifteen patients. Five patients had full chimerism, nine had mixed chimerism and one patient had graft failure. The average of donor cells was 78.38% at 1 month (N=9), 81.09% at 3 months (N=12), 81.27% at 6 months (N=14) and 80.39% at 12 months after transplantation (N=7). In addition, flow cytometry analyses of peripheral blood cells isolated from SCD patients at pre-transplantation and several periods after HSCT, demonstrated significant increased numbers of regulatory T-cell subsets ($p < 0.05$). CD4+CD25^{hi}GITR+ T-cell counts increased at 12 months (mean±SD: 6.33±6.31) after transplantation when compared to pre-transplantation (1.35±1.54) and CD8+CD28-CD57+ T-cell subset increased at 24 months (247.8±273.7) after transplantation compared to pre-transplantation (29.14±30.67).

Conclusion: Our results demonstrated that most patients did not have full chimerism after transplantation, indicating that sustained mixed engraftment is able to cure SCD patients. Immune reconstitution evaluations showed increased numbers of T-cell subsets with regulatory profile suggesting their involvement with immune tolerance development after HSCT in SCD patients.

The IBD-associated autophagy gene *Atg16l1* differentially regulates Treg and Th2 cells to control intestinal inflammation

Kabat, A., Pott, J., Maloy, K.

University of Oxford, Sir William Dunn School of Pathology, Oxford, United Kingdom

Autophagy is a homeostatic cellular degradation pathway with emerging roles in immune regulation. A polymorphism in the essential autophagy gene *Atg16l1* is associated with susceptibility to inflammatory bowel disease, however it remains unclear how autophagy contributes to intestinal immune homeostasis. Using targeted deletion of *Atg16l1* in T cells, we demonstrate a profound requirement for autophagy in the maintenance of balanced adaptive immune responses within the intestinal mucosa. Selective deletion of *Atg16l1* in T cells resulted in spontaneous intestinal inflammation and dysregulated type 2 humoral responses to dietary and microbiota antigens, including IgE responses. Disease correlated with a profound loss of Foxp3⁺ Treg cells, while mucosal Th2 population was selectively enhanced. We demonstrate that, in contrast to other intestinal T helper cells, autophagy intrinsically limits mucosal Th2 cell expansion, revealing a novel aspect of regulation of type 2 responses by autophagy. Furthermore, through selective ablation of *Atg16l1* in Treg cells we show for the first time that disruption of autophagy pathway in Treg cells is sufficient to drive severe systemic and intestinal inflammation, as autophagy is critically important for Foxp3⁺ Treg cells for their survival and metabolic adaptation to the intestinal environment. This study reveals a fundamental role of autophagy in orchestrating mucosal T cell responses, providing a new perspective on how impaired autophagy may predispose to intestinal inflammation and hypersensitivities, suggesting new translational perspectives for their treatment.

Medizinische Klinik, Hamburg, Germany, ⁶Icahn School of Medicine at Mount Sinai, Immunology Institute, New York, United States, ⁷Charité Universitätsmedizin, Immune Dynamics, Berlin, Germany

Interleukin (IL)-17-producing T helper cells (TH17) are major drivers of inflammation and have been involved in different human autoimmune diseases. Tissue inflammation is a beneficial host response to infection but can also contribute to inflammatory diseases and autoimmunity if it is unregulated. The crosstalk between the inflamed tissue and the immune system during an inflammatory immune response is a key factor for preserving the tissue integrity and to maintain the normal physiological processes. However, how inflamed tissue is able to regulate the magnitude of an immune response by controlling pro-inflammatory immune T cells is not well characterized so far. Here, we show that intestinal epithelial cells (IEC) are the main source of the alarmin interleukin-33 (IL-33) upon T-cell dependent intestinal inflammation. Moreover, we find that TH17 cells express the IL-33 receptor (ST2) *in vivo*. IL-33 promotes a reduced expression of pro-inflammatory genes (*Tbx21*, *Ifng* and *Csf2*) and induces the expression of *Il10* in mouse as well as human TH17 cells. Finally, we show that pro-inflammatory TH17 cells acquire immune-suppressive properties in response to IL-33. Our results give new insights into the control of pro-inflammatory TH17 in both mice and men, and provide a mechanism by which epithelial cells of the small intestine are able to regulate inflammatory responses via the IL-33/ST2 axis in order maintain systemic immune homeostasis.

MR1-dependent activation of intrahepatic MAIT cells by bacterially exposed biliary epithelial cells and liver B cells

Jeffery, H.C.¹, van Wilgenburg, B.², Kurioka, A.², Parekh, K.¹, Stirling, K.¹, Roberts, S.¹, Dutton, E.E.³, Hunter, S.¹, Geh, D.¹, Braitch, M.K.¹, Rajanayagam, J.¹, Iqbal, T.⁴, Pinkney, T.⁴, Brown, R.⁴, Withers, D.R.³, Adams, D.H.^{1,4}, Klenerman, P.², Oo, Y.H.^{1,4}

¹University of Birmingham, Centre for Liver Research & NIHR Biomedical Research Unit, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom, ²Oxford University, Peter Medawar Building for Pathogen Research, Oxford, United Kingdom, ³University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom, ⁴University Hospital of Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Mucosal-Associated Invariant T-cells (MAITs) are innate-like T-cells characterised by the invariant TCR-chain, Va7.2-Ja33 and high CD161 expression. They are activated by bacterial vitamin B metabolites presented on MR1, and function in antibacterial immunity at mucosal sites. MAITs are found in the human liver but the detailed characteristics of liver-infiltrating MAITs (LI-MAITs) in health and chronic liver diseases and their role in liver immune surveillance remained unexplored and were investigated in this study.

LI-MAITs were present at reduced frequency (% total CD3⁺ T-cells) in diseased compared to normal livers and ratios of CD4⁺/CD8⁺/CD4⁺CD8⁻ subsets altered. In normal and diseased livers LI-MAITs localized predominantly around bile ducts in portal tracts as shown by immunohistochemistry for TCR-Va7.2 and 4-colour confocal microscopy for CD3/CD161/TCR-Va7.2/nucleus. Consistent with this distribution, in flow cytometry analysis they expressed biliary-tropic chemokine receptors CCR6, CXCR6, and integrin α E β 7. LI-MAITs were also present at lower density in the hepatic sinusoids and possessed tissue-homing chemokine receptor CXCR3 and integrins LFA-1 and VLA-4, suggesting their recruitment via hepatic sinusoids. LI-MAITs had an activated, effector memory phenotype, expressed integrin α 4 β 7 and receptors for IL-12, IL-18 and IL-23 and produced cytokines IFN- γ , TNF- α , and IL-17. Importantly, in co-culture assays, in response to *E. coli*-exposed macrophages, liver B-cells and biliary epithelial cells, MAITs up-regulated IFN- γ , TNF- α and CD40-Ligand and degranulated in an MR1-dependent, cytokine-independent manner.

Our findings provide the first evidence of an immune surveillance effector response for MAITs towards biliary epithelial cells and B-cells in human liver that might be targeted therapeutically in the future.

Expression of CCR2 on CD4⁺ T-cells is critical for mediating colonic inflammation and modulating gut microbiota to promote intestinal tumorigenesis

Jala, V.¹, Bodduluri, S.¹, Chilton, P.², Chheda, Z.², Sharma, R.², Haribabu, B.¹

¹University of Louisville, Dept. of Microbiology and Immunology, Louisville, United States, ²University of Louisville, Louisville, United States

CCR2/CCL2 axis is critical for recruitment of immune/inflammatory cells including peripheral blood monocytes/macrophages, immature dendritic cells and mast cells. The molecular mechanisms involving CCR2/CCL2 axis in promoting colon cancer are unknown. We investigated CCR2 dependent recruitment of immune cells and modulation of gut microbiota in the context of colon tumorigenesis. Our data demonstrated that lack of CCR2 in the *Apc*^{Min/+} mice (a spontaneous intestinal tumor model) background significantly increased survival and decreased small intestinal and colon tumors both in size and number compared to *Apc*^{Min/+} mice. Analysis of tumors suggested that CCR2^{-/-}*Apc*^{Min/+} displayed decreased tumor infiltrating F4/80⁺ cells, CD8⁺ T cells as well as inflammatory mediators (e.g., IL-6, CXCL1, IL-23 and IL-17) compared to *Apc*^{Min/+} mice. Gut microbiota analysis suggested that significant

reduction in tumor promoting *Bacteroides* genus in CCR2^{-/-}*Apc*^{Min/+} mice compared to *Apc*^{Min/+} mice indicating critical role for CCR2 in maintaining gut homeostasis. To define the role of CCR2 on CD4⁺ T-cell function, we adoptively transferred of splenic CD4⁺ T- cells from CCR2^{-/-}*Apc*^{Min/+} mice into Rag2^{-/-} mice. Interestingly, Rag2^{-/-} mice transferred with CCR2^{-/-}*Apc*^{Min/+} CD4⁺ T- cells did not develop colitis, whereas CD4⁺ *Apc*^{Min/+} T-cell transferred mice developed significantly severe colitis. Next, in CD45Rb^{hi} T-cell induced colitis model, adoptive transfer of CCR2^{-/-} CD4⁺ CD45Rb^{hi} T-cells in to Rag2^{-/-} mice also failed to develop colitis and significantly reduced IL-17 production. In summary, results suggests that expression of CCR2 is critical for recruitment of tumor-associated macrophages (TAMs) as well as activation and recruitment of Th17 cells to promote intestinal inflammation and tumorigenesis.

1058

Aeroallergen-induced IL-33 predisposes to respiratory virus-induced asthma by dampening type I and III interferon production

Werder, R.¹, Lynch, J.¹, Simpson, J.¹, Loh, Z.¹, Zhang, V.¹, Spann, K.², Sly, P.³, Mazzone, S.¹, Upham, J.⁴, Phipps, S.¹

¹University of Queensland, School of Biomedical Science, Brisbane, Australia, ²Queensland University of Technology, Brisbane, Australia, ³University of Queensland, Queensland Children's Medical Research Institute, Brisbane, Australia, ⁴University of Queensland, School of Medicine, Brisbane, Australia

Frequent viral lower respiratory infections (vLRI) and allergic sensitization in early life are independent risk factors for asthma onset, yet together significantly increase the development of persistent asthma. We developed an experimental model of asthma to investigate this synergy. Neonatal BALB/c mice were inoculated with low dose pneumonia virus of mouse (PVM; 1pfu) then exposed to low dose (1 μ g) cockroach antigen or vehicle control at 3 days post infection (dpi). Some mice were re-infected 6 weeks later and exposed to weekly doses of allergen. Virus and allergen co-exposure was critical in both early and later life for disease onset and progression, including airway hyperreactivity, airway remodelling and type 2 inflammation. Allergen exposure during primary vLRI increased IL-33 release and impaired antiviral cytokine production, leading to increased epithelial viral burden, Th2-type inflammation and airway smooth muscle growth. Neutralisation of IL-33 in early life prevented type 2 inflammation, airway remodelling and reversed the dampened interferon response mediated by cockroach antigen. Substitution of allergen with exogenous IL-33 attenuated antiviral cytokines, elevated viral load and promoted airway remodelling. Mechanistically, we found that IL-33 degraded IRAK1 to dampen type I IFN production by plasmacytoid DC. In summary, we identify a novel role for IL-33 in regulating antiviral immunity and as a target to attenuate the synergistic interplay between two important environmental insults in the onset and progression of asthma.

1375

Notch-STAT5b is central for the development of TCRαβ⁺CD8αα⁺ small intestinal intraepithelial lymphocytes*Ishifune, C.¹, Maekawa, Y.², Hozumi, K.³, Yasutomo, K.¹*¹Graduate School of Medicine, Tokushima University, Department of Immunology and Parasitology, Tokushima, Japan, ²Gifu University Graduate School of Medicine, Department of Parasitology and Infectious Diseases, Gifu, Japan, ³Tokai University School of Medicine, Department of Immunology, Isehara, Japan

Intraepithelial lymphocytes (IELs) in the small intestine are divided into several subsets and TCRαβ⁺CD8αα⁺ IELs and TCRγδ⁺ IELs have suppressive roles in colitis models. However, the molecular mechanisms underlying IELs development and their functions are largely obscure.

We found that TCRαβ⁺CD8αα⁺ IELs and their maturation from Thy1⁺ to Thy1^{neg} Granzyme B⁺ cells in the small intestine were markedly decreased in CD4-Cre dependent Notch1, 2-Rbpj signal deficient mice compared with control mice. We did not find any reduction of IELs precursors in the thymus and their ability to differentiate toward CD8αα⁺ cells in CD4-Cre Rbpj^{fl/fl} mice *in vitro*. Villin1-Cre dependent Jagged1, Dll1 or Dll4 deficient mice had normal number of IELs. Those data indicate that both Notch1 and Notch2 regulate the differentiation of TCRαβ⁺CD8αα⁺Thy1^{neg} IELs but Jagged1, Dll1, Dll4 in the intestinal epithelium is not involved in the differentiation. TCRαβ⁺CD8αα⁺ IELs from CD4-Cre Rbpj^{fl/fl} mice have reduced expression of STAT5b but not STAT5a. CD4-Cre Stat5a/b^{fl/fl} mice had few numbers of TCRαβ⁺CD8αα⁺ IELs, suggesting that STAT5a/b is required for the regulation of TCRαβ⁺CD8αα⁺ IELs. Furthermore, overexpression of constitutive-active STAT5b in CD4-Cre Rbpj^{fl/fl} mice could partially rescue the reduction of TCRαβ⁺CD8αα⁺ IELs but not their maturation.

These data indicate that Notch1 and Notch2 control the differentiation of TCRαβ⁺CD8αα⁺ IELs in the small intestine without affecting its precursor development. Furthermore, Notch-mediated differentiation of TCRαβ⁺CD8αα⁺ IELs would be, at least partly, regulated by the activation of STAT5b signaling.

Probiotics in Crohn disease: selecting strains able to trigger Paneth cells-derived antimicrobial response and downregulate inflammatory responses*Hrdy, J.^{1,2}, Cesaro, A.³, Lapadatescu, C.⁴, Chamailard, M.³, Pot, B.², Grangette, C.²*¹First Faculty of Medicine, Charles University in Prague, Institute of Immunology and Microbiology, Prague, Czech Republic, ²Bactéries Lactiques et Immunité des Muqueuses, Centre d'Infection et d'Immunité de Lille, CNRS UMR 8204, Institut Pasteur de Lille, Université Lille Nord de France, Lille, France, ³Récepteurs Nods-Like dans l'Infection et l'Immunité, Centre d'Infection et d'Immunité de Lille, Inserm U 1019-CNRS UMR 8204, Institut Pasteur de Lille, France, Université Lille Nord de France, Lille, France, ⁴Bioprox Company, Levallois, France

In genetically susceptible individuals, an inappropriate mucosal immune response against intestinal microbiota appears to be the principal mechanism leading to the pathogenesis of IBD. Importantly, Paneth cells showed impaired secretion of

antimicrobial peptides in Crohn disease patients. Our aim was to select probiotic strains able to restore the functionality of Paneth cells and dampen inflammatory immune responses. The capacity of probiotic strains to induce defensin expression was tested *in vitro* using the murine epithelial cell line mCcl2. Induction of activation markers on bone marrow derived dendritic cells (BMDC) after 24 hrs of coculture with bacterial strains was followed by flow cytometry. The potential of probiotic strains to promote either Th17 or Tregs was evaluated by coculture of naive CD4⁺CD25⁻ cells with probiotic-primed BMDC. Mouse model of *Citrobacter rodentium* infection and TNBS acute colitis were used for testing capacity of probiotic strains to decrease inflammation *in vivo*. The best inducers of defensins in mCcl2 were *E. coli*, *L. reuteri* or *L. acidophilus* strains. *L. acidophilus* strains were the most potent inducers of activation markers on BMDC and the best inducer of IL-17, while *L. reuteri* strains were the best inducers of Tregs. In a mouse model of *Citrobacter rodentium* infection, selected strains were able to decrease parameters of inflammation and to increase defensin gene expression in colon of infected mice. In conclusion, we have identified several promising probiotic strains in the context of IBD. Detailed mechanism of action needs to be clarified. This work was supported by ANR project BIOpaneX, AZV15-26877.

Characterization of the inflammatory response in the upper respiratory tract following influenza infection*Palomino Segura, M., F. Gonzalez, S.**Institute for Research in Biomedicine (IRB), Bellinzona, Switzerland*

Influenza virus is responsible of high morbidity and mortality worldwide and a leading cause of death amongst young children, old people and the immuno-compromised. Despite the fact that the initial phase of the infection occurs in the upper respiratory tract, little is known about the immune reaction that follows infection and how it affects the outcome of the disease. Our research focused on elucidating the role of the inflammatory response in the mucosa of the trachea during early stages following influenza infection. Using 2-photon microscopy we observed a the dense network of dendritic cells (DC) located under the mucosa of the trachea from mice, which increased significantly their number at day 3 post infection (p.i.) with influenza virus. The characterization of the tracheal subgroups of DC according to the expression of different surface markers indicated that at day 3 p.i. the majority of the infiltrated DC correspond to the inflammatory phenotype (CD45⁺, CD11c⁺, MHCII⁺, CD11b⁺, Ly6c^{hi}). The recruitment of DC coincided in time with a prominent infiltration of NK cells and elevated levels of IFNγ at day 3 p.i.. We hypothesized that the latter are responsible of this early secretion of IFNγ, which most likely affected the maturation state of the inflammatory DC. Additionally, we observed that IFNγ production is crucial for the recruitment of neutrophils to the site of infection. In future studies we will evaluate how the manipulation of the early inflammation events will influence the initiation of the adaptive response and the outcome of the disease.

Monoclonal intestinal IgAs are poly-reactive but recognize a specific amino acid sequence of protein expressed by multiple bacteria

Usui, F.¹, Okai, S.¹, Hasegawa, M.², Yamamoto, K.³, Nishiyama, E.³, Mori, H.³, Yamada, T.³, Kurokawa, K.⁴, Shinkura, R.¹

¹Nagahama Institute of Bio-Science and Technology, Immunology, Shiga, Japan, ²Nagahama Institute of Bio-Science and Technology, Protein Function Analysis, Shiga, Japan, ³Tokyo Institute of Technology, Graduate School of Bioscience and Biotechnology, Tokyo, Japan, ⁴Tokyo Institute of Technology, Earth-Life Science Institute, Tokyo, Japan

Immunoglobulin A (IgA) is the main antibody isotype secreted into the intestinal lumen. It plays a critical role in the defense against pathogens and in the maintenance of intestinal homeostasis. However, the molecular mechanisms of how secreted IgA regulates intestinal microbiota are not completely understood. We generated IgA-producing hybridomas derived from the intestinal IgA-secreting cells of wild-type mice. Four monoclonal IgAs (W27, W30, W34, W43) bound to more than 10 different intestinal bacteria with variable affinity. To elucidate their specific antigens, two different bacteria (*Escherichia coli* and *Pseudomonas fulva*) were lysed and used for Western blotting. Unexpectedly, all those four monoclonal IgAs recognized a single protein at the size of about 50 kDa. On the contrary, these four monoclonal IgAs did not recognize any proteins expressed in *Bifidobacterium bifidum*, *Blautia coccoides* and *Lactobacillus casei*. Mass spectrometry analysis revealed that four monoclonal IgAs recognized a same protein, serine hydroxymethyltransferase (SHMT) in *E. coli*. Most bacteria have *glyA* gene encoding SHMT. We further identified the epitope of SHMT in its N terminus. W27 recognized specific four amino acids (EEHI) in their N-terminal motif of *E. coli* and *Pseudomonas fulva*, but W27 did not recognize the different AAs in the corresponding position of *Blautia coccoides* and *Lactobacillus casei*. Our observations strongly suggest that W27 selectively binds to variable colitogenic/pathogenic bacterial species with the strict recognition of SHMT motif, while ignoring the beneficial ones (*Bifidobacterium bifidum*, *Blautia coccoides* and *Lactobacillus casei*). Thus we show a plausible molecular mechanism how intestinal IgA regulates gut microbiota.

IL-27-producing CD4⁺ T cells regulate protective immune responses during malaria infection

Kimura, D.¹, Doe, H.¹, Miyakoda, M.¹, Kimura, K.¹, Hara, H.^{2,3}, Yoshida, H.², Yui, K.¹

¹Nagasaki University, Molecular Microbiology and Immunology, Nagasaki, Japan, ²Saga University, Biomolecular Sciences, Saga, Japan, ³Kagoshima University, Immunology, Kagoshima, Japan

Malaria infection causes immune modulation or suppression by mechanisms not clearly understood. Here, we report the induction of novel regulatory CD4⁺ T cells that produce IL-27, a heterodimeric regulatory cytokine of IL-12 family consisted of

p28 and EB13 subunits, in mice infected with malaria parasites. IL-27-producing CD4⁺ T cells were induced in mice infected with 4 different strains of malaria parasites, but were undetectable in mice infected with *Listeria monocytogenes*. These cells are foxp3⁻CD11a^{hi}CD49d^{hi} malaria antigen-specific CD4⁺ T cells, express inhibitory receptors, PD-1 and LAG-3, produce IL-27 in response to malaria antigen, and inhibit IL-2 production and clonal expansion of other T cells in an IL-27-dependent manner. Intracellular cytokine staining indicated that these CD4⁺ T cells are distinct from IFN- γ -producing Th1 or IL-10-producing Tr1 cells, and we propose to designate them as Tr27 cells. While innate immune cells have been considered the major IL-27 producers, these T cells were the major source of IL-27 during malaria infection.

In mice lacking IL-27 in T cells, IL-2 production was restored and clonal expansion and IFN- γ production by specific CD4⁺ T cells were improved during malaria infection, culminating in the reduced parasite burden when compared with those in IL-27-sufficient mice. This study highlights novel, IL-27 producing regulatory CD4⁺ T cells (Tr27 cells) and their critical roles in the regulation of the protective immune responses against malaria infection.

Immunomodulation of *Plasmodium* pathogenicity by hepatic gamma-delta T cells in experimental cerebral malaria

Silva-Santos, B., Ribot, J., Neres, R., Mancio-Silva, L., Zuzarte-Luis, V., Gomes, A.Q., Mota, M.M., Pamplona, A.
Instituto de Medicina Molecular, Lisbon, Portugal

Symptomatic malaria infection has been associated with activation and expansion of pro-inflammatory $\gamma\delta$ T cells in the peripheral blood of *Plasmodium falciparum*-infected children. However, previous studies failed to identify a non-redundant role for $\gamma\delta$ T cells in animal models of severe malaria. Here we show that mice lacking $\gamma\delta$ T cells (TCR $\delta^{-/-}$) are strikingly resistant to experimental cerebral malaria (ECM) when infected with *P. berghei* ANKA sporozoites (or mosquito bite), while fully susceptible if challenged with *P. berghei* ANKA-parasitized red blood cells. This reveals an unappreciated pathogenic role of murine $\gamma\delta$ T cells that is strictly dependent on the liver stage of infection. We further show that the presence of $\gamma\delta$ T cells significantly modulated the expression of ~20% of the parasite genome at the end of the liver stage, with a focus on the induction of GPI-anchored proteins associated with pathogenicity. As consequence, TCR $\delta^{-/-}$ mice displayed reduced immune activation and an intact blood-brain barrier, in contrast with TCR $\delta^{+/+}$ controls. Of particular relevance was the impairment in the pro-inflammatory cytokine interferon- γ (IFN γ), which was reduced in the serum, in splenic CD4⁺ and CD8⁺ T cells and in the brain of TCR $\delta^{-/-}$ mice. Importantly, IFN $\gamma^{-/-}$ mice phenocopied the ECM resistance of TCR $\delta^{-/-}$ mice. We thus propose that hepatic $\gamma\delta$ T cells modulate *Plasmodium* pathogenicity and the inflammatory syndrome associated with CM. This unravels the importance of the liver stage, which has been widely neglected in CM pathogenesis, while elucidating the potential of targeting $\gamma\delta$ T cells in future therapeutic approaches.

The parasitic worm-derived immunomodulator, ES-62 and its drug-like small molecule analogues are protective in a model of chronic asthma

Harnett, W.¹, Coltherd, J.², Rodgers, D.², Lawrie, R.², Al-Riyami, L.¹, Suckling, C.¹, Harnett, M.²

¹University of Strathclyde, Glasgow, United Kingdom, ²University of Glasgow, Glasgow, United Kingdom

Chronic asthma is associated with persistent lung inflammation and long-term remodelling of the airways. The condition has proved refractory to conventional treatments such as steroids, despite their efficacy in controlling acute airway contraction and bronchial inflammation. As the increase in asthma incidence noted in industrialised countries has not been mirrored in developing regions, it has been suggested that helminth infection may protect humans against developing the disease. Consistent with this, we have previously shown that ES-62, an immunomodulator secreted by the filarial nematode *Acanthocheilonema viteae*, can protect against airway hyper-responsiveness and inflammation in a mouse model of acute asthma. We now report that ES-62 can also prevent cellular infiltration of the lungs, particularly neutrophils and mast cells, and in addition mucus hyper-production and airway thickening in a chronic disease mouse model and this is associated with increased levels of IL-10-producing, putative MZ-like regulatory B cells. Importantly, ES-62 can act even after airway remodelling has been established, arresting pathogenesis and ameliorating the inflammatory flares resulting from repeated exposure to allergen that are a debilitating feature of severe chronic asthma. Moreover, two drug-like synthetic analogues of ES-62, termed 11a and 12b mimic its therapeutic actions in restoring levels of regulatory B cells and suppressing neutrophil and mast cell responses. These studies therefore provide a platform for developing ES-62-based drugs, with compounds 11a and 12b representing the first step in the development of a novel class of drugs to combat the hitherto intractable disorder of chronic asthma.

2366

Low affinity CD8 T cells participate in the T cell response to *Plasmodium* infection

King, T.¹, Neeld, D.², Evavold, B.², Lamb, T.¹

¹Emory University School of Medicine, Pediatric Infectious Diseases, Atlanta, United States, ²Emory University School of Medicine, Microbiology and Immunology, Atlanta, United States

Previous studies have demonstrated expansion and activation of CD8 T cells in response to *Plasmodium*-infected red blood cells (iRBCs). In the case of *Plasmodium berghei* ANKA infections in C57BL/6 mice, activated CD8 T cells mediate the development of symptoms resembling cerebral malaria (experimental cerebral malaria; ECM). Using monomeric MHC-I loaded with immunodominant *Plasmodium* epitopes we measured the frequency and 2 dimensional affinity of the T cell receptor (TCR) of polyclonal CD8 T cells in spleen and brain in *Plasmodium*-infected mice. Here we show that the majority of *Plasmodium*-reactive CD8+T cells that expand in the spleen have low affinity

TCRs; for the glideosome associated protein 50 (GAP50)₄₀₋₄₈ epitope at day 5 post-infection with *P. berghei* ANKA 1.2% of the polyclonal CD8 T cells are tetramer +ve high affinity GAP50₄₀₋₄₈-reactive whereas 30% are tetramer -ve with low affinity TCRs to GAP50₄₀₋₄₈. In *P. berghei* ANKA infection low affinity CD8 T cells migrate to the brain in large numbers indicating that they are important component of the pathogenic response. Adoptive transfer experiments with P14 transgenic T cells reactive to the P14 epitope of lymphocytic choriomeningitis virus (LCMV) show that only *Plasmodium*-reactive cells migrate to the brain during infection providing further evidence that the low affinity CD8 T cells in the brain are *Plasmodium*-reactive. Taken together, these results demonstrate that both low and high affinity CD8 T cells participate in the polyclonal CD8 T cell response to *Plasmodium* infection.

Plasmodium-associated TIM3 expression on $\gamma\delta$ T cells results in functionally impaired cells and decreases the risk of clinical malaria

Schofield, L.^{1,2,3}, Ioannidis, L.^{1,3}, Karl, S.^{1,3}, Robinson, L.^{1,3,4}, Tan, Q.^{1,3}, Poole, D.^{3,5}, Betuela, I.⁴, Hill, D.^{1,3}, Siba, P.^{4,6}, Hansen, D.^{1,3}, Mueller, I.^{1,3}, Eriksson, E.^{1,3}

¹Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, ²Australian Institute for Tropical Health and Medicine, James Cook University, Townsville, Australia, ³Melbourne University, Parkville, Australia, ⁴Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, ⁵Monash Institute of Pharmaceutical Sciences, Monash University, Parkville, Australia, ⁶School of Veterinary and Biomedical Sciences, James Cook University, Townsville, Australia

Recent studies suggest that dysfunctional $\gamma\delta$ T cells induce tolerance to the *Plasmodium* parasite. However, the immunological basis for this dysregulation is not completely understood. Thus, investigation of the biology and immunoregulation of $\gamma\delta$ T cells will further elucidate host immune factors affecting malaria disease outcomes. This study focused on T-cell immunoglobulin domain and mucin domain 3 (TIM3) expression on $\gamma\delta$ T cells in a malaria mouse model and in children (n=132, 5-10 years) living in malaria endemic areas of Papua New Guinea. We assessed the underlying mechanisms contributing to TIM3 upregulation, effect on functional capacity and association with malaria exposure and outcomes. In mice TIM3 expression was upregulated following malaria infection and was maintained both after clearance of infection and in chronically-infected mice. Similarly, the frequency of TIM3+ $\gamma\delta$ T cells was increased in malaria-exposed individuals compared to healthy controls from non-malaria endemic areas. Of note, children with recent *P. vivax* infection had fewer TIM3+ $\gamma\delta$ T cells compared to children with recent *P. falciparum* infection or co-infections with multiple species. Furthermore, TIM3 upregulation was IL-12/IL18-dependent and associated with exposure to distinct species and clones. Functional assessment of TIM3+ $\gamma\delta$ T cells demonstrated a lack of cytokine production and cytotoxic capacity following stimulation. Notably, presence of these cells was associated with decreased risk of acquiring clinical episodes. Collectively, our findings provide fundamental

insight into the immune-specific processes involved in innate immune regulation and suggest that this is a contributing mechanism to limit clinical symptoms during malaria infection.

The NLRP3 inflammasome negatively regulates type 2 immunity to gastrointestinal helminth infection

Alhallaf, R.¹, Agha, Z.¹, Miller, C.M.¹, Robertson, A.A.², Dent, L.A.³, Cooper, M.A.², Masters, S.L.⁴, Smith, N.C.¹, Loukas, A.¹, Giacomin, P.R.¹

¹Australian Institute for Tropical Health and Medicine, James Cook University, Cairns, Australia, ²Institute for Molecular Bioscience, The University of Queensland, Brisbane, Brisbane, Australia, ³School of Biological Sciences, University of Adelaide, Adelaide, Australia, ⁴Division of Inflammation, The Walter and Eliza Hall Institute of Medical Research, Parkville, Victoria, Australia

Inflammasomes have a key role in the immunopathobiology of several chronic inflammatory diseases, as well as controlling immunity to viruses, bacteria, fungi and protozoan parasites, by regulating the function of pro-inflammatory IL-1-family cytokines such as IL-18 and IL-1 β . However, roles for inflammasomes in regulating immunity and inflammation during infections with large, metazoan pathogens such as parasitic helminth remain unclear. Using a murine model of gastrointestinal nematode infection (*Trichuris muris*), we demonstrate that helminth infection is associated with increased IL-18 expression and this is dependent on a component of certain inflammasomes, namely NLRP3. Mice deficient in NLRP3 display reduced parasite antigen-specific Type 1 immune responses and intestinal immunopathology, coincident with amplified Type 2 cytokine responses, goblet cell hyperplasia, eosinophilia and accelerated worm expulsion. Similar results were observed when NLRP3 was targeted therapeutically using a specific chemical inhibitor. Critically, delivery of exogenous rIL-18 to NLRP3-deficient mice restored parasite-induced Th1 responses and chronicity of infection. NLRP3 also negatively regulated protective immunity to infection with the hookworm-like nematode, *Nippostrongylus brasiliensis* and humans experimentally infected with hookworms displayed elevated IL-18 expression, consistent with inflammasome activation. Together, these data highlight a previously unrecognised role for NLRP3 in limiting protective immunity to gastrointestinal helminths, suggesting that targeting the NLRP3-inflammasome axis may be a novel approach for limiting the immunopathology associated with helminth infections.

The IL-12 response to *Toxoplasma gondii* in humans involves a pathogen sensing mechanism and myeloid cell subsets distinct from those utilized by mice

Jankovic, D., Tosh, K., Mittereder, L., Sher, A.
Laboratory of Parasitic Diseases, NIAID, NIH, Bethesda, United States

Toxoplasma gondii is an intracellular protozoan parasite that infects mice as part of its natural transmission cycle and induces

disease in humans, an end-stage host. As one of the natural hosts of *T. gondii*, the mouse has been used extensively for elucidating the cellular and molecular basis of immunity to this pathogen while little is known how human cells detect and respond to *T. gondii*. In addressing this issue, we found that primary monocytes and dendritic cells from peripheral blood of healthy donors produce IL-12 and other proinflammatory cytokines when exposed to toxoplasma tachyzoites. Cell fractionation studies determined that IL-12 and TNF- α secretion is limited to CD16+ monocytes and the CD1c+ subset of dendritic cells. Interestingly, these myeloid subsets represent the opposite counterparts from those triggered by the parasite in mice. Moreover, while the innate cytokine response to *T. gondii* in the mouse depends on the interaction of TLR11 and TLR12 with soluble parasite ligand, profilin, the response in human myeloid cells instead requires phagocytosis of the live pathogen. We speculate that these marked distinctions in the pathways utilized for innate recognition of toxoplasma in mouse and man reflect the differing roles of the two hosts in the biology of this parasite.

System biology approaches to identify Gene-microRNA pathophysiology related networks in Chagas disease

Ferreira, L.R.P.^{1,2,3,4}, Laugier, L.⁵, Ferreira, F.M.^{1,2,3,4}, Cabantous, S.⁵, Cândido, D.D.S.^{1,2,3}, Rozanski, A.⁶, Lannes-Vieira, J.⁷, Chevillard, C.⁵, Kalil, J.^{1,2,3}, Cunha-Neto, E.^{1,2,3}

¹Heart Institute of São Paulo (InCor), Laboratory of Immunology, Sao Paulo, Brazil, ²University of Sao Paulo - School of Medicine, Division of Clinical Immunology and Allergy, Sao Paulo, Brazil, ³Institute for Investigation in Immunology, iii-INCT, Sao Paulo, Brazil, ⁴Universidade Santo Amaro (UNISA), Sao Paulo, Brazil, ⁵INSERM U906 - AIX Marseille Université AMU, Faculté de Médecine, Marseille, France, ⁶Hospital Sírio-Libanês, Sao Paulo, Brazil, ⁷Laboratory of Biology of Interactions, Oswaldo Cruz Institute (FIOCRUZ), Rio de Janeiro, Brazil

The objective of this study was to integrate gene and miRNA expression profiling data from heart of mice acutely infected with the protozoan parasite, *Trypanosoma cruzi* (*T. cruzi*). The gene expression profiling was obtained using time-series microarray data of hearts from mice uninfected and infected for 15, 30 and 45 days with Colombiana *T. cruzi* strain (n=4 per group), same samples previously used for microRNA profiling. The differentially expressed genes (DEGs) and differentially expressed miRNAs (DEMs) were used to conduct functional enrichment analysis and construct gene-miRNA interaction networks. We found that *T. cruzi* acute infection displays specific gene expression profile involving previously described pathways like: pathogen-associated molecular patterns (PAMPS) recognition, production of Nitric oxide by Macrophages and NF- κ B signaling. We also found pathways, not described yet related to *T. cruzi* infection, like: triggering receptor expressed on myeloid cells (TREM)-1, Tyrosine-protein kinase (Tec), and High mobility group box 1 (HMGB1) signaling. By integrating mRNA and miRNA expression data, we could identify miRNA targets

that are important players in each one of these pathways. We also describe how these identified pathways could lead to the development and establishment of each one of the main clinical parameters of heart Chagas disease: myocarditis, fibrosis, arrhythmia and heart hypertrophy. Our data identified specific molecular features of acute *T. cruzi* infection that may translate in the identification of novel relevant drugable targets.

195

Caspase-11 activation is an important effector mechanism against *Leishmania amazonensis* infection

Carvalho, R.V.H.^{1,2}, Lima-Júnior, D.S.¹, Zamboni, D.S.¹

¹University of São Paulo, Department of Cell Biology, Ribeirão Preto Medical School, Ribeirão Preto, Brazil, ²University of São Paulo, Department of Biochemist and Immunology, Ribeirão Preto Medical School, Ribeirão Preto, Brazil

Introduction: Leishmaniasis is a disease that affects millions of people worldwide. Although several studies have been performed in order to better understand its pathogenesis, more effective treatments and vaccines haven't been successfully developed so far. The innate immune response against *Leishmania* spp. has been shown to be coordinated by pattern recognition receptors, such as Toll-like receptors and NLRP3, among others. NLRP3 interacts with an inflammatory caspase called caspase-1, although the functions of another inflammatory caspase, caspase-11, is yet obscure. Thus, the aim of this work is to evaluate the contribution of caspase-11 in the recognition and restriction of *L. amazonensis* infection.

Methods and results: Bone marrow-derived macrophages from C57BL/6 (WT) and caspase-11^{-/-} mice were used to perform in vitro studies with *Leishmania amazonensis*. After 24h of infection, supernatant was collected and used for ELISA. BMDMs from caspase-11^{-/-} mice showed decreased secretion of IL-1 β compared to WT mice, and were less capable of killing *L. amazonensis* parasites, as shown by FACS and Giemsa staining. Mice were infected in vivo in the ear with 10⁶ total parasites and the lesion was followed by eight weeks, then they were euthanized and had their lymph node and ear processed for parasite titer. Caspase-11^{-/-} mice showed larger lesion and higher parasite titers compared to WT mice.

Conclusion: Together, our results suggest that *Leishmania amazonensis* triggers Caspase-11 activation, which could possibly be involved in induction of the non-canonical activation of NLRP3 inflammasome, an important mechanism for the restriction of Leishmaniasis.

Absence of Bim, a pro-apoptotic member of the BCL-2 family, sensitizes mice to *T. cruzi* infection

Torres, M.H.¹, Nascimento, R.¹, Rodrigues, E.¹, Matteucci, K.², Cabral, P.¹, Gonzales, M.¹, Bortoluci, K.R.^{2,3}, Alvarez, J.M.¹, Amarante-Mendes, G.P.^{1,4}

¹University of São Paulo, Institute of Biomedical Sciences, Department of Immunology, São Paulo, Brazil, ²Federal University of São Paulo, Centro de Terapia Celular e Molecular (CTC-Mol),

São Paulo, Brazil, ³Federal University of São Paulo, Department of Biological Sciences, São Paulo, Brazil, ⁴Instituto de Investigação em Imunologia (INCT-iii), São Paulo, Brazil

Bim is a potent pro-apoptotic member of the BCL-2 family that engages the intrinsic/mitochondrial apoptosis pathway. Bim was shown to participate at different steps of the immune response, such as negative selection of self-reactive thymocytes and elimination of activated T cells. However, little is known about the role of Bim on the control of infections. The overall impression is that Bim has a negative role, since *bim*^{-/-} mice is more resistant to *Leishmania major*, *Mycobacterium tuberculosis* and the lymphocytic choriomeningitis virus (LCMV) infections. Here, we investigated the role of Bim on experimental Chaga's Disease. In contrast to the observations mentioned above, *bim*^{-/-} mice showed an impaired control of the parasitemia, which resulted in overall decreased survival compared to the WT mice. Peritoneal macrophages (PM) from *bim*^{-/-} mice displayed a reduced production of NO, IFN- γ and IL-6, and decreased microbicidal activity, when isolated at the peak of parasitemia. This deficiency seems not to be due to an intrinsic defect of the *bim*^{-/-} macrophages, since PM isolated from naïve WT and *bim*^{-/-} mice behave similarly in response to *in vitro* infection. In fact, the defect seems to represent a differential composition of PM subpopulations in response to *T. cruzi* infection. In addition, we found that the antigen-specific CD8⁺ T response was impaired in *bim*^{-/-} mice also at the peak of parasitemia. Together, our results challenge our understanding of the function of Bim in the control of infections, and suggest that Bim plays a positive role in the control of *T. cruzi*.

The effects of chronic psychological stress on the immune response to lymphoma

Nissen, M.¹, Sloan, E.², Mattarollo, S.¹

¹University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia, ²Monash University, Institute of Pharmaceutical Sciences, Melbourne, Australia

Immunotherapies have revolutionized treatment for cancer, including lymphomas. However the effectiveness of immunotherapies remain sub-optimal, for reasons that are not well defined.

Chronic stimulation of beta-adrenoceptor signalling pathways, which occurs for example during periods of prolonged stress, has been demonstrated to dysregulate the immune system and may be one factor that adversely impacts immunotherapeutic efficacy. To address this, we investigated the impact of chronic beta-adrenergic signalling on lymphoma progression and response to immunotherapy, by administration of a beta-adrenoceptor agonist isoprenaline.

We injected mice daily with isoprenaline and found that beta-adrenergic stimulation enhances lymphoma growth and leads to increased mortality. It also reduces the effectiveness of an alpha-Gal-Cer based autologous tumor cell vaccine, as demonstrated by increased tumor growth and a corresponding

decrease in survival of treated animals. This reduction in immunotherapy effectiveness is associated with impaired CD8+ T cell function. The proliferation of antigen specific CD8+ T cells in response to autologous tumor cell vaccine is significantly inhibited by beta-adrenergic signalling. Similarly, fewer CD8+ T cells express the activation markers CD44 and KLRG1 in response to anti-PD-1 and anti-4-1BB therapeutic antibody therapy, and the effectiveness of these two therapies are abolished while under the effect of beta-adrenergic signalling.

These findings suggest that chronic beta-adrenergic signalling causes immunosuppression during lymphoma immunotherapy. We predict from this findings that cancer immunotherapies may have limited efficacy in those individuals who are experiencing chronic psychological stress, and that immunotherapies may be improved in this setting by blocking beta-adrenergic signalling pathways.

Neuroimmunology, Bonn, Germany, ³University of Bonn,

Experimental Immunology, Bonn, Germany, ⁴University of Bonn,

Reconstructive Neurobiology, Bonn, Germany

It is well known that systemic inflammation may alter neuronal function via induction of immune responses in the CNS, including expression of chemokines. Here we show that CCL17, a ligand of CCR4, is expressed in a subset of hippocampal neurons. Expression of CCL17 was analyzed in wild-type and CCL17-EGFP (CCL17^{E/+}) reporter mice. Steady-state expression of CCL17 was enhanced by systemic challenge with LPS, but not with CpG or Poly I:C. Gene expression analysis of isolated hippocampi indicated local upregulation of GM-CSF and TNF after LPS treatment. Furthermore, LPS-induced CCL17 expression was partly reduced in GM-CSF^{-/-} mice and nearly absent in TNFR^{-/-} mice. Preliminary data point towards a CCL17-dependent regulation of microglial activity. Consistently, analysis of Iba-1⁺ cells in hippocampal sections revealed an altered morphological activation state of microglia in CCL17^{E/E} mice after systemic LPS challenge. To investigate the functional consequences of inducible ablation of CCL17⁺ cells *in vivo*, CCL17-DTR (CCL17^{DTR/+}) mice were injected with diphtheria toxin (DT). Depletion of CCL17⁺ neurons was confirmed by histology and TUNEL staining, and was associated with an initial rapid loss of body weight and sustained persistent body weight fluctuations. Additionally, increasing numbers of Iba-1⁺ cells in the hippocampal CA1 region were observed. Concurrent with the loss of hippocampal neurons mice showed behavioral abnormalities and sensitivity to stress. In conclusion, CCL17 expression in hippocampal neurons appears to modulate microglial responses to systemic inflammation. Our newly generated CCL17-DTR mice may be a valuable model system

for the analysis of inducible neuroinflammation within the hippocampus.

IFN- γ signaling at the blood-brain barrier (BBB) endothelial cells has inflammatory function but in parenchyma plays a regulatory role during autoimmunity

Sonar, S., Lal, G.

National Centre for Cell Science, Infection and Immunity, Pune, India

Background: IFN- γ , a Th1 cytokine known to have inflammatory and protective function in neuronal autoimmunity. How does IFN- γ signaling at BBB regulate the transendothelial migration of effector CD4 T cells and also have a regulatory function in experimental autoimmune encephalomyelitis (EAE) is not clearly understood.

Methods: EAE was induced by myelin oligodendrocyte glycoprotein (MOG) peptide injection. MOG specific Th1 and Th17 were adoptively transferred into C57BL/6, T-bet^{-/-}, CCR6^{-/-} or RORc^{-/-} mice. BBB was analyzed by multicolor microscopy.

Results: Passive as well as active EAE induced in the C57BL/6 mice showed a punctate distribution of tight- and adherence-junction molecules ZO-1 and VE-cadherin at the brain and spinal cord endothelial vessels. T-bet^{-/-} mice showed resistance to MOG induced active EAE whereas reconstituted with purified wild-type CD4 T cells resulted in disrupted BBB and caused EAE. Intrathecal injection of IFN- γ in the brain disrupted the BBB and promoted infiltration of leukocytes. ROR γ t^{-/-} Th1 cells were crossed the BBB but did not induce the EAE. IFN- γ induced the nitric oxide in the CNS parenchyma, which in turn induced apoptosis in infiltrating leukocytes and protected from EAE. Furthermore, IFN- γ increased surface expression of ICAM-1, and various chemokines in brain endothelial cells, and promoted apical (luminal side) to basal (abluminal side) transendothelial migration of effector CD4 T cells in STAT-1 and ICAM-1 dependent manner.

Conclusions: IFN- γ signaling at BBB promotes transendothelial migration of encephalitogenic CD4⁺ T cells into neuronal tissues, and plays an active role in the initiation of neuronal autoimmunity.

The neuroimmunology of encephalitis in a mouse model of Dengue virus infection - interaction between draining cervical lymph nodes and the brain

Vu, L., King, N.J.C.

University of Sydney, Pathology, Sydney, Australia

Currently affecting 3.97 billion people globally, Dengue, the most common arboviral disease, has been increasingly reported as being associated with neurological manifestations. Using a non-lethal mouse encephalitis model, in which wild type C57BL/6 mice were intracranially infected with human DENV-2 isolates, we investigated the neuroimmunology of this disease. Using 18-colour flow cytometry, we found that central

nervous system (CNS) DENV infection of wild type mice results in a strong intracerebral influx of leukocytes, most of which are CD8+ effector T cells. While intracerebral trafficking of these T cells was antigen-independent, correlating with increased CXCL10, CCL5, CCL3, and CCL2 mRNA expression, their antiviral function was MHC-restricted. Using intracranial injection of Ova- or DENV NS4 Ag-loaded splenocyte targets, DENV-specific CD8+ effector T cells exhibited considerable cytolytic activity *in vivo* and were IFN- γ -dependent, suggesting a collaborative role of perforin/granzyme and IFN- γ , which in turn presumably amplifies MHC expression. Monofunctional (IFN- γ + only) DENV-specific CD8+ T cells were detected in the cervical lymph nodes (CLN) by d3 post infection, preceding peak accumulation of multifunctional (IFN- γ +, TNF+ or CD107a+/GrzB+) DENV-specific CD8+ T cells in the CNS on d6. CD8 and/or CD4 depletion or CLN excision resulted in a significant reduction in infiltrating CD8+ T cells into the CNS, slightly increased viral load but did not alter overall clinical outcomes. This suggests that DENV-specific responses in the CNS are initiated within the draining CLN and CNS-lymph node interaction boosts DENV-specific CD8+ effector T cell numbers to limit viral replication in this DENV-2 encephalitis mouse model.

Anti-inflammatory effects of GABA_A receptor modulators

Neumann, S.^{1,2}, Gowing, E.², Lateef, Z.³, Chebib, M.⁴, Young, S.¹, Clarkson, A.^{2,4}

¹University of Otago, Department of Pathology, Dunedin, New Zealand, ²University of Otago, Department of Anatomy, Brain Health Research Centre, Dunedin, New Zealand, ³University of Otago, Department of Microbiology and Immunology, Dunedin, New Zealand, ⁴The University of Sydney, Faculty of Pharmacy, Sydney, Australia

Inflammatory processes are known to contribute to tissue damage in the central nervous system (CNS) across a broad range of neuro-pathologies, including stroke. The main inhibitory neurotransmitter of the CNS, gamma amino butyric acid (GABA), has been implicated in shaping peripheral immune responses by binding to GABA_A receptors on antigen-presenting cells and lymphocytes. Here, we investigated the effects of several subtype-specific GABA_A receptor modulators on nuclear factor kappa B (NF- κ B)-mediated inflammation *in vitro*. In addition, we tested the most promising of these drug candidates in a mouse model of focal stroke.

We found that GABA_A receptor modulators DS2 and tracazolate reduced NF- κ B activation over a wide concentration range *in vitro*, whereas zolpidem and bumetanide only decreased NF κ B activation at high concentrations. Treatment with DS2 *in vivo* from 1 hour post-stroke significantly reduced infarct sizes when mice were dosed at 0.1 mg/kg but not at higher doses. Motor tasks improved in mice treated with DS2 at all doses; however, the lowest dose of DS2 (0.1 mg/kg) was most beneficial.

Subtype-selectivity of GABA_A modulators influenced their ability to inhibit activation of NF- κ B and thus the production of pro-inflammatory cytokines. It remains to be determined if the improved recovery of stroked animals treated with DS2 depends on modulation of GABA_A receptors in the CNS or on

peripheral immune cells. However, as previous unpublished data shows that DS2 does not cross the blood-brain-barrier, it is likely that DS2 is mediating the degree of infarct volume via the modulation of the peripheral immune response.

A natural variant of the TCR signaling molecule Vav1 reduces both effector T cell functions and susceptibility to neuroinflammation

Kassem, S.¹, Gaud, G.¹, Colacios, C.¹, Bernard, I.¹, Malissen, B.², Saoudi, A.¹

¹INSERM U 1043, CNRS UMR 5282, Toulouse, France, ²CIML, Marseille, France

The guanine nucleotide exchange factor Vav1 is essential for transducing T cell antigen receptor signals and therefore plays an important role in T cell development and activation. Our previous genetic studies identified a locus on rat chromosome 9 that controls the susceptibility to neuroinflammation and contains a non-synonymous polymorphism in the major candidate gene *Vav1*. To formally demonstrate the causal implication of this polymorphism, we generated a knock-in mouse bearing this polymorphism (Vav1^{R63W}). Using this model, we show that Vav1^{R63W} mice display reduced susceptibility to experimental autoimmune encephalomyelitis (EAE) induced by MOG₃₅₋₅₅ peptide immunization. This is associated with a lower production of effector cytokines (IFN- γ , IL-17 and GM-CSF) by autoreactive CD4 T cells. Despite increased proportion of Foxp3⁺ regulatory T cells in Vav1^{R63W} mice, we show that this lowered cytokine production is intrinsic to effector CD4 T cells and that Treg depletion has no impact on EAE development. Finally, we provide a mechanism for the above phenotype by showing that the Vav1^{R63W} variant has normal GEF activity but reduced adaptor functions. Together, these data highlight the importance of Vav1 adaptor functions in the production of inflammatory cytokines by effector T cells and in the susceptibility to neuroinflammation.

3443**miR-155 controls T helper cell 17 development during autoimmune demyelination via Hsp40 genes expression***Cichalewska, M., Mycko, M., Cwiklinska, H., Selmaj, K.**Medical University of Lodz, Department of Neurology, Laboratory of Neuroimmunology, Lodz, Poland*

MicroRNAs (miRNA) are small, endogenous RNAs that represent a group of non-protein coding gene products that regulate transcription, degradation or activation of mRNA. MicroRNAs have been implicated as regulatory mechanisms in the immune system and miR-155 has been found to play key role in various immune cell functions. We and others have described miR-155 upregulated in T helper (Th) cells during development of the experimental autoimmune encephalomyelitis (EAE), an animal model of MS. Here we address function of miR-155 in Th differentiation during EAE. To manipulate miR-155 activity a set of specific oligonucleotide mimics and antagomir inhibitors were tested. An active myelin antigen immunization EAE model and myelin specific Th transfer as autoimmune demyelination models have been used. We have found that immunization of miR-155 deficient mice with MOG peptide 35-55 led to decreased generation of Th17 response. Searching for molecular mechanisms of miR-155 action in

T cells we have analyzed a gene expression profiles of miR-155 deficient Th cells. Intriguingly, we have found that most upregulated genes in miR-155 deficient were two genes of heat shock protein 40 family, Dnaja2 and Dnajb1. These two genes were also upregulated in Th cells following miR-155 antagomir treatment. Finally, a MOG TCR transgenic Th cells transfected with either Dnaja2 or Dnajb1 were less encephalitogenic in EAE transfer model. Thus our results provide evidence for specific and selective role of miR-155 in the process of myelin antigen adaptive response and autoreactive T cell development via targeting hsp40 genes. Supported: NCN Sonata to MC.

181**The P2X7 receptor in amyotrophic lateral sclerosis***Bartlett, R.^{1,2}, Watson, D.^{1,2}, Sluyter, V.^{1,2}, Yerbury, J.^{1,2}, Sluyter, R.^{1,2}**¹University of Wollongong, Wollongong, Australia, ²Illawarra Health and Medical Research Institute, Wollongong, Australia*

The P2X7 receptor channel is activated by the damage-associated molecular pattern molecule extracellular ATP. P2X7 plays important roles in neuroinflammation and is upregulated in amyotrophic lateral sclerosis (ALS), a rapidly fatal neuromuscular disease characterised by the aggregation of misfolded proteins, microglia activation and motor neuron loss. Cell-to-cell transfer of aggregated proteins, such as mutant superoxide dismutase 1 (mSOD1), is involved in ALS progression. Using G93A mSOD1 cells and mice, this study aimed to identify the roles of P2X7 in ALS. P2X7 was identified in both murine microglia and motor neurons. P2X7 activation resulted in the generation of reactive oxygen species formation and death in microglia. P2X7 activation also caused rapid mSOD1 release from mSOD1-transfected motor neurons independently of cell death. mSOD1 released from motor neurons was predominately in a pelletable fraction indicative of protein aggregation. This

pelletable fraction could be engulfed by microglia and induce tumour necrosis factor release from these cells. Treatment of mSOD1-transgenic ALS mice with the P2X7 antagonist Brilliant Blue G delayed weight loss and prolonged survival in female but not male mice. Treatment had no effect on clinical score, motor coordination, or a number of other disease or systemic features. Combined, these results suggest that P2X7 may be involved in select ALS disease pathways, consistent with the multi-systemic and multi-factorial nature of this disease.

1598**Dynamics of inflammatory immune response in a mouse model of traumatic spinal cord injury, potential therapeutic targets***Hassanpour Golakani, M.¹, Mohammad, M.², Li, H.¹, Saxena, M.¹, Breit, S.¹, Ruitenber, M.³, Brown, D.⁴**¹University of New South Wales/St Vincent's Centre for Applied Medial Research (AMR), Laboratory of Neuroinflammation, Darlinghurst, Australia, ²University of Sharjah, Department of Medical Laboratory Sciences, Faculty of Health Sciences, Sharjah, United Arab Emirates, ³University of Queensland, Queensland Brain Institute, Brisbane, Australia, ⁴Westmead Hospital, Department of Immunology/Immunopathology, Sydney, Australia*

The dynamics of inflammatory responses post spinal cord injury (SCI) are largely unknown. In this study we aimed to characterize the various immune cells in and around the injury site and their relationship with locomotor functional recovery at various time points post SCI.

Severe contusive SCI was induced and locomotor function was assessed at 7, 14, 21, and 28 days post injury (dpi). The entire spinal cord was removed, and immune cells were isolated, characterized, and localized using FACS, immunohistology and immunofluorescence. The frequency of immune cell subsets was correlated with behavioral assessment at various time points post injury.

The number of infiltrating macrophages and CD11c&B220⁺ cells had both beneficial and detrimental effects depending on the time post SCI. While macrophages had adverse effects on locomotion recovery in early stages of 7-14 dpi, they significantly contributed to improved recovery at later stages. CD11c&B220⁺ cells on the other hand were advantageous in early and detrimental in the more chronic stage of SCI.

These findings highlight that the dynamics of inflammatory responses post SCI are a double-edge sword with respect to functional recovery, and that they may be therapeutically manipulated.

4045**Multiple sclerosis patient lymphocytes' crosstalk with microglial cells directs remyelination***El Behi, M.¹, Sanson, C.², Bachelin, C.², Guillot-Noel, L.¹, Fransson, J.², Stankoff, B.³, Maillart, E.³, Sarranzin, N.², Guillemot, V.⁴, Abdi, H.⁵, Rebeix, I.², Fontaine, B.³, Zujovic, V.²**¹Brain and Spine Institute, Neuroimmunology, Paris, France, ²Brain and Spine Institute, Neurobiology, Paris, France, ³AP-HP, Groupement Hospitalier Pitié-Salpêtrière, Neurology, Paris, France,*

⁴Brain and Spine Institute, Biostatistics, Paris, France, ⁵University of Texas, School of Brain and Behavioral Sciences, Texas, United States
Myelin destruction leads to irreversible neurological disabilities in multiple sclerosis (MS), an autoimmune disease of the central nervous system. However, an endogenous remyelination process can be triggered and is highly influenced by the state of activation of microglia cells (MIG) which itself depends on MIG dialogue with T lymphocytes (LT). Therefore, we asked whether LT from healthy donors (HD) and MS patients differentially influence MIG activation state and remyelination.

We adapted experimental designs to study remyelination within a humanized context by developing a new in vivo model combining human LT grafting and lysolecithine-induced demyelination in Nude mice spinal cord. We show that remyelination is significantly decreased in mice grafted with MS LT compared to HD LT. Mechanistically, we demonstrate that MS LT supernatants drove microglial activation towards a pro-inflammatory M1 state, resulting in a decrease in oligodendrocyte precursor cells (OPC) differentiation into myelinating cells.

Finally, we observed heterogeneous remyelination patterns among MS patients. Using multivariate analysis comparing patients with high and low remyelination ability, we uncovered new molecular players with previously unknown roles in OPC differentiation under pathological conditions and validated some of them in vitro as potential targets in MS patients to improve remyelination. Thereby, we propose the concept of using characteristics of MS patients displaying high repair capacities to discover innovative pro-remyelinating molecules.

Delayed inhibition of the NLRP3 inflammasome during pathogenic influenza A virus infection in mice reduces disease severity and prolongs survival

Tate, M.¹, Pinar, A.¹, Dowling, J.¹, McAuley, J.², Robertson, A.³, Cooper, M.³, Mansell, A.¹

¹Hudson Institute of Medical Research and Monash University, Centre for Innate Immunity and Infectious Diseases, Melbourne, Australia, ²University of Melbourne, Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ³University of Queensland, Institute of Molecular Bioscience, Brisbane, Australia

Introduction: Fatal disease caused by emerging avian influenza A viruses (IAV) is often associated with severe lung pathology, infiltrating leukocytes and an excessive cytokine response termed the 'cytokine storm'. Mortality rates for pathogenic infections such as the current avian H7N9 IAV are >30%, with limited therapeutic strategies available. We recently identified activation of the NLRP3 inflammasome by the PB1-F2 virulence factor found in pathogenic IAV causes hyperinflammation during infection. We have now characterized PB1-F2 derived from H7N9 avian IAV and determined whether targeting of the NLRP3 inflammasome may provide a strategy to protect from fatal IAV.

Results: We have found that a peptide derived from pathogenic

H7N9 PB1-F2 induced IL-1b secretion from human PBMCs and murine macrophages which was Caspase-1-, ASC- and NLRP3-dependent. Furthermore, NLRP3-deficient mice exposed to H7N9 PB1-F2 peptide display reduced neutrophil recruitment to the lung and ablated IL-1b secretion. Importantly, treatment of murine macrophages and human PBMCs with a specific NLRP3 inhibitor termed MCC950 significantly inhibited H7N9-induced IL-1b secretion and mice treated with MCC950 display reduced neutrophil recruitment and IL-1b in the lung.

Critically, temporal targeting of NLRP3 with MCC950 protected mice from pathogenic PR8 IAV-induced mortality, reducing cellular infiltrates and inflammatory cytokines, providing evidence for potentially targeting the inflammasome in pathogenic IAV disease.

Conclusion: This is the first demonstration that reduced IL-1 β and targeted intervention of inflammasome activation therapeutically protects against the detrimental outcomes of pathogenic IAV infection such as that posed by emerging avian influenza.

Pyrin, encoded by the *MEFV* gene, is implicated in the innate immune response to a number of bacterial pathogens. These bacteria secrete toxins that indirectly stimulate pyrin-dependent IL-1 β release by inhibiting Rho-GTPase signalling and alteration of cytoskeletal dynamics. *MEFV* is so called due to mutations in this gene being responsible for the recessively inherited autoinflammatory disease Familial Mediterranean Fever (FMF). FMF is characterised by short periodic attacks of fever and serositis (often peritoneal or pleural). We have studied several families with a dominantly inherited autoinflammatory disease that is clinically distinct from FMF and is predominantly characterised by neutrophilic dermatosis, prolonged bouts of fever and an absence of any form of serositis. This disease, which we have named Pyrin-Associated Autoinflammation with Neutrophilic Dermatitis (PAAND), is caused by a single amino acid substitution (S242R) in the linker region between the PYRIN and B-box domains of the pyrin protein. Phosphorylation of the highly conserved serine 242 residue creates a non-canonical 14-3-3 binding motif that we show is disrupted by either the S242R mutation or treatment with *Clostridium difficile* Toxin B (TcdB) leading to increased IL-1 β production. This suggests that dephosphorylation of serine 242 is a primary mechanism of pyrin activation in the innate immune response, which is deregulated in individuals presenting with PAAND. Targeting of IL-1 β has proven to be a successful therapy for treating PAAND in at least one patient.

Human monocytes engage an alternative inflammasome pathway

*Gaidt, M.*¹, *Ebert, T.*¹, *Chauhan, D.*¹, *Schmidt, T.*¹, *Schmid-Burgk, J.*¹, *Rapino, F.*², *Robertson, A.*³, *Cooper, M.*³, *Graf, T.*², *Hornung, V.*¹

¹University of Bonn, Bonn, Germany, ²Universitat Pompeu Fabra and Institutió Catalana de Recerca i Estudis Avançats, Barcelona, Spain, ³University of Queensland, Brisbane, Australia

Interleukin-1 β (IL-1 β) is a cytokine, whose bioactivity is controlled by activation of the inflammasome. However, in response to lipopolysaccharide human monocytes secrete IL-1 β independently of classical inflammasome stimuli. Here, we report that this constituted a species-specific response that is not observed in the murine system. Indeed, in human monocytes, lipopolysaccharide triggered an 'alternative inflammasome' that relied on NLRP3-ASC-caspase-1 signaling, yet was devoid of any classical inflammasome characteristics including pyroptosome formation, pyroptosis induction and K⁺ efflux dependency. Genetic dissection of the underlying signaling pathway in a monocyte trans-differentiation system revealed that alternative inflammasome activation was propagated by TLR4-TRIF-RIPK1-FADD-CASP8 signaling upstream of NLRP3. Importantly, involvement of this signaling cascade was limited to alternative inflammasome activation and did not extend to classical NLRP3

activation. Since alternative inflammasome activation embraces both sensitivity and promiscuity of TLR4, we propose a pivotal role for this signaling cascade in TLR4-driven, IL-1 β -mediated immune responses and immunopathology in humans.

Roles of innate immune regulator TAPE in RIG-I signaling and antiviral defenses

Chen, K.R.^{1,2}, *Yang, C.-Y.*³, *Lin, C.-Y.*², *Lin, W.-Y.*², *Lo, Y.-C.*², *Chuang, H.-C.*³, *Tan, T.-H.*³, *Ling, P.*^{1,2,4}

¹National Cheng Kung University, Institute of Basic Medical Sciences, Tainan, Taiwan, Republic of China, ²National Cheng Kung University, Department of Microbiology and Immunology, Tainan, Taiwan, Republic of China, ³National Health Research Institutes, Zhunan, Taiwan, Republic of China, ⁴National Cheng Kung University, Department of Medical Laboratory Science and Biotechnology, Tainan, Taiwan, Republic of China

Pattern-recognition receptors detect pathogen-associated molecular patterns to trigger downstream pathways leading to type I IFN production to defend pathogen infection. RIG-I-like receptors (RLRs) are key cytosolic sensors for recognizing viral RNA to trigger antiviral immunity. The underlying mechanisms linking RLR-mediated viral recognition to antiviral immunity remain to be further explored. Through our previous work, we uncovered an innate immune regulator termed TAPE (TBK1-Associated Protein in Endolysosomes), also known as CC2D1A, which is implicated in the viral RNA sensor TLR3 and RLR pathways. Yet, the in vivo role of TAPE in antiviral defenses and the mechanistic mechanisms of how TAPE regulates cytosolic RIG-I signaling still remain to be established. TAPE conditional knockout mice were generated for our study. Results from in vivo studies showed that *TAPE*^{eff} CD11c-Cre mice exhibited a more severe mortality than WT mice upon influenza A virus (IAV) infection. Ex vivo studies also showed that TAPE-deficient mouse embryonic fibroblasts and macrophages were defective in type-I interferon induction upon RLR ligand stimulation. In addition, our biochemical analyses showed that the N-terminal region of TAPE was critical for interacting with the CARD domain of RIG-I while the C-terminal region of TAPE contributed most to the interaction with MAVS/IPS-1, a RLR downstream mediator. Together, our results suggest a crucial role for TAPE in linking RIG-I to type I IFN-mediated antiviral responses. Future work will further determine the in vivo role of TAPE in IAV and other RNA virus infection, and explore the mechanistic mechanisms of how TAPE regulates RIG-I signaling.

NLRP3 inflammasome-mediated, IL-1 β -dependent inflammatory responses drive severe, steroid-resistant asthma

*Kim, R.*¹, *Pinkerton, J.*¹, *Essilfie, A.-T.*¹, *Robertson, A.*², *Baines, K.*¹, *Mayall, J.*¹, *Starkey, M.*¹, *Wark, P.*¹, *Gibson, P.*¹, *O'Neill, L.*³, *Cooper, M.*², *Horvat, J.*¹, *Hansbro, P.*¹

¹Hunter Medical Research Institute & University of Newcastle, Priority Research Centre for Healthy Lungs, New Lambton Heights, Australia, ²Institute for Molecular Bioscience, The University

of Queensland, Division of Chemistry and Structural Biology, Brisbane, Australia, ³Trinity Biomedical Sciences Institute, Trinity College Dublin, School of Biochemistry and Immunology, Dublin, Ireland

Excessive NLRP3 inflammasome and concomitant IL-1 β responses are implicated in many inflammatory diseases. However, the direct contributions to pathogenesis, mechanisms involved and potential for therapeutic targeting remain poorly understood. In the lung, NLRP3 inflammasomes are associated with emphysema, infections and severe, steroid-resistant (SSR) asthma, which is the major unmet clinical need in asthma management. It is underpinned by exaggerated innate and T_H1/T_H17 immunity, neutrophilic inflammation and bacterial infections. Here we developed novel mouse models of *Chlamydia*, and *Haemophilus*, respiratory infection and ovalbumin-induced SSR allergic airways disease (SSRAAD). These models share the hallmark features of human disease, including elevated NLRP3 inflammasome and concomitant IL-1 β responses. We also examined the relationships between NLRP3 and IL-1 β levels, and airway neutrophil numbers and disease severity in a population of human asthmatics. The roles and potential for targeting of infection-induced NLRP3 inflammasome, caspase-(CASP)1, and IL-1 β responses in the lung in SSRAAD were examined using a highly-selective NLRP3 inhibitor, MCC950, the specific CASP1 inhibitor, Ac-YVAD-cho, and neutralising anti-IL-1 β antibody, α -IL-1 β , respectively. We show that *Chlamydia* and *Haemophilus* infections increase NLRP3, CASP1, IL-1 β and T_H1/T_H17 responses that drive steroid-resistant neutrophilic inflammation and airways hyper-responsiveness in experimental SSR asthma. Neutrophilic airway inflammation and severity of human SSR asthma correlated with IL-1 β and NLRP3 expression. Treatment with α -IL-1 β , Ac-YVAD-cho, and MCC950 suppressed IL-1 β responses and the important steroid-resistant features of disease. Thus, NLRP3 inflammasome responses may drive SSR asthma and be therapeutically targeted in this and other NLRP3-mediated diseases.

The molecular mechanism of Toll-like receptor 4 signaling in cells

Latty, S.¹, Saki, J.², Klenerman, D.¹, Bryant, C.²

¹University of Cambridge, Chemistry, Cambridge, United Kingdom,

²University of Cambridge, Veterinary Medicine, Cambridge, United Kingdom

The TLR/IL-1 Receptor superfamily are critically required to generate immune responses, yet little is known about the fundamental mechanisms by which they signal. We show that in macrophages Toll-like receptor 4 (TLR4) can exist as monomers or pre-formed dimers. Upon administration of the full agonist lipopolysaccharide (LPS) or other lipid-based ligands, including partial agonists, TLR4 dimers, but not oligomers are present irrespective of ligand-efficacy. To determine how different efficiencies in TLR4 signaling are achieved we first showed in single cell signaling assays that the kinetics of nuclear factor κ B translocation into the nucleus is dose dependently delayed with lower doses of LPS or maximal concentrations of a partial

agonist. LPS stimulation of TLR4 drove the rapid formation of visible, reversible MyD88 oligomeric protein complexes (MyDDosomes) within the cell. In response to a partial agonist there was a reduction in the number of MyDDosomes formed in comparison to LPS suggesting that TLR4 signalling efficiency may be linked to the number of stable MyDDosomes formed over time with, presumably, a critical threshold of MyDDosomes determining when κ B translocation is stimulated.

All-trans retinoic acid enhances extracellular hsp90a dimerization in human monocytes through RAR/RXR- and Ca²⁺-dependent mechanisms

Hoang Thi, X., Jong Hyeok, J., Bon Hyang, N., Bon, H.

Gachon University, Life Science, Seongnam, Korea, Republic of

Heat shock protein 90 (hsp90) is ATP-dependent molecular chaperone and plays a role in maintaining conformational integrity of various cellular proteins. Recent studies have shown that hsp90 can be secreted and communicate with immune system under stress conditions such as inflammation and infection. In this study, we investigated the effects of all-trans retinoic acid (ATRA), an active form of vitamin A, on extracellular hsp90a dimerization of human monocyte THP-1. Cells were treated with ATRA for 24 h, subjected to BS3-cross linking reaction for 30 min, and then analyzed by western blot. Dimer form of hsp90a in ATRA-treated cells increased approximately 3 times in comparison with DMSO-treated cells. Experiments with intracellular cross-linker EGS indicated that ATRA-induced hsp90a dimerization only occurs outside of cells. Experiments with agonists or antagonists for RAR α or RXR revealed that ATRA-induced hsp90a dimerization depends on RAR/RXR pathway. Intracellular Ca²⁺ levels were increased by ATRA and this increase was reversed by the treatment with RAR α or RXR antagonists or calcium channel blockers. ATRA-induced hsp90a dimerization was reversed by the treatment of calcium channel blockers, while addition of exogenous calcium ion enhanced the hsp90a dimerization. Our results suggest that ATRA enhances extracellular hsp90a dimerization of human monocytes through RAR/RXR- and Ca²⁺-dependent mechanisms.

Caspase-4/5 control non-canonical inflammasome activation in human monocytes in response to extracellular LPS

Vigano, E., Diamond, C.E., Mortellaro, A.

Singapore Immunology Network (SigN), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore

Inflammasomes are molecular platforms regulating the release of the pro-inflammatory cytokines IL-1 β and IL-18 in response to microbes and sterile signals. Classical inflammasome activation requires caspase-1, which in turn processes pro-IL-1 β and pro-IL-18 to mature cytokines, as well as inflammatory cell death, known as pyroptosis. In mice a "non-canonical" inflammasome pathway controlled by caspase-11 has recently been identified. Caspase-11 plays a critical role in the control

of IL-1 α secretion and pyroptosis in response to many gram-negative bacteria and cytoplasmic lipopolysaccharide (LPS). Putative human orthologues of caspase-11 are caspase-4 and caspase-5. However, it remains unclear whether the non-canonical inflammasome pathway exists in humans, which roles caspase-4/5 play and the mechanisms regulating their activation. We found that LPS stimulation induces processing of caspase-5, but not that of caspase-4, in human monocytes. Caspase-4 and -5 specifically regulate IL-1 α and IL-1 β release. Caspase-5 processing was dependent on TLR4, activation of the tyrosine kinase Syk and calcium flux, but not on the IFN type I pathway and generation of reactive oxygen species. These mechanisms were unique to monocytes and absent in monocyte-derived macrophages and dendritic cells. We identified caspase-4 and -5 as key immune effectors underpinning inflammasome activation in human monocytes in response to extracellular LPS. This novel view of the molecular mechanisms underlying inflammasome activation in monocytes may open up avenues for new pharmacological interventions aimed at mitigating systemic inflammation in autoinflammatory disorders and more.

RIPK3 promotes cell death and NLRP3 inflammasome activation in the absence of MLKL

Vince, J., Lawlor, K.

The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

RIPK3 and its substrate MLKL are essential for necroptosis, a lytic cell death proposed to cause inflammation via the release of intracellular molecules. Whether and how RIPK3 might drive inflammation in a manner independent of MLKL and cell lysis remains unclear. Here we show that following LPS treatment, or LPS-induced necroptosis, the TLR adaptor protein TRIF and inhibitor of apoptosis proteins (IAPs: X-linked IAP, cellular IAP1 and IAP2) regulate RIPK3 and MLKL ubiquitylation. Hence, when IAPs are absent, LPS triggers RIPK3 to activate caspase-8, promoting apoptosis and NLRP3-caspase-1 activation, independent of RIPK3 kinase activity and MLKL. In contrast, in the absence of both IAPs and caspase-8, RIPK3 kinase activity and MLKL are essential for TLR-induced NLRP3 activation. Consistent with *in vitro* experiments, interleukin-1 (IL-1)-dependent autoantibody-mediated arthritis is exacerbated in mice lacking IAPs, and is reduced by deletion of RIPK3, but not MLKL. Therefore RIPK3 can promote NLRP3 inflammasome and IL-1 inflammatory responses independent of MLKL and necroptotic cell death.

Immunity to Viruses 3

Early growth response gene (Egr) 2 and 3 are essential for adaptive immunoresponses of T cells

Lli, S.¹, Miao, T.², Symond, A.², Wang, P.²

¹Brunel University, Bioscience, London, United Kingdom, ²BICMS, Queen Mary University of London, Immunology, London, United Kingdom

Egr2 and 3 are important for maintaining immune homeostasis. Here we defined a fundamental and overlapping function of Egr2 and 3 for controlling the transition between clonal expansion and differentiation of effector T cells. Naive T cells deficient in Egr2 and 3 were severely impaired in clonal expansion and displayed innate like inflammatory differentiation, while forced Egr2 expression in T cells induced hyper-proliferation and impaired effector differentiation in response to viral infection. A novel GFP-Egr2 knockin model demonstrated that two populations of CD44^{high} T cells were induced by viral infection: Egr2 positive highly proliferating cells and Egr2 negative highly differentiated cells. Egr2 bound to and promoted expression of proliferation regulators and differentiation repressors (Myc, Myb, Bcl6, Bcl9, Id3, Lef1, Tcf7 while suppressing expression of transcription factors required for lineage-specific differentiation (T-bet, Runx2, Runx3, Prdm1, Zeb2, ROR α , ROR γ). The function of Egr2 and 3 was tightly regulated in a reciprocal fashion by antigen and effector cytokines, which is essential for optimal coupling of clonal expansion and effector differentiation in response to viral infection. Thus, Egr2 and 3 enforce a checkpoint in early adaptive immunoresponses by promoting clonal expansion and restraining innate like responses of T cells.

Extreme memory inflation of high affinity HLA-C restricted CMV-specific CD8+ T cells specific for immediate-early antigen

Hosie, L.¹, Pachnio, A.¹, Riddell, S.², Moss, P.¹

¹University of Birmingham, Birmingham, United Kingdom, ²Fred Hutchinson Cancer Research Center, Seattle, United States

Human Cytomegalovirus (HCMV) infects the majority of the human population, leading to a uniquely strong cellular immune response that, with age, comes to dominate the peripheral lymphoid pool during chronic infection. This phenomenon is termed 'memory-inflation'. Recently, HCMV infection has been associated with vascular pathology and increased mortality in older individuals, thought due in part to the magnitude of the total HCMV-specific CD8+T-cell response. As such, it is vital to understand the breadth of HCMV immunodominant antigens for inclusion within adoptive immunotherapies.

PBMCs of seropositive individuals were stimulated *ex vivo* with CD8+T-cell HCMV-peptides followed by flow cytometric analysis. Here we report for the first time, to our knowledge, memory-inflation of three HCMV-specific CD8+T-cell populations restricted through HLA-Cw*0702.

We demonstrate that:-

- HLA-C-specific CD8+T-cell clones recognize peptide from **'immediate early'** (IE) HCMV proteins expressed very early during episodes of viral reactivation
- HLA-C-restricted HCMV-specific CD8+T-cells increase dramatically with age to **dominate the CD8+T-cell repertoire** and can individually comprise 32% of the CD8+T-cell pool.
- These CD8+T-cells increase their polyfunctionality, peptide avidity and cytotoxic potential dramatically with age.
- *Ex vivo* CD8+T-cell populations become **increasingly oligoclonal** with age demonstrated by *TCRVB* conservation.

These HCMV-IE-specific, HLA-C-restricted CD8+T-cells, demonstrate both remarkable expansion and selection for strong functional activity *in vivo*, representing one of the **largest CD8+T-cell populations to be recorded**.

These findings are invaluable for understanding the breadth of HCMV-CD8+T-cell memory-inflation. Consequently, it is hoped that the inclusion of these HLA-C specificities will advance current anti-HCMV adoptive therapy to HLA-Cw*0702 positive patients.

The m15 locus of murine cytomegalovirus modulates natural killer cell responses and promotes dissemination to the salivary glands

Chan, B.¹, Arapovic, M.², Masters, L.¹, Jonjic, S.², Shellam, G.¹, Smith, L.¹, Redwood, A.^{1,3}

¹University of Western Australia, Pathology and Laboratory Medicine, Perth, Australia, ²University of Rijeka, Department for Histology and Embryology, Faculty of Medicine, Rijeka, Croatia, ³Murdoch University, Institute for Immunology and Infectious Diseases, Murdoch, Australia

Murine cytomegalovirus (MCMV) expresses in excess of 170 open reading frames (ORFs), many of which have unknown function. In addition, MCMV and other cytomegaloviruses exhibit complex gene regulation, including the expression of alternative splice variants, the use of alternative start sites and the expression of multiple mRNA species from a single locus. Such complex regulation can complicate the study of gene function. We show here that the MCMV locus composed of the m14, m15 and m16 ORFs expresses five overlapping mRNA transcripts that are all co-terminal with the predicted end of the m16 ORF. Functional inactivation of any one of these ORFs has no impact on viral replication. However, disruption of all five transcripts leads to an increase in viral virulence during acute infection. Whilst slight, this elevated virulence is reproducible in multiple mouse strains. Conversely, disruption of this locus also leads to significant viral attenuation, evidenced during chronic infection of the salivary glands. Attenuation at this site is likely due to reduced dissemination. This complex phenotype is associated with heightened natural killer (NK) cell responses, including enhanced proliferation and IFN γ production. Depletion of NK cells, but not T cells, rescues viraemia and salivary gland replication. These data demonstrate that multiple transcripts can modulate, perhaps in a concerted fashion, the function of anti-viral NK cells. In addition, these data highlight

the need to define the transcriptional regulation of a viral locus before assigning gene function.

NF- κ B dependent antiviral immunity in drosophila

Goto, A.¹, Ogado, K.¹, Daeffler, L.¹, Hoffmann, J.¹, Imler, J.-L.²
¹CNRS UPR 9022, IBMC, Strasbourg, France, ²CNRS, UPR 9022, University of Strasbourg, Strasbourg, France

The Toll and IMD pathways of host-defense, which regulate different members of the NF- κ B family of transcription factors, play an important role in the control of fungal and bacterial infections in the model organism *Drosophila melanogaster*. Antiviral immunity involves the cell intrinsic mechanism of RNA interference and ill-characterized inducible responses. We recently showed that the virus-induced cytokine Dieldel suppresses the IMD pathway of host-defense, and that the *dieldel* gene has been hijacked by several insect DNA viruses. These data point to a role of the IMD pathway in the control of viral infections.

Using the picorna-like virus *Drosophila C virus* (DCV) as a model, we show that a restricted number of components of the IMD pathway, including the NF- κ B factor Relish, are required for antiviral immunity *in vivo* and in a macrophage-like cell line. Genome wide profiling of the transcriptome further identified ten genes that are regulated by Relish in flies and this cell line. Their characterization in loss- and gain- of function experiments revealed that two of these ten genes are necessary and sufficient to control viral infection. While one of them is the orthologue of a gene participating in antiviral immunity in mammals, the other one is a recent acquisition of drosophila.

Altogether, our findings point to a new pathway regulating the NF- κ B protein Relish and involved in antiviral immunity. They further highlight how drosophila can be used both to identify evolutionarily conserved defense mechanisms, and to reveal original, host-specific, antiviral factors.

Differential recognition of influenza A viruses by M1₅₈₋₆₆ epitope-specific CD8⁺ T cells is determined by extra-epitopic amino acid residues

van de Sandt, C.E.¹, Kreijtz, J.H.C.M.^{1,2}, Geelhoed-Mieras, M.M.¹, Nieuwkoop, N.J.¹, Spronken, M.I.¹, van de Vijver, D.A.M.C.¹, Fouchier, R.A.M.¹, Osterhaus, A.D.M.E.^{1,3,4,5}, Rimmelzwaan, G.F.^{1,3}

¹ErasmusMC, Viroscience, Rotterdam, Netherlands, ²BioNovion, Oss, Netherlands, ³ViroClinics Biosciences BV, Rotterdam, Netherlands, ⁴University of Veterinary Medicine, Research Center for Emerging Infections and Zoonoses (RIZ), Hannover, Germany, ⁵Artemis One Health Research Foundation, Utrecht, Netherlands

Natural influenza A virus (IAV) infections elicit both virus-specific antibody and CD4⁺ and CD8⁺ T cell responses. IAV-specific CD8⁺ cytotoxic T lymphocytes (CTLs) contribute to clearance of influenza virus infections and are generally directed against more conserved epitopes. However, viral CTL epitopes can display variation, allowing IAVs to evade from recognition by epitope-specific CTLs. Due to functional constraints, some epitopes, like

the immunodominant HLA-A*0201 restricted matrix protein 1 (M1)₅₈₋₆₆ epitope, are highly conserved between IAVs regardless of their subtype or host species of origin. We hypothesized that human IAVs evade recognition of this highly conserved epitope by impairing antigen processing and presentation by extra-epitopic amino acid substitutions. Activation of specific T cells was used as read out for antigen presentation. We showed that the M1₅₈₋₆₆ epitope in the M1 protein derived from a human IAV was poorly recognized compared to the M1 protein derived from an avian IAV. Furthermore, we demonstrated that naturally occurring variation at extra-epitopic amino acid residues affect CD8⁺ T cell recognition of the M1₅₈₋₆₆ epitope. These data indicate that human IAVs can impair recognition by M1₅₈₋₆₆-specific CTLs, while retaining the conserved amino acid sequence of the epitope, which may represent a yet unknown immune evasion strategy for IAVs. This difference in recognition may have implications for the viral replication kinetics in HLA-A*0201 individuals and spread of IAVs in the human population. The findings may aid the rational design of universal influenza vaccines that aim at the induction of cross-reactive virus-specific CTL responses.

Control of lymphoid stromal cell expansion during virus infection

Alexandre, Y.¹, Gregory, J.¹, Mueller, S.N.^{1,2}

¹University of Melbourne, Department of Microbiology and Immunology, Parkville, Australia, ²ARC Centre of Excellence in Advanced Molecular Imaging, University of Melbourne, Parkville, Australia

Subsets of lymphoid stromal cells (LSC), including the fibroblastic reticular cells (FRC) create a network on which immune cells migrate in lymphoid organs. FRC also express chemokines to attract naïve T cells and dendritic cells (DC) in the lymph node (LN). Inflammation triggers lymph node swelling and is accompanied by the expansion of the LSC network. It has been suggested that DC trigger FRC stretching while entry of naïve T cells in the LN triggers the expansion of the FRC network. Yet, little is known about the behaviour of LSC during viral infections *in vivo*. We found that infection with herpes simplex virus (HSV) or vaccinia virus induced remodelling of the LSC network in LN, characterised by a strong expansion of FRC. In contrast, LCMV Armstrong infection induced little LN hypertrophy and poor FRC expansion despite expression of Ki67, a marker of proliferation, by FRC. We found that LCMV infected LSC, especially FRC and marginal reticular cells (MRC), after peripheral but not systemic infection. Depletion of CD8 T cells prior to LCMV infection further reduced LSC expansion and increased infection of FRC and MRC, suggesting that this was not due to CTL-mediated killing. Co-infection of mice with HSV and LCMV inhibited LSC expansion without affecting the priming of T cell responses. Our data suggest that viral targeting of LSC by LCMV is influenced by route of infection and limits LN hypertrophy independently of CD8 T cell responses.

3234

Increased severity of influenza in Down syndrome may be due to a rapid inflammatory response rather than virus-induced pathology

Zanin, M.¹, Wong, S.-S.¹, Duan, S.², DeBeauchamp, J.¹, Webby, R.¹

¹St Jude's Children's Research Hospital, Department of Infectious Diseases, Memphis, United States, ²St Jude's Children's Research Hospital, Department of Immunology, Memphis, United States

Down Syndrome (DS), a trisomy of chromosome 21, is associated with increased prevalence and severity of respiratory infections and immunological abnormalities. To study the immune response to influenza virus in DS, we utilized the Ts65Dn mouse strain, a commonly used DS mouse model. Ts65Dn and wild-type mice were inoculated with Influenza A/California/04/2009 (H1N1) and lung, lymph nodes and spleen were collected on day 5 and 8 post inoculation. Ts65Dn mice showed increased morbidity and mortality over wild-type mice, although lung viral replication was less in Ts65Dn mice. Influenza-specific serum antibody titers were reduced in Ts65Dn mice compared to wild-type. By day 5, there were no significant differences in the number of infiltrating innate cells in the lungs. In the spleen, Ts65Dn mice showed significantly fewer CD4⁺ T-cells and a trend of fewer CD8⁺ T-cells. Ts65Dn mice also demonstrated higher serum IL-3 and G-CSF at baseline compared to wild-type, which did not change significantly after infection. Conversely, the pro-inflammatory cytokines IL-6 and IP-10 were significantly elevated in Ts65Dn mice post infection. In the adaptive arm, Ts65Dn mice showed fewer circulating plasma cells (CD138⁺) after infection. Our data suggests that the increased mortality observed in these mice could be due to a rapid hyperinflammatory responses that occurred within 5 days post infection rather than pathology caused by the virus.

3844

A potent clinical stage Smac mimetic antagonizes cellular inhibitors of apoptosis and promotes hepatitis B virus clearance *in vivo*

Ebert, G.^{1,2}, Allison, C.^{1,2}, Preston, S.^{1,2}, Cooney, J.^{1,2}, Toe, J.^{1,2}, Stutz, M.^{1,2}, Ojaimi, S.^{1,2}, Baschuk, N.³, Nachbur, U.^{2,4}, Silke, J.^{2,4}, Pellegrini, M.^{1,2}

¹Walter and Eliza Hall Institute, Infection and Immunity Division, Melbourne, Australia, ²Department of Medical Biology, University of Melbourne, Melbourne, Australia, ³Faculty of Science Technology and Engineering, School of Molecular Science, LaTrobe University, Department of Biochemistry, Melbourne, Australia, ⁴Walter and Eliza Hall Institute, Cell Signalling and Cell Death Division, Melbourne, Australia

Background: Cellular inhibitor of apoptosis proteins (cIAPs) are critically required for the activation of NFκB and the promotion of cell survival downstream of TNF receptor engagement. Drug or genetic targeting of cIAPs results in programmed cell death downstream of death receptor signalling. Smacs/Diablo are mitochondrial derived pro-apoptotic proteins that bind to cIAPs and antagonise their function. Small molecule drug inhibitors of IAPs (Smac mimetics) were developed to promote immune / TNF mediated killing of

cancer cells. We hypothesized that by using Smac mimetics we could promote immune mediated killing of hepatitis B virus (HBV) infected hepatocytes and eliminate infection.

Design: We antagonized cIAPs through gene targeting and by using a clinical stage IAP antagonist in a preclinical mouse model of chronic HBV infection. We examined effects on HBV infection markers in the blood and liver cells.

Results: Loss of cIAPs in gene-targeted animals promoted a rapid control of infection such that serum HBV-DNA was undetectable within 2-3 weeks. Importantly, animals treated with Smac mimetic showed a functional cure of chronic HBV infection with undetectable serum HBV-DNA and HBs antigen and the appearance of anti-HBs antibody within 6 weeks of treatment. The treatment preferentially caused the death of HBV infected hepatocytes *in vivo*. Additionally, Smac mimetics enhanced the efficacy of clinical nucleoside analogues in promoting viral clearance.

Conclusion: cIAPs are central regulators of host responses to HBV, they are critical determinants of infectious outcomes and antagonizing their function by a Smac mimetic can promote the clearance of HBV infection *in vivo*.

1602

High rates of cross-reactivity among apparently unrelated specificities shape antigen-specific T cell receptor repertoires

Thomas, P.¹, Dash, P.¹, Hertz, T.², Gartland, A.³, Bradley, P.³

¹St. Jude Children's Research Hospital, Immunology, Memphis, United States, ²Ben-Gurion University of the Negev, Beersheba, Israel, ³Fred Hutchinson Cancer Research Center, Seattle, United States

We have analyzed several thousand antigen-specific T cell receptor repertoires from multiple animals infected with influenza virus and/or murine cytomegalovirus (mCMV). Insights into the overall structure of antigen-specific repertoire landscapes towards 7 different specificities were generated from single cell paired TCR $\alpha\beta$ sequencing. In addition to characterization of repertoire features such as diversity, clonal structure, convergent recombination, and key determinants features of antigen-specificity, we observed a surprisingly high rate of single or dual chain sharing between otherwise unrelated responses. These shared receptors were often observed in across multiple animals in independent experiments. However, sharing appeared more likely to occur in animals where the two epitopes were presented simultaneously. Cloning and expression of these unique specificities has allowed further receptor characterization. Additional data indicate that some combinations of co-presented epitopes result in broader repertoires recruited to one or both epitopes. In summary, T cell receptors have a greater propensity for cross-reactivity across otherwise unrelated specificities, an effect that appears to be driven by co-presentation and substantially shapes the magnitude and diversity of antigen-specific repertoires.

Identification of repurposed drugs that increase immune checkpoint blockade efficacy in cancer using network analysis of responding tumours

Zemek, R.^{1,2}, Rinaldi, C.^{1,2}, Millward, M.^{1,3}, Nowak, A.K.^{1,2,3}, Bosco, A.⁴, Lake, R.^{1,2}, Lesterhuis, W.J.^{1,2}

¹University of Western Australia, School of Medicine & Pharmacology, Perth, Australia, ²National Centre for Asbestos Related Diseases, Perth, Australia, ³Sir Charles Gairdner Hospital, Medical Oncology, Perth, Australia, ⁴Telethon Kids Institute, Perth, Australia

Immune checkpoint blockade, such as anti-CTLA4 and anti-PD1 has shown outstanding results in several cancer types, with durable complete regression in a proportion of patients. Conversely, the majority of patients do not display tumour regression. It is unknown what molecular events determine this dichotomous response, nor which co-treatments are likely to combine effectively with checkpoint blockade.

To compare the molecular events in responders versus non-responders, we treated mice with bilateral AB1-HA mesothelioma tumours, which respond symmetrically to anti-CTLA4. We used a weighted gene correlated network analysis (WGCNA) of gene expression profiling data from responding versus non-responding tumours to identify modules associated with response. In addition, we used upstream regulator analysis and interrogated genome-wide drug-perturbation signatures in the connectivity map database to identify repurposed drugs that would phenocopy the response-associated network, and thus increase the response rate to anti-CTLA4.

We found two modules highly significantly differentially expressed; one enriched for cancer-associated genes, one for immune related genes. A central hub in both modules, which was upregulated in responding mice was inducible nitric oxide synthase (iNOS). Cotreatment with competitive iNOS inhibitor L-NNA inhibited the response to anti-CTLA4 while conversely the NO generator isosorbide dinitrate significantly enhanced the cure rate from 10 to 80% in AB1-HA mesothelioma-bearing mice. The drug repurposing approach identified all-trans retinoic acid as a candidate synergistic drug. Indeed, cotreatment with anti-CTLA4 increased the response rate from 10% to 60%.

Thus, we can identify therapeutic targets and drugs that act synergistically with checkpoint blockade in cancer.

3097

A novel approach using a bi-specific CD19xCD47 antibody to harness the phagocytic potential of macrophages to effectively suppress malignant B cells

Chauchet, X., Hatterer, E., Cons, L., Chatel, L., Richard, F., Salgado-Pires, S., Papaioannou, A., Shang, L., Fischer, N., Masternak, K., Johnson, Z., Kosco-Vilbois, M., Buatois, V., Ferlin, W.
Novimmune, Geneva, Switzerland

The up-regulation of the "don't eat me" signal CD47, and the subsequent engagement of SIRP- α , helps malignant cells evade innate immune surveillance and subsequent phagocytosis.

Targeting this axis is therefore an innovative approach to harness local phagocytes for tumor control. Development of monoclonal antibodies (Ab) that neutralize CD47 is hampered by its ubiquitous expression resulting in potential rapid Ab elimination and hematological toxicity including anemia and thrombocytopenia. To overcome such liabilities, a bispecific antibody was generated that relies on a high affinity anti-CD19 and a low affinity anti-CD47 thus focusing blockade of CD47 to B cells. *In vitro*, the bispecific Ab significantly enhances Ab-dependent cellular phagocytosis (ADCP) of B-cell lymphomas as compared to monoclonal Abs engaging either CD47 or CD19. Using xenograft mouse models, the co-blockade of CD19 and CD47 results in tumor growth suppression of several malignant B cell lines. Examined *ex vivo*, macrophages from the tumor microenvironment of bispecific Ab-administered mice show enhanced ADCP of malignant B cells; interestingly, the number of myeloid-derived suppressor cells (MDSCs) is reduced. Mechanistic studies have revealed that the ADCP induced by the bispecific Ab relies on Fc-gamma receptor (FcγR) I and/or FcγRIII engagement but not FcγRIIA ligation on macrophages. The bispecific Ab offers a novel way to safely harness the targeted phagocytic potential of macrophages in the tumor microenvironment.

Japan, ³Sapporo Medical University, Dept. of Gynecology, Sapporo,

Japan, ⁴Sapporo Medical University, Dept. of Respiratory Medicine, Sapporo, Japan

Cancer stem-like cells (CSCs) are defined as the small population of cancer cells that have stem cell-like phenotypes and high capacity for tumor initiation. These cells may have a huge impact in the field of cancer therapy since they are extremely resistant to standard chemotherapy and therefore likely to be responsible for disease recurrence. We have analyzed the immunopathological properties of CSCs of human solid cancers and identified several genes that were characteristic to CSCs. Remarkably, some of them were expressed exclusively in testicles among normal adult organs and involved in the spermatogenesis and function of spermatozoa. siRNA-mediated knockdown of these genes caused decreased sphere-forming capacity and tumor-initiating capacity, therefore indicating that they might be associated with the maintenance of stem-like phenotype of CSCs. Furthermore, it was indicated that expression of the CSC-specific genes might be regulated by epigenetic mechanisms such as histone modification and DNA methylation. Our data suggest that spermatogenesis-associated genes are aberrantly expressed in CSCs and function as key molecules for tumor initiation. In the field of tumor immunology, the CSC-specific gene products might serve as ideal targets for cancer immunotherapy. We show evidence that CSC-specific cytotoxic T-cells are induced from peripheral blood of cancer

patients. We named these functioning antigens "Somato-Germinomics antigens" and propose an immunotherapeutic strategy targeting to CSCs.

Adenosine is a potent immunosuppressor, which hampers an effective immune reaction towards cancer cells within the tumour microenvironment. In particular, adenosine inhibits tumour cell killing performed by cytotoxic lymphocytes and enhances proliferation of immunosuppressive cell types. Preclinical studies have identified that blockade of CD73 (the ectonucleotidase that generates adenosine) and antagonism of A2A adenosine receptor (A2AR) signaling heightens anti-tumour immune responses. However, it is yet to be established as to whether targeting both stages of the adenosinergic pathway in combination further enhances anti-tumour efficacy. To determine whether co-targeting CD73 and the A2AR would provide improved tumour control or show redundancy we developed double-deficient mice. In response to AT-3 mammary carcinoma and SM1WT1 melanoma, A2AR and CD73 double-knockout mice displayed significantly improved primary tumour control compared to wildtype mice or single gene-deficient controls, indicative of their non-redundant functions. Following, we assessed the therapeutic efficacy of A2AR antagonism alongside anti-CD73 in experimental and spontaneous metastases models. When given concurrently, these therapies reduced metastatic burden and enhanced survival benefit. In particular, anti-CD73 therapeutic activity was mediated by Fc receptor engagement, indicative of the multi-functionality of CD73, alongside adenosine production. Similarly, these *in vivo* findings were paralleled in mixed lymphocyte reactions utilizing human anti-CD73. This study illustrates the importance of targeting the adenosinergic pathway revealing its multi-faceted impact on tumour development and metastatic progression. As we move forward to clinical utility of adenosine-related therapies in oncology, this study provides evidence that targeting different parts of the adenosinergic pathway in combination may potentiate therapeutic response.

Treating metastatic disease through manipulation of regulatory T cells

Hughes, E., Bloom, A., Paisey, S., Smart, K., Ager, A., Gallimore, A.
Cardiff University School of Medicine, Infection and Immunity,
Cardiff, United Kingdom

Regulatory T cells (Tregs) play an important role in preventing the development of autoimmunity. Tregs have also been implicated in controlling tumour immunity since depletion of

Tregs slows the growth of primary tumours and, in some cases, causes complete regression. Metastasis is the main cause of fatality in cancer patients but the impact of Tregs in metastatic disease is poorly understood. We hypothesised that depletion of Tregs would prevent the spread of metastases. 4T1 murine mammary carcinomas were grown in DERE mice, which express the diphtheria toxin (DTx) receptor on Tregs. Tumour bearing mice were treated with DTx to deplete Tregs before or after resection of the primary tumour. Metastasis of 4T1 cells in mice was monitored using PET/CT imaging over a period of 3 weeks after removal of the primary tumour. Following Treg depletion, the growth of primary tumours was markedly reduced such that tumours regressed. In marked contrast, the number of metastases was not affected by Treg depletion. Immunohistochemical analysis of primary tumours and lung metastases showed major differences in the organization of tumour cells and immune cell infiltrates. We conclude that there are fundamental differences in the physiology and immune response between the primary tumour and the lung metastases, and depletion of Tregs alone is not enough to control the progression of metastatic disease in breast cancer.

2003

An unusually long 13-mer tumor antigenic peptide "molded" around distinct T-cell receptors when presented by HLA-B*0702 and provided the basis for polyclonal T-cell receptor recognition

Chan, K.F.^{1,2,3,4}, Gras, S.^{3,5}, Beringer, D.^{3,5}, Kjer-Nielsen, L.², Cebon, J.¹, Mccluskey, J.², Rossjohn, J.^{3,5,6}, Chen, W.^{1,4}

¹Ludwig Institute for Cancer Research, Olivia Newton-John Cancer and Wellness Centre, Melbourne, Australia, ²The University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ³Monash University, Department of Biochemistry and Molecular Biology, School of Biomedical Sciences, Melbourne, Australia, ⁴La Trobe University, Department of Biochemistry & Genetics, La Trobe Institute of Molecular Science, Melbourne, Australia, ⁵Monash University, Australian Research Council Centre of Excellence for Advanced Molecular Imaging, Melbourne, Australia, ⁶Cardiff University School of Medicine, Institute of Infection and Immunity, Cardiff, United Kingdom

Peptides presented by major histocompatibility complex class I (MHC-I) molecules are largely 8 to 10 amino acids in length because of the molecules closed ends. Nonetheless, a growing number of studies have shown that peptide longer than 10 amino acids can be presented for CD8⁺ T-cell (T_{CD8}⁺) recognition and is equally capable of eliciting potent T_{CD8}⁺ responses as peptides of canonical length. Long peptides were frequently observed to form a prominent central bulge when presented by MHC-I molecules. Such bulged peptide/MHC-I (pMHC-I) conformation poses great challenge for T-cell receptor (TCR) binding, thus results in predominantly biased TCR repertoire. Some TCRs were observed to perch on a rigid bulged pMHC-I, but others were shown to deform the bulged pMHC-I and created a flatter conformation. No studies have described that such TCR docking modes could be simultaneously used by distinct TCRs recognizing a common bulged pMHC-I.

We previously reported an immunodominant 13-mer NY-ESO-1₆₀₋₇₂ peptide derived from cancer-testis antigen NY-ESO-1. This peptide is restricted to HLA-B*0702 and is naturally presented by melanoma cells. It adopts a super-bulge in the centre when complexed to HLA-B*0702. Unlike other reported cases, T_{CD8}⁺ responses to the NY-ESO-1₆₀₋₇₂/HLA-B*0702 is not only immunodominant but also involves diverse TCR repertoire, at least 10 different Vβ families.

In this study, we solved the structures of two TCRs, KFJ5 and KFJ37, in complexes with NY-ESO-1₆₀₋₇₂/HLA-B*0702 and showed that the polyclonal TCR recognition is explained by the flexible arrangements of the presented peptide. Our findings elucidated a novel mechanism for polyclonal TCR/pMHC-I interactions.

Systemic inflammation in tumour microenvironment provoked by cytotoxic lymphocyte synapse dwell time

Jenkins, M.R.^{1,2}, Rogers, A.J.¹, Rudd-Schmidt, J.A.¹, Lopez, J.A.¹, Mannering, S.I.^{3,4}, Voskoboinik, I.^{1,5}, Trapani, J.A.^{1,2}

¹Peter MacCallum Cancer Centre, Cancer Immunology Research, East Melbourne, Australia, ²The University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia, ³St Vincent's Hospital, The University of Melbourne, Department of Medicine, Fitzroy, Australia, ⁴St Vincent's Institute of Medical Research, Immunology and Diabetes Unit, Fitzroy, Australia, ⁵The University of Melbourne, The Department of Genetics, Melbourne, Australia

Failure of cytotoxic T lymphocytes (CTL) or natural killer cells (NK) to kill target cells by perforin/granzyme-induced apoptosis causes severe immune dysregulation. Infants deficient in perforin suffer a fatal 'cytokine storm' resulting from macrophage over-activation, but the link to failed target cell death is not understood. We show that prolonged target cell survival amplifies the quanta of inflammatory cytokines secreted by CTL/NK cells and that interferon-γ directly invokes the activation and secondary over-production of pro-inflammatory IL-6 from naïve macrophages. Further, using live cell microscopy to visualise hundreds of synapses formed between WT, perforin-null or granzyme A/B-null CTL/NK and their targets in real time, we show that hyper-secretion of cytokine and chemokines is linked to failed disengagement of perforin- or granzyme-deficient lymphocytes from their targets, with mean synapse time increased five-fold. The signal for detachment arose from the dying target cell and was caspase-dependent, as delaying target cell death with various forms of caspase-blockade also prevented their disengagement from fully competent CTL/NK cells and caused cytokine hyper-secretion. Our findings are supported by recent in vivo data; lymphocytes, which fail to quickly kill tumour cells, cause changes to immune cell recruitment and inflammatory environment. We provide the cellular mechanism through which failed killing by lymphocytes causes systemic inflammation involving recruitment and activation of myeloid cells.

3660**Inflammatory monocytes promote inflammation-induced tumor development in a model of cutaneous squamous cell carcinoma***Lelios, L., Cecconi, V., van den Broek, M., Becher, B., Greter, M.**University of Zurich, Institute of Experimental Immunology, Zurich, Switzerland*

Cutaneous squamous cell carcinoma (SCC) is one of the major non-melanoma skin cancers and derives from transformed epidermal squamous cells. Tumor-associated myeloid cells have been shown to play an important role in tumor development by suppressing anti-tumor immune responses on one hand and supporting tumor growth and metastasis on the other. Langerhans cells (LCs) - the resident mononuclear phagocyte population of the epidermis - have been shown to reside within SCC tumors and to promote epidermal mutagenesis. However, the distribution, phenotype and role of LCs and other skin-resident or infiltrating myeloid cells during SCC development remains unclear. In order to address the functions of these myeloid cell types (monocytes, macrophages, and dendritic cells), we used the *K14-HPV8-E6* transgenic mouse model of ultraviolet light (UV) induced SCC where we blocked the development or recruitment of different myeloid cells to the skin. We demonstrated that neither tumor-associated LCs nor resident macrophages and dendritic cells promoted SCC growth. However, the early recruitment of monocytes to the site of UV exposure was necessary for the development of SCC indicating that chronic inflammation maintained specifically by skin-infiltrating inflammatory monocytes promotes tumorigenesis.

1382**Role of IL17 producing $\gamma\delta$ T cells (T $\gamma\delta$ 17) in gall bladder cancer pathogenesis***Chiplunkar, S.¹, Patil, R.¹, Shah, S.¹, Shrikhande, S.², Goel, M.², Dikshit, R.²**¹Advanced Centre for Treatment, Research & Education in Cancer, Tata Memorial Centre, Chiplunkar Lab, Mumbai, India, ²Tata Memorial Hospital, Mumbai, India*

Gall bladder cancer (GBC) is the most common malignancy of the biliary tract. 70-80% of GBC patients are associated with inflammatory condition of cholelithiasis. The immune microenvironment in GBC is not well investigated. The present study aims to understand the dynamics and functions of pro inflammatory (Th17, T $\gamma\delta$ 17, Tc17) and anti-inflammatory (Regulatory T cells; Tregs) immune cells in GBC. In the current prospective study of GBC patients, we report that the levels of IL17 producing inflammatory subtypes of $\gamma\delta$ (T $\gamma\delta$ 17), CD4 (Th17) and CD8 (Tc17) T cells were increased in peripheral blood and tumor infiltrating lymphocytes (TIL) of GBC patients compared to healthy individuals (HI) as analysed by multicolour flow cytometry. Regulatory T cells (Tregs) were decreased in peripheral blood and increased in TILs of GBC patients but their suppressive potential was comparable to HI. Serum cytokines profile of GBC patients showed elevated levels of cytokines (IL6, IL23 and IL1 β) required for differentiation of IL17 producing cells. We demonstrated that T $\gamma\delta$ 17 cells migrate towards the tumor

bed through CXCL9-CXCR3 axis. IL17 secreted by T $\gamma\delta$ 17 induced VEGF production and other angiogenesis related factors in GBC cells. T $\gamma\delta$ 17, Th17, Treg and serum IL17 were associated with poor survival of GBC patients. Taken together, our data strongly suggests that T $\gamma\delta$ 17 is a pro-tumorigenic subtype of $\gamma\delta$ T cells that contribute to the negative clinical outcome of GBC patients. Our data has unravelled novel pro tumorigenic functions of T $\gamma\delta$ 17 cells in GBC, opening new avenues for targeted therapies.

4758**Targeting cereblon for anti-tumor immunity***Hesterberg, R.^{1,2}, Beatty, M.¹, Epling-Burnette, P.K.¹**¹Moffitt Cancer Center, Tampa, United States, ²University of South Florida, Tampa, United States*

Growing emphasis has been placed on defining novel regulatory circuits to improve anti-tumor immunity. Modulation of intracellular T-cell signaling thresholds could be a valuable approach to extend beyond immune checkpoint blockade. A series of E3 ubiquitin ligases (E3-UbL) are involved in energy and self-tolerance by controlling proteasomal-mediated degradation and molecular trafficking of key signaling intermediates involved in T-cell activation. Recently cereblon (CRBN), a novel E3 ubiquitin ligase substrate receptor for the DDB1/Cul4/Rbx1 complex, has been linked to T-cell signaling regulation. Cereblon is the direct pharmacological target of the immunomodulatory drug (IMiDs[®]) class used in several hematological malignancies. Treatment with IMiDs reduces inflammation and enhances T-cell activation in both optimal and suboptimal stimulatory conditions. Proliferation, IL-2 and IFN γ are enhanced in T-cells from CRBN-deficient (C57B/6 *crbn*^{-/-}) mice with both native polyclonal and fixed T-cell receptor repertoires. Here, we show that CRBN mediates a novel pathway of regulation that is distinct from other E3-UbL proteins associated with tolerance. Compared to wild-type T-cells, *crbn*^{-/-} T-cells display metabolic changes including higher oxygen consumption (OCR) and acidification rates (ECAR) indicating that cereblon-regulated substrates control metabolic activity. It has been previously demonstrated that tumors suppress T-cell function through metabolic competition. B16-melanoma growth was significantly reduced in *crbn*^{-/-} mice consistent with improved anti-tumor T-cell immunity. Adoptive cell transfer of *crbn*^{-/-} T-cells into B16-melanoma bearing mice demonstrated this phenotype to be T-cell intrinsic. These results reveal a novel E3-UbL regulatory circuit involved in metabolic control that may be exploited pharmacologically to improve anti-tumor immunity.

31

IL-17 from discovery to targeting

Miossec, P.

University of Lyon, Dpt of Immunology and Rheumatology, Lyon, France

IL-17 now IL-17A, was first identified in 1995 as a T cell derived cytokine with effects on inflammation and neutrophil activation. Using the example of Rheumatoid arthritis (RA), it was shown that its inhibition reduced the production of inflammatory mediators by explants of inflamed synovitis. This effect resulted from synergistic interactions between IL-17 and proinflammatory cytokines such as TNF or IL-1. In addition to its effect on inflammation and related destruction, the role of IL-17 was shown in inflammation chronicity through an effect on reduced apoptosis of mesenchymal cells and induction of anti-apoptotic molecules. At the site of inflammation, increased local production of IL-17 results from local interactions between activated T cells with various mesenchymal cells, either from bone marrow, synovium.

Taken together, these results support the early targeting of IL-17 in chronic inflammation associated with matrix destruction. Reduced effect of IL-17 inhibition can be expected when inflammation had a long term effect on mesenchymal cells. Recent clinical results are in line with these observations. Impressive results with anti-IL-17A antibodies have been observed in psoriasis. This led to the registration of the first anti-IL-17A antibody in January 2015. Interesting results have been obtained in psoriatic, arthritis, spondylarthritis, and rheumatoid arthritis. Other options include the inhibition of TNF and IL-17A with bispecific molecules. As the family members IL-17A and IL-17F share proinflammatory activities, another option is the dual inhibition of IL-17A and IL-17F, even with the added inhibition of TNF with a single tri-specific molecule.

Preclinical efficacy of Periostin short interfering RNA in pulmonary fibrosis

Hinne, J.¹, D'Alessandro-Gabazza, C.N.¹, Toda, M.¹, Yasuma, T.², Kentaro, F.³, Nishihama, K.², Kobayashi, T.³, Etsuko, H.¹, Gabazza, E.¹, Yazunori, Y.⁴

¹Mie University School of Medicine, Department of Immunology, Tsu, Japan, ²Mie University School of Medicine, Department of Diabetes and Metabolism, Tsu, Japan, ³Mie University School of Medicine, Department Pulmonary and Critical Care Medicine, Tsu, Japan, ⁴Aqua Company, Tsu, Japan

Idiopathic Pulmonary Fibrosis (IPF) is a fatal disease with a mortality rate of 3 years after diagnosis. While pathogenetic mechanisms are incompletely understood, the currently accepted paradigm proposes that injury to the alveolar epithelium is followed by a burst of pro-inflammatory and fibroproliferative mediators that invoke responses associated with normal tissue repair. Recent research in this area has focused on treatment regimen which seems to improve lung function but none has so far been found to increase survival.

Periostin which is a recently characterized matricellular protein belonging to the fasciclin 1 family has been shown to be elevated in IPF patients and in bleomycin (BLM) induced lung fibrosis.

In this study we evaluated the effect of periostin siRNA on BLM-induced lung fibrosis.

The results indicate that periostin is significantly increased on day 3 after BLM treatment and reduced on days 7 and 14 but elevated on day 21. There was increased infiltration of inflammatory cells in the scrambled siRNA treated group as compared to periostin siRNA treated group. The levels of periostin, TGF-beta 1 and collagen were significantly reduced in periostin siRNA treated group as compared to scrambled siRNA treated group. Fibrosis was also significantly reduced as measured by the Ashcroft score. The overall survival was also improved in the periostin siRNA treated group as compared to the control groups.

These results show that blockade of periostin with siRNA may be an effective treatment option for the management of pulmonary fibrosis.

3722

The balance between inflammation and immunity in the tumor microenvironment is determined by IL-1 β

Kaplanov, I., Karnetsky, R., Carmi, Y., Voronov, E., Apte, R.N.

Ben Gurion University of the Negev, Beer Sheva, Israel

We used the model of orthotopically injected 4T1 breast cancer cells IL-1 β deficient (IL-1 β KO) and wild-type (WT) mice to probe the role of microenvironment IL-1 β in the balance between inflammation and immunity. Both, WT and IL-1 β KO mice developed tumors, which progress in WT mice and undergo regression in IL-1 β KO mice after 14 days. Progression of the primary tumor in WT mice corresponded with development of lung metastases and poor survival rates, whereas in IL-1 β KO mice regression of primary tumor, with no metastases was observed. Tumor regression in IL-1 β KO mice is CD8⁺ T cell dependent, WT mice, microenvironment IL-1 β promotes, through induction of MCP-1, recruitment of LY6C^{high}CCR2⁺ monocytes to the primary tumor and directs monocyte differentiation to inflammatory and tumor promoting mannose receptor-bearing macrophage lineage cells. In IL-1 β KO mice differentiation pathway of monocytes to macrophages is arrested at the stage of immature macrophages. However, in IL-1 β KO mice, and not in WT mice, LY6C^{low}CCR2 cells were abundant at the tumor site. This cell population might further differentiate into monocyte-derived macrophages or monocyte-derived dendritic cells, possibly with APC function. At the early time intervals after tumor injection into lungs from both WT and IL-1 β KO mice, similar local inflammatory responses were apparent, which progressed in WT mice during development of lung metastases but disappeared in IL-1 β KO mice. Overall, the results suggest that anti-IL-1 β therapy could modify the myeloid cell load and subpopulations in the tumor and modify systemic inflammatory responses, thus reducing tumor invasiveness.

MicroRNAs mediate anti-inflammatory effects of eicosapentaenoic acid in mouse adipose tissue

Moustaid-Moussa, N.¹, Ramalingam, L.¹, Yen, E.¹, Wijayatunga, N.¹, Pahlavani, M.¹, Kottapalli, R.², Gunaratne, P.³, Rajapakshe, K.⁴, Coarfa, C.⁴, Kalupahana, N.S.^{1,5}

¹Texas Tech University, Nutritional Sciences and Obesity Research Cluster, Lubbock, United States, ²Texas Tech University, Center for Biotechnology & Genomics and Obesity Research Cluster, Lubbock, United States, ³University of Houston, Biology & Biochemistry, Houston, United States, ⁴Baylor College of Medicine, Molecular and Cellular Biology, Houston, United States, ⁵University of Peradeniya, Faculty of Medicine, Physiology, Peradeniya, Sri Lanka

Obesity is associated with the expansion of adipose tissue that creates a system in which the body transitions into an inflammatory state. We previously reported that mice fed high fat diets supplemented with the omega-3 fatty acid, eicosapentaenoic acid, (HF-EPA) exhibited reduced adipose and systemic inflammation and macrophage infiltration into adipose tissue, compared to mice fed high fat diets without EPA (HF). Further, microRNAs (miRNAs), a class of small, non-coding RNAs, were identified as key regulators of metabolic genes and processes associated with diseases including obesity. Accordingly, we hypothesized that specific microRNAs are mediating anti-inflammatory effects of EPA in adipose tissue. To test this hypothesis, we tested whether EPA regulates inflammatory genes (RNA-Seq) and microRNAs (miRNA profiling) in visceral white adipose tissue (VAT) of mice. We identified 200 genes and 64 miRNAs that were differentially expressed (95% confidence, $p < 0.05$) in VAT from HF compared to HF-EPA fed mice. Ingenuity® Pathway Analysis (IPA) was used to determine mRNA-miRNA pairs regulated by EPA. Among these, several pro-inflammatory miRNAs such as miR-221 was downregulated by EPA. Other major canonical pathways associated with inflammation were also reduced by EPA. These findings were further validated in mouse fat tissue and confirmed that EPA significantly reduced miR-221 expression ($p < 0.05$). We conclude that global genomic studies are important in identifying new pathways regulated by omega-3 fatty acids that may lead to novel targets to prevent/treat metabolic complications associated with obesity.

1636

mPGES1-dependent PGE₂ orchestrates T cell responses during autoimmunity

Maseda, D., Johnson, E., Crofford, L.J.

Vanderbilt University, Medicine, Nashville, United States

Eicosanoids, particularly prostaglandin E₂ (PGE₂), are critical molecules in the initiation and resolution of inflammation during immune responses. PGE₂ is associated with modulating autoimmunity through altering the IL-23/IL-17 axis and regulatory T cells, whose balance is critical for controlling pathogenic

T cells. The inducible microsomal prostaglandin E synthase 1 (mPGES1) is a membrane enzyme that regulates local PGE₂ levels and is highly expressed at sites of inflammation. Hematopoietic

and stromal cells express mPGES1, but its role in T cell function remains underappreciated. Freshly isolated naïve T cells deficient in mPGES1 depict a significant decrease in *ptger2* and *ptger4* (PGE₂ receptors EP2 and EP4) and *tgfbr1* expression compared with WT naïve T cells. Since TGFβ is key for the generation of both regulatory and Th17 cells we addressed the effect of mPGES1 in Th17 and Treg function. mPGES1^{-/-} naïve T cells produced more IL-17A than their WT counterparts under Th17 polarizing conditions *in vitro*, and exogenous PGE₂ shifted the production from IL-17A to IFNγ. In contrast, during immunization experiments, WT mice demonstrated increased Th17 and Treg responses than mPGES1^{-/-} mice, including enhanced antigen-specific IL-17A, IL-6 and IFNγ recall responses. Furthermore, mPGES1 displayed opposite effects on pathogenic and regulatory T cells in the T-cell transfer colitis model, with mPGES1 deficiency limiting intestinal damage driven by effector T cells, but enhancing *de novo* generation of Tregs and increasing colonic lamina propria homing of CD4⁺FoxP3⁺ cells. Taken together, these data demonstrate the pleiotropic and context-dependent actions of mPGES1 and PGE₂ in inflammation and immunity.

Genetic ablation of CCR6 aggravates colitis in a spontaneous colitis mouse model

Basheer, W.¹, Kunde, D.¹, Korner, H.², Eri, R.¹

¹University of Tasmania, School of Health Sciences, Launceston, Australia, ²Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia

Introduction and Background: Chemokine receptor 6 (CCR6) is expressed by both pro-inflammatory cells and regulatory T cells and its ligand CCL20 is predominantly expressed by intestinal epithelial cells. CCR6/CCL20 axis is implicated to play a major role in the pathogenesis of IBD. The CCR6/CCL20 axis is paradoxical as it is involved in both immune regulation and activation. The contradictory role of CCR6/CCL20 in inflammation/intestinal homeostasis requires further investigation in a relevant spontaneous model of colitis.

Aim: To assess the role of CCR6 in an inflammatory environment of spontaneous colitis model Winnie, with established colitis.

Methods: CCR6 deficient Winnies were generated and assessed with clinical, histological & immunological parameters.

Results: Clinical parameters showed significant increase in the colon weight/body weight in CCR6 deficient Winnie mice compared to sex and age matched controls. Histological examinations revealed the aggravated colitis specifically in mid to proximal colon region. Immuno-phenotyping of colonic lymphocytes indicated reduction in the Fox P3⁺ Tregs and increased Th17 cells.

Discussion and conclusion: Our studies indicate that CCR6 deficiency aggravates colitis in an established chronic colitis setting. Further detailed mechanism of CCR6 function will provide an insight in understanding of CCR6/CCL20 in the pathogenesis of IBD.

3259

IL-33 released from liver sinusoidal endothelial cells induce neutrophil extracellular traps during liver sterile inflammation

Huang, H.^{1,2}, Yazdani, H.¹, Hui-Wei, C.¹, Tohme, S.¹, Loughran, P.¹, Turnquist, H.¹, Tsung, A.¹

¹University of Pittsburgh, Department of Surgery, Pittsburgh, United States, ²Huazhong University of Science and Technology, Department of Surgery, Wuhan, China

Neutrophil extracellular traps (NETs) have been found to exacerbate liver ischemia/reperfusion (I/R) injury which is one of well-known surgical stress. We here sought to determine the role of IL-33 released from Liver sinusoidal endothelial cells (LSECs) in NET formation during liver I/R. There was a significant increase in serum IL-33 level in patients who underwent major liver resection in which liver I/R is inevitable, compared to age/gender-matched healthy volunteers. In a murine non-lethal model of warm liver I/R, NET formation decreased in IL-33 KO mice compared with WT mice, associated with significant less serum level of myeloperoxidase (MPO)-DNA complexes and tissue level of citrullinated-histone H3. Treatment of soluble ST2 (sST2) significantly reduced NET formation whereas recombinant IL-33 (rIL-33)-treatment increased NETs in mice after liver I/R. Significantly less organ damage and lower levels of systemic inflammation were found in IL-33 KO mice or sST2-treated WT mice compared to control mice after liver I/R. rIL-33 administration during I/R exacerbated hepatotoxicity and systemic inflammation. *In vitro*, WT LSECs released IL-33 after hypoxia (1% O₂), promoted WT neutrophils to form NETs. NET formation was blocked by IL-33 neutralizing antibody or sST2. IL-33 KO LSECs failed to induce NET formation in WT neutrophils. ST2 KO neutrophils did not form NETs in response to rIL-33. After neutrophil depletion in mice, the adoptive transfer of ST2 KO neutrophils significantly decreased in NET formation, conferred from liver I/R injury. Our study demonstrates IL-33 from LSECs induces neutrophils to form NETs in excessive inflammation and hepatotoxicity during liver I/R.

Promotion of expansion and differentiation of hematopoietic stem cells by IL-27 into myeloid progenitors to control infection in emergency myelopoiesis

Yoshimoto, T.¹, Furusawa, J.-I.¹, Chiba, Y.¹, Xu, M.¹, Hasegawa, H.¹, Nakae, S.², Kobayashi, F.³, Yoshida, H.⁴, Mizoguchi, I.¹

¹Tokyo Medical University, Department of Immunoregulation, Institute of Medical Science, Tokyo, Japan, ²University of Tokyo, Laboratory of Systems Biology, Center for Experimental Medicine and Systems Biology, Institute of Medical Science, Tokyo, Japan, ³Kyorin University of Medicine, Department of Infectious Diseases, Tokyo, Japan, ⁴Saga University, Department of Biomolecular Sciences, Faculty of Medicine, Saga, Japan

Emergency myelopoiesis is inflammation-induced hematopoiesis to replenish myeloid cells in the periphery, which is critical to control the infection with pathogens. Previously, pro-inflammatory cytokines such as IFN- α and IFN- γ were demonstrated to play a critical role in the expansion of

hematopoietic stem cells (HSCs) and myeloid progenitors, leading to production of mature myeloid cells, although their inhibitory effects on hematopoiesis were also reported. Therefore, the molecular mechanism of emergency myelopoiesis remains incompletely understood. Here, we clarify that one of the IL-6/IL-12 family cytokines, IL-27, plays an important role in the emergency myelopoiesis. Among various types of hematopoietic cells in bone marrow, IL-27 predominantly and continuously promoted the expansion of only Lineage-Sca-1⁺c-Kit⁺ (LSK) cells, especially long-term repopulating HSCs and myeloid-restricted progenitor cells with long-term repopulating activity, and the differentiation into myeloid progenitors in synergy with stem cell factor. These progenitors expressed myeloid transcription factors such as *Spi1*, *Gfi1*, and *Cebpa/b* through activation of STAT1 and STAT3, and had enhanced potential to differentiate into migratory DCs, neutrophils, and mast cells. The experiments using mice deficient for one of IL-27 receptor subunits, *WSX-1*, and IFN- γ revealed that the blood stage of *Plasmodium berghei* XAT infection enhanced IL-27 expression through IFN- γ production, and the IL-27 then promoted the expansion of LSK cells, differentiating and mobilizing them into spleen, resulting in enhanced production of neutrophils to control the infection. Thus, IL-27 is one of the limited unique cytokines directly acting on HSCs to promote differentiation into myeloid progenitors downstream of IFN- γ during emergency myelopoiesis.

Bromodomain inhibitors reverse inflammation and disease features in experimental chronic obstructive pulmonary disease

Jones, B.¹, Harrison, C.¹, Dua, K.¹, Hsu, A.¹, Starkey, M.¹, Jarnicki, A.², Smithers, N.³, Knight, D.¹, Wark, P.¹, Adcock, I.⁴, Hansbro, P.¹

¹University of Newcastle, Centre for Asthma and Respiratory Diseases, New Lambton Heights, Australia, ²University of Melbourne, Dept of Pharmacology and Therapeutics, Parkville, Australia, ³GlaxoSmithKline, Epinova DPU, Stevenage, United Kingdom, ⁴Imperial College London, National Heart & Lung Institute, London, United Kingdom

Introduction: Chronic obstructive pulmonary disease (COPD) is a progressive lung disease characterised by chronic airway inflammation that has limited treatment options. Emerging evidence suggests that increased acetylation of histones associated with pro-inflammatory genes drives chronic inflammation in the lungs of patients with COPD. Histone acetylation is governed by histone acetyltransferases (HATs) that drive acetylation, and inhibitory histone deacetylases (HDACs). HAT activity is dependent on a conserved bromodomain, which may be targeted therapeutically.

Methods: We assessed the role(s) and therapeutic potential of targeting HAT bromodomains in our mouse model of cigarette smoke (CS)-induced experimental COPD. We treated mice with a highly-selective, proprietary bromodomain inhibitor for 4 weeks after 8 weeks of CS exposure to induce the development of experimental COPD. Treatment was with either continued CS exposure or smoking cessation. Mechanistic pathways were assessed using RT-qPCR, ELISA and ChIP-Seq.

Results: In mouse and human lung tissues we found aberrant HAT & HDAC expression and activity that led to increased histone H4 acetylation. Treatment with the bromodomain inhibitor abrogated inflammatory cells, particularly neutrophils in the BALF. Furthermore treatment protected against emphysema-like alveolar enlargement and restored lung function parameters including airway resistance and TLC.

Conclusion: COPD is associated with aberrant histone acetylation. Inhibition of bromodomains restricts progression of experimental COPD, by reducing inflammation, alveolar enlargement and restoring lung function parameters. This inhibition suggests that histone acetylation is a potential driving force that leads to the progression and development of COPD. Inhibition could have the potential therapeutic benefit in human COPD.

Protein phosphatase magnesium dependent 1A, the Janus of microenvironment acts as an immunomodulator

Lavi, S.¹, Ben Dov, H.¹, Backal, L.¹, Ben Dov, R.¹, Ben Meir, D.¹, Weingarten, G.², Wertheimer, E.², Barzilai, A.^{2,3}

¹Tel Aviv University, Cell Research and Immunology, Tel Aviv, Israel,

²Tel Aviv University, Pathology, Sackler School of Medicine, Tel Aviv, Israel, ³Sheba Medical Center, Department of Dermatology, Ramat Gan, Israel

Tumor microenvironment has been gradually recognized as a key contributor to cancer progression. Using conditional Protein phosphatase magnesium dependent 1A (PPM1A) knockout mice we identified PPM1A as a major regulator of the microenvironment. In the PPM1A ablated mice the wound healing process goes awry and culminates into uncontrolled inflammation and angiogenesis, features that are two of the hallmarks of cancer. We investigated the role of PPM1A in cancer, using different mouse models. To our surprise, the absence of PPM1A could be either tumor promoting or tumor suppressive depending on the tumor initiating protocol.

Skin fibroblasts play critical roles in normal wound healing and in cancer. While fibroblasts can have a tumor suppressing activity, the phenotype of the fibroblast changes to a tumor promoting state as carcinogenesis progresses. Multipotent skin precursor cells (SKPs) capable to differentiate to fibroblasts were isolated from WT and KO mice and cultivated as 3D spheroids. PPM1A ablation led to major changes in gene expression and in functional characteristics of the SKPs. PPM1A was shown to be a major player in cellular ROS (reactive oxygen species) signaling. The absence of PPM1A led to altered expression of the immunomodulatory genes, genes regulating cell death of immune cells and the recruitment of antigen presenting cells. The role of PPM1A in immunomodulation and tumorigenesis will be discussed.

Our studies might lead to the development of a new strategy in cancer treatment involving immunomodulation of the tumor microenvironment via the manipulation of PPM1A or its targets.

Drugs/drug analogues modulate MAIT cell function in an MR1-dependent manner

Mucosal Associated Invariant T (MAIT) cells are an abundant subset of T cells, whose T cell receptor is restricted by the monomorphic MHC class I related molecule MR1. Acting as signature biomarkers of microbial infection, stimulating MAIT cell antigens (Ags), such as 5-OP-RU, originate from the microbial biosynthesis of riboflavin. MR1 also binds non-stimulating Ags, which act as competitive inhibitors of stimulating Ags.

Given the small molecule nature of MR1 ligands identified thus far, we reasoned that drugs and drug analogues could represent a source of exogenous MR1 ligands. Indeed when screening a library of drugs/drug analogues we identified novel MR1 ligands. Some of these upregulated MR1 and inhibited human and mouse MAIT cell activity in response to 5-OP-RU, as determined by *in vitro* analyses. Furthermore, these drugs/drug analogues acted in a dose dependent manner as competitive inhibitors of human MAIT cells stimulated with 5-OP-RU to proliferate and to produce IFN γ and TNF α cytokines *ex vivo* and mouse MAIT cell proliferation *in vivo*. Additionally, a drug and metabolites thereof strongly activated a subset of MAIT cells in a dose-dependent and MR1-restricted manner.

Thus MR1 has the potential to accommodate a range of structurally distinct ligands that have the capacity to directly modulate MAIT cell function by either competitively inhibiting MAIT cell activation or activating subsets of MAIT cells. These findings suggest that widely used drugs can inadvertently modulate MAIT cell function. Given the monomorphic and evolutionary conserved nature of the MAIT-MR1 axis this effect has a global impact.

CD8 T-cells responding to infection recognize pathogen-derived epitopes presented by MHC class-I molecules. While most of such epitopes are generated by proteasome-mediated antigen cleavage, analysis of tumor antigen processing has revealed that epitopes may also derive from proteasome-catalyzed peptide splicing (PCPS). To determine whether PCPS contributes to epitope processing during infection, we analyzed the fragments produced from a *Listeria monocytogenes* polypeptide by purified proteasomes. Mass spectrometry demonstrated the generation of a known H-2K^b-presented linear epitope (LLO₂₉₆₋₃₀₄) and four spliced peptides, which were trimmed by ERAP into six spliced peptides with *in silico* predicted H-2K^b binding affinity. These spliced peptides, which displayed sequence similarity with LLO₂₉₆₋₃₀₄ bound to H-2K^b molecules in cellular assays and one of them was recognized by CD8 T-cells of infected mice. This spliced epitope differed by one amino acid from LLO₂₉₆₋₃₀₄ and double staining with LLO₂₉₆₋₃₀₄⁻ and spliced peptide-folded MHC multimers showed that LLO₂₉₆₋₃₀₄ and its spliced variant were recognized by the same CD8 T-cells. Thus, PCPS multiplies the variety of peptides that is processed from an antigen and leads to the production of epitope variants that can be recognized by cross-reacting pathogen-specific CD8 T-cells. Such mechanism may reduce the chances for pathogen immune evasion.

Counting T cells and peptides: a quantitative view of immunogenicity and antigen presentation during virus infection

Tscharke, D.¹, Croft, N.², Smith, S.¹, Wong, Y.C.¹, Flesch, I.¹, Pickering, J.¹, Keller, E.¹, Purcell, A.²

¹The Australian National University, John Curtin School of Medical Research, Acton, Australia, ²Monash University, Dept. Biochemistry and Molecular Biology, Clayton, Australia

We are using advanced mass spectrometry methods to detect and quantify the presentation of many native vaccinia virus peptides by MHC class I on multiple mouse cell types, and comparing these data with the magnitude of corresponding CD8⁺ T cell responses. We found that presentation of viral peptides on MHC I during virus infection is complex and dynamic. In general, dendritic cells present peptides at much higher levels than infected target cells, with primary fibroblasts being especially poor. Most (~90%) of viral epitopes are generated from their

source protein co-incident with expression, suggesting that few viral proteins reach their fully mature state before entering the antigen presentation pathway. Strikingly, the abundance of peptides being presented is poorly reflected in the anti-viral CD8+ T cell repertoire. We have now identified many new vaccinia virus peptides presented on MHC I during infection and for the first time have been able to directly determine the fraction of presented viral peptide-MHC complexes that are immunogenic. For vaccinia virus we found that around 2/3 of peptide-MHC complexes (>120) are immunogenic, with around a third of these eliciting robust responses. The identification of these was substantially more efficient than has been possible by the use of algorithms or expression cloning approaches. Together these data demonstrate that there are many surprises waiting in viral immunopeptidomes and showcase the advances that can be made with current cutting edge methodologies.

1886

Endoplasmic reticulum aminopeptidases 1 and 2 are part of the peptide loading complex and trim peptides independent of MHC class I molecules

Urban, S., Schmidt, K., Ebstein, F., Kloetzel, P.-M.

Charite Universitätsmedizin Berlin, Institute of Biochemistry, Berlin, Germany

Generation of high-affinity peptide ligands, which are presented to T cells by major histocompatibility complex (MHC) class I molecules on the cell surface involves the sequential action of different proteolytic enzymes. In many cases, the proteasome system generates such peptide ligands as precursor molecules exhibiting the correct C-terminal anchor residue for MHC class I binding, while having an N-terminal extension. In order to increase the affinity and the amounts of antigenic peptides for optimized T cell recognition, these precursor peptides may be trimmed by endoplasmic reticulum aminopeptidases ERAP1 and ERAP2. Up to now, no experimental evidence has been reported to address the outstanding question of whether ERAP1 and ERAP2 interact with the peptide loading complex (PLC), and it is still unclear whether such trimming occurs with or without prior binding of precursor peptides to MHC class I proteins. Here, we observed that both ERAP1 and ERAP2 are intrinsic components of the PLC and furthermore demonstrate that epitope precursor peptides from human cytomegalovirus (HCMV) pp65 and melanoma antigen MART-1 are not trimmed when they are bound to MHC class I molecules.

University, Machida, Japan, ⁴Centre International de Recherche en Infectiologie, Lyon, France

MARCH I is an E3 ubiquitin ligase for MHC II that regulate intracellular degradation and transport. We previously

demonstrated differences of structural fluctuation of the MHC II/peptides that can be the basis of variable conformations that often referred as type A and type B. Here, we hypothesized that ubiquitination of MHC II relies on certain structures that formed with bound peptides. With X-ray single molecule analysis that can monitor the real-time motion of proteins, we found that the MSD curves of MHC II/peptide motions were correlated with the SDS sensitivity of the complexes. Pulse-chase experiment revealed that the half-life of type B complexes in BM-DC of wild type mice were much faster than those in BM-DC of MARCH I -/- mice. In contrast, the half-life of type A complexes in BM-DC of wild type mice were similar to those of MARCH I -/- mice. Furthermore, the abilities of T cell stimulation by type B complexes in both immature and mature BM-DC of wild type mice were much weaker than those in BM-DC of MARCH I -/- mice. In contrast, the abilities of T cell stimulation by type A complexes in both immature and mature BM-DC of wild type mice were similar to those of MARCH I -/- mice. Our results suggest that ubiquitination of MHC II/peptides complex occurs bound peptides dependent manner. MARCH I may distinguish conformational differences produced by the motion of MHC II/peptides complexes.

Stability, conformation and peptide binding of HLA-B*27:05 are all influenced by tapasin

Junghans, V.¹, Rasmussen, M.², Buus, S.², Bowness, P.³, Paulsson, K.¹

¹University of Lund, Experimental Medical Science, Immunology, Antigen Presentation, Lund, Sweden, ²University of Copenhagen, Experimental Immunology, Copenhagen, Denmark, ³Oxford University, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Ankylosing spondylitis (AS) is linked to polymorphism in the super family of HLA-B*27 molecules. Up to date the exact role and mechanism of how HLA-B*27 is involved in AS pathogenesis remain unknown. To improve our understanding of HLA-B*27:05 and in particular un-conventional conformations (suggested as a link to disease) of HLA-B*27:05 we used unique conformation specific antibodies against heterodimers (W6/32), free heavy chains (free HC) (HC10) and homodimers (HD6). HLA-B*27:05 were studied at the cell surface of tapasin-deficient and -proficient cells. Tapasin did not affect the cell surface amount of W6/32 reactive conformations of HLA-B*27:05. However, on the tapasin-deficient cells non-conventional conformations of HLA-B*27:05 were present to a higher extent. Interestingly, the stability of not only HD6-reactive conformations but also HC10 was increased. To elaborate on the role of tapasin and also peptides we used recombinant Tpn₁₋₈₇ added exogenously to cells as well as to recombinant HLA-B*27:05. On the cell surface Tpn₁₋₈₇ modulated levels of HD6 reactive epitopes. Moreover, Tpn₁₋₈₇ facilitated folding of HLA-B*27:05 complexes with seven-mers although HLA-B*27:05 formed the most complexes with peptides of 10-11 amino acids in length and stability analysis suggested longer peptides to form complexes of higher stability than those formed with 8-10 amino acid long peptides. In conclusion our data show that HLA-B*27:05 is influenced by tapasin both regarding peptide binding and conformations,

validated biomarker for diagnosing TB in HIV infected patients. Immunoregulatory enzyme, Indoleamine 2,3 dioxygenase (IDO) is capable of modulating cell mediated immunity. IDO catalyses the breakdown of tryptophan (Trp) metabolites collectively known as kynurenines (Kyn). Elevated IDO activity has been proposed as a prognostic biomarker for TB. We investigated whether IDO activity, as measured by Kyn-to-Trp ratio, using UPLC-MS/MS can act as a biomarker for diagnosing TB in HIV infected patients.

We determined IDO activity in the plasma of 32 HIV patients who developed TB during a longitudinal study and compared with 70 control subjects, age and CD4 cell count matched, in the same HIV infected cohort who did not develop TB.

IDO activity was significantly higher in TB cases than controls at the time of TB diagnosis ($P = 0.0001$). At 6 months prior to TB diagnosis, IDO activity was significantly higher in TB cases than controls ($P = 0.0001$). To evaluate diagnostic significance of IDO activity using a receiver operating characteristic curve, we selected 0.70 as the optimal cut-off. At time of TB diagnosis using confirmed TB as gold standard, IDO activity gave a diagnostic sensitivity of 100% and a specificity of 98.5% with Positive and Negative predictive values of 96.9% and 100% for detecting active TB cases.

Our results, demonstrate the plausibility of increased IDO activity as a biomarker of active TB in HIV positive patients.

HCV induces a strong increase of inflammatory monocytes, more than HIV itself

Schiavone, F.^{1,2}, Lichtner, M.³, Zuccalà, P.³, Mascia, C.³, Tieghi, T.³, Marocco, R.³, Savinelli, S.³, Vita, S.³, Mengoni, F.³, Vullo, V.³, Mastroianni, C.M.³

¹Sapienza University, Molecular Medicine Dep, Rome, Italy, ²Italian Institute of Technology, CLNS, Rome, Italy, ³Sapienza University, Public Health and Infectious Disease Dep, Rome, Italy

Fibrosis progression in HIV-HCV coinfecting patients (pts) is faster compared to HCV mono-infected pts.

Subpopulations of inflammatory monocytes Mo seemed to be implicated in both HCV and HIV infection and were linked to several age related-disease such as atherosclerosis.

In our single-centre study, we enrolled 56 patients (matched for sex, age and degree of liver fibrosis). We stratified them in four groups: 25 HCV pts, 20 HIV/HCV coinfecting pts (between them 10 pts with active HCV infection (AHI) and 10 with HCV viral clearance (VHC)), 17 HIV pts and 10 healthy donors (HD).

We evaluated mDC, pDC, S1anDC and typical, atypical and intermediate Mo by cytofluorimeter. Liver fibrosis was measured using Fibroscan and Fib-4 score. Kruskal-Wallis ANOVA with Dunn's test was used for statistical analysis.

ANOVA shows a statistically difference in all groups for intermediate Mo ($p=0,001$) and atypical Mo ($p=0,0411$). In particular pts with HCV infection presented an increase of intermediate Mo compared to AHI ($p=0,0001$), to VHC ($p=0,0009$) and to HIV+ ($p=0,0001$). Considering atypical Mo we found an increase in pts with HCV infection compared to HD ($p=0,0163$), to VHC ($p=0,0362$) and HIV+ ($p=0,0266$). However considering all the subpopulation of DCs, there were no differences.

Inflammatory Mo are higher in HCV infected pts and can be a constant source for myeloid cells in the liver, but also in other organs suggesting a role of these cells in the higher cardiovascular risk described in HCV infected subjects. A possible immune recovery will be presented in pts undergoing DAA therapy.

558

Pathogenesis of HIV persistence: B-cell immune tolerance specific for the conformational antigenic determinants (BIT-CAD) of native trimeric envelope glycoprotein subunits (TEGS)

Vyas, G.^{1,2}, Bozzini, R.², Aiyer, R.²

¹University of California (UCSF), Laboratory Medicine, San Francisco, United States, ²TheraBiol, Inc., San Francisco, United States

Acute HIV infection is marked by rapid destruction of CD4+ T-cells in the gut-associated lymphoid tissues (GALT). We hypothesize that the quaternary structure of membrane-bound trimeric gp41 interacting with gp120 expresses CAD, which are shared by diverse HIV subtypes; furthermore, since B-cells also express CD4, GALT-destroying HIV establishes BIT-CAD to enable persistent infection.

To test this hypothesis, we co-cultured plasma-derived founder-transmitted HIV-R5 (FTHIV) with human lymphocytes. Supernatant virions were concentrated, and inactivated with beta-cyclodextrin and benzonase. TEGS embodying HIV gp41 and gp120 in their native conformation and devoid of p24/polymerase/DNA/RNA were concentrated 100X for immunizing rabbits. TEGS elicited high titer (30-150,000) antibodies assayed by enzyme Immunoassay (EIA) using FTHIV. While FTHIV and TEGS of either R5 or X4 phenotypes, and a cloned gp41 protein blocked the EIA reactivity of limiting antiserum dilutions, monomeric cloned proteins (gp120, gp140, and gp160) did not. These results suggest that TEGS elicited CAD-specific antibodies not reactive with the linear epitopes (LE) of each of the cloned envelope proteins. Isolation of monoclonal anti-CAD from a phage library of the rabbit's splenocytes is pending.

These preliminary data support our hypothesis that BIT-CAD underlies the pathogenesis of persistent HIV infection, and are consistent with other reports that

- (1) HIV-infected sera have high titer antibodies against multiple LE on gp41/gp120;
- (2) clinical trials of HIVIG and IVIG showed no significant difference;
- (3) mAb derived from single B cells of infected patients do not neutralize their own HIV, and
- (4) the cytoplasmic tail of gp41 is key to protective immunity.

Analysis of monocyte subsets in HIV-1 infected individuals using or not antiretroviral therapy

Silva de Carvalho, A.É.¹, Morais, C.O.B.¹, Barletto, J.¹, Castro, F.O.F.², Ribeiro, C.B.², Tavares, C.², Silva, J.M.², Silva, L.C.S.², Fonseca, S.G.²

¹Pontifical Catholic University of Goiás, Biomedicine, Goiânia, Brazil, ²Universidade Federal de Goiás, Instituto de Patologia Tropical e Saúde Pública, Goiânia, Brazil

Introduction: Monocytes play important role in HIV-1 infection, since it acts as a reservoir and vehicle of spreading the virus in tissues. Based on the levels of CD14 and CD16 expression, monocytes may be divided into 3 subsets: classical (CD14^{high}CD16⁻), intermediate (CD14^{high}CD16⁺) and non-classical (CD14^{low}CD16⁺).

Objective: To evaluate the monocyte subsets in HIV-1 infected individuals in use or not of Antiretroviral Therapy (ART) and non-infected individuals.

Methods: We analyzed four study groups: individuals not infected with HIV-1 (n=11); HIV-1-infected individuals without the use of ART (n=8); HIV-1-infected individuals using two Reverse Transcriptase Inhibitors Nucleoside (T1) (n=6) and HIV-1-infected individuals using two Reverse Transcriptase Nucleoside Inhibitors associated with one Reverse Transcriptase not Nucleoside Inhibitor (T2) (n=10). Monocyte subsets from peripheral blood were determined by flow cytometry and the statistical analyzes performed with the GraphPad Prism 6 and non-parametric test were applied.

Results: The percentages of CD14^{high}CD16⁺ subsets were lower in T1 (p=0.003) and T2 (p=0.0011) groups compared to non-infected individuals. The percentages of CD14^{low}CD16⁺ subsets were reduced in T1 (p=0.01), T2 (p=0.0004) and in the patients who did not use ART (p=0.001) compared to non-infected individuals. CD14^{high}CD16⁻ subsets showed higher percentages in T1 (p=0.0006) and T2 (p< 0.0001) groups compared to non-infected individuals.

Conclusion: Monocytes are also important targets of ART, contributing to the control of HIV-1 infection, and the type of antiretroviral therapy may influence the expansion of monocyte subsets.

The uncharacteristic role of T memory stem cells in HIV-1 infection

Flynn, J.K.^{1,2,3}, Cashin, K.^{1,2}, Paukovics, G.², Jakobsen, M.R.⁴, Ostergaard, L.⁴, Churchill, M.J.^{2,5}, Gorry, P.R.^{1,2,5}

¹RMIT University, Melbourne, Australia, ²Burnet Institute, Melbourne, Australia, ³Monash University, Melbourne, Australia, ⁴Aarhus University, Aarhus, Denmark, ⁵University of Melbourne, Melbourne, Australia

The long-lifespan, robust proliferative potential and self-renewal capacity of T memory stem cells (TSCM) has generated much clinical interest. However these traits raise particular concerns for the preservation of the HIV-1 reservoir and viral persistence. Defining the susceptibility of CD4⁺ T-cell subsets to HIV-1 infection is important as treatments are currently being investigated to purge latent HIV-1 from CD4⁺ memory T-cell reservoirs.

We quantified the susceptibility of CD4⁺ T subsets cells, including TSCM, to infection by HIV-1 subtype C (C-HIV) strains from treatment-naïve subjects (MUSH cohort, Jakobsen et al 2013). These subjects progressed from chronic to advanced stages of disease whilst maintaining CCR5-using (R5) viruses or experiencing emergence of dominant CXCR4-using (X4) strains.

This is the first study to demonstrate TSCM were susceptible to infection by R5 and X4 C-HIV viruses (higher for R5 strains p< 0.05). Mutagenesis studies established the V3 region of the HIV-1 envelope as the determinant underlying the preferential targeting of naïve CD4⁺ T-cells by emergent X4 C-HIV variants in this study. In contrast, the tropism of R5 C-HIV viruses for memory CD4⁺ T-cell subsets was maintained during chronic disease progression.

This study provides new insights into the natural history of tropism alterations for CD4⁺ T-cell subsets by C-HIV strains. The maintenance of infection of key HIV-1 viral reservoirs, including central memory, transitional memory and TSCM cells, suggest that although not preferentially targeted by X4 viruses, TSCM and other memory T-cells are likely to be viral reservoirs in subjects with either R5 or X4 C-HIV infection.

VIH-1 induce a deregulation in B-cell populations through a regulatory B-cell-like phenotype *in vitro*

López-Abente, J.¹, Muñoz-Fernández, M.A.², Correa-Rocha, R.¹, Pion, M.¹

¹'Gregorio Marañón' Health Research Institute (IISGM), Laboratory of Immune-Regulation, Madrid, Spain, ²'Gregorio Marañón' Health Research Institute (IISGM), Laboratory of Molecular Immunobiology, Madrid, Spain

HIV-1 patients usually show general immune system deregulation and hyper-activation. At the humoral immunity level, HIV infection induces hyper-gammaglobulinemia and loss of memory B cells. In our group, we have previously reported that HIV-1 particles caused a direct marked effect on the activation, proliferation and phenotype of B cells.

In the present study, we considered the phenotype and functions of HIV-treated B-cell. B cells were extracted from buffy coat and treated with HIV-1 or different stimuli. Using quantitative PCR, we analyzed the expression of different cytokines in B-cell and, by flow cytometry; we analyzed the phenotype of these cells. Moreover, the function of B cells on CD4⁺ or CD8⁺ T cells were determined after co-culture experiments *in vitro*.

Surprisingly, B cells exposed to HIV showed a higher level of mRNA for IL-10, TGF-β, EB13 or IL-12(p35) *in vitro*. In addition, HIV-treated B cells exposed to lymphocytes were able to reduce the proliferative and the TNFα production capacities of CD4⁺ and CD8⁺ T cells, confirming the immunosuppressive profile of these B cells.

These results may explain the general deregulation of the immune system and the high concentration of IL-10 in plasma observed in HIV patients. These preliminary outcomes are highly promising as a means of understanding the hyper-activation of the immunity in HIV patients and further experiments *ex vivo* are needed to confirm these results.

562**Adipose tissue macrophage dynamics in SIV-infected and ART-treated rhesus macaques**

Fahlberg, M.¹, Walker, E.², Penney, T.², Kuroda, M.², Didier, E.³

¹Tulane University National Primate Research Center, Immunology/Microbiology, Covington, United States, ²Tulane University National Primate Research Center, Immunology, Covington, United States, ³Tulane University National Primate Research Center, Microbiology, Covington, United States

Aging-related diseases including cardiovascular disease, lymphoma, and type 2 diabetes occur at younger ages in HIV/HAART chronically-infected people than in the general population. Reasons for this 'accelerated aging' are unclear. Weight gain and lipodystrophy afflict HAART patients, and conversely, untreated HIV infection causes progressive weight loss, indicating that adipose tissue dysregulation may critically contribute to the increased rate of biological aging and pathogenesis of infection. We investigated mesenteric adipose tissue macrophage (ATM) dynamics after a previous study showed high monocyte turnover predicted progression to AIDS in rhesus macaques. We found that CD163+, CD163+CD206+, and CD206+ ATMs represent approximately 12% of total nucleated cells in adipose of uninfected rhesus macaques. We next examined the relative frequency of ATMs in SIVmac239 uninfected (n=4), infected (n=3), and infected + ART (n=4) macaques and found a reduction of CD163+ ATMs and an increase of CD163+206+ ATMs (37.7% ±21.4 and 56.8% ±9.3) in uninfected macaques compared to infected (69.6% ±13.6 and 25.8% ±12.8) and SIV/ART (68.1% ±12.7 and 25.0% ±8.3). We further differentiated ATMs by CD34, a surface marker found on adipose-derived mesenchymal stem cells, and observed novel expression of CD34 on CD163+ ATMs of uninfected macaques (43.3% ±13.0), and this proportion increased significantly after SIV infection (61.7% ±7.2). Furthermore, evidence of recent cell division (via BrdU uptake) was found in CD34+ ATMs at 24 hours post-injection and CD34- ATMs at 48 hours post-injection. Ongoing work is investigating the origins, infiltration, and proliferation of ATMs after infection and antiretroviral treatment.

563**Partial efficacy of broadly neutralizing antibody PGT121 against cell-associated simian-human immunodeficiency virus (SHIV) infection**

Parsons, M.¹, Lloyd, S.¹, Center, R.², Amarasena, T.¹, Swiderek, K.³, Kent, S.¹

¹University of Melbourne, Melbourne, Australia, ²Burnet Institute, Melbourne, Australia, ³Theraclone Sciences, Seattle, United States

Background: Prophylactic vaccines are required to alleviate HIV-1 spread. Broadly neutralizing antibodies (BnAbs), capable of neutralizing arrays of viral isolates, are promising prophylactics. Although BnAbs protect macaques from challenge with cell-free SHIV, their efficacy against cell-associated virus (CAV) remains unclear. While some in vitro studies have raised concerns about BnAbs being less potent against CAV, several BnAbs equally capable of neutralizing cell-free and CAV in vitro have been identified. Amongst these antibodies is PGT121, which

recognizes an epitope including the third variable loop of HIV-1 envelope and surrounding glycans. As HIV-1 preventatives will likely need to eliminate both cell-free virus and CAV, we assessed if passively transferred PGT121 protected macaques from cell-associated SHIV challenge.

Methods: Twelve macaques, six intravenously infused with PGT121 (1mg/kg) and six intravenously infused with isotype control (1mg/kg)/no antibody, were challenged intravenously, one hour following antibody infusion, with 24.5x10⁶ splenocytes from a SHIVSF162P3-infected animal. Animals were followed up for viremia onset.

Results: All six isotype control/no antibody animals developed viremia one week post-challenge. Three of six PGT121-infused animals were completely protected. Two PGT121-infused animals developed peak viremia two weeks post-challenge. Interestingly, these two animals exhibited low plasma PGT121 levels one week post-infusion. The remaining PGT121-infused animal exhibited a seven week delay prior to developing viremia.

Conclusions: These data provide evidence that BnAbs can protect against CAV. The partial nature of the observed protection relates to early suboptimal plasma concentrations of PGT121 and/or long-term persistence of cells harboring virus until waning of therapeutic antibody to suboptimal concentrations.

564**Impact of RNA export TREX-2 component GANP on nuclear transport in viral infection**

Shimoda, M.^{1,2,3}, Maeda, K.^{1,2}, Singh, S.K.², Sakaguchi, N.⁴, Akira, S.^{1,2}

¹Osaka University, Research Institute for Microbial Diseases, Department of Host Defense, Suita, Japan, ²Osaka University, WPI Immunology Frontier Research Center, Department of Host Defense, Suita, Japan, ³Kumamoto University, Department of Immunology, Kumamoto, Japan, ⁴Osaka University, WPI Immunology Frontier Research Center, Suita, Japan

HIV-1 disease is caused by infection with HIV-1 viruses. At the primary step, reverse-transcribed HIV-1 genome is inserted into the host genome by mediating the activity of viral integrase (IN) protein. To encounter the integration sites of host genome, the viral components must be passing through the nuclear pores on nuclear envelope (NE). Nuclear pores are among the largest complex, named as nuclear pore complexes (NPCs). HIV-1 IN forms the preintegration complexes (PICs) with host factors for nuclear import through the NPCs. Mammalian transcription/export-2 (TREX-2) complex is assembled with ribonucleoproteins and involved in RNA transport. We have reported that the TREX-2 component GANP is involved in targeting of AID/APOBEC3 cytidine deaminases in immune cells. Since GANP is localized with NPC at the NE, we examined whether GANP was involved in the maintenance of NE function during the HIV-1 infection. We found that HIV-1 infection dispersed GANP from NE to the cytoplasm and GANP physically interacts with IN through the PIC-independent mechanism during the entry of viral genome into the host chromatin. These results demonstrate that GANP is a unique factor and is interacting with the HIV-1 genome and IN, which might play an important role at the integration process in the viral infection.

HIV induces interferon stimulated genes in two phases in macrophages while inhibiting interferon induction

Nasr, N.¹, Alshehri, A.A.¹, Wright, T.K.¹, Shahid, M.¹, Heiner, B.M.¹, Harman, A.N.¹, Botting, R.A.¹, Helbig, K.², Kelleher, A.D.³, Suzuki, K.³, Beard, M.², Hertzog, P.⁴, Cunningham, A.L.¹

¹The Westmead Institute for Medical Research, University of Sydney, Centre for Virus Reserach, Westmead, Australia, ²School of Molecular and Biomedical Science, The University of Adelaide, Adelaide, Australia, ³The Kirby Institute, The University of New South Wales, NSW, Australia, ⁴Hudson Institute of Medical Research and Monash University, Clayton, Australia

We have previously shown that HIV induces a subset of Interferon (IFN) stimulated genes (ISG) in monocyte-derived macrophages (MDMs) and dendritic cells while inhibiting type I interferons. Here we show that the induction of the ISGs viperin, IFITs 1-3 occurs in two phases: the first phase is minor and transient occurring early after infection (2-24 hpi) while the second major phase is persistent and induced late (>48hpi). First phase ISG induction was due to the presence of shed extracellular vesicles (EV) in the HIV-1 inocula. Treatment of MDMs with HIV containing EVs induced ISG via IRF1 (as shown by gene knockdown). Similar levels of ISGs were induced upon treatment of MDMs with either isolated EVs or their contained key proteins, Hsp90α, β, or Nef. The second phase was dependent on newly transcribed viral mRNA as shown by knockdown of MAVS, Tat and by transcriptional gene silencing of HIV-1 with shRNA targeting the NF-κB binding site in the HIV-1 promoter. IRF1 and IRF7 bind to motifs in the promotor regions of the ISGs and here we show that their knockdown also significantly decreased second phase ISG induction. Individual knockdown of the IFITs 1, 2 and 3 reduced their antiviral activity against HIV consistent with their activity as a complex. Elucidating the mechanisms of ISG induction and their roles in HIV infection may contribute to immunotherapeutic strategies to limit the size of HIV reservoirs in macrophages.

Association of FcγRIIIb genotypic variants with markers of disease severity in HIV-1 infected women

Lassauniere, R.^{1,2}, Gray, G.E.³, Louise, K.⁴, Tiemessen, C.T.^{1,2}

¹National Institute for Communicable Diseases, Centre for HIV and STI's, Johannesburg, South Africa, ²University of the Witwatersrand, Faculty of Health Sciences, Johannesburg, South Africa, ³Perinatal HIV Research Unit, Chris Hani Baragwanath Hospital, Soweto, South Africa, ⁴Gertrude H. Sergievsky Centre, College of Physicians and Surgeons, and Department of Epidemiology, Mailman School of Public Health, Columbia University, New York, United States

Cellular receptors for the Fc portion of immunoglobulin G (IgG) - so called Fc gamma receptors (FcγR) - mediate several key immune effector functions that include antibody-dependent cellular cytotoxicity, phagocytosis, respiratory burst, and release of pro-inflammatory mediators. The magnitude of FcγR-mediated immune responses is affected by genotypic variants that alter the receptor's binding affinity for IgG (FcγRIIIa-H131R and FcγRIIIa-F158V), subcellular localization (FcγRIIIb-I232T),

post-translational modification (FcγRIIIb-HNA1a/b/c), and surface density (gene copy number variability). In a cross-sectional study, we indirectly assessed a role for FcγR-mediated effector functions in modulating HIV-1 disease severity using FcγR variants as a proxy for functional capability. We genotyped 282 HIV-1 infected, treatment-naïve South African Black women for all known functional FcγR variants and compared markers of HIV-1 disease severity - plasma viral load and CD4⁺ T cell count - across different genotypes. The FcγRIIIb-HNA1b|1b genotype (confers reduced neutrophil-mediated effector functions) significantly associated with lower viral loads compared to the HNA1a|1a and HNA1b|1c genotypes (P=0.038 and P=0.009, respectively) and higher CD4⁺ T cell counts compared to the HNA1a|1a genotype (P=0.017) and all heterozygous combinations (P< 0.05 for all comparisons). In addition, possession of more than two *FCGR3B* gene copies (confers enhanced neutrophil-mediated effector functions) associated with higher viral loads (P=0.015), while less than two *FCGR3B* gene copies associated with higher CD4⁺ T cell counts (P=0.042). In conclusion, this study describes a novel association for FcγRIIIb allotypes, and by inference a potential role for neutrophils, in modifying HIV-1 disease severity.

567

Effect of illicit drug use on inflammation and microbial translocation in HIV infection

Castro, F.O.F.¹, Ribeiro, C.B.¹, Tavares, C.¹, Silva, J.M.¹, Sousa, J.B.², Silva, L.C.S.¹, Pfrimer, I.A.H.², Guilarde, A.¹, Fonseca, S.G.¹

¹Universidade Federal de Goiás, Instituto de Patologia Tropical e Saúde Pública, Goiania, Brazil, ²Departamento de Biomedicina da Pontifícia Universidade Católica de Goiás, Goiania, Brazil

Introduction: The human immunodeficiency virus (HIV) infection causes a rupture in the intestinal mucosa leading to microbial translocation and hyperactivation of the immune system and progression to AIDS. The use of illicit drugs has been shown to alter the immune system function.

Objective: To evaluate the impact of drug use in inflammation and microbial translocation of HIV-infected individuals. The study population consisted of 43 HIV-1-infected individuals including: 18 marijuana-users, 6 cocaine-users and 9 marijuana+cocaine users; and 16 healthy-donors no drug users. All HIV-infected individuals were under antiretroviral therapy.

Methods: TNF-α, IL6, IL10 and soluble CD14 (sCD14) were measured in the plasma samples using Elisa Kit. C-reactive protein was measured in the serum using turbidimetry.

Results: TNF-α plasma levels were higher in HIV-marijuana/cocaine users (p=0,0137) and in HIV-cocaine users (p=0,0029) compared to HIV no-drug-users. IL-6 plasma levels were lower in HIV-marijuana users compared to HIV-no-drug-users (p=0.0087). In respect of IL-10 no differences were found between the groups. CRP levels were higher in HIV-marijuana/cocaine users compared to HIV no-drug-users (p< 0.05). sCD14 levels showed higher levels in HIV-no-drug-users than healthy donors (p< 0,0164), and comparing to HIV-no-drug-users the sCD14 levels were higher in HIV-marijuana users (p< 0,0128), HIV-cocaine users (p< 0,0494), HIV-cocaine/marijuana users (p< 0,0375).

Conclusion: The concomitant use of cocaine and marijuana accelerates the inflammatory responses, increasing the inflammatory cytokine production and microbial translocation in HIV infected individuals and it may lead to faster disease progression.

Role of complement in progression of HIV-associated neurological disorders (HAND)

Mahajan, S.D., Aalinkeel, R., Abou-Jaoude, E., Parikh, N.U., Reynolds, J.L., Jacob, A., Schwartz, S.A., Quigg, R.J., Alexander, J.J. State University of New York at Buffalo, Medicine, Buffalo, United States

Microglia are believed to be latently infected with HIV-1 and represent a CNS viral reservoir. Microglial activation and latent viral activation contributes to the development of HIV-associated neurological disorders (HAND). The complement system plays diverse roles in the pathogenesis of HIV-1 infection by playing a critical role in clearing HIV-1 and also promoting productive HIV-1 replication. We hypothesize that complement proteins may play a role in the activation of latent virus in the microglia and that complement activation enhances HIV-1 infectivity, contributing to the progression of HAND. We used untransfected (CHME-5) and HIV transfected (CHME-5/HIV) primary human microglial cell lines and evaluated the expression levels of several complement proteins/receptors such as C9, C5aR, C3aR, C5L2 by immunofluorescence and real time QPCR. Our results show significant increase in the expression levels of C9, C5aR and C5L2 in CHME-5/HIV cells as compared to the CHME-5 cells. Additionally, since, complement can be activated through HIV-1 envelope proteins, we treated CHME-5 with HIV-1 Tat (100ng), and observed significant transcriptional upregulation of C5aR (64%; $p < 0.01$), C5L2 (87%; $p < 0.001$) and NF κ B (55%; $p < 0.05$), as compared to the untreated control ($n=3$), indicating that Tat induced complement activation is accompanied by NF- κ B activation. A balance between complement activation and complement regulations may contribute to HIV-1 latency and persistence and the development of HAND, thus, therapeutic approaches targeting the complement system for the treatment of HAND need to be explored.

Isolation of resting CD4+ T cells from a model system of HIV-infected blood

de Jong, S., MacDonald, N., Morin, P., Kokaji, A., Thomas, T.E. STEMCELL Technologies Inc., Research and Development, Vancouver, Canada

Resting CD4⁺ T cells are of major interest in the study of human immunodeficiency virus type 1 (HIV-1) infection. Although infected cells are largely non-permissive for HIV-1 replication integration of the viral genome into the cell's DNA generates a latent reservoir of potentially infectious cells. Latently infected resting CD4⁺ T cells are rare, can escape the viral immune response and can persist for long periods of time

despite successful antiretroviral therapy. The latent reservoir is recognized as a major barrier to curing HIV-1 infection since given an appropriate stimulus or an interruption of therapy, latently infected cells can reactivate and produce infectious virions.

Currently, complex multi-step immunomagnetic isolations and or flow cytometry-based cell sorting is required to obtain pure resting CD4⁺ T cells. We have recently developed an EasySep™ immunomagnetic column-free method for fast and easy isolation of untouched resting CD4⁺ T cells from human PBMCs. Moreover, the procedure can be automated using RoboSep™, minimizing sample handling and eliminating cross-contamination.

Resting CD4⁺ T cells (defined as CD3⁺CD8⁻CD25⁻CD69⁻HLA-DR⁻) were isolated either from healthy donor PBMCs or from a model system of HIV infection in which in vitro activated CD4⁺ T cells had been spiked into healthy donor PBMCs. Starting with an average resting CD4⁺ T cell content of 21.5±8.6% in healthy donors and 13.5±5.9% in the model system, we obtained average purities of 97.1±1.9% ($n=23$) and 90.0±5.3% ($n=21$), respectively. The purified resting CD4⁺ T cells are suitable for immediate use in downstream assays.

570

Investigations on the extra-neural cholinergic system in HIV infection

Ahmad, A.¹, Aldbah, Z.¹, Samarani, S.¹, Allam, O.¹, Routy, J.-P.², Tremblay, C.³

¹CHU Saint Justine, Montreal, Canada, ²McGill University, Montreal, Canada, ³Montreal University, Montreal, Canada

The extra-neural cholinergic system (ENCS) is present in humans as well as in animals. The main effector molecule of the system, Acetylcholine (ACh), is an evolutionarily conserved neurotransmitter. It is also produced abundantly by non-neural cells. Both CD4⁺ T cells and gastro-intestinal tract epithelial cells constitute the main source of this molecule. ACh exerts its effects via Ach receptors (AChR) of nicotinic (n) and adrenergic (a) types, which are expressed abundantly in immune cells in the body. The ENCS modulates differentiation, proliferation and functioning of several types of immune cells. Presently, very little is known about the functioning of the ENCS in HIV infection. We show here for the first time an increase in the concentrations of ACh in the circulation of HIV-infected individuals, whereas anti-retroviral therapy (ART) tends to restore them to their physiological levels. We also found that the expression of the α -7nAChR tended to decrease on CD3⁺CD4⁺ T cells in the virus-infected individuals. Furthermore, the concentrations of SLURP-1 (Secreted Ly6/Urokinase type plasminogen activator Receptor-related Peptide-1), an allosteric ligand for the α -7nAChR, was also increased in the circulation of HIV-infected individuals, and ART also tended to normalize them. Furthermore, a synthetic α -7nAChR agonist decreased and a synthetic antagonist of the receptor increased replication of a T-tropic HIV strain in human IL-2 and PHA-activated blasts. Our results suggest that ACh mimetics and/or α -7nAChR agonists that do not cross blood brain barrier may be beneficial in attenuating aberrantly activated immune system in HIV-infected individuals.

571

NKG2D acts as a co-receptor for natural killer cell-mediated anti-HIV-1 antibody-dependent cellular cytotoxicityParsons, M.S.¹, Richard, J.², Lee, W.S.¹, Vandervan, H.¹, Grant, M.³, Finzi, A.², Kent, S.J.¹¹University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ²Centre de Recherche du CHUM, Université de Montréal, Department of Microbiology, Infectiology and Immunology, Montreal, Canada, ³Memorial University of Newfoundland, Division of BioMedical Sciences, St. John's, Canada

There is growing interest in utilising natural killer (NK) cell-mediated antibody-dependent cellular cytotoxicity (ADCC) to protect against HIV-1 acquisition or to eliminate infected cells following latency reversal. While the predominant NK cell receptor responsible for mediating ADCC is CD16 (FcγRIIIa), there are a plethora of other activating and inhibitory receptors that can influence NK cell responses upon encountering antibody-coated target cells. Indeed, it has been shown that ligation of certain activating receptors, including NKG2D, can synergise with CD16 ligation to enhance NK cell calcium flux. Since NKG2D expression levels on NK cells have been linked to HIV-1 disease progression and HIV-1 accessory proteins regulate the expression of NKG2D ligands on HIV-1-infected cells, we examined whether NKG2D signalling was involved in anti-HIV-1 ADCC. We utilised the LDH-release cytotoxicity assay and a flow cytometry-based infected cell elimination assay to assess ADCC against a CD4⁺ T cell line either pulsed with HIV-1 envelope glycoprotein (gp120) or infected with HIV-1. We demonstrate that antibody-mediated blockade of NKG2D on NK cells results in reduced antibody-dependent killing against gp120-pulsed target cells [median: 29.2% (Range: 9.7-55.3%)] as compared to conditions containing an isotype control, [39.7% (22.3-65.1%), $p=0.014$]. The blockade of NKG2D also results in diminished ADCC against cells infected with Nef- and Vpu-deficient HIV-1 [14.1% (9.3-19.8%)] as compared to conditions containing an isotype control [21.3% (20.9-27.1%)]. These observations are highly important for understanding antibody-dependent NK cell responses against HIV-1 and might be helpful in improving the efficacy of antibody-based vaccines and/or therapeutics.

Immunity to Bacteria & Fungi

Impact of *E. coli* Nissle 1917, *Lactobacillus amylovorus* and *Salmonella* Typhimurium on intestinal IL-8, IL-12/23 p40, TNF alpha, claudin-1 and occludin in gnotobiotic piglets

Splichalova, A., Splichal, I., Slavikova, V.

Institute of Microbiology of the Czech Academy of Sciences, v.v.i., Novy Hradek, Czech Republic

Objectives: A lower part of the gastrointestinal tract (GIT) harbors a majority of body microbiota. Protective effects of *E. coli* Nissle (EcN) and *Lactobacillus amylovorus* (LA) against infection with *Salmonella* Typhimurium (ST) in gnotobiotic piglets were evaluated.

Methods: Colostrum-deprived germ-free piglets (GF) were colonized with EcN or LA four hours after hysterectomy or bred as GF piglets. One week later they were infected with ST for 24 hours. Bacterial colonization of the intestine (CFU counting), secretion of IL-8, IL-12/23 p40 and TNF alpha (xMAP technology) and transcriptions of claudin-1 and occludin (RT-qPCR) and their protein expression (IF) were monitored.

Results: The infection with ST caused bacteremia, somnolence, anorexia, and diarrhea in the piglets and high levels of IL-8, IL-12/23 p40 and TNF alpha. Their levels in the piglets preliminary associated with EcN were almost completely suppressed but not in the case of preliminary associated with LA. The transcription of claudin-1 in GF, EcN and LA piglet groups in colon were comparable but in ST group highly increased. In contrast, the transcription of occludin was depressed in ST group.

Conclusions: The preliminary association of GF piglets with EcN suppressed symptoms of *Salmonella*-induced gastroenteritis and high levels of the inflammatory mediators but LA suppress them partially. Surprisingly the transcriptions of claudin-1 and occludin in *Salmonella*-infected piglets showed quite opposite trends.

Prevention of actinomycetoma by *Nocardia brasiliensis* in BALB/c mice

Vazquez Marmolejo, A.V., Lopez Ulloa, J.A., Longoria Lozano, O., Zavala Ramirez, J.M., Perez Rivera, L.I., Salinas Carmona, M.C. Universidad Autonoma de Nuevo Leon, Inmunologia, Monterrey, Mexico

Introduction: *Nocardia brasiliensis* is the main etiological agent of actinomycetoma in Mexico. Microabscesses and chronic granuloma are the hallmark of this disease. An animal model of actinomycetoma by *Nocardia brasiliensis* in BALB/c mice has proved helpful for understanding pathogenesis, but it is still not fully understood. IgM but no IgG antibodies protect against infection. Inhibition of nitric oxide synthase (iNOS) function by aminoguanidine hemisulfate (AG) inhibits the capacity of macrophages to eliminate bacteria in vivo and in

vitro, but sustained production of NO can augment the adverse on inflammation of the host.

Objective: To study the effect of pharmacological inhibition of iNOS on the onset and progression of *Nocardia brasiliensis* actinomycetoma.

Methodology: BALB/c mice received a 2% AG solution ad libitum one week before inoculation with either *Nocardia brasiliensis* (1 X106 CFU) or saline in the left footpad. BALB/c mice drinking pathogen-free water were used as controls. The mice were observed for 97 days after infection and sacrificed. Blood, spleen and kidney bacterial burdens were quantitated. Sera were assessed for anti-*Nocardia brasiliensis* IgG antibodies. We determined macrophage phagocytosis in vitro and NO levels were measured in plasma and cell culture supernatants.

Results: AG-treated mice did not develop actinomycetoma. No bacterial burden was found in AG-treated mice. Antibody titers were similar in all infected mice. Macrophages from AG-treated mice cleared less bacterial than those of controls after in vitro infection. NO production was significantly less in AG treated mice.

Conclusions: AG- treatment prevents actinomycetoma by *Nocardia brasiliensis* in BALB/c mice.

574

Pre-treatment of in vivo novel ligand molecule generated from a *Staphylococcus aureus* mutant bacterium protected host from MRSA infection

Lee, B., Lee, M.-J., Khan, A.

Pusan National University, College of Pharmacy, Busan, Korea, Republic of

Innate immunity is a first line defense reaction against bacterial infections and links to the activation of host adaptive immunity. To protect hosts from infection of pathogenic bacteria, hosts induce innate immune responses, such as cellular and humoral innate immunity. *Staphylococcus aureus* is a commensal bacterium that induces several diseases in clinic. But, healthy people are almost protected from methicillin-resistant *S. aureus* (MRSA) infection, suggesting that hosts' innate immune cells may produce an unidentified ligand molecule(s) that activates host innate immunity to protect host from bacterial infection. To identify a novel ligand molecule(s) derived from *S. aureus* cells, we screened 10 different *S. aureus* mutants to screen which mutant strain can activate host innate immunity. As results, one *S. aureus* mutant strain produced gamma delta T cell-mediated IL-17A at the early-staged infection, indicating that this mutant is capable of producing unidentified ligand molecule(s) *in vivo* conditions. To purify this molecule(s), large amounts of peritoneal fluids were collected after injection of acetone-treated *S. aureus* mutant bacteria into mice peritoneal cavity. After lyophilization of collected fluid, an active fraction was purified to homogeneity by performing of column chromatographies. When biological activities of the purified fractions were addressed and examined the protection effects from USA300 sMRSA strain infection, purified fraction induced neutrophil-mediated phagocytosis, a typical cellular innate response. Furthermore, pre-treatment of purified fraction protected host from MRSA-infection. These results suggest

that the host defense molecule(s) is invaluable molecule(s) that elicits host's innate immunity, leading to protect host from pathogenic microbe infection.

575

A novel proteomic approach for investigating the human antibody response during *Mycobacterium tuberculosis* infection

Hermann, C., Smith, M., Blackburn, J.M.

University of Cape Town, Institute for Infectious Diseases and Molecular Medicine, Department of Integrative Biomedical Sciences, Cape Town, South Africa

Tuberculosis (TB) remains one of the three major killers among the world's infectious diseases. Despite major advances in vaccine research and our understanding of the human immune system, the rules of immune protection against TB remain unclear. Recently, more emphasis has been placed on investigating the antibody response to *Mycobacterium tuberculosis* (M.tb) antigens during infection using mainly microarray technology. However, this technology comes at its own cost and limitations and might therefore be less available to researchers. Here, we report a novel approach for assessing antigens of serum antibodies from TB patients using state-of-the-art proteomics.

In a proof-of-concept study, the human antibody response to M.tb antigens was investigated in patients with active TB and healthy controls. M.tb antigens were isolated from bacterial lysates using purified serum antibodies from patients and healthy controls. The identities of isolated antigens were determined by tryptic digestion, measurement using a Q Exactive Orbitrap mass spectrometer and MaxQuant analysis. Unique antigens were detected in TB patients or healthy controls - TB patients showing more reactivity to Esx proteins and virulence factors. Furthermore, cross-reactivity was observed to M.tb antigens by antibodies in healthy controls. These findings reiterate observations made in recent microarray studies, but also add novel antigens detected in TB patients for the first time.

Thus, this approach might prove an important alternative to microarray technology in the investigation of the antibody response to M.tb infection. Furthermore, this technology might broaden available targets for vaccination and facilitate the future development of an effective TB vaccine.

576

Group A streptococcus induced less P65 nuclear translocation and non-classical NF- κ B activation in macrophage, which possibly leads to a weaker inflammatory response

Wu, S.¹, Ma, C.¹, Gao, X.¹, Zhang, L.¹, Miao, Q.¹, Li, W.¹, Song, X.¹, Wang, X.¹, Liu, J.², Wei, L.¹

¹School of Basic Medicine, Hebei Medical University, Department of Immunology, Shijiazhuang, China, ²Saint Louis University School of Medicine, Division of Infectious Diseases, Allergy and Immunology, Departments of Internal Medicine, Molecular Microbiology and Immunology, St. Louis, United States

Objectives: To explore the pathogenic mechanism of Group A streptococci (GAS) and How GAS evades phagocytosis of immune cells?

Methods: We detected the classical inflammatory signal pathway of macrophages infected with GAS by protein microarray, real-time PCR, Western blot, immunoprecipitation, and flow cytometry.

Results: GAS induced a lower level of inflammatory mediators in macrophages than either G+ *Staphylococcus aureus* (SA) or G- *Escherichia coli* (E.coli). Therefore, we checked the conventional inflammatory signal pathway, and found that GAS and SA induced both TLR2 and TLR4 expression, while G- E.coli solely activated TLR4 in RAW264.7 cells. Though MyD88, the main adaptor protein, was activated by the three pathogens, there was no difference in MyD88 expression in macrophages. NF- κ B is the classical transcription factor of inflammatory signals, and our results showed that GAS, similar to E.coli, induced a weaker p65 nuclear translocation compared to SA. Interestingly, GAS activated NF- κ B by inducing p65:p52 heterodimer but not the classical heterodimer of NF- κ B (p65:p50), while E.coli activated NF- κ B by inducing both p65:p50 and p65:p52 heterodimers.

Conclusions: Compared to SA and E.coli infection, GAS induced a weaker nuclear translocation and distinct combination of NF- κ B subunits in macrophages that probably lead to a weak inflammatory response.

577

The difference of biological activity of various soluble beta-glucans in cytokine induction

Yamanaka, D., Motoi, M., Ishibashi, K., Adachi, Y., Ohno, N.
Tokyo University of Pharmacy and Life Sciences, Laboratory for Immunopharmacology of Microbial Products, Tokyo, Japan

Beta-glucan is one of the main antigen synthesized by fungi. In the case of 1,3-beta-glucan, dectin-1 plays an important role in mammalian immune systems. On the other hand, several pathogenic fungi such as *Candida albicans* produce not only 1,3-beta-glucan but also long chain of 1,6-beta-glucan. The biological roles of 1,6-beta-glucan in immune systems have not been clarified yet. The aim of this work was to study the reactivity of leukocytes to 1,6-glycosidic chain rich beta-glucans. We first prepared soluble 1,6-/1,3-beta-glucan (AgCAS and ABG) from edible mushroom, *Agaricus brasiliensis*. Soluble fraction of Pustulan (Calbiochem) from *Lasallia pustulata* was also used as a standard for 1,6-beta-glucan. Splenocytes were isolated from C57BL/6 mice and then exposed to various soluble beta-glucans such as SPG (long 1,3-/1,6-beta-glucan), Laminarin (short 1,3-/1,6-beta-glucan), AgCAS and Pustulan in the presence or absence of exogenous GM-CSF. After incubation, the concentrations of IFN- γ were determined by ELISA. Although strong response to SPG and Laminarin was not observed, AgCAS and Pustulan could induce cytokine release in the presence of GM-CSF. We next examined that the influence of direct cell-cell contact or IL-12 on beta-glucan-induced cytokine synthesis. In spite of no change in TNF- α release, IFN- γ production by AgCAS and ABG was significantly suppressed by anti-MHC class II or anti-IL-12p40 antibodies. In conclusion, *Agaricus*-derived beta-glucans and Pustulan has a higher

potential than SPG and Laminarin on cytokine induction in mice and its biological activity was regulated, at least in part, by a IL-12 mediated-pathway and direct cell-cell interactions.

Improving anti-bacterial immune responses in patients with COPD by blocking inhibitory T-cell receptors

Tan, D.B.A.^{1,2}, Teo, T.-H.¹, Setiawan, A.M.¹, Kirkham, L.-A.³, Moodley, Y.^{1,4,5}
¹University of Western Australia, School of Medicine and Pharmacology, Perth, Australia, ²Institute of Respiratory Health, Perth, Australia, ³University of Western Australia, School of Pediatrics and Child Health, Perth, Australia, ⁴Institute of Respiratory Health, Stem Cell Unit, Perth, Australia, ⁵Fiona Stanley Hospital, Department of Respiratory Medicine, Perth, Australia

Chronic Obstructive Pulmonary Disease (COPD) is the most common respiratory cause of mortality and morbidity worldwide. Notably, acute exacerbations of COPD (AECOPD) accelerates the decline in lung function. AECOPD is usually associated with pulmonary infections but little is known about the mechanisms causing increased susceptibility in COPD. We hypothesize that chronic inflammation in AECOPD patients induces excess T-cell inhibitory molecules (e.g. CTLA-4) that then inhibit anti-bacterial immune responses in COPD patients. Peripheral blood mononuclear cells (PBMC) were isolated from AECOPD patients, stable COPD patients and healthy controls. Production of IFN γ by PBMC was measured by ELISA post-challenge with viable non-typeable *Haemophilus influenza* (NTHI) or anti-CD3. Bacterial killing was assessed by investigating bacterial viability counts. T-cell expression of CTLA-4 was measured by flow cytometry. Plasma levels of inflammatory biomarkers were measured by ELISA. AECOPD patients exhibited higher plasma levels of CRP and IL-6 than stable COPD patients ($p=0.07$ and $p=0.09$ respectively) and healthy controls ($p < 0.01$ for both). PBMC from AECOPD patients have lower production of IFN γ against NTHI compared to stable COPD patients and healthy controls, but increased expression of CTLA-4 on CD4+ T-cells ($p < 0.05$). Blocking of CTLA-4 increased anti-CD3 induced IFN γ by PBMC from COPD and AECOPD patients. However in response to NTHI challenge, IFN γ responses and bacterial killing were only improved in a subset of patients after CTLA-4 blocking. Increased expression of CTLA-4 could account for the increased frequencies of infections in COPD patients. Blocking multiple anti-inflammatory signals could improve anti-bacterial responses to prevent AECOPD.

579

Toll-like receptor 8 polymorphisms in *Helicobacter pylori* infection

Ferrand, J.¹, Hold, G.L.², Ferrero, R.L.¹, El-Omar, E.M.², Gantier, M.¹
¹Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia, ²University of Aberdeen, Division of Applied Medicine School of Medicine and Dentistry, Aberdeen, United Kingdom

Helicobacter pylori-driven chronic inflammation is strongly associated with gastric cancer. Polymorphisms in host

immune sensors have previously been associated with gastric cancer development in patients infected by *H. pylori*, with the example of the DNA sensor Toll-like receptor (TLR) 9. This study aimed to define whether polymorphisms in the RNA sensor TLR8 were also risk factors in *Helicobacter pylori*-driven chronic inflammation and gastric cancer development. Two TLR8 polymorphisms, rs3764879 and rs3764880, previously associated with disease protection against other pathogens, were analysed in a Scottish cohort of Caucasian patients: (i) with *H. pylori* infection, hypochlorhydria and gastric atrophy (n=64); (ii) with *H. pylori* infection but no precancerous lesions (n=46); and (iii) with no evidence of *H. pylori* infection or lesions (n=56). No significant differences were observed between infected patients with or without precancerous abnormalities. However, analyses of infected versus non-infected patients indicated that the A alleles of TLR8 rs3764880 and the C alleles of TLR8 rs3764879 could be associated with increased risk of infection. This hypothesis was refuted in a larger cohort of 253 infected and 187 control German Caucasian patients, where no association between TLR8 rs3764880 and *H. pylori* infection status reached significance.

Collectively these results indicate that the TLR8 gene is not a susceptibility factor in *H. pylori* infection or *H. pylori*-driven cancer development. Nonetheless, it remains a possibility that TLR8 polymorphisms regulate some aspect of the inflammatory response to *H. pylori* infection, which could not be assessed in the cohorts studied.

The cleaner fish lumpfish (*Cyclopterus lumpus* L.) - immunity, diseases and vaccination

Rønneseth, A.¹, Eggestøl, H.Ø.¹, Lunde, H.S.¹, Colquhoun, D.J.², Wergeland, H.I.¹, Haugland, G.T.¹

¹University of Bergen, Bergen, Norway, ²Norwegian Veterinary Institute, Oslo, Norway

Lumpfish (*Cyclopterus lumpus* L.) are now farmed and increasingly used as cleaner fish in the fight against salmon louse infestation in farmed Atlantic salmon. This biological treatment is done to overcome the increasingly extensive resistance to chemotherapeutics in salmon lice. To improve the health of the farmed lumpfish (10 mill produced in 2015 in Norway) and increase the overall efficiency of the cleaner fish strategy, vaccines against bacterial pathogens of lumpfish have been introduced, but require further development. Salmon vaccines, particularly against bacterial diseases are very successful and development of vaccines for lumpfish is based on a similar strategy. The elucidation of lumpfish immune responses and characterization of relevant bacterial pathogens are crucial for development of efficient vaccines. We have performed RNA sequencing to obtain a global transcriptional profile of the immunological responses of lumpfish upon bacterial challenge. This is the first presentation of transcriptomic data from lumpfish. We will present an updated overview of lumpfish pathogens, diseases and adaptive immune responses upon bacterial challenge and vaccination.

581

Salmonella Typhimurium *rfaG* mutant shows reduced transcription of Toll-like receptor 4 in intestine of gnotobiotic piglets

Splichal, I., Splichalova, A., Slavikova, V.

Institute of Microbiology of the Czech Academy of Sciences, v.v.i., Novy Hradek, Czech Republic

Objectives: A lipopolysaccharide (LPS) is a virulence factor of Gram-negative bacteria. Shortening of its chain modifies type of LPS and decreases bacterial virulence. *Salmonella* Typhimurium (ST) is enteric pathogen that causes self-limiting gastroenteritis in the human and the pig.

Methods: One-week-old hysterectomy-derived germ-free piglets (GF) were infected with *S. Typhimurium* (ST) or its isogenic *rfaG* mutant for 24 hours. *Salmonella* CFU counting, TLR4, MyD88 and TRIF transcriptions in the ileum were evaluated by RT-qPCR, IL-8, TNF-alpha and HMGB1 proteins by ELISA.

Results: ST and its *rfaG* mutant comparably colonized the ileum of the gnotobiotic piglets. While TLR4 transcription was increased in ST group, the transcriptions in *rfaG* group were similar with GF piglets. MyD88 was decreased but TRIF increased in ST group while *rfaG* group was comparable with GF piglets. IL-8, TNF-alpha and HMGB1 were induced in ST piglets only.

Conclusions: TLR4 is the receptor for LPS. While ST induced high levels of IL-8, TNF-alpha and HMGB1 in ileum that may be harmful, the rough LPS mutant did not induce them at all. Future incorporation of other molecules related to LPS and TLR4 as MD-2, CD-14 and LBP would contribute to clarify relations of LPS type and TLR4-signaling.

A role for CD1a in mycobacterial immunity was discovered through its ability to present didehydroxymycobactins, a family of peptidolipids that were isolated from *Mycobacterium tuberculosis*, to CD1a-restricted T cells. The most potent didehydroxymycobactin for T cell stimulation is DDM-838, which is characterized by the presence of a (Z)-C20:1 fatty acyl chain. Using DDM-838 bound to CD1a tetramers, polyclonal T cell responses were detected *ex vivo* in tuberculosis patients, but the natural functions of these newly discovered, lipid-specific T cells remain unknown. Because DDM-838 cannot be acquired in sufficient quantities from natural sources, an efficient route for the synthesis of large quantities of DDM-838 is needed. We report a solution-phase synthesis of DDM-838, along with the synthesis of a series of analogues with unnatural stereochemistry of the lipopeptide backbone and the lipid portion. DDM-838 structure-activity relationships were studied by loading CD1a tetramers with the synthetic lipopeptides and measuring binding of CD1a-restricted T cell lines, as well as the ability of analogues to activate T cells. The natural form of DDM-838 was the most active species but various analogues also exhibited activity with certain T cell lines, indicating a spectrum of TCR recognition of these CD1a-presented lipid antigens. Our synthetic approach to DDM-838 will support structural and functional studies to understand how these antigens are recognized by the human immune system and permit large scale human clinical studies.

Invasive aspergillosis (IA) is a severe invasive mold infection affecting immunocompromised patients. Despite the use of antimicrobial drugs, IA remains a major cause of mortality and morbidity, partly due to the inability of the host immune system to respond appropriately to *Aspergillus*. One of the established risk factors for IA is neutropenia which is encountered by patients undergoing chemotherapy and stem cell transplantation. Here we investigate the role of neutrophils in modulating the host immunity to *Aspergillus*.

The co-incubation of PMN and PBMC with heat-inactivated (HI) *Aspergillus* markedly diminished IL1 β , IL6 and TNF α production. Using a transwell system to effect of separation between HI *Aspergillus*-stimulated PBMC and PMN, we observed the suppression of IL1 β production. Blocking CR3 with anti-CD11b, reversed the attenuation effect of IL1 β . On the other hand, TNF α production was not contact-dependent and might be influenced by neutrophil-secreted product instead. The addition

of myeloperoxidase (MPO) did suppress TNF α production, suggesting that the attenuative effect of TNF α is dependent on MPO, a neutrophil degranulatory product.

Our study suggests that neutrophils have an extended modulatory role besides its primary phagocytic function by dampening proinflammatory cytokine production by PBMC in response to *Aspergillus*. The absence of neutrophils and its inhibitory effect, may explain the elevated proinflammatory production seen in neutropenia. Our investigation has added a novel dimension to our current understanding on the pathogenesis of IA.

Memory CD4 and CD8 T cells are dispensable for BCG-vaccine mediated protection

Steigler, P., Kirman, J.

University of Otago, Microbiology and Immunology, Dunedin, New Zealand

Despite nearly a century of widespread use, the only available tuberculosis (TB) vaccine, bacille Calmette-Guerin (BCG), has had little success lowering the global TB burden. Due to the urgent need for a more effective TB vaccine, newly developed TB vaccines are entering clinical trials without a solid understanding of the mechanism of protective memory immunity against TB. The current paradigm, that memory CD4 T cells provide resistance against TB, is based on adoptive transfer studies performed in immunodeficient mice that may be flawed due to T cell activation following adoptive transfer. Therefore, the protective ability of naturally arising memory CD4 T cells to protect against secondary TB infection remains to be shown. To determine the protective role of memory CD4 and CD8 T cells against mycobacterial infection, we developed a novel murine model of systemic memory T cell depletion. To measure the efficacy of BCG in the absence of T cells, BCG vaccinated mice were depleted of memory CD4 or CD8 T cells or both subsets, then intranasally challenged with mycobacteria and lung bacterial burden measured. Irrespective of whether memory T cells were present or not, all groups of BCG vaccinated mice were significantly protected against mycobacterial challenge compared to unvaccinated mice. Importantly, mice depleted of memory T cells of mice had similar lung bacterial burdens to non-depleted BCG vaccinated mice. These findings suggest that BCG mediated immunity can be mediated by cells other than memory CD4 or CD8 T cells and have major implications for TB vaccine design.

Periodontopathic bacteria increases the risk of rheumatoid arthritis by affecting gut immune system

Sato, K.¹, Takahashi, N.², Nakajima, M.¹, Matsuda, Y.¹, Yamada, M.¹, Yokoji, M.¹, Kato, T.³, Ohno, H.³, Yamazaki, K.¹

¹Niigata University Graduate School of Medical and Dental Sciences, Division of Oral Science for Health Promotion, Niigata, Japan, ²Niigata University Graduate School of Medical and Dental Sciences, Division of Periodontology, Niigata, Japan, ³RCAI RIKEN Center for Integrative Medical Science, Laboratory for Intestinal Ecosystem, Yokohama, Japan

Periodontitis has been implicated as a risk factor for various diseases including rheumatoid arthritis (RA). *Porphyromonas gingivalis*, a representative periodontopathic bacterium, has drawn much attention because of expressing a bacterial peptidyl arginine deiminase which generates citrullinated proteins, major antigens in RA. However, clinical studies demonstrated inconsistent results and therefore, underlying mechanisms linking periodontal disease and RA remain elusive. We have demonstrated that *P. gingivalis* oral administration induced change of gut microbiota, reduced gene expression of tight junction protein in the ileum, and endotoxemia. Given that the change of gut microflora is associated with RA, we hypothesized that the association between periodontal disease and RA could be mediated by the modulation of gut microflora. DBA1/J mice were orally infected with *P. gingivalis* W83 were administered with collagen type II to induce arthritis. Arthritis development was evaluated by visual scoring of paw swelling and micro-CT analysis. IL-17 production of lymphocytes separated from spleen, mesenchymal lymph nodes, and inguinal lymph nodes were analyzed by flow cytometry and ELISA. Serum levels of IL-17 were measured by ELISA. *P. gingivalis* infection increased the incidence and severity of collagen-induced arthritis. IL-17 levels of serum and culture supernatants of lymphocytes from secondary lymphoid tissues were significantly higher in *P. gingivalis*-administered mice. *P. gingivalis* infection induced elevated IL-17 gene expression and decreased tjp-1 expression in the intestine. These results may provide novel mechanisms for the link between periodontitis and RA where periodontopathic bacteria affect gut immune system by modulating gut microbiota composition.

Poly-functional CD4⁺ T cells specific to PE/PPE antigens are protective against pulmonary *Mycobacterium tuberculosis* infection

Sayes, F.¹, Bottai, D.², Brosch, R.¹, Majlessi, L.¹

¹Institut Pasteur, Genome and Genetics, Paris, France, ²University of Pisa, Ricerca Traslationale e delle Nuove Tecnologie in Medicina e Chirurgia, Pisa, Italy

Mycobacterium tuberculosis (*Mtb*), possesses at least three type VII secretion systems, ESX-1, -3 and -5 that are actively involved in pathogenesis and host-pathogen interaction. We recently showed that an attenuated *Mtb* vaccine candidate (*Mtb* Δ*ppe25-pe19*), which lacks the characteristic ESX-5-associated *pe/ppe* genes, but harbors all other components of the ESX-5 system, induces strong epitope-mediated cross-reactive CD4⁺ T-cell immunogenicity against non-ESX-5-associated PE/PPE protein homologs. These proteins are named after their characteristic N-terminal Pro-Glu (PE) or Pro-Pro-Glu (PPE) motifs and are unique to mycobacterial species.

Here, we have dissected the different components of this specific immune response and demonstrate the marked poly-functionality of the cross-reactive Th1 effector subsets specific to these shared PE/PPE epitopes in mice immunized with the *Mtb* Δ*ppe25-pe19* vaccine candidate. We provide evidence that the *Mtb* Δ*ppe25-pe19* strain, despite its significant attenuation, is comparable to WT *Mtb* with regard to: (i) its antigenic repertoire

related to the different ESX systems, (ii) the induced Th1 effector subset composition, and (iii) its particular features at stimulating the innate immune response. Indeed, significant contribution of PE/PPE-specific bi- and poly-functional Th1 effector cells in the protective immunity against pulmonary *Mtb* infection was found.

These results offer detailed insights into the immune mechanisms underlying the remarkable protective efficacy of the live attenuated *Mtb* Δ*ppe25-pe19* vaccine candidate, as well as the specific potential of PE/PPE proteins as protective immunogens.

Otitis-prone children produce functional antibodies to pneumolysin and pneumococcal polysaccharides

Kirkham, L.-A.^{1,2}, Wiertsema, S.^{1,3}, Corscadden, K.², Mateus, T.¹, Mullaney, G.¹, Zhang, G.⁴, Richmond, P.^{1,2,5}, Thornton, R.^{1,2}

¹University of Western Australia, School of Paediatrics and Child Health, Perth, Australia, ²Telethon Kids Institute, Perth, Australia, ³Currently at Nutricia Research, Utrecht, Netherlands, ⁴Curtin University, School of Public Health, Perth, Australia, ⁵Princess Margaret Hospital for Children, Perth, Australia

Background: The pneumococcus is an important cause of otitis media (OM) but data are conflicting on whether otitis-prone children have impaired humoral immunity to pneumococcal antigens. We found similar anti-capsular and anti-protein antibody titres in healthy and otitis-prone children, however functional antibody levels are considered to better correlate with protection. We aimed to determine whether the anti-pneumococcal antibodies produced by otitis-prone children are functional by measuring anti-pneumolysin antibody neutralising titres and polysaccharide-specific opsonising titres. Antibody potency was compared between otitis-prone and healthy children.

Methods: The pneumolysin neutralising assay was conducted on cholesterol-depleted complement-inactivated sera from 165 otitis-prone children (cases) and 61 healthy age-matched controls. The multiplexed opsonophagocytosis assay was conducted on sera from 20 cases and 20 controls. Neutralising and opsonising titres were calculated with antigen-specific IgG titres to determine antibody potency for pneumolysin, vaccine polysaccharides (4, 6B, 14, and 23F) and non-vaccine polysaccharides (1, 5, 7F and 19A).

Results: There were no significant differences in functional antibody titres nor potency between cases and controls for the antigens tested. Anti-pneumolysin neutralising titres increased with number of episodes of OM but antibody potency did not. Pneumolysin antibody potency was lower in children colonised with pneumococci compared with non-carriers, and this was significant in the otitis-prone group ($p < 0.05$).

Conclusions: Production of functional anti-pneumococcal antibodies in otitis-prone children demonstrates that they respond to current conjugate vaccines and are likely to respond to pneumolysin-based vaccines as effectively as healthy children. Whether these functional circulating antibodies confer protection against pneumococcal OM requires further investigation.

The transcription factor Ets1 cooperates with IL17 signaling to regulate antibacterial skin immune responses

Sunshine, A., Luo, W., Sinha, S., Garrett-Sinha, L.A.
State University of New York at Buffalo, Biochemistry, Buffalo,
United States

The transcription factor Ets1 regulates differentiation of lymphocytes and its loss leads to autoimmune disease. To identify roles for the cytokine IL17 in the autoimmune phenotype of mice lacking Ets1, we crossed Ets1^{-/-} mice to mice deficient in IL17RA that lack IL17 signaling. We unexpectedly found that Ets1/ IL17RA double knockout (DKO) mice do not show amelioration of autoimmune symptoms, but rather exhibit enhanced autoimmunity as evidenced by increased plasma cells and autoantibodies. In addition, DKO mice have strikingly elevated levels of serum IgG1 and IgE, suggesting a Th2 bias. By 4-6 months of age, DKO mice spontaneously develop severe inflammatory skin lesions colonized by *S. aureus* - a phenotype absent from single knockout mice. To determine if DKO mice are more susceptible to bacterial infection, we introduced a virulent, bioluminescent strain of *S. aureus* into surgical cuts on the skin of DKO mice before overt skin lesions develop. We monitored bacterial burden over time showing that DKO mice fail to clear the infections, which instead spread to distal areas. To address the mechanistic basis for this concerted role of IL-17RA and Ets1, we are currently examining several aspects of skin immunity including the innate effector functions of keratinocytes as well as the differentiation program of both conventional and gd T cells. We are also testing the potential role of autoantibodies in damaging the skin barrier function. The outcome of our studies will likely have important implications of understanding human skin inflammatory and infectious diseases.

589

Differential response of dendritic cells upon co-infection with different *Aggregatibacter actinomycetemcomitans* serotypes

Rojas, L., Alvarez, C., Melgar-Rodriguez, S., Pujol, M., Monasterio, G., Garcia, K., Diaz-Zuñiga, J., Fariña, V., Hernandez, M., Vernal, R.
Universidad de Chile, Periodontal Biology Laboratory, Santiago,
Chile

Aim: *Aggregatibacter actinomycetemcomitans* is a periodontopathogenic bacteria involved in periodontitis. Based on the variable immunogenicity of the LPS-O-polysaccharide of *A. actinomycetemcomitans*, six different serotypes have been described. The serotype b induces higher levels of pro-inflammatory cytokines in stimulated human dendritic cells (DCs) compared with the other serotypes. Recently, it was reported that some periodontitis patients can harbour two or three different *A. actinomycetemcomitans* serotypes in their periodontal lesions; thus, it has been proposed variations of the immune response during these co-infections. This study aimed to analyze the response of DCs when co-infected with different combinations of the most prevalent *A. actinomycetemcomitans* serotypes (a-c).

Methods: PBMCs were differentiated into DCs and then stimulated with the *A. actinomycetemcomitans* serotypes a, b, or c and the combinations a+b, a+c, b+c, or a+b+c. The cytokines IL-1 β , IL-5, IL-6, IL-10, IL-12, IL-23, IFN- γ , and TNF- α and the chemokines and chemokine receptors CCL2, CCL5, CCL11, CCL17, CCR2, CCR3, CCR4, CCR5 were quantified by qRT-PCR. In addition, total MMP-2 was analyzed by ELISA, active MMP-9 was analyzed by fluorescence assay, and gelatinolytic activity of these MMPs was analyzed by gelatin-zymography. Finally, bone resorption activity was quantified by in-vitro bone resorption pits-assay.

Results: When DCs were stimulated with the different combinations of *A. actinomycetemcomitans* serotypes, significantly lower levels of cytokines, chemokines, chemokine receptors, MMPs, and bone resorption activity were detected compared with the same cells stimulated with serotype b.

Conclusions: On DCs, distinct *A. actinomycetemcomitans* serotype co-infections can modulate the immuno-stimulatory potential of serotype b.

Immune response to *Mycobacterium leprae*: potential application for leprosy diagnosis

Fraga, L.¹, Marçal, P.^{2,3}, Zandim, P.³, Oliveira, L.⁴, Ottenhoff, T.⁵, Geluk, A.⁵, Teixeira, H.²

¹Universidade Federal de Juiz de Fora - Campus Governador Valadares, Basic Department of Health, Governador Valadares, Brazil, ²Universidade Federal de Juiz de Fora, Biological Sciences, Juiz de Fora, Brazil, ³Universidade Vale do Rio Doce, Ciências da Saúde, Governador Valadares, Brazil, ⁴Universidade Federal de Juiz de Fora - Campus, Basic Department of Health - Programa Multicêntrico de Bq e BM, Governador Valadares, Brazil, ⁵Leiden University Medical Center, Leiden, Netherlands

The clinical form of leprosy is characterized by dermatoneurological spectrum changes with different immune response patterns. The diagnosis of leprosy has been based on dermatoneurological examination, smear microscopy and histopathology. The development of specific and sensitive serologic test is very important for early diagnosis, preventing the disease transmission and the sequelae onset. The purpose of this study was to evaluate the serum samples from leprosy patients, subjects in contact with clinical leprosy and healthy subjects for reactivity against four specific recombinant proteins of *M. leprae* (ML0405, ML2055, ML2331 and Ag85B) using ELISA. The results showed that the group of multibacillary patients had higher IgG production compared to the healthy control and paucibacillary groups for all tested antigens. The group of subjects in contact with multibacillary leprosy showed higher production of specific IgG to the ML2055 and ML0405 antigens compared to the healthy control group (CS). IgM levels to both ML2055 and Ag85B antigens were higher in the MB contact group compared to the CS group. The IgM levels of the multibacillary group were higher than the levels of the CS group only for the ML2331 antigen. Levels of specific antibodies against the ML0405 antigen decreased after the implementation of multidrug therapy. Our results suggest that

a serologic test using the ML0405, ML2331, ML2055 and Ag85B antigens could be developed as an additional test for the early diagnosis of leprosy. The control of specific antibody levels for ML0405 could be used as an effective marker for monitoring the treatment progress. FAPEMIG, CNPq, FNS/MS.

Characterization of secreted molecules from lactobacilli with systemic immune-modulatory activity

Mata Forsberg, M., Björkander, S., Johansson, M.A., Sverremark-Ekström, E.

Stockholm University, Department of Molecular Biosciences, Wenner-Gren Institute, Stockholm, Sweden

Lactobacilli are commensal lactic acid-producing bacteria with the capacity to influence and modulate mucosal and systemic immunity *in vitro* and *in vivo*. Early-life colonization with lactobacilli is associated with decreased risk of allergy development and supplementation of certain lactobacilli spp are known to ameliorate gut inflammatory diseases and improve epithelial barrier function. However, the direct mechanism of these bacteria on systemic immune responses remains elusive. Human PBMC were stimulated with *S. aureus* cell free supernatant (CFS) in the presence or absence of lactobacilli-CFS. Pro- and anti-inflammatory cytokine responses were evaluated using ELISA and flow cytometry. Classical bio-molecular/chemical techniques were employed to characterize and identify the bioactive molecules present in the lactobacilli-CFS.

We show that CFS of multiple lactobacilli spp dampen *S. aureus*-induced IFN- γ and IL-17A secretion. Size fractionation suggests that molecules of different size differentially dampen these cytokines. Heat-inactivation of the CFS prevented dampening of IL-17A but not of IFN- γ . Even though lactobacilli-CFS potently induced IL-10-production in PBMC, blocking of IL-10 did not prevent lactobacilli-mediated dampening. Addition of lactic acid to *S. aureus*-stimulated PBMC cultures selectively reduced the frequency of IFN- γ + unconventional T-cells and NK-cells in a dose dependent manner.

We conclude that lactobacilli-CFS induce and modulate both pro- and anti-inflammatory cytokine-responses in PBMC. Lactobacilli mediate dampening of IFN- γ by an IL-10-independent mechanism through the release of multiple molecules. Finally, lactic acid production may have a contributing role in the dampening of pro-inflammatory cytokine responses.

592

Complement-opsonization of *A. fumigatus* modifies dendritic cell function

Steger, M.¹, Posch, W.¹, Lass-Flörl, C.¹, Haas, H.², Wilflingseder, D.¹

¹Medical University of Innsbruck, Division of Hygiene and Medical Microbiology, Innsbruck, Austria, ²Medical University of Innsbruck, Division of Molecular Biology, Innsbruck, Austria

Background: In this study, interactions of dendritic cells (DCs) with complement-opsonized and non-opsonized *Aspergillus fumigatus* strains and various mutants thereof were investigated. The opsonization pattern of the different strains

and mutants, the binding and internalization by dendritic cells as well as the cytokine secretion and initial signaling pathways were investigated.

Methods: Fungi were opsonized using normal human serum as complement source. The opsonization pattern, binding of conidia to DCs and internalization were characterized by FACS analyses. Inhibition of fungal growth in presence of DCs and interactions with complement receptors were detected using confocal microscopy. Furthermore, phosphorylation of ERK1/2 and p38 were detected by immunoblot analysis.

Results: We could demonstrate in this study that melanin and β -1,3-glucan have high impact on the fungal virulence compared to the wildtype *Aspergillus* strains. With respect to dendritic cell binding and internalization complement-opsonization of conidia enhanced these processes compared to their non-opsonized counterparts independent on the fungal strain used.

Conclusion: These data revealed, that melanin and β -1,3-glucan are key effectors of masking complement deposition and binding of conidia by DCs. However opsonization of swollen conidia enhanced internalization in DCs as well as production of pro-inflammatory cytokines, thereby resulting in a favorable TH1 immune response. These *in vitro* studies propose that the use of immune cells, like DCs or neutrophils, in combination with complement opsonins might act as potent vaccines against invasive aspergillosis.

593

Elevated neutrophil TLR activation during acute severe leptospirosis

Lindow, J.^{1,2}, Montgomery, R.¹, Reis, E.², Tsay, A.¹, Wunder, E.^{1,2}, Araújo, G.², Nery, N.², Mohanty, S.¹, Shaw, A.¹, Reis, M.², Ko, A.^{1,2}

¹Yale University School of Medicine, New Haven, United States, ²Fiocruz, Salvador, Brazil

The role of the innate immune response in the pathogenesis of leptospirosis and progression to organ failure is poorly defined. To determine whether increased neutrophil function associated with renal and/or lung dysfunction, we used flow cytometry to quantitate the expression levels of neutrophil pathogen recognition receptors and activation markers in a cohort of leptospirosis patients with different disease outcomes. We found elevated levels of TLR2 on neutrophils from acute leptospirosis patients, with significantly higher levels in patients with organ dysfunction ($9.1 \pm 2.8\%$ v. $3.0 \pm 0.8\%$, $p=0.04$). However, we observed no significant differences in baseline activation of neutrophils in any patient group, though neutrophils from patients with organ dysfunction had higher activation responses to TLR4 stimulation. These results suggest excess inflammation from neutrophils may contribute to the organ pathogenesis observed in leptospirosis, and may represent a novel avenue for therapeutics in human leptospirosis.

594

HIF-1 α stabilization through metabolic hypoxia via glutaminolysis in a murine model of pulmonary tuberculosis

Torres Rojas, M.¹, Abarca Rojano, E.², Huerta Yopez, S.¹, Hernández Pando, R.³, Rangel Santiago, J.¹, Mayoral Márquez, H.⁴, Domínguez López, M.L.⁵

²Instituto Politécnico Nacional, Laboratorio de Respiración Celular, Escuela Superior de Medicina, México, Mexico, ³Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Departamento de Patología Experimental, México, Mexico, ⁴Instituto Politécnico Nacional, de Respiración Celular, Escuela Superior de Medicina, México, Mexico, ⁵Instituto Politécnico Nacional, Laboratorio de Inmunoquímica I, Escuela Nacional de Ciencias Biológicas, México, Mexico

Tuberculosis is a chronic infection in which Mycobacterium tuberculosis triggers not only a complex immune response but also others modifications including metabolism of the host and the guest. For the study of these events many animal models had been developed. The murine model of pulmonary tuberculosis of Hernandez-Pando et al., which comprises 120 days after infection, is characterized by two immunopathogenic phases: the TH1 immune response which is protective or antibacterial with a climax on 21th day of infection and the TH2 immune response initiating the progressive phase of the disease on the 28th day of infection presenting pneumonia, large bacillary load and high mortality rates. Using immunohistochemistry essays we found out that HIF-1 α , an inflammatory transcription factor, is progressively higher through the advance of the infection days in the murine model, pattern that is also observed in the expression of glutaminolysis enzymes (glutaminase 1 and glutamate dehydrogenase) and in the expression of GPR91, a succinate receptor. According to these results we conclude that glutaminolysis might be functioning as an anaplerotic way of producing succinate, which in turn blocks the activity of the prolyl hydroxylase enzymes promoting the stabilization of HIF-1 α , finally leading to inflammation and a chronic or even a fatal progression of the infection.

Group A streptococcus-induced macrophage death is through glycogen synthase kinase-3 beta activation and mitochondrial damage

Tsao, N.¹, Lin, W.-C.¹, Shen, Y.-C.¹, Kuo, C.-F.²

¹I-SHOU University, Department of Biological Science and Technology, Kaohsiung, Taiwan, Republic of China, ²I-SHOU University, Department of Nursing, Kaohsiung, Taiwan, Republic of China

Group A streptococcus (GAS) causes pharyngitis, scarlet fever, impetigo, necrotizing fasciitis, and streptococcal toxic shock syndrome in humans. In our previous study, we find that streptococcal pyrogenic exotoxin B (SPE B) and streptolysin S (SLS) both contributed to GAS evasion from the immune cell killing and mediated the GAS-infected macrophage

death. In this study, we explored the mechanisms involved in macrophage defense and GAS-induced cell death. The wild-type GAS-infected Raw 264.7 cells, but not in SLS or SPE B mutant-infected cells, manifested the increased levels of intracellular reactive oxygen species (ROS) and the decrease of mitochondrial membrane potential ($\Delta\psi_m$). Surveys of mitochondrial ROS production using MitoSOX indicated that the mitochondrial ROS was the primary source of cellular ROS after GAS infection, which regulated the decrease of $\Delta\psi_m$ and cell death in GAS-infected cells. Glycogen synthase kinase-3 beta (GSK-3 β) plays an important role in regulation of ROS-mediated cell death. The wild-type GAS infection induced GSK-3 β activation in Raw 264.7 cells. Inactivation of GSK-3 β not only decreased mitochondrial ROS production but also inhibited the cell death of infected macrophages. Furthermore, inactivation of GSK-3 β also enhanced the bactericidal activity of GAS-infected Raw264.7 cells. Taken together, we suggest that GAS infection-mediated GSK-3 β activation regulated mitochondrial ROS production and $\Delta\psi_m$ reduction, and further contributed to the bactericidal inhibition in GAS-infected Raw 264.7 cells.

Vitamin D suppresses pro-inflammatory responses associated with *Streptococcus pneumoniae*

Hoe, E.¹, Nathanielsz, J.¹, Toh, Z.Q.¹, Spry, L.¹, Marimla, R.¹, Balloch, A.¹, Mulholland, K.^{1,2}, Licciardi, P.¹

¹Murdoch Childrens Research Institute, Melbourne, Australia,

²London School of Hygiene and Tropical Medicine, London, United Kingdom

S. pneumoniae is the most common bacterial respiratory pathogen and a leading cause of death in children under 5 years of age, mostly in developing countries. Risk factors for pneumococcal infections include nutrition, indoor air pollution and reduced exposure to sunlight. Recently, epidemiological evidence suggests that Vitamin D₃ (VitD₃) deficiency may also contribute to pneumococcal disease pathogenesis. VitD₃ has diverse immunomodulatory functions although its role during bacterial infections remains unclear. In this study, we examined the effects of VitD₃ pre-treatment of peripheral blood mononuclear cells (PBMCs) and purified immune cell subsets isolated from healthy adult volunteers on the response to specific innate [heat-killed pneumococcal serotype 19F (HK19F; TLR2) and LPS; TLR4] and adaptive (CD3/CD28) stimuli. We found that VitD₃ significantly reduced important pro-inflammatory cytokines TNF- α , IFN- γ , IL-8 and IL-1 β for all PBMC-stimulated ligands (3 to 53-fold), while anti-inflammatory IL-10 was increased (2-fold, p=0.016) in HK19F-stimulated monocytes. We also found that IFN- γ levels were higher (11.7-fold) in VitD₃-deficient adults stimulated with HK19F compared to VitD₃-sufficient adults. VitD₃ also shifted the T_H1/T_H2 balance towards an anti-inflammatory phenotype, increased the frequency of monocytes (3-fold, p=0.046) and CD4 expression on T cells (1.2-fold, p=0.008) which are important in protection against *S. pneumoniae*. These results demonstrate an important role for VitD₃ in the control of pneumococcal inflammation and supports further *in vivo* and clinical studies to confirm the potential benefits of VitD₃ in infants at high-risk of pneumococcal disease.

598

Emerging roles of an innate immune regulator TAPE in Toll-like receptors, RIG-I-like receptors, and beyond*Ling, P.^{1,2}, Chen, K.-R.², Kao, C.-C.¹, Chuang, H.-C.³, Tan, T.-H.³*¹National Cheng Kung University, Microbiology and Immunology, Tainan, Taiwan, Republic of China, ²National Cheng Kung University, Institute of Basic Medical Sciences, Tainan, Taiwan, Republic of China, ³National Health Research Institutes, Immunology Research Center, Zhunan, Taiwan, Republic of China

Pattern-recognition receptors (PRRs) trigger innate immune defenses against pathogen infection via signaling pathways linking to inflammation and cell-autonomous immunity like phagocytosis and autophagy. IKK family kinases, IKK α and IKK β , function to relay PRR signals to proinflammatory cytokine production to amplify immune responses. TBK1, a non-canonical IKK kinase, links several nucleic acid sensors to type I interferon induction against viral infection and also regulates the autophagic clearance of intracellular bacteria. TBK1-Associated Protein in Endolysosomes designated TAPE, also known as CC2D1A, is an innate immune regulator acting upstream of Trif to regulate the TLR3 and TLR4 pathways, or upstream of MAVS to regulate the cytosolic RIG-I-like receptor (RLR) pathways. Notably, TAPE is a regulator implicated in both the endosomal TLR and cytosolic RLR pathways at such an early step. We are thus interested in investigating in vivo role of TAPE in innate immunity and molecular mechanisms by which TAPE regulates TLRs, RLRs, and possibly other PRRs. TAPE conditional knockout (cKO) mice, in which TAPE is selectively disrupted in immune cells, were generated for our study. Our results showed that upon influenza A virus infection, TAPE cKO mice exhibited a more severe mortality than wild type mice. Further, TAPE cKO mice were shown to be more susceptible to *Salmonella* infection but more resistant to LPS-induced septic shock. Ex vivo studies showed that TAPE was implicated in the autophagic clearance of *Salmonella*. Together, our data support a critical role for TAPE in regulating innate immune defenses through TLRs, RLRs, and autophagy.

In vivo analysis of the interaction of antigen presenting cells (APC) in intestine of BALB/c mice with *Brucella abortus* administered intragastrically*López-Santiago, R.¹, Venegas-Brett, K.¹, Benito-Pineda, K.E.¹, Perea-Flores, M.J.², Sánchez-Argaes, A.B.¹, Gutiérrez-Hoya, A.^{1,3}*¹Instituto Politécnico Nacional, ENCB, Inmunología, México DF, Mexico, ²Instituto Politécnico Nacional, Centro de Nanociencias y Micro y Nanotecnologías, México DF, Mexico, ³FES-Zaragoza, UNAM, México DF, Mexico

Brucellosis is an infectious disease caused by *Brucella* spp. The infection causes abortions in the livestock and sterility in males. Humans acquire the infection through the ingestion of contaminated daily products.

In the 1970's it was observed in *in vitro* studies that *Brucella abortus* selectively attaches to B lymphocytes, which was used to identify lymphocytic leukaemia. The interaction was mediated by a lectin-like receptor and not by the BCR, but it was

not further studied the effect of the interaction on the B cell. So far, it is unknown whether *Brucella* binds to the B cell in an *in vivo* infection, and the role of the B cell in the pathogenesis or in the immune response to *Brucella*. The aim of the present work was to show the interaction of *B. abortus* with the antigen presenting cells (APC) in the Peyer's patches and the mesenteric lymph node of BALB/c mice infected intragastrically. *B. abortus* was captured mainly by B cells of both lymphoid organs, and by a small fraction of dendritic cells. The binding was already observed at 30 minutes after the infection. Images by laser scanning microscopy strongly suggested that the bacterium is internalized into the B cells by macropinocytosis. B cells which uptake the bacteria underwent activation as was shown by the cell surface markers CD40, CD80 and CD86. The phenotype and function of the APC infected with *B. abortus* must be defined, so it can be elucidated their role in the protection or the pathogenesis of brucellosis.

Adults with bronchiectasis do not have reduced antibody titres to vaccine candidate antigens of nontypeable *Haemophilus influenzae* or *Streptococcus pneumoniae**Thornton, R.^{1,2}, Marsh, R.³, Wiertsema, S.¹, Mateus, T.^{1,2}, Granland, C.¹, Shorten, M.⁴, Thompson, P.⁴, Richmond, P.^{1,2,5}, Kirkham, L.-A.^{1,2}*¹University of Western Australia, School of Paediatrics and Child Health, Perth, Australia, ²Telethon Kids Institute, Perth, Australia, ³Menzies School of Health Research, Darwin, Australia, ⁴Institute for Respiratory Health, Perth, Australia, ⁵Princess Margaret Hospital for Children, Perth, Australia

Background: Nontypeable *Haemophilus influenzae* (NTHi) and *Streptococcus pneumoniae* are important in infective exacerbations in bronchiectasis patients and often persist in the lungs despite antimicrobial therapy. Impaired immune responses to these bacteria may contribute to persistence but little data on pathogen-specific immune responses exists. The aim of this pilot study was to measure antibody responses to vaccine candidate antigens for NTHi and *S. pneumoniae* in adults with bronchiectasis and compare to healthy controls.

Methods: Multiplex fluorescent bead-based assays were conducted on sera and saliva samples from 19 adults with bronchiectasis and 17 age and gender-matched healthy controls. IgA and IgG titres were measured against the pneumococcal protein vaccine candidates pneumolysin (Ply), pneumococcal surface protein A 1 and 2 (PspA1, PspA2) and choline binding protein A (CbpA); and NTHi vaccine candidate proteins P4, P6, P26 and protein D (PD).

Results: Significantly higher antibody titres were observed in adults with bronchiectasis compared to healthy controls for serum and salivary anti-P4 IgA (1066 vs 559 AU; $p=0.037$ and 29 vs 12 AU; $p=0.003$ respectively) and anti-P26 IgG (5864 vs 2030; AU $p=0.027$ and 1.2 vs 0.2 AU; $p=0.003$ respectively). No significant differences were observed between cases and controls for antibody to the other proteins.

Conclusions: In this small study, adults with bronchiectasis had similar anti-bacterial antibody titres to healthy controls. Where differences existed, adults with bronchiectasis had more antibody than their healthy counterparts. Whether antibodies

present are functional, or can be boosted to confer protection from acute exacerbations requires further investigation.

B-cell epitope mapping of the *Helicobacter pylori* proteome

Adamsson, J.¹, Perkins, T.², Marshall, B.J.², Lundin, S.B.^{1,2}

¹Gothenburg University, Dept. of Microbiology and Immunology, Göteborg, Sweden, ²University of Western Australia, Marshall Centre for Infectious Diseases Research, Nedlands, Australia

The bacterium *Helicobacter pylori* is a major cause of diseases, including duodenal ulcer and gastric cancer. Its genome is highly variable, and strains harboring certain variants of virulence factors are conferring increased risk of gastric cancer development.

To increase understanding of the process of carcinogenesis, we aimed to study the B-cell response to *H. pylori* in extraordinary detail.

We mapped all linear B-cell epitopes of the *H. pylori* proteome using high-density peptide arrays. Overlapping 15-mer peptides were printed onto the chip surface, using an overlap of 10 aa, thereby covering the entire *H. pylori* proteome on each chip. Binding of IgG- or IgA-antibodies to each peptide on the chip was assessed by the use of serum pools (n=10 sera per pool) from *H. pylori*-infected or *H. pylori* uninfected individuals, followed by incubation with fluorescence-conjugated anti-IgG or anti-IgA antibodies.

The protein with the highest response, both regarding epitope numbers and intensity of response, was *cagA*. This agrees with the knowledge that *cagA* is an immunodominant antigen of *H. pylori*.

Around 20% of proteins tested had at least one epitope with a high antibody response in *H. pylori*-infected individuals. Consistent with the mucosal infection site, IgA-antibodies reacted to more than 80% of these epitopes, whereas IgG-antibodies bound to only around 30% of the epitopes.

Detailed mapping of the B-cell responses to *H. pylori* may provide an understanding of how the adaptive immune response to *H. pylori* influences gastric cancer development.

602

Influence of the moricin-like antimicrobial peptide on perturbation of fungal cell membranes

Kim, S.-R., Choi, K.-H., Kim, S.-W.

National Academy of Agricultural Science, Department of Agricultural Biology, Wanju-gun, Korea, Republic of

Moricin like peptide (MLP) is a 33-residue antimicrobial peptide which was isolated from the Japanese oak silkworm, *Antheraea yamamai*. This peptide was shown to contain potent antimicrobial activities against several human pathogenic bacterial and fungal strains. In this study we investigated the mechanism of action towards human pathogenic fungi. To understand the antifungal mechanisms of MLP, flow cytometric analysis using PI staining and 1,6-diphenyl-1,3,5-hexatriene (DPH) fluorescence analysis were conducted against *Candida albicans* cells. The results demonstrated that MLP perturbed

and disrupted the fungal plasma membrane. Furthermore, we confirmed that *C. albicans* cells treated with MLP showed several diagnostic markers of yeast apoptosis: accumulation of intracellular ROS, phosphatidylserine exposure, active metacaspase, dissipation of the mitochondrial membrane potential. In addition, nuclear fragmentation was seen by DAPI and TUNEL assay. These evidence strongly support antifungal property of MLP by promoting apoptosis in *C. albicans*.

603

Influence of platelet-activating factor receptor (PAFR) on *Brucella abortus* infection: Implications for manipulating the phagocytic strategy of *B. abortus*

Kim, S.

Institute of Agriculture and Life Science, Gyeongsang National University, Jinju, Korea, Republic of

Brucella abortus is an intracellular pathogen which can infect and persist in host cells through multiple interactions. Above all, its interaction to host cell receptor is important to understand the pathogenic mechanisms of *B. abortus*. Accordingly, we demonstrated that platelet-activating factor receptor (PAFR) affects host cell response against *B. abortus* infection. First of all, *B. abortus* infection to macrophage induces secretion of platelet-activating factor (PAF), which is a PAFR agonist. The stimulation of PAFR by PAF remarkably increases *B. abortus* uptake into macrophages. It induces Janus kinase 2 (JAK2) and p38 α phosphorylation, indicating that PAFR-mediated activation of JAK2 signaling leads to enhanced uptake of *B. abortus*. Moreover, the dynamics of F-actin polymerization revealed that PAFR-mediated *B. abortus* uptake is related with the reorganization of F-actin and JAK2. Upon *B. abortus* phagocytosis, reduced PAFR in the membrane and subsequently increased levels of PAFR colocalization with endosomes were observed which indicate that *B. abortus* uptake into macrophages allowed PAFR trafficking to endosomes. This study demonstrated that PAFR has a compelling involvement in *B. abortus* uptake as a promoter of phagocytosis, which is associated with JAK2 activation. Thus, our findings establish a novel insight into a receptor-related phagocytic mechanism of *B. abortus*.

604

Analysis of a molecular mechanism underlying the susceptibility to *Staphylococcus aureus* infection in Hyper-IgE syndrome

Wada, T., Nishikawa, Y., Minegishi, Y.

Tokushima University, Institute for Genome Research, Division of Molecular Medicine, Kuramoto, Tokushima, Japan

Introduction: Hyper-IgE syndrome (HIES) is a primary immunodeficiency, characterized by recurrent skin abscesses and pneumonia due to infection with *Staphylococcus aureus*. We identified that most cases of HIES are caused by dominant negative (DN) mutations in a single allele of STAT3 gene. However, the molecular mechanisms underlying the susceptibility to *S. aureus* infection remain unclear. To investigate the molecular mechanism of HIES, we established STAT3-DN knock-in mice as

a mouse model of HIES.

Methods and results: STAT3-DN mice and wild-type (WT) mice were epicutaneously infected with *S. aureus*, *S. epidermidis* or *Streptococcus pyogenes*, and the wound size and bacterial burden of the skin lesions at the site of infection were measured. STAT3-DN mice infected with *S. aureus* but not *S. epidermidis* or *S. pyogenes* developed larger skin lesions with higher bacterial burden than WT mice. In contrast to WT mice, histological examination revealed that accumulation of inflammatory cells were impaired in the skin lesions of STAT3-DN mice. Next, neutrophil influx and IL-17A production, which are essential for elimination of *S. aureus*, were evaluated in these lesions. Flow cytometric and real-time PCR analysis revealed that recruitment of neutrophils and production of chemoattractants were impaired. Furthermore, production of IL-17A by CD3+TCR $\gamma\delta$ + cells and CD3+CD4+ cells were also decreased compared to WT mice.

Conclusion: Impaired inflammatory cell response and IL-17A production might lead to the susceptibility to staphylococcal infection in HIES.

605

The role of Interleukin-33 and its signaling in the development of infectious colitis

Mchedlidze, T., Kindermann, M., Mahapatro, M., Neurath, M., Wirtz, S.

University Erlangen, Medical Department 1, Erlangen, Germany

Infections with proteobacteria of the genus *Salmonella* are a significant health problem. Alarmin-like cytokine IL-33 is crucial in sensing damage during inflammatory conditions and therefore potentially plays an important role in immunity against infections. Previous studies implicated this cytokine in bacterial sepsis, but still the precise role of IL-33 in intestinal diseases remains poorly understood.

To identify IL-33 expression in the context of *S. typhimurium* infection, we employed IL-33-LacZ reporter mice and observed strong reporter gene activity after infection compared to steady-state. Upregulated intestinal IL-33 expression was also confirmed by qRT-PCR analysis. In order to assess the role of IL-33 pathway during *S. typhimurium* infection IL-33^{-/-} mice were compared to littermate controls. In fact, in IL33-deficient animals showed increased bacterial burden compared with controls. Besides, lack of IL-33 was associated with increased immune cell infiltration and tissue damage in cecum and ileum. Moreover, extensive epithelial cell loss was detected by immunofluorescent staining of β -catenin. The strong differences between the two groups was associated with increased mRNA levels of antimicrobial peptides such as Angiogenin 4, Defensin α 5, Cryptidin and Lysozyme demonstrated a substantial decrease in IL-33^{-/-} mice compared to controls. In line with this, the more severe pathology of knock-out animals was associated with decreased presence of polymorphonuclear granulocytes/neutrophils and macrophages. Similar results were observed in mice lacking the IL-33 receptor chain ST2 suggesting that IL-33 signal transduction protects from *S. typhimurium* infection-dependent pathology.

Enhancing effect of Peptide-25 on the induction of functional activation of CD8 cytotoxic T lymphocytes

Tamura, T.¹, Shimohakamada, Y.^{2,3}, Umemura, M.⁴

¹National Institute of Infectious Diseases, Department of Mycobacteriology, Leprosy Research Center, Higashimurayama, Japan, ²National Sanatorium Tama-Zenshoen, Higashimurayama, Japan, ³National Institute of Infectious Diseases, Department of Mycobacteriology, Leprosy Research Center, Higashimurayama, Japan, ⁴Tropical Biosphere Research Center, University of the Ryukyus, Division of Molecular Microbiology, Department of Tropical Infectious Diseases, Nakagami, Japan

The effector cells involved in protective immune response against *Mycobacterium tuberculosis* are macrophages and CD8 cytotoxic T cells (CTL). Therefore, effectiveness of a vaccine against tuberculosis is mainly judged by its capability to induce memory CTL.

It has been reported that CD4 T cells are indispensable to induce functional activation of CTL. However, how CD4 T cells instruct or support functional activation of CTL during priming phase has not been resolved in detail. Therefore, we examined helper function of CD4 T cells in the CTL development.

Peptide-25 is the major T cell epitope of Ag85B of *Mycobacterium tuberculosis*. We found that this peptide induced Th1 differentiation even in the absence of IFN- γ and IL-12. Therefore, we examined whether Peptide-25 can enhance CTL activation. To examine the role of Peptide-25 in CTL development, we established *in vitro* analysis system by using Peptide-25, Peptide-25 specific CD4 T cells, OVA specific CD8 T cells and DC. By using this system, we found that CD4 T cells activated by Peptide-25 induced DC maturation even in the absence of IFN- γ and CD40 ligand association, and the mature DC induced the functional activation of CTL. To identify regulatory factors responsible for DC maturation, we analyzed gene expression profile of CD4 T cells and identified 27 genes. One of the genes was IL-17F. By using IL-17F^{-/-} mice, we found that Peptide-25 induced CTL activation was diminished in the absence of IL-17F. These results suggest that Th1-inducing peptide regulate the functional activation of CTL by inducing IL-17F production.

607

Evaluating the host immune response to bacterial pathogens in children with obstructive sleep apnoea and recurrent tonsillitis

Mateus, T.^{1,2}, Kirkham, L.-A.^{1,2}, Coates, H.^{1,2}, Vijayasekaran, S.³, Richmond, P.^{2,3}, Thornton, R.^{2,3}

¹UWA, School of Paediatrics and Child Health, Perth, Australia,

²Telethon Kids Institute, Perth, Australia, ³UWA, Perth, Australia

Obstructive sleep apnoea (OSA) affects 2-3% of children under 10 years of age. The pathogenesis of OSA is not well understood but correlates with an increase in allergic response. We evaluated the antibody response to the following respiratory pathogens: nontypeable *Haemophilus influenzae* (NTHi), *Streptococcus pneumoniae* and Group A streptococcus (GAS). Serum IgG and IgA to vaccine candidate proteins from NTHi (P4, P6 and PD), *S. pneumoniae* (Ply, PspA1, PspA2 and CbpA) and GAS (ScpA) were

assessed in children with OSA (n=40), recurrent tonsillitis (RT, n=21), OSA+recurrent tonsillitis (OSA+RT, n=16) and healthy controls (n=55) using a multiplex bead based assay. Atopic status was assessed using total IgE levels and parental questionnaire. Our results showed that IgG and IgA titers against all bacterial proteins from NTHi, *S. pneumoniae* and GAS were significantly higher ($p \leq 0.003$) in children with OSA and OSA+RT compared to children with RT and healthy controls. Total IgE titers were not significantly different between the 4 groups. Whilst overall atopy appears similar across the cohorts, differences in pathogen specific IgE responses may still exist. The IgE pathogen specific responses and the relative abundance of the bacterial species in the adenoids, tonsils, nasopharyngeal and throat swabs of the same cohorts are currently under investigation.

608

Immunopathogenesis of non-tuberculous mycobacterial infection in cystic fibrosis patients

Lutzky, V.¹, Ratnatunga, C.¹, Thomson, R.², Smith, D.^{2,3}, Reid, D.^{2,3}, Bell, S.^{2,4}, Miles, J.¹

¹QIMR Berghofer Medical Research Institute, Human Immunity Laboratory, Brisbane, Australia, ²The Prince Charles Hospital, Department of Thoracic Medicine, Brisbane, Australia, ³QIMR Berghofer Medical Research Institute, Lung Inflammation and Infection Laboratory, Brisbane, Australia, ⁴QIMR Berghofer Medical Research Institute, Lung Bacteria Laboratory, Brisbane, Australia

Non-tuberculous mycobacteria (NTM) are a family of bacteria found in food, soil and water distribution supplies. A number of NTM species are pathogenic in humans causing localized cutaneous lesions and pulmonary disease. NTM is a significant problem in cystic fibrosis (CF) patients affecting 20% of individuals. *Pseudomonas aeruginosa* is the major pathogen in the CF lung. Prevalence is high in CF and, once acquired, chronic infection will almost always ensue. Clinical outcomes from these lung pathogens are often poor, with increased risk of treatment toxicity and contra-indication for lung transplantation. Thus, there is an urgent need to understand the pathomechanisms behind NTM-driven pulmonary disease and develop effective therapies for treatment.

In this study, we have performed a comprehensive dissection of immune compartment composition in CF patients who have active NTM lung infection (CFA), previous NTM lung infection (CFN) or chronic *Pseudomonas* infection (CFC). Our results show that both CFA and CFN patients have higher number of circulating regulatory T cells, compared to chronic infected patients. In the CFA cohort there was also an increase in CD4+ displaying an exhausted phenotype. Additionally, CD8+ cells from patients exhibited aberrant function both at rest and post mitogen stimulation. In summary, we show that NTM infection in CF patients exhibit a distinct immune signature that can be used to identify future biomarkers and novel immune targets for use in immunotherapeutic modulation.

609

Immunomodulatory muropeptide against *Candida albicans*

Win, M.S.^{1,2}, Lim, J.¹, Ravikumar, S.¹, Goh, J.¹, Sam, Q.¹, Tan, Z.¹, Huang, Z.³, Yue, W.³, Chai, L.^{1,4}

¹National University Hospital, Department of Medicine, Singapore, Singapore, ²National University Cancer Institute of Singapore, Department of Haematology-Oncology, Singapore, Singapore, ³Institute of Molecular and Cell Biology (IMCB), A*STAR, Singapore, Singapore, ⁴Yong Loo Lin School of Medicine, National University of Singapore, Department of Medicine, Singapore, Singapore

Invasive candidemia causes major morbidity in patients with weakened immune system. The interplay and balance of Th1 and Th2 response dictates the efficiency of adaptive immune response against *Candida*. We studied the modulatory effect of the muropeptide, muramyl dipeptide (MDP), on immune response to *Candida* in a murine candidiasis model. Balb/c mice were intravenously inoculated with *Candida albicans* (1×10^6 CFU/ml) after being primed with intravenous injection of MDP (100 µg) for 2 days. By 3 days, there was significant decrease in the kidney fungal load when compared to non-MDP-primed mice. Histopathological examination of the kidneys showed higher incidence of interstitial inflammation in MDP primed mice. MDP had induced higher IFN γ and TNF α production. Splenocytes of the MDP-primed mice stimulated with heat-killed *Candida* revealed augmented IFN γ , TNF α and IL6 production. mRNA expression of STAT1 & T-bet also showed up-regulation in MDP-primed mice while the expression of GATA-3 was down-regulated, indicating the augmentation of Th1 adaptive immunity in the MDP primed mice. NOD2 knockout mice shows similar reduction in the fungal load in the MDP primed mice and non-primed mice. This illustrates that priming effect of MDP may direct Th1 activation by NOD2 independent pathways warranting further study of the alternative pathways involved in the process.

610

The expression of microRNA-146a is related with antibody titers and clinical symptoms in brucellosis patients

Shi, Y.¹, Yu, J.¹, Zheng, Y.¹, Han, X.²

¹Inner Mongolia Medical University, Inner Mongolia Key Laboratory of Molecular Biology, Hohhot, China, ²Inner Mongolia Medical University, School of Nursing, Hohhot, China

Brucellosis is one of the most common zoonosis worldwide. Human brucellosis is characterized by atypical symptoms, including fever, sweating, arthralgia/arthritis, constitutional symptoms, hepatomegaly, splenomegaly and host immune inhibition. MicroRNAs (miRNA) are endogenous 22-nucleotide RNAs that play important regulatory roles in gene regulation. miRNAs also modulate the innate and adaptive immune responses to pathogens. The potential applications of miRNAs as diagnostic or prognostic biomarkers have been demonstrated in various types of diseases. MicroRNA-146a (miR-146a) is involved in immune response and related with many infectious diseases. In this study, the expression of microRNA-146a in sera samples from 20 brucellosis patients and 20 healthy volunteers were analyzed by real time PCR assay. The mean expression

level of miR-146a in brucellosis patients was 0.71 μ M and ranged from 0.04 to 1.58 μ M. While that was 6.75 μ M and ranged from 0.18 to 22.53 μ M in healthy volunteers. The relation of expression level of miRNA-146a and antibody titer was analyzed by standard agglutination test (SAT), a confirmative serological assay for brucellosis. The 1:50 group showed an average of 4.6 ng/ul, and 1:100 showed 3.31, while 1:200 showed 1.54 ng/ul. The expression levels of the three groups differed significantly ($p < 0.01$). We also analyzed the possible correlation between miR-146a level and common clinical symptoms. Patients with symptom of fever and/or sweating showed lower level of miR-146a. The results indicate that the expression levels of miR-146a are significantly inhibited in brucellosis patients and negatively relate with serum antibody titers and clinical symptoms of fever and sweating.

611

Colonization of resident pathobionts in the I κ B ζ signal-deficient skin accelerates atopic dermatitis-like syndrome

Kim, Y., Lee, Y.-S., Lee, S.-H., Yang, J.-Y., Kweon, M.-N.

University of Ulsan College of Medicine/Asan Medical Center, Seoul, Korea, Republic of

I κ B ζ , encoded by the *Nfkbiz* gene, is a member of the nuclear I κ B family of proteins that act as a transcriptional regulator via association with NF- κ B. Previous studies showed spontaneous development of atopic-like dermatitis in the I κ B $\zeta^{-/-}$ mice; however, underlying mechanism is still unveiled. In this study, we revealed that high levels of skin pathologic score, serum IgE Ab, and trans-epidermal water loss (TEWL) in the I κ B $\zeta^{-/-}$ mice than I κ B $\zeta^{+/+}$ mice. Predominant levels of pro-inflammatory cytokines (i.e., IL-1b, IL-6, and TNF- α) and chemokines (i.e., MCP-1, MIP-1 α , RANTES, and KC) were detected in skin homogenates of I κ B $\zeta^{-/-}$ mice. Importantly, numerous numbers of langerin⁺CD11b⁺CD103⁺ and langerin⁺CD11b⁻CD103⁺ cells were recruited into the inflamed skin of I κ B $\zeta^{-/-}$ mice. We also found that expansion of IFN- γ -, IL-17-, IL-22-secreting CD4⁺ T cells and IL-17-secreting TCR $\gamma\delta$ ⁺ T cells in the skin of I κ B $\zeta^{-/-}$ mice when compared to those of I κ B $\zeta^{+/+}$ mice. Of note, universal bacteria 16s rRNA levels were markedly increased and some *staphylococci* species were specifically expanded in the skin of I κ B $\zeta^{-/-}$ mice. Oral treatment of antibiotics containing cephalixin and enrofloxacin ameliorated skin inflammation. These results demonstrate that colonization of commensal *staphylococci* species might be one of causes of skin dysbiosis which provoked in I κ B $\zeta^{-/-}$ mice, and highlight that I κ B ζ gene has a potential regulatory role in microbiota-skin immunity axis.

612

Role of renal CD169⁺ F480⁺ resident macrophages in acute systemic candidiasis

Teo, Y.J., Ruedl, C.

Nanyang Technological University, Singapore, Singapore

Systemic Candidiasis is one of the most frequent nosocomial infections to date, with mortality rate as high as 40%. Although the importance of neutrophils in this infection is well-established,

current understanding of the role of mononuclear phagocytic (MNPs) subsets, which includes DCs and macrophages, against invasive *Candida* infection is limited due to the lack of appropriate tools to specifically ablate mononuclear phagocytic cell subsets. Here, we reiterate the essential roles of neutrophils in host defense against invasive *Candida* infection, where the ablation of neutrophils *in vivo* causes rapid death of the mice as soon as 2 days post infection. Correspondingly, these mice display significantly higher fungal burden in kidneys and liver, with kidneys having the highest fungal load. To elucidate the role of tissue resident macrophages in the immunity against systemic candidiasis, we utilized CD169-DTR transgenic mouse in which CD169⁺F480⁺ cells can be specifically ablated in all organs upon DT injection. We observed that DT treated CD169-DTR mice consistently exhibit increased susceptibility to systemic *Candida* infection compared to the wild type mice. Importantly, these transgenic mice exhibited exceedingly high fungal burden only in the kidney while *Candida* presence was undetectable in all other organs. These observations suggest that renal CD169⁺F480⁺ resident macrophages are irreplaceable in the host defense against systemic candidiasis. Whether these renal CD169⁺F480⁺ resident macrophages are involved in clearing the fungal burden or regulating the host immune system against invasive *Candida* infection remains a question and is currently our main focus of study.

613

Phospholipase C mediates the therapeutic effects of Trp-Lys-Tyr-Met-Val-D-Met against sepsis

Kim, H.S.¹, Lee, S.K.¹, Park, M.Y.¹, Kim, J.C.¹, Bae, Y.-S.^{1,2}

¹Sungkyunkwan University, Biological Sciences, Suwon, Korea, Republic of, ²Sungkyunkwan University, Health Sciences and Technology, Seoul, Korea, Republic of

Severe sepsis, a principal cause of death in intensive care units, results from a detrimental or damaging host reaction to infection. Previously we demonstrated that an immune stimulating peptide, Trp-Lys-Tyr-Met-Val-D-Met (WKYMVm), strongly induced therapeutic effects against polymicrobial sepsis by stimulating bacterial clearance and suppressing inflammatory cytokine production. We also reported that the peptide-induced anti-septic activity was mediated by an important leukocyte chemoattractant receptor, formyl peptide receptor 2 (FPR2). Here, we further investigated the mechanism involved in WKYMVm-induced therapeutic effects against sepsis focusing on putative role of phospholipase C (PLC). WKYMVm strongly stimulated mouse neutrophils, resulting in calcium increase which was completely blocked by a PLC-selective inhibitor (U-73122). PLC-specific inhibitor U-73122 markedly blocked the therapeutic effects of WKYMVm against sepsis. WKYMVm-induced inhibition of lung inflammation and lymphocyte apoptosis in cecal ligation and puncture were markedly blocked by the PLC-selective inhibitor, U-73122. We also found that WKYMVm-stimulated bactericidal activity and neutrophil migration to event area were also strongly inhibited by U-73122. Taken together our results, we suggest that PLC activity is required for the therapeutic activity of WKYMVm against sepsis.

614

The role of IL-21 producing and nonproducing follicular helper T cells in mycobacterial infection*Shimohakamada, Y.^{1,2}, Tamura, T.², Umemura, M.³**¹National Sanatorium Tama-Zenshouen, Higashimurayama, Japan, ²Leprosy Research Center, National Institute of Infectious Disease, Department of Mycobacteriology, Higashimurayama, Japan, ³Tropical Biosphere Research Center, University of the Ryukyus, Molecular Microbiology Group, Development of Tropical Infectious Diseases, Nakagami, Japan*

T follicular helper (Tfh) cells are the specialized CD4 T cell subset that has evolved the appropriate mechanisms to induce the activation and differentiation of B cells into antibodies secreting cells. Therefore, Tfh cells are believed to be involved in induction of the humoral immunity. However, the involvement of Tfh cells in the protective immunity was not clearly demonstrated in mycobacterial infected mice. In this study, to verify the role of Tfh cells in the protective immunity in pulmonary *M. bovis* Bacille Calmette-Guerin (BCG) infection, we used IL21 GFP reporter mouse (IL21 GFP mouse) which was introduced sequence encoding GFP into the il21 locus, because Tfh cells are identified by elevated expression levels of IL-21 secretion. We have found that IL-21 producing (IL21 GFP+) and IL-21 non-producing (IL21 GFP-) cells were detected in a population of Tfh cells (CD4+ PD1+ CXCR5+ CD62L-) in the BCG infected mice. To evaluate of IL21 GFP- Tfh cells, we examined the transcription factors that could regulate the helper T cell function. We found that some of IL21 GFP- Tfh cells have foxp3 molecules.

These results suggest that mycobacterial infection may induce differentiation of inducible Treg cells from conventional naive CD4 T cells.

Acknowledgement: We thank Dr. Stephen L Nutt (The Walter and Eliza Hall Institute of Medical Research) for providing IL-21 GFP mouse.

615

Attenuation by platelets of macrophage inflammatory responses to bacterial endotoxin*Ando, Y., Oku, T., Tsuji, T.**Hoshi University, Microbiology, Tokyo, Japan*

Considerable evidence has been accumulated concerning the roles of platelets in immune responses. In this study, we focused on the cellular interaction between platelets and macrophages and examined the influences of platelets on the inflammatory responses of macrophages induced by bacterial components. When mouse bone marrow-derived macrophages (BMDMs) were co-cultured with platelets, BMDMs produced lower levels of nitric oxide (NO), TNF- α and IL-6 in response to a bacterial endotoxin (LPS) and zymosan. The attenuation in the macrophage susceptibility to LPS appeared to be mediated by soluble factors secreted from platelets. The mRNA levels of NOS2 (iNOS), TNF- α and IL-6 in LPS-stimulated BMDMs that had been cultured with a conditioned medium of unactivated or thrombin-activated platelets were also decreased as analyzed by RT-qPCR. The ability of the platelet-conditioned medium to suppress macrophage NO production was recovered in a

high-molecular-weight fraction (>670 kDa) after gel-filtration chromatography on a Superose 6 column. These results suggest that platelets control the susceptibility of macrophages to prevent excessive responses to LPS and provide mechanistic insight into the development of septicemia and new therapeutic strategies for septic shock.

Immunity to Parasites

PD-1 dependent exhaustion of CD8⁺ T cells drives chronic malaria*Karunaratne, D.S.¹, Horne-Debets, J.M.¹, Faleiro, R.¹, Q. Liu, X.², E. Lineburg, K.¹, Meng Poh, C.³, Grotenbreg, G.M.³, Hill, G.R.¹, MacDonald, K.P.A.¹, Good, M.F.², Renia, L.⁴, Ahmed, R.⁵, Sharpe, A.H.⁶, Wykes, M.N.¹**¹QIMR Berghofer Medical Research Institute, Herston, Australia,**²Institute for Glycomics, Griffith University, Gold Coast Campus,**Gold Coast, Australia, ³Singapore Immunology Network, Agency for Science, Technology and Research (A STAR), Singapore,**Singapore, ⁴Singapore Immunology Network, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, ⁵Emory Vaccine Center, Atlanta, United States, ⁶Harvard Medical School, Department of Microbiology and Immunobiology, Boston, United States*

Malaria, caused by *Plasmodium* parasites, is a highly prevalent and devastating disease that can persist for years. There has been considerable difficulty in developing a malaria vaccine, highlighting our incomplete understanding of immunity against this disease. Antibodies and CD4⁺ T cells are thought to protect against blood-stage infections. We used an experimental rodent malaria model, to show that programmed death-1 (PD-1) mediates a 95% reduction in numbers and functional capacity of parasite-specific CD8⁺ T cells during acute malaria, driving chronic disease. Furthermore, we demonstrated PD-1 also affect CD4⁺ T cell function that, improved effector CD4⁺ and CD8⁺ T cell function during the chronic phase of infection, compared to wild-type mice. Importantly, in contrast to widely held views, parasite-specific CD8⁺ T cells are required to control both acute and chronic blood-stage disease even when parasite-specific antibodies and CD4⁺ T cells are present. Our findings provide a molecular explanation for chronic malaria which will be relevant to future malaria-vaccine design and may need consideration when vaccine development for other infections is problematic.

Exogenous calreticulin, incorporated onto non-infective *Trypanosoma cruzi* epimastigotes, promotes their internalization into mammal hosts cells*Sosoniuk Roche, E.¹, Vallejos, G.¹, Aguilar Guzmán, L.¹, Pizarro Bäuerle, J.¹, Weinberger, K.¹, Rosas, C.¹, Valck, C.¹, Michalak, M.², Ferreira, A.¹**¹University of Chile, Faculty of Medicine, Immunology, Santiago,**Chile, ²University of Alberta, Department of Biochemistry, Alberta, Canada*

Chagas disease is an endemic pathology in Latin America, now emerging in developed countries, caused by the intracellular protozoan *Trypanosoma cruzi*. *T. cruzi* life cycle involves three stages: amastigotes, epimastigotes, and trypomastigotes. We have shown that, in infective trypomastigotes, *T. cruzi* Calreticulin (TcCRT), an endoplasmic reticulum (ER) resident chaperone, translocates to the cellular membrane, where it captures complement component C1q thus interfering with C4 activation, with consequent blocking of the classical pathway. Trypomastigote-bound C1q is detected as an "eat me" signal by macrophages and promotes the infective process. Thus, TcCRT is a new virulence factor. Different from infective trypomastigotes, non-infective epimastigotes express only marginal levels of TcCRT on their external membranes. We now show that epimastigotes bind exogenous rTcCRT to still unidentified moieties on their cellular membrane and, in the presence of C1q, this parasite form is internalized into normal fibroblasts. On the other hand, CRT- deficient fibroblasts show impaired parasite penetration. Consequently, CRTs, from both parasite and host cell origins, are important in the establishment of a C1q-dependent synapsis that allows the first contact between these two cell types. Perhaps, the epimastigote inability to infect mammal cells is due, at least partly, to an impaired capacity to translocate their CRT from the ER to the parasite surface. Financed by Regular FONDECYT project 1130099, from CONICYT-Chile.

Characterisation of CD4⁺ T cell responses during malaria

Edwards, C.^{1,2}, *de Labastida Rivera, F.*¹, *Montes de Oca, M.*¹, *Ng, S.*^{1,3}, *Engwerda, C.*¹

¹QIMR Berghofer Medical Research Institute, Brisbane, Australia,

²University of Queensland, School of Medicine, Brisbane, Australia,

³Griffith University, School of Natural Sciences, Brisbane, Australia

CD4⁺ T cells are important in determining disease outcome during *Plasmodium* infection. Recently, a subset of CD4⁺ T cells which co-produce IFN γ and IL-10 (Tr1 cells) has been identified in mouse models of malaria. Importantly, Tr1 cell frequency has also been reported to significantly increase in response to *P. falciparum* infection in children living in malaria endemic regions of Africa. However, whether Tr1 cells are beneficial by prevention of inflammation and associated tissue damage or detrimental by suppression of anti-parasitic immune responses remains unclear. To better understand the role of Tr1 cells in malaria we isolated these cells from healthy and *P. falciparum* infected volunteers, as well as naïve CD4⁺ T cells and Th1 cells from the same individuals, using cytokine capture and cell sorting. Isolated cell populations were subjected to RNA-seq analysis to identify distinctive markers of Tr1 cells during malaria. Results from these studies will be presented and discussed.

619

Reactive oxygen and nitrogen species levels produced by *Leishmania major*-infected phagocytes as host surrogate parasite virulence markers

Ben-Cheikh, A., Sghaier, M.R., Bali, A., Mkannez, G., Atri, C., Chourabi, K., Attia, H., Guerfali, F.Z., Laouini, D.
Institut Pasteur de Tunis, Transmission, Control and Immunobiology of Infections, Tunis-Belvedere, Tunisia

Zoonotic cutaneous leishmaniasis (ZCL) caused by *Leishmania (L.) major* shows various clinical manifestations, ranging from asymptomatic infection without apparent lesion, to extensive lesions that might cause severe disfiguring scars. This clinical expression is due to the host immune status, to the parasite intrinsic virulence or to both. Ability to predict clinical outcome is crucial when prescribing treatment or determining possible control measures in epidemiological studies.

During its life cycle, *Leishmania* encounters various hostile conditions such the two highly toxic radicals for *Leishmania*, reactive oxygen and nitrogen species (ROS and RNS) generated during phagocytosis by host cells

In this work, we sought to identify host cellular surrogate markers for *Leishmania* virulence that can discern between virulent and low virulent isolates i.e., the cellular levels of nitric oxide (NO) and reactive oxygen species production.

Using a selected couple of *L. major* isolates according to their contrasting virulence and three cell types i.e., human activated THP1 cells, human polymorphonuclear neutrophils (PMN) and murine macrophagic Raw 264.7 cells, we showed that virulent parasites are inducing higher NO and ROS amounts than non-virulent ones, contrasting with their corresponding parasite load. A collection of well-characterized isolates will be used to infect cells, to monitor NO and ROS produced amounts upon infection and to correlate them with lesion severity and pathogenicity in experimental animal model.

TLR4 and RANTES triggered immunomodulation is critical for malaria disease outcome: a northeast India tribal population based study

*Bujarbaruah, D.*¹, *Kalita, M.P.*², *Hazarika, S.*³, *Baruah, V.*², *Basumatary, T.K.*², *Pathak, P.K.*⁴, *Mahanta, B.*⁴, *Bose, S.*²

¹Dimoria College, Zoology, Guwahati, India, ²Gauhati University, Biotechnology, Guwahati, India, ³Dimoria College, Botany, Guwahati, India, ⁴Community Health Centre, Rani, Guwahati, India

The study aimed to evaluate the critical role of TLR4 in association with serum-CD14 levels, its downstream immunomodulatory targets in the pathogenesis of malarial infection, and deciding the outcome of the disease.

Methods: Clinically proved malaria cases of tribal ethnicity (n=60) were enrolled on follow-up basis with all clinical details, pathogen load and informed consent; from northeast India. Blood collection was done on follow-up basis (baseline and third day). Differential TLR4 expression was evaluated by MUSE platform. TLR4 stimulators co-receptor sCD14 and chemokine RANTES levels were studied by ELISA. The differential expression of both TLR4 and RANTES at both protein and mRNA level was

correlated with downstream expression of pro-inflammatory and inflammatory markers NFkBp65, TNF α and IFN γ ; chemokine receptor CCR5; pathogen load, and association with disease susceptibility, severity and recovery. Statistical analysis was performed by SPSSV13.0 software.

Results: TLR4 expression increased in mild malaria cases(3.12 \pm 1.42%) compared to controls(1.02 \pm 0.36%) and severe malaria cases(1.22 \pm 0.98%). TLR4 expression increased significantly on recovery in paired cases(p=0.037). Expression of RANTES was significantly lower in severe malaria cases(15708.92ng/L) compared to mild(16147.74ng/ml)(p=0.046) and control cases (18587.2ng/L)(p< 0.001); and increased after recovery in individual paired mild malaria cases (p=0.106). TLR4 and RANTES expression inversely correlated with parasite load. NFkBp65, TNF α and IFN γ levels were significantly elevated on mild malaria cases compared to controls and severe malaria cases; TLR4, RANTES levels; and correlated with disease recovery at both protein and mRNA level.

Conclusions: TLR4 and associated immunomodulators plays a critical role in malaria susceptibility, severity and recovery, and has immense therapeutic implications.

621

Severe acquired toxoplasmosis in children

Fitrani, D.A.

Harapan Kita Women and Children Hospital, Pediatrics, Jakarta-Barat, Indonesia

Introduction: Toxoplasmosis is a disease caused by the parasite *Toxoplasma gondii*. Toxoplasmosis can be postnatally acquired in children and the symptoms may vary.

Method: Case Presentation.

Results: We present a 14 months old boy with recurrent fever since he was 5 months old. His parents complained that his stomach got bigger and his face paler since he was 9 months old. He had history of severe anemia without bleeding. He was born full term without perinatal problems. The physical examination showed malnourished, gross motor delay, multiple lymphadenopathy and severe hepatosplenomegaly. Laboratory findings were anemia (5,9 g/dL), thrombocytopenia (64.000/ μ L), elevated ESR (102 mm/hour) and AST level (600 U/L). His procalcitonin level rised from 2 to 10 ng/mL. He received transfusions periodically but there were no significant changes and the platelets level was decreased more. He was first suspected had malignancy with secondary infection, but infection source was unconfirmed. Bone marrow puncture showed normoblastic marrow. The *Toxoplasma* IgM level was normal with elevated IgG level (39.00 IU/mL) and total IgE level (471.19 IU/mL). Biopsy of lymph gland showed reactive follicular hyperplasia suggesting infection confirmed by PCR *Toxoplasma* test which showed active toxoplasmosis. The patient received pyrimetamine and clindamycin for a few days but eventually he died due to severe blood loss caused by thrombocytopenia.

Conclusion: Severe multiple organ involvement is occasionally found in toxoplasmosis and can be misdiagnosed. The serodiagnostic of toxoplasmosis can be subsided and must be confirmed with physical examination and other diagnostic tests. Keywords: Toxoplasmosis, acquired, severe, children

Human antibodies to *Plasmodium falciparum* merozoite surface antigens interact with Fc γ receptors to mediate immunity to malaria

Feng, G.¹, Wines, B.¹, Stubbs, J.¹, Richards, J.¹, Hogarth, M.¹, Osier, F.², Beeson, J.¹

¹The Burnet Institute of Medical Research and Public Health, Centre for Biomedical Research, Melbourne, Australia, ²KEMRI, Centre for Geographic Medicine Research, Kilifi, Kenya

Antibodies are known to protect against *P. falciparum* malaria by inhibiting parasite replication. The merozoite form of malaria parasites invades human red blood cells and replicates inside them, and is a major target of acquired antibodies. Recent studies have shown that opsonic phagocytosis of *P. falciparum* merozoites by monocytes, mediated by acquired human antibodies, is strongly associated with protective immunity to malaria. Fc γ -receptors have important roles in antibody-mediated opsonic phagocytosis and subsequent immune activation and regulation. Understanding how antibodies interact with Fc γ -receptors may be crucial in developing highly effective vaccines. We evaluated the role of different Fc γ -receptors in promoting opsonic phagocytosis using Fc γ -receptor blockers, and confirmed that mutation of the FcR-binding site of a recombinant human monoclonal antibody to a major merozoite surface protein ablated its ability to promote opsonic phagocytosis. Human immunization with a candidate vaccine induced antibodies that promote opsonic phagocytosis. To further investigate the roles of specific Fc γ receptors in immunity, we used recently developed Fc γ -receptor binding assays to define the ability of acquired human antibodies in engaging Fc γ RIIIa and Fc γ RIIIa in a longitudinal cohort of African children exposed to malaria. Together, our data suggest that activating Fc γ -receptors are key mediators in opsonic phagocytosis of merozoites and children with higher Fc γ -receptor binding activity are protected from malaria. Our findings support the potential of vaccines optimized to induce antibodies to merozoite surface antigens that interact with Fc γ -receptors, advance our understanding of the mechanisms and targets of protective immunity, and establish new assays for vaccine evaluation.

Effects of helminth eradication on the immune system

Weisman, Z.¹, Mahdi, J.A.^{2,3}, Kalinkovich, A.^{1,4}, Stein, M.⁴, Greenberg, Z.^{4,5}, Borkow, G.¹, Adlerstein, D.^{1,2}, Bentwich, Z.^{1,2}

¹R. Ben-Ari Institute of Clinical Immunology, AIDS Center, Kaplan Medical Center, Rehovot, Israel, ²Ben Gurion University of the Negev, Microbiology Immunology and Genetics, BeerSheva, Israel, ³University of Gondar, Microbiology Immunology and Parasitology, Gondar, Ethiopia, ⁴Hebrew University, Hadassah Medical School, Rehovot, Israel, ⁵Public Health Laboratory, The Ministry of Health, Jerusalem, Israel

Background: Helminth infection has a profound effect on the immune system. However, the precise nature of the immune changes that are elicited by human helminth infection have not been sufficiently characterized. Furthermore, the reversibility of these changes after treatment has not been documented

sufficiently. We observed immune profiles of Ethiopian immigrants to Israel cohort.

Methods: A longitudinal follow up study involving different group of subjects were conducted. Each group had a baseline data for series of peripheral blood tests, including: IgE and Eosinophil levels, T-cell populations, T-cell receptors phenotypes, and cytokines measurement. These tests were all repeated at one year interval. Results were compared between newly-arrived-Ethiopian-Israelis (NEW-Eth-II), Long-stayed-Ethiopian-Israelis (OLD-Eth-II), and Non-immigrant-Israeli controls (NON-Imm-II).

Results: Out of the 184 individuals 111 were NEW-Eth-II, who had a high prevalence of helminth infection, the immunological changes were elevated IgE levels and eosinophil counts, decreased CD4/CD8 ratio, increased proportion of HLA-DR+CD3+, HLA-DR+CD4+ and HLA-DR+CD8+ cells, decreased proportion of CD45RA+CD4+ (naive) and CD28+CD8+ cells, increased proportion CD45RO+CD4+ (memory) cells, and increased secretion of IL-4 and IL-5 (Th2 type cytokines). In the OLD-Eth-II, who were all negative for helminth infection, we did not observe these immune changes and did not differ markedly from that of the NON-Imm-II controls. Significant normalizations in the above-mentioned variables were observed in 33 NEW-Eth-II who had received successful treatment but not in those who missed the treatment.

Conclusions: These findings demonstrate that helminth infection is associated with profound immune changes, and can be normalized within a short time after helminth eradication.

625

Peroxybioflavonoids (MALSUP): a possible cure for severe cases of plasmodium falciparum malaria infection in Nigeria

Thornthwaite, J.T.¹, Akanni, E.O.², Ayankuule, A.A.³, Alli, O.A.T.²

¹Cancer Research Institute of West Tennessee, Henderson, United States, ²Ladoke Akintola University of Technology, Medical Laboratory Science Department College of Health Sciences, Osogbo, Nigeria, ³Ladoke Akintola University of Technology, Pharmacology & Therapeutics Department, Osogbo, Nigeria

Development of an antimalarial treatment capable of providing a permanent cure for malaria is presented. A trial of a novel formulation of Citrus Bioflavonoids and Artemisinin (PeroxyBioflavonoid™ or MALSUP™) was conducted in Osogbo, Nigeria following exciting reports from our previous study on malaria infected children for over 10 years in Haiti who are yet to record another episode of the infection. Children, ages 2-15, positive for P falciparum parasites, and whose parents gave consent, were among the 127 enrolled subjects treated with the MALSUP™ for 16 consecutive days. Serums were collected on days 0, 5, 10, 16, 30, and 60. The study shows that 90.2% of the patients showed no recurrence (termed "cured" in compliance with the literature definition where patients go at least 28 days without recurrence) by being parasite free by the standard blood tests at 30-60 days. Patient with serums (n=112) and buffy Coats (n=25) were obtained with 15 patients being lost to follow-up. Eleven so-called failures were reported, and three were from one family suggesting non-compliance. The cured patients

are currently being followed to confirm no recurrence of the infection. These data show for the first time a real possibility for a cure of Malaria in Nigeria. The one time, low dose, long term treatment minimizes the ability of the parasites to develop resistance. Having the serums and buffy coats obtained during the course of treatment will enable us to find the underlying antibody and cell-mediated immunological mechanism(s) of permanent immunity.

Nod2/Rip2-mediated signaling contributes to shape adaptive immunity in visceral leishmaniasis

Nascimento, M.¹, Ferreira, M.², Quirino, G.³, Krishnaswamy, J.⁴, Liu, D.⁵, Berlink, J.⁵, Fonseca, D.³, Zamboni, D.³, Almeida, R.⁶, Carregaro, V.³, Cunha, T.³, Eisenbarth, S.⁵, Silva, J.S.³

¹Ribeirão Preto Medical School, Immunology, Ribeirão Preto, Brazil, ²Ribeirão Preto School of Medicine, University of São Paulo, Ribeirão Preto, Brazil, ³Ribeirão Preto Medical School, Ribeirão Preto, Brazil, ⁴Yale University School of Medicine, Immunology, New Haven, United States, ⁵Yale University School of Medicine, New Haven, United States, ⁶Federal University of Sergipe, Aracaju, Brazil

IFN-γ and IL-17A-producing cells are described to be related to protection against *Leishmania infantum* (*L. infantum*). How the immune system coordinates, or the parasite manipulates, the balance between Th1 and Th17 during visceral leishmaniasis (VL) is still unknown. We showed that Th17 is suppressed during *L. infantum* infection, and B cells are the major source of IL-17A. By using *Nod2*^{-/-} and *Rip2*^{-/-} mice we characterized this pathway as a negative regulator for Th17 cells in VL. On the other hand, the high level of Th1 induction was dependent on the NOD2-RIP2 signaling in CD8α⁺XCR1⁺ dendritic cells (DCs), which was crucial for IL-12 production through the phosphorylation of p38 and JNK. As a consequence, *Nod2*^{-/-} and *Rip2*^{-/-} mice showed a Th1 defective response, more Th17, and higher parasite loads compared to WT mice. Together, the data demonstrate that NOD2-RIP2 pathway plays a role in shaping adaptive immunity and promotes protection against VL caused by *L. infantum*.

627

The programmed death-1-PD-L1 axis mediates lethality of malaria

Horne-Debets, J.^{1,2}, Karunarathne, D.¹, Faleiro, R.¹, Renia, L.³, Ahmed, R.⁴, Sharpe, A.⁵, Wykes, M.¹

¹QIMR Berghofer, Brisbane, Australia, ²The University of Queensland, The School of Medicine, Brisbane, Australia, ³A*STAR, Singapore, Singapore, ⁴Emory Vaccine Center, Atlanta, United States, ⁵Harvard Medical School, Boston, United States

Programmed death-1 (PD-1)-mediated dysfunction, or 'exhaustion' of T cells is a phenomenon that promotes cancer and chronic viral infections. Although the effects of PD-1 on chronic diseases have been well characterised, the role of PD-1 in severe infections has been less thoroughly examined. We previously showed that PD-1-dependent exhaustion of T cells resulted in incomplete protection against acute malaria, leading to chronic disease. In our current study, we utilised an acute,

lethal murine model of malaria to examine the effects of PD-1 on early T cell function in severe infections. We found from days 5-7 post-infection, PD-1 was expressed by a large proportion of T cells. Mechanistic studies showed mice deficient in PD-1, or administered with PD-1-blocking antibodies, survived lethal disease. Using PD-1-deficient mice that were also unable to express interferon-gamma or perforin, we showed a role for these effector molecules in protection. Adoptive transfer studies showed that dendritic cell-expressed PD-L1 was responsible for lethality. Overall, we demonstrated the capacity of the PD-1/PD-L1 axis to negate T cell immunity to this acute, lethal, systemic infection.

MIF promotes classical activation and conversion of inflammatory Ly6C^{high} monocytes into Tip-DCs during murine toxoplasmosis

Ruiz-Rosado, J.D.D.¹, Olguín, J.E.¹, Saavedra, R.¹, Juárez-Avelar, I.¹, Robledo-Avila, F.H.², Fernández, J.¹, Vazquez-Mendoza, A.¹, Terrazas, L.I.¹, Satoskar, A.R.³, Partida-Sánchez, S.², Rodríguez-Sosa, M.¹

¹Universidad Nacional Autónoma de México, Biomedicine, Mexico City, Mexico, ²Nationwide Childrens Hospital, Research Institute, Columbus, United States, ³Ohio State University, Pathology, Columbus, United States

Toxoplasma gondii (*T. gondii*) is an obligate intracellular parasite that causes toxoplasmosis, a usually asymptomatic disease in healthy individuals but a potentially fatal illness in immunocompromised hosts. The cytokine Macrophage Migration Inhibitory Factor (MIF) is known to mediate immunity against *T. gondii* infection. However, the mechanism of MIF in the resistance to acute toxoplasmosis remains poorly understood. Here, we used *T. gondii*-infected WT and *Mif*^{-/-} mice to determine the role of MIF in the immune response against *T. gondii*. We found that the absence of MIF resulted in reduced numbers of IFN- γ producing Natural Killer (NK) cells in the site of infection and consequently impaired maturation of CD11b⁺ Dendritic Cells (DCs). Additionally, infected *Mif*^{-/-} mice showed increased parasitic burden in brain and significantly less numbers of both, TNF- α /iNOS producing CD11b⁺ DCs (TipDCs) and classically activated Ly6C^{high} monocytes, compared to acutely infected WT mice. The adoptive transfer of bone marrow WT or *Mif*^{-/-} Ly6C^{high} monocytes into *T. gondii*-infected mice, demonstrated that MIF is required for Ly6C^{high} monocytes differentiation to TipDCs, which increased their anti-microbial activity to *T. gondii*. Finally, administration of rMIF into *T. gondii*-infected *Mif*^{-/-} mice restored the numbers of TipDCs and reversed the susceptible phenotype of *Mif*^{-/-} mice. Collectively, these results demonstrate a novel role for MIF in promoting activation and functional differentiation of inflammatory monocytes into TipDCs and highlight the potential of rMIF as a therapeutic agent in toxoplasmosis or other protozoan infectious diseases.

629

Differential regulation of TLR2 and associated immunomodulation is pivotal for deciding the fate of malaria infection

Kalita, M.P.¹, Bujarbaruah, D.², Begum, R.H.³, Pathak, P.K.⁴, Basumatary, T.K.¹, Bose, M.¹, Shyam, N.⁵, Bose, S.¹

¹Gauhati University, Biotechnology, Guwahati, India, ²Dimoria College, Zoology, Guwahati, India, ³Assam University, Diphu Campus, Lifescience and Bioinformatics, Diphu, India, ⁴Community Health Centre, Rani, Guwahati, India, ⁵Diphu Civil Hospital, Diphu, India

The present prospective study aimed to evaluate the role of differential TLR2 and co-receptor CD14 expression and resulting downstream cytokine modulation in susceptibility to malaria disease, and outcome of the disease.

Methods: Blood samples of clinically proven cases of malarial disease (N=55) were collected on follow-up basis (baseline, and after 3 days) along with healthy controls (N=60), from Assam. Differential TLR2 and mCD14 expression was studied by ELISA and MUSE analysis respectively. Serum level expression of cytokines NF κ B, TNF α , IL12, IL10, myd88 was evaluated by ELISA and RT-PCR. Statistical analysis was performed by SPSS software.

Results: Expression of TLR2 was found to be significantly lower in severe malaria cases (6676.66 \pm 1396.13pg/ml) compared to malaria (7399.125 \pm 2612.334pg/ml). The paired follow-up mild malaria cases after recovery showed an increased level of TLR2 (9358.12 \pm 2168pg/m). Expression of CD14 was in concurrence with TLR2 data as shown: Severe (3.1 \pm 0.846%) < Controls (3.32 \pm 1.03%) < mild (4.25 \pm 1.72%); and increased on recovery in mild malaria paired samples of individuals (5.69 \pm 1.84%). Serum level expression of TNF- α was found to be down regulated in severe malaria (3.022 \pm 0.456pg/ml) compared to both mild malaria (3.5816 \pm 0.1877)(p=0.212) and healthy controls (3.015 \pm 0.876)(p=0.382). NF κ B protein expression levels were found to be down-regulated in the severe malaria cases (0.145 \pm 0.062) compared to mild (0.523 \pm 0.4932 μ g/ml)(p=0.114) and controls (0.378 \pm 0.1213)(p=0.687). Both increase in IL12 and IL10 expression was noted in mild and severe malaria cases compared to controls. The protein expression data was concurrent with mRNA data. TLR2 expression correlated positively with mCD14, TNF α , NF κ B levels and recovery.

Conclusions: TLR2 mediates recovery from malaria through modulation of key immunomodulators in association with mCD14, and has prognostic and therapeutic significance.

630

Effects of the host immune response against precedent infection on the establishment of successively infected gastrointestinal nematode

Ishiwata, K.

Jikei University School of Medicine, Department of Tropical Medicine, Tokyo, Japan

The fact that eggs of several species of soil-transmitted helminth are often detected in a sample of clinical stool examinations suggests that patients are usually infected with more than one species of gastrointestinal parasites. Host immune responses

against one species of infected parasite may affect other species of concurrently resident parasites. In this study, I examined effects of precedent infection of *Nippostrongylus brasiliensis* (Nb) on consecutively infected *Heligmosomoides polygyrus* (Hp). These two gastrointestinal nematodes dwell in the small intestine of mice, although the former is expelled by day 10 post-infection (pi) and the latter persists to infect over day 40 pi. Precedent Nb infection rendered both shortened infection period and impaired egg production performance (fecundity) of consecutively infected Hp. The impairment of fecundity was restored when the worms were transferred surgically into the small intestine of nude mice. This indicated that the impairment is reversible host immune-mediated effect. The impairment neither depends on antibodies nor mast cells, but depends on IL-4R signaling. When Nb was treated with pyrantel pamoate just before establishment of Hp in the intestinal lumen, the impairment was reduced. This suggested the importance of coexistence of Nb. The impairment is unlikely due to the nutritious competition between two species, because in IL-4Ra KO mice, that fail to expel Nb, the fecundity level of Hp of mixed infection was not significantly different from that of singularly infected Hp. These results suggest that precedent parasite infection disturbs prosperity of the consecutively infected parasite through the host immune response.

631

Antibody and complement interactions in human immunity to malaria

Kurtovic, L.^{1,2}, Feng, G.¹, Reiling, L.¹, Fowkes, F.¹, Kazura, J.³, Dent, A.³, Beeson, J.^{1,2}

¹Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ²Monash University, Department of Immunology, Melbourne, Australia, ³Case Western Reserve University, Cleveland, United States

Malaria is a major cause of global morbidity and mortality, particularly in young children. An efficacious vaccine is urgently needed; however, this has proven to be challenging as the targets and mechanisms of protective immunity are undefined. The sporozoite developmental stage of the malaria parasite is an attractive target that prevents the onset of blood-stage parasitemia and may induce sterile immunity. Leading vaccine candidate, RTS,S, is based on the sporozoite antigen, CSP. RTS,S-induced anti-CSP antibodies are associated with protection, however, it is unknown how these antibodies function. Antibody functions may include invasion-inhibition/neutralisation, opsonisation, lysis, and complement activation via C1q-fixation. Here we investigated if anti-CSP antibodies could fix complement, and whether this is an important immune mechanism against sporozoites.

Using cohorts of malaria-exposed individuals we characterised the prevalence and acquisition of anti-CSP antibodies, and measured their ability to fix complement proteins. Anti-CSP antibodies were predominately IgG1, IgG3 and IgM, and could effectively fix C1q and subsequent complement proteins. Little C1q-fixation was observed for samples that lacked acquired anti-CSP antibodies, indicating that complement activation was antibody-dependent. Additionally, we identified a specific CSP

epitope that is targeted by C1q-fixing antibodies. We also show evidence that sporozoites are susceptible to C1q-fixation and complement activation. This utilised human antibodies, and vaccine-induced antibodies generated in rabbits. Antibody-complement interactions may be important in immunity to malaria, and could lead to sporozoite neutralisation, invasion-inhibition, or direct lysis.

Defining the key functions of antibody-complement interactions will be valuable for understanding immunity to malaria and developing highly effective malaria vaccines.

Fighting at the frontier: chondroitin sulfate proteoglycans and the immune response to pathogens in the placenta

Randall, L.¹, Gunatillake, T.², Hasang, W.¹, Kirby, J.¹, Said, J.², Stephen, R.¹

¹The Peter Doherty Institute for Infection and Immunity and The University of Melbourne, Department of Medicine, The University of Melbourne, Australia, ²The University of Melbourne, Centre for Health, Research & Education, North-West Academic Centre, St Albans, Australia

During pregnancy, the maternal immune system is in an altered state. This allows a careful balance between the arms of the immune system so that the fetus is not rejected. Products produced by the placenta have a role in modulating the immune response. However, the placenta is also a site of choice for key pathogens that greatly impact the health of the mother and the infant. The malaria-causing parasite, *Plasmodium falciparum*, sequesters in the placenta by attaching to the glycosaminoglycan chondroitin sulfate A, which may lead to severe anaemia in the mother and poor outcomes in the baby. Proteins with glycosaminoglycan chains, known as proteoglycans, are often components of the extracellular matrix but they may have important immunomodulatory functions. Here, we characterise the chondroitin sulfate proteoglycans within the placenta. Chondroitin sulfate A and isolated placental chondroitin sulfate proteoglycans are tested for their ability to modulate the cellular immune response to *P. falciparum*-infected red blood cells, as well as to other parasite and bacteria products. The impact of infection on the expression of chondroitin sulfate proteoglycans in the placenta is also examined.

633

IgG antibody and cytokines in *Plasmodium vivax* infected individuals living in a low malaria transmission area in Amazon region, Pará state, Brazil

Santos, M.C.^{1,2}, Silva, A.N.¹, Oliveira, C.F.¹, Póvoa, M.M.³, Ventura, A.M.^{2,3}, Ohnishi, M.D.², Cunha, M.G.¹

¹Universidade Federal do Pará, Belém, Brazil, ²Universidade do Estado do Pará, Belém, Brazil, ³Instituto Evandro Chagas, Ananindeua, Brazil

Introduction: The acquired antibody immune response in malaria has been reported to antigens from asexual stage of the Plasmodium. Among the best characterized antigens of this stage is the Merozoite Surface Protein 1 (MSP1). However,

few studies have evaluated the acquisition of IgG antibody and cytokines in *Plasmodium vivax* malaria.

Objective: This study was conducted to analyze the IgG antibody response and TNF- α , INF- γ and IL-10 cytokines levels among infected individuals living in low malaria transmission area, where *P. vivax* is the most prevalent species.

Methods: The IgG antibodies against MSP119 and cytokines were evaluated by ELISA in sera from 99 malaria patients living in Pará state, Brazil. The median age was 35 years, 70% male and the median parasitaemia was 6,140 parasites/ μ l. The samples sera were collected on the day of parasite detection by thick blood smear (day0, n=99), and day14 (n=63). At the moment of diagnosis all patients received treatment.

Results: The percentage of sera that recognized the recombinant protein (PvHis6MSP119) was 96% (day0) and 98% (day14). At day0 we detected IL-10 and INF- γ , but not TNF- α . After treatment (day14), only INF- γ was detected, but the levels decreased in comparison to patent infection. The levels of this cytokine (pg/ml) were 31,64 \pm 74,94(day0) and 17,80 \pm 57,19 (day14). Both IgG and INF- γ response were detected in the sera before and after treatment.

Conclusion: The MSP1 was immunogenic and antibody response occurred together with INF- γ production. It suggests that INF- γ can participate in effector mechanisms mediated by IgG antibodies in *P. vivax* malaria.

The role of IL-17 in *Trichinella spiralis* infection

*Takamoto, M.*¹, *Yamanoi, M.*², *Nakayama, J.*²

¹Shinshu University School of Medicine, Department of Infection and Host Defense, Matsumoto, Japan, ²Shinshu University School of Medicine, Department of Molecular Pathology, Matsumoto, Japan

Differentiation of Th cell subsets influences one another. During nematode infection, Th2 immune response becomes dominant, therefore Th1 and Th17 cells are considered to play only limited role against nematode infection. In order to investigate the role of IL-17 in the protection against nematode infection, we infected mice lacking Th2 immune response (STAT6 KO) with an intestinal nematode, *Trichinella spiralis*. IFN- γ deficiency resulted in Th17 cell differentiation (Immunol Lett 127, 55-9, 2009), therefore STAT6 and IFN- γ receptor (GR) double KO (DKO) mice were compared to STAT6 KO littermates. Recovery of muscle larvae in DKO mice infected with muscle larvae were decreased compared to STAT6 KO mice. IL-17 production from the mesenteric lymph nodes was higher in DKO than in STAT6 KO mice. Mucus production and pathological change in the small intestine were now being investigated. Further experiments should be necessary also using GR KO and IL-17 KO mice.

Malaria-induced bone disorder triggered by chronic inflammation in the bone

*Lee, M.S.J.*¹, *Maruyama, K.*², *Ishii, K.J.*^{3,4}, *Akira, S.*², *Coban, C.*¹

¹Immunology Frontier Research Center (IFReC), Osaka University, Laboratory of Malaria Immunology, Osaka, Japan, ²Immunology Frontier Research Center (IFReC), Osaka University, Laboratory of Host Defense, Osaka, Japan, ³Immunology Frontier Research Center, Osaka University, Laboratory of Vaccine Science, Osaka, Japan, ⁴National Institute of Biomedical Innovation, Laboratory of Adjuvant Innovation, Osaka, Japan

Malaria is a life-threatening infectious disease that puts almost half of the world's population at risk. The disease can quickly develop into complication and cause death, or in some cases may leave the survivors with life-long sufferings due to chronic infection. Physical growth retardation in Africa is found to be associated with the burden of infectious diseases, with high prevalence among malaria-infected children regardless of nutritional status. This observation raises the concern that malaria infection could impose a detrimental effect on growth development. However, the pathology of malaria in bone has been an overlooked area that currently there are no studies directly addressing the effect of malaria on bone. In order to comprehensively understand the effect of malaria infection on bone, mice were infected with *Plasmodium* parasite to study the bone development during the acute phase of infection and the recovery phase after parasite clearance. The suppression of bone cells differentiation during acute infection brings bone development to a halt, rendering impaired bone growth. Nevertheless, once the infection is resolved, the exacerbate bone resorption leads to further bone loss. The parasite metabolite was found to accumulate in the bone during the clearance of parasites and remain there permanently, thereby eliciting chronic inflammation in a MyD88-dependent manner. These studies suggest the necessity of bone therapy and supplementation alongside antimalarial treatment to mitigate the risk of malaria-induced bone loss.

Plasmodium falciparum protein PfEMP1 modulates activation of transcription factors and dampens the cytokine and chemokine response from monocytes/macrophages

Sampaio, N.^{1,2}, *Eriksson, E.*^{1,2}, *Schofield, L.*^{1,3}

¹Walter and Eliza Hall Institute of Medical Research, Population Health and Immunity, Parkville, Australia, ²University of Melbourne, Department of Medical Biology, Parkville, Australia, ³James Cook University, Australian Institute of Tropical Health and Medicine, Townsville, Australia

Plasmodium falciparum-induced malaria is a serious global disease burden, with significant mortality rates amongst young children. Cells of the innate immune system are essential for anti-malaria immunity, where monocytes/macrophages play a central role in parasite killing and cytokine production. However, the cytokine response from these cells can also contribute to pathogenesis due to excessive inflammation.

Thus, understanding how protective and pathogenic cytokine responses are regulated is a vital step towards modulating this response in order to lower disease burden. *P. falciparum* Erythrocyte Membrane Protein 1 (PfEMP1) is an important virulence factor found on the infected red blood cell surface. It mediates parasite binding to host cells, and has high antigenic variation in order to evade detection by antibodies. Using transgenic PfEMP1-null parasite strains, we showed PfEMP1 significantly inhibits NF- κ B activation in RAW macrophages upon stimulus with trophozoite-stage infected red blood cells. PfEMP1 also modulated activation of CREB, IRFs and C/EBP- α , resulting in decreased expression of immune genes, and reduced TNF and IL-10 release from macrophages. Similarly, human primary monocytes released lower levels of IL-1 β , IL-6, IL-10, MCP-1, MIP-1 α , MIP-1 β and TNF in response to wild type PfEMP1-containing parasites, compared to PfEMP1-null parasites, suggesting this immune regulation by PfEMP1 is important in naturally occurring *P. falciparum* infections. Collectively this data indicates that PfEMP1 is an immune-inhibitory molecule that affects the activation of a range of transcription factors, dampening the cytokine and chemokine immune response. These findings could potentially have implications for management of cytokine-induced severe disease caused by *P. falciparum* infection.

Investigating the role of malaria-specific T cells in malaria pathogenesis

Ghazanfari, N., Gregory, J., Fernandez-Ruiz, D., Mueller, S.N., Heath, W.

The University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia

Human cerebral malaria causes a diffuse encephalopathy associated with coma and is responsible for most malaria-related deaths globally. The presence of CD8⁺ T cells is required for the development of cerebral malaria in mice. The mechanism underlying cerebral malaria pathogenesis is not well understood. To address this, we used intravital microscopy to image the brains in live animals undergoing malarial infection. We injected mice with antigen-specific PbT-I CD8⁺ T cells or antigen-specific PbT-II CD4⁺ T cells a day before infection with *Plasmodium berghei* ANKA (PbA) blood-stage parasites. Two-photon laser scanning microscopy was performed through a cover-slipped cranial window, which allows observation of the immune responses occurring in the brain in real time. CB57Bl/6 mice infected with PbA showed symptoms of cerebral malaria 5-7 days after infection. PbT-I and PbT-II T cells were both present in the brain blood vessels from day 4 post-infection and entered the brain parenchyma by day 5. Flow cytometric analysis after intravascular Ab labelling confirmed the accumulation of transgenic T cells as well as endogenous CD4⁺ and CD8⁺ T cells within the brain parenchyma of both acutely infected and long-term cured mice. The presence of PbT-I T cells in the brain of cured mice was also confirmed by intravital microscopy. These results suggest that both CD4⁺ and CD8⁺ T cells infiltrate the brain during experimental cerebral malaria, with some cells forming

long-term memory in this site. They also raise the possibility that infiltration of CD4⁺ T cells into the brain parenchyma may contribute to cerebral immunopathology.

RIPK1 and PGAM5 control Leishmania replication through distinct mechanisms

Farias Luz, N.¹, Balaji, S.², Okuda, K.³, Bertin, J.⁴, Gough, P.⁴, Gazzinelli, R.³, Bozza, M.⁵, Borges, V.¹, Ka-Ming Chan, F.²

¹Centro de Pesquisas Gonçalo Moniz- Fundação Oswaldo Cruz, Imuno Regulation, Salvador, Brazil, ²University of Massachusetts Medical School, Department of Pathology, Worcester, United States, ³University of Massachusetts Medical School, Division of Infectious Diseases and Immunology, Worcester, United States, ⁴Pattern Recognition Receptor Discovery Performance Unit, Immuno-Inflammation Therapeutic Area, GlaxoSmithKline, Collegeville, United States, ⁵Universidade Federal do Rio de Janeiro, Departamento de Imunologia, Instituto de Microbiologia, Rio de Janeiro, Brazil

Leishmaniasis is an important parasitic disease found in the tropics and sub-tropics. Human infection is mediated by phlebotomic bites from sand flies. The two major forms of the disease affect the skin and visceral organs and are referred to as cutaneous and visceral leishmaniasis respectively. Cutaneous and visceral leishmaniasis affect an estimated 1.5 million people worldwide. Despite its human health relevance, relatively little is known about the host immune mechanisms that control Leishmania replication. Necroptosis is a recently identified form of cell death with potent anti-viral effects. RIPK1 is a critical kinase that mediates necroptosis downstream of death receptors and toll-like receptors. Heme, a product of hemoglobin catabolism during certain intracellular pathogen infections, is also a potent inducer of macrophage necroptosis. In this study, we examined the impact of heme and necroptosis on Leishmania replication. We found that although heme potently inhibited Leishmania replication in bone marrow derived macrophages (BMDMs), Leishmania did not induce extensive necroptosis. Surprisingly, inhibition of RIPK1 kinase activity dramatically enhanced parasite replication in BMDMs and in mice. We further found that phosphoglycerate mutase family member 5 (PGAM5), a downstream effector of RIPK1, was also required for inhibition of Leishmania replication. In mouse infection, both PGAM5 and RIPK1 kinase activity are required for IL-1 β expression in response to Leishmania. However, PGAM5, but not RIPK1 kinase activity, was directly responsible for Leishmania-induced IL-1 β secretion in BMDMs. Collectively, these results revealed that RIPK1 and PGAM5 function independently to exert optimal control of Leishmania replication

639

IL-17 is associated with protection in human visceral leishmaniasis*Singh, O.P.¹, Ansari, N.², Kumar, R.¹, Nylen, S.³, Rai, M.¹, Sacks, D.², Sundar, S.¹*¹Banaras Hindu University, Medicine, Varanasi, India, ²National Institute of Allergy and Infectious Diseases, National Institute of Health, Bethesda, United States, ³Karolinska Institutet, Department of Microbiology Tumor and Cell Biology, Stockholm, Sweden

Visceral leishmaniasis (VL) is a potentially fatal parasitic disease that impose a huge health problem on the vulnerable population claiming the lives of 0.2- 0.4 million worldwide. Better understandings of disease pathogenesis that dampen the immune response are critical for controlling the disease. We had previously shown the role of IL-27 and IL-21 in differentiation and expansion of antigen-specific IL-10 producing T cells and inhibition of Th17 differentiation in VL patients. Here, we investigated the IL-17 association with protection in human VL. We found elevated mRNA expression of indolamine 3-3-dioxygenase in VL patients, the enzyme that negatively regulates T-cell effector function during infection. No up-regulation of IL-17 or ROR γ T mRNA expression in spleens cells and plasma IL-17 levels were detected in active VL, however significantly elevated mRNA levels of both subunits of IL-23 were detected in post treated VL splenic biopsies compared to active patients. IFN- γ or/and IL-10 neutralization does not affect IL-17 levels in whole blood cells of active VL and 6 months cured VL. However, plasma IL-17 and IFN- γ levels were elevated in 6 month cured VL which were further enhanced with SLA stimulation in whole blood. Analysis of Th17/Th1 cytokines response in subjects from a cohort of endemic healthy individuals who were protected against VL showed that IL-17 is strongly associated with protection against VL. These findings were further supported by enhance parasite clearance with recombinant IL-17 (rhIL-17) and rhIFN- γ by inducing TNF- α mRNA and down regulating IL-10 in monocyte derived macrophages infected with *L. donovani* amastigote.

Infectious status of sporozoites evokes innate response, leading to cell-mediated protective CD8+T cell response against Plasmodia infection*Parmar, R., Patel, H., Yadav, N., Tyagi, R., Dalai, S. Institute of Science, Nirma University, Biotechnology, Ahemdabad, India*

Multiple immunizations with radiation-attenuated sporozoites has reportedly conferred sterile-protection against liver stage infection of plasmodia. It is reflective of immunity in endemic areas where people are repeatedly exposed to parasite and maintain their anti-malarial immunity. CD8⁺T cells are the major effector cell populations which extends protective immunity against liver-stage infection. The infectious status of sporozoite has played an instrumental role in liver stage immunity, and impact the host response, which leads to CD8⁺T cell response in rendering sterile-protection. Present study shows that innate immunity induced by infectious spz challenge is qualitatively

different, and helps rescue the loss of CD8⁺T cell response as has been observed in γ -spz immunization without intermittent challenge. The danger signals perceived from the pathogen attack are decisive in establishing the nature of innate immune response, leading to long-term protection. The initial host response against the pathogen might dictates the protective memory response, and encompasses an array of innate immune factors. The DCs are an indispensable component of priming and generation of CD8⁺T cell responses. However, their role in evoking the long-term protective immunity to *Plasmodia* liver stage infection is still not clear. Present study assesses *plasmodium* infection to measure host innate response by the generation of long-lived protective CD8⁺T cells in the liver. In conclusion, our results suggest that infectious status of sporozoites may influence the maintenance of protective CD8⁺T cell response by modulating the activation status of DCs.

Acquisition and longevity of antibodies to Plasmodium vivax pre-erythrocytic antigens in western Thailand*Longley, R.^{1,2,3}, Reyes-Sandoval, A.⁴, Montoya-Diaz, E.⁴, Dunachie, S.^{5,6}, Kumpitak, C.², Nguitragoon, W.⁷, Mueller, I.^{1,3,8}, Sattabongkot, J.²*¹Walter and Eliza Hall Institute of Medical Research, Population Health and Immunity, Melbourne, Australia, ²Mahidol University, Mahidol Vivax Research Unit, Bangkok, Thailand, ³University of Melbourne, Department of Medical Biology, Melbourne, Australia, ⁴Jenner Institute, Oxford, United Kingdom, ⁵Mahidol University, Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, ⁶University of Oxford, Centre for Tropical Medicine, Oxford, United Kingdom, ⁷Mahidol University, Department of Molecular Tropical Medicine, Bangkok, Thailand, ⁸Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain

Plasmodium vivax (Pv) is the dominant species causing malaria in Thailand, yet little is known about naturally acquired immune responses to Pv in this low-transmission region. The pre-erythrocytic antigens Pv CSP, TRAP and CelTOS are currently being assessed pre-clinically as potential vaccine candidates. We therefore aimed to assess naturally acquired antibody responses to these proteins in an endemic region of western Thailand. We utilized a cross-sectional survey of 546 volunteers to demonstrate a strong association of increasing IgG positivity and magnitude with age, and in individuals currently infected with *Plasmodium*. Of interest, for CSP only, we found a significantly higher IgG magnitude in asymptomatic Pv infected volunteers compared to those uninfected, but observed no increase in magnitude in symptomatic Pv cases. We also utilized samples from a longitudinal cohort study to investigate the stability of these IgG responses. Two groups of individuals were assessed: one group whom remained Pv-free (by qPCR detection, n=98) and another whom experienced two or more blood-stage Pv infections during the year of follow up (n=50). IgG positivity was maintained over the one-year period in the absence of Pv infections. In contrast, for most proteins we saw a slight but significant decline in IgG magnitude over time. The exception was for CSP, where IgG magnitude was long-lived in the absence of on-going exposure, and only decreased

significantly over time in exposed volunteers. These findings demonstrate the presence of antibody responses to pre-erythrocytic antigens in Thailand, and show that long-lasting humoral immunity can develop in low-transmission regions.

642

TNF deficiency leads to splenomegaly following cutaneous infection with *Leishmania major*

Hu, S.^{1,2}, Marshall, C.¹, Darby, J.¹, Lyons, A.B.³, Körner, H.¹

¹Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, ²Institute of Clinical Pharmacology, Anhui Medical University, Hefei, China, ³School of Medicine, University of Tasmania, Hobart, Australia

Cutaneous leishmaniasis in resistant C57BL/6 (B6.WT) mice is resolved spontaneously by Th-1 mediated production of TNF- α and IFN- γ , with consequent induction of inducible nitric oxide synthase. Intriguingly, TNF gene knockout C57BL/6 mice (B6.TNF^{-/-}) show an uncontrolled fatal infection involving the liver and spleen, which are the two main targets in visceral leishmaniasis. The exact role of TNF or the specific mechanism, which is responsible for the fatal outcome of *Leishmania* infection in this gene-deficient mouse strain, is not yet understood.

B6.TNF^{-/-} mice spleens significant enlarged from Day 28 post-infection, with increasing more than 2-fold larger than B6.WT mice on Day 35 and Day 42. A limiting dilution assay showed *Leishmania major* (*L. major*) was present from Day 21 in B6.TNF^{-/-} mice, but none were evident in B6.WT mice. The splenic architecture of infected B6.TNF^{-/-} mice was disorganized, *L. major* detectable throughout the spleen and a significant lymphoid cell infiltration.

A growing population of inflammatory bone marrow-derived cells emerged in the spleens of *L. major*-infected B6.TNF^{-/-} mice, exhibiting a CD45⁺CD11b⁺CD11c^{high}CCR2⁺Ly6C⁺ phenotype and, surprisingly, a strong expression of F4/80. *In vitro*, at steady state, macrophages from B6.TNF^{-/-} mice showed no difference compared to B6.WT. After exposure with *L. major* promastigotes, they showed potential M2-like phenotype succumbing more easily to infection.

We are currently sorting this population from B6.TNF^{-/-} mice and examining the characteristics and potential downstream mechanisms that may affect the immunity against *L. major* infection in the absence of TNF.

643

Clec9a⁺CD8⁺ DCs are key players in controlling *Plasmodium chabaudi chabaudi* AS infection

Lai, S.M.^{1,2}, Gupta, P.¹, Renia, L.², Ruedl, C.¹

¹Nanyang Technological University, SBS, Singapore, Singapore,

²Singapore Immunology Network (SigN), A*STAR, Singapore, Singapore

Plasmodium chabaudi chabaudi AS (*PccAS*) causes both acute and chronic malaria in mice. Dendritic cells (DCs), so-called immune "sentinels", are key players involved in establishing both acute-phase and parasite-specific adaptive immune responses. Functionally distinct and phenotypically heterogeneous DC

subsets have been identified, but their exact contribution in chronic malaria has yet to be elucidated. Using a Clec9A-diphtheria toxin receptor (DTR) transgenic mouse, wherein CD8⁺ and CD103⁺ DCs are specifically ablated following DT administration, has enabled us to study *in vivo* the role of this particular DC subset in controlling blood-stage *PccAS* infection. C57BL/6J-Clec9A-DTR mice exhibit high acute-phase parasitemia with significant recrudescence episodes, in stark contrast with wild-type mice which present sub-patent recrudescence. These mice also display significantly compromised IFN γ production, effector T-cell poly-functionality and an overall systemic skewing towards anti-inflammatory IL-10 response. Additionally, antibody isotype imbalance was clearly observed in Clec9A-DTR mice; with high levels of T_{h2}-skewed *Plasmodium*-specific IgG1 as opposed to strongly T_{h1}-inclined IgG2c responses in wild-type mice. In fact, infected Clec9A-DTR serum, when passively transferred into C57BL/6J wildtype recipients, was not as protective against *PccAS* infection as infected wildtype serum. Our findings suggest that Clec9a⁺CD8⁺ DCs are key players in mediating anti-*PccAS* immunity, culminating in robust effector T-cell functions and T_{h1}-inclined polarization of *Plasmodium*-specific antibody responses, both of which are required for protective immunity against *PccAS* infection.

Immune-modulation by a Novel *Leishmania* antigen facilitates faster clearance of intracellular parasites from infected macrophages and synergizes with anti-leishmanial drugs

Arora, S., Tiwari, A.

PGIMER, Immunopathology, Chandigarh, India

Disturbed balance of host-parasite interaction during active disease and limited success of anti-leishmanial drugs rationale the use of immunomodulators as a feasible alternative. The high toxicity and developing resistance of anti-leishmanial drugs endorse the need for development of novel alternative approaches. We evaluated the immunotherapeutic properties of novel *Leishmania* recombinant antigens (recAg) in terms of macrophage activation and intracellular parasite clearance alone as well as in combination with standard anti-leishmanial drugs, in order to assess the potential use of immunomodulators for early clearance of intracellular parasites along with sub-optimal doses of anti-leishmanial drugs, that way reducing the toxicity also. Percentage of cells producing intracellular NO (14.25 \pm 2.76%) and ROS (30.6 \pm 3.51%) as assessed by flow cytometry using DAF-2DA and DCF-2DA dyes, were significantly increased among peritoneal macrophages when stimulated with recAg. Treatment of infected macrophages with recAg enhanced their phagocytic (47.00 \pm 3.46) as well as killing index (33.97 \pm 2.48) that coupled with increased intracellular parasite clearance. The recAg showed synergistic effect with miltefosine causing almost complete clearance of amastigotes at sub-optimal drug dose (10 μ M) at 48 h and significantly reducing

the number of infected cells. A concomitant increase in the production of inflammatory cytokines, IL-6 (3026.38±324.53), TNF- α (357.03±38.34) and MCP-1 (3574.74±784.62) was also observed when infected cells were stimulated with recAg. The leishmania recAg potentiates effector functions of parasitized macrophages and synergizes with antileishmanial drug miltefosine in early clearance of parasites at suboptimal drug dose, thus placing it as a promising candidate for adjunct therapy.

645

IL-17 regulates permissiveness to infection with *Leishmania donovani*

Frame, T., Rivera, F., Engwerda, C., Beattie, L.

QIMR Berghofer Medical Research Institute, Herston, Australia

Visceral leishmaniasis occurs when *Leishmania* parasites infect tissue resident macrophages in the visceral organs, primarily in the liver, spleen and bone marrow. IL-17 is a pro-inflammatory cytokine that plays a crucial role in host defence against microbial infection. Studies in various pathogen infection models have shown control of pathogen growth to be dependent on IL-17 production. We have shown an increase in IL-17-producing cells in the liver early after *Leishmania donovani* infection, predominantly from CD4, CD8 and $\gamma\delta$ T cells. Unexpectedly, IL-17-deficient mice had lower liver parasite burdens, suggesting that IL-17 is playing a deleterious role in the control of *L. donovani*. The lower parasite burdens were independent of nitric oxide or super oxide induction in IL-17-deficient mice, indicating that a novel pathway for parasite control is at play. Using intravital 2-photon microscopy, we saw no difference in behaviour of IL-17-producing cells between naïve and treated mice. Flow cytometry allowed us to observe an enhanced immune cell response in the presence of IL-17, suggesting that IL-17 is not immune-suppressive. Instead, we hypothesise that IL-17 impairs parasite growth by regulating the availability of nutrients within macrophages, possibly via regulation of essential metals including iron, zinc and copper. These results will be discussed.

646

Role of heme oxygenase-1 in the pathogenesis and immune regulation during *Fasciola hepatica* infection

Carasi, P.^{1,2}, Rodriguez, E.¹, Anegón, I.³, Freire, T.¹

¹Facultad de Medicina, Universidad de la Republica, Inmunobiología, Montevideo, Uruguay, ²Facultad de Ciencias Exactas, UNLP, Microbiología General, La Plata, Argentina, ³Centre Hospitalier Universitaire de Nantes, Faculté de Médecine, INSERM UMR 1064-ITUN, Nantes, France

Fasciola hepatica is a prevalent helminth parasite that affects mainly livestock and humans. Infection results in polarization of the host's immune response and generation of a modified type-2-helper (Th2) immune response characterized by the secretion of classical Th2 molecules and high quantities of potent regulatory cytokines (IL-10, TGF β). Heme oxygenase-1 (HO-1), an enzyme with anti-inflammatory and antioxidant

properties, has become an interesting target in transplantation, oncology and infectious diseases due to its ability to modulate immune responses. The aim of this work was to evaluate the involvement HO-1 in *F. hepatica* pathogenesis and in the host immune regulation induced by this parasite. Infected animals with *F. hepatica* expressed high levels of HO-1 in the liver and a recruitment of F4/80⁺ HO-1⁺ cells in the peritoneal cavity. To evaluate the immune-regulatory role of HO-1, the enzyme was chemically induced or inhibited, using CoPP and SnPP respectively, in *F. hepatica*-infected mice. SnPP-treated animals presented lower levels of liver damage and production of IL-4, IL-5 and IL-10. In addition, there was a significant decrease in the expression of the regulatory molecules TGF β and FIZZ by the livers from SnPP-treated animals. Finally, HO-1 induction by CoPP-treatment in infected animals was associated with higher levels of liver damage and TGF β -production by the liver as compared to infected-animals. Taken together these results suggest that HO-1 is involved in the immunoregulatory mechanisms elicited by *F. hepatica* in the mammalian host and in its pathogenesis.

Dissecting the functional effector responses mediated by human IgG subclasses against *Plasmodium falciparum* merozoites

Irani, V.^{1,2}, Tan, P.S.³, Guy, A.^{1,4}, Andrews, D.¹, Sanders, P.¹, Feng, G.¹, Reiling, L.¹, Alagesan, K.^{5,6}, Kolarich, D.⁵, Lahoud, M.³, Beeson, J.^{1,2}, Ramsland, P.^{1,7}, Richards, J.^{1,2}

¹Centre for Biomedical Research, Burnet Institute, Melbourne, Australia, ²University of Melbourne, Department of Medicine, Parkville, Australia, ³Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ⁴Monash University, Department of Immunology, Melbourne, Australia, ⁵Max Planck Institute of Colloids and Interfaces, Department of Biomolecular Systems, Potsdam, Germany, ⁶Institute of Chemistry and Biochemistry, Freie Universität Berlin, Berlin, Germany, ⁷School of Science, RMIT University, Melbourne, Australia

Naturally-acquired antibody responses against malaria antigens play an important role in protecting individuals from malaria endemic areas from symptomatic malaria. Some antibodies target merozoites, the extracellular form of blood-stage parasites, and are able to inhibit erythrocyte invasion. Naturally-acquired antibodies to different merozoite antigens are typically skewed towards IgG1 or IgG3 responses. Even though both subclasses are considered to be cytophilic antibodies, the specific differences in their effector responses are unclear and the observations that IgG3 responses are generally more strongly associated with clinical protection remain unexplained. It is therefore unclear whether optimal vaccine induced responses need to induce IgG1 or IgG3 responses, or if there are no significant functional differences.

To assess this, we chose to make IgG subclass switch variants in which chimeric recombinant antibodies that contained the same Fv region were combined with different human IgG subclass backbones. We chose well-characterised invasion inhibitory monoclonal antibodies to merozoite antigens that are

leading vaccine candidates (mAb R217 against EBA-175; mAb 1F9 against AMA-1; and mAb QA1 against Rh5). We expressed these subclass switch antibodies recombinantly in HEK293F cells and examined differences in effector responses in various *in vitro* functional assays. As expected, these subclass switch mAbs demonstrated the same epitope-specificity, affinity, and glycosylation patterns. Significant differences were observed for complement fixation. These findings suggest that human IgG subclasses do mediate differences in functional immunity against *P. falciparum*. This work increases our understanding of the IgG subclass contributions to natural immunity and helps design an effective vaccine against *P. falciparum*.

Polymer nanoparticles in malaria: a dual role in targeted drug delivery and in vaccination approaches

Fernández-Busquets, X.^{1,2}, Marques, J.¹, Ranucci, E.³, Ferruti, P.³, Manfredi, A.³, Vilanova, E.⁴, Mourão, P.⁴

¹Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain,

²Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain,

³Università degli Studi di Milano, Milano, Italy, ⁴Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Most malaria vaccination strategies rely on antigens present in laboratory-maintained parasite strains. Because of the high clonal variability that *Plasmodium* exhibits in the wild, when these vaccines reach their clinical application after over a decade of product development and clinical trials, the original antigens might have disappeared from the parasites circulating in the human population. In addition, in each person are found several pathogen strains in a typical malaria infection in high-transmission endemic areas, which will dramatically reduce the efficacy of prophylaxis based on only a predetermined set of antigens. These could be some of the reasons why current malaria vaccines in clinical assays do not offer prospects of complete protection. Experimental evidence presented here and elsewhere has shown that malaria parasites are targeted by different sulfated polysaccharides and polyamidoamines, which in turn bind plasmodia from widely diverging malarias. The antiparasitic mechanism of these natural and synthetic polymers operates through inhibition of *Plasmodium* invasion of red blood cells. The failure of egressed parasites to quickly invade a new host cell will expose the pathogen to the immune system for a longer time, representing a new vaccination concept that requires the existence of an active malaria infection at the time of administration. This strategy is not a classical vaccine because it is not administered before contact with the pathogen, but the resulting prophylactic effect would provide protection against all the *Plasmodium* strains infecting the patient at the moment of treatment. Grants: 2013-0584 (Fondazione Cariplo, Italy), BIO2014-52872-R (MINECO, Spain, including FEDER funds).

Human dendritic cell interactions with *P. falciparum* provide insight into the development of host immunity to malaria

Yap, X.Z.^{1,2}, Lundie, R.J.^{1,3}, Macri, C.F.³, Leal Rojas, I.⁴, Feng, G.¹, Radford, K.J.⁴, Beeson, J.G.^{1,2,3}, O'Keefe, M.³

¹Burnet Institute, Melbourne, Australia, ²University of Melbourne, Parkville, Australia, ³Monash University, Clayton, Australia, ⁴University of Queensland, Mater Research Institute, Woolloongabba, Australia

Malaria is an urgent global health problem and there is a need for effective malaria vaccines. However, interactions between the malaria parasite *P. falciparum* and host immune cells are poorly understood. Little is known about *P. falciparum* interactions with human dendritic cells (DCs). Due to the integral role of DCs in immune regulation, understanding how they respond to *P. falciparum* will be vital for development of malaria vaccines. Furthermore, due to the heterogeneity of the DC population it is important to understand how different DC subsets and tissue microenvironments affect antimalarial responses.

We investigated DC responses to *P. falciparum* using human peripheral blood DCs and spleen and bone marrow (BM) DCs from a humanised mouse model. DC responses were measured to two parasite stages: an extracellular stage (merozoite) and an intracellular stage (parasitized red blood cell; pRBC). We also investigated the effect of the parasite-to-DC ratio on DC activation.

Human blood DCs did not upregulate activation markers upon exposure to *P. falciparum* merozoites or pRBCs. Furthermore, pRBCs suppressed DC activation by TLR ligands in a dose-dependent fashion. For splenic and BM DCs, merozoites induced low levels of DC activation while pRBCs induced similar suppressive patterns to those seen in human blood DC.

Our findings reveal that DC activation in response to *P. falciparum* is limited and that pRBCs can suppress DC activation, even in the presence of other positive stimuli. This has key implications in understanding vaccine development and immunity to malaria.

Immunity to Viruses

Highly pathogenic avian influenza virus causes severe symptoms due to insufficient contact between DCs and T cells

Ikejiri, A.¹, Yasui, F.¹, Kitabatake, M.², Sakaguchi, N.^{1,3}, Kohara, M.¹

¹Tokyo Metropolitan Institute of Medical Science, Department of Microbiology and Cell Biology, Tokyo, Japan, ²Nara Medical University, Department of Immunology, Nara, Japan, ³Osaka University, WPI Immunology Frontier Research Center, Osaka, Japan

Background: Highly pathogenic avian influenza virus (H5N1) infection causes severe symptoms resulting in an elevated mortality rate. However, the reason why patients cannot eliminate the viruses and succumb to them is not well known. We investigated temporal changes of the humoral immune response in mouse infected with low pathogenic pandemic

H1N1 or highly pathogenic H5N1 viruses. Mice infected with H5N1 could not induce sufficient neutralizing antibodies compared to H1N1. To clarify the insufficient induction of antibodies against H5N1, we focused on the antigen-presenting cells including dendritic cells (DCs) and macrophages.

Methods: BALB/c mice were infected with A/Tokyo/2619/2009 (H1N1) or A/Whooper swan/Hokkaido/1/08 (H5N1). To reinforce antibody responses after H5N1 infection, mice were inoculated intradermally with H5 HA protein-expressing recombinant vaccinia virus (rVV-H5 HA) 5 weeks before H5N1 challenge. After infection, spleens were collected to verify the localization of antigen-presenting cells by immunofluorescent staining.

Results and conclusion: The localization of macrophages in marginal zone and follicular DCs in germinal center were similar in the spleens of mice infected with H1N1 and H5N1. While the interaction of CD11c⁺ DCs with T-cells of mice infected with H5N1 decreased compare to H1N1. And the cell-cell contact between DCs and T-cells was loose and thin in H5N1 group. Furthermore, mice sensitized with rVV-H5 HA produce sufficient antibody and recovered the tight interaction of DCs with T-cells. These results imply that the severe symptom in H5N1 virus infection was associated with interaction of DCs with T-cells to induce efficient neutralizing antibodies.

S1, a Cytomegalovirus encoded SLAMF6 homolog captured from the host by retrotranscription

Angulo, A.¹, Martinez-Vicente, P.², Farré, D.¹, Pérez-Carmona, N.¹, Engel, P.¹

¹University of Barcelona, Cell Biology, Immunology and Neurosciences, Barcelona, Spain, ²Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Cytomegaloviruses (CMVs) are ubiquitous, species-specific members of the herpesvirus family that have evolved multiple mechanisms to dampen host immune defenses and establish lifelong infections. Thus, CMVs contain a copious arsenal of gene products with immunomodulatory roles, including homologs of cellular immune proteins captured from their hosts during co-evolution. We have previously reported the presence of a number of homologs of signalling lymphocytic activation molecule (SLAM) family receptors in CMVs that infect human and other primates. Among them, squirrel monkey CMV (SMCMV) encodes a homolog of SLAMF6, a molecule expressed on the surface of NK, T and B cells and known to modulate immune functions through homotypic interactions. This viral homolog, S1, is a glycoprotein that exhibits an overall identity of 77% with the host SLAMF6 (*Saimiri boliviensis* SLAMF6, sbSLAMF6), including a nearly complete identity (97%) on its ligand-binding N-terminal immunoglobulin domain. Accordingly, we demonstrate that S1 specifically interacts with sbSLAMF6 and it is a self-binding protein. Furthermore, an S1-Fc fusion protein blocks sbSLAMF6 homotypic interactions. Interestingly, the interactions between the viral protein and sbSLAMF6 or between sbSLAMF6-sbSLAMF6 are stronger than human SLAMF6 homophilic interactions. We have generated a number of monoclonal antibodies (mAbs) that selectively recognize S1, sbSLAMF6 or both molecules, being some of them able

to target S1-sbSLAMF6 or sbSLAMF6-sbSLAMF6 interactions. Using anti-S1 mAbs we find S1 abundantly expressed at the cell surface during SMCMV infection. A detailed characterization of S1 should provide important information on how pathogens exploit in a novel manner SLAMF6-mediated pathways to suppress host surveillance.

The role of intrinsic and aeroallergen-specific immune responses in the heightened susceptibility of atopics to respiratory viral infections: rat model studies

Jones, A.¹, Lauzon-Joset, J.-F.¹, Mincham, K.¹, Thomas, J.¹, Szakaly, R.², Rosenthal, L.², Bosco, A.¹, Holt, P.¹, Strickland, D.¹

¹Telethon Kids Institute, The University of Western Australia, Subiaco, Australia, ²University of Wisconsin School of Medicine and Public Health, Department of Medicine, Madison, United States

Background: Common (usually benign) respiratory infections exemplified by rhinovirus (HRV) can trigger asthma exacerbations requiring hospitalization in atopics. It is unclear whether sensitization plays a direct role in this context, or whether generic features of the underlying Th2high atopic immunophenotype are responsible for this effect.

Objective: To elucidate the cellular and molecular mechanisms underlying susceptibility to respiratory infection-induced asthma exacerbations in atopics, employing an animal model.

Methods: Our model comprised Th2high (atopic equivalent) BN rats and immunologically normal (non-atopic) PVG rats, unsensitized and OVA-sensitized. The animals were inoculated intranasally with attenuated HRV-like mengovirus, with or without aerosol exposure to OVA, and cellular and transcriptomic profiling was performed on bronchoalveolar lavage (BAL).

Results: Cellular profiling identified a strong neutrophilic response in PVG BAL at 24 hours post-infection, whilst the BN response was bimodal, characterised by peaks in macrophages (with minimal neutrophils) at 24 hours and 9 days post-infection. The acute BAL-cell transcriptome in infected PVGs displayed strong upregulation of genes associated with Th1/type1 interferon pathways, in contrast to a Th2-associated response in BNs including IL-33. OVA challenge of sensitized/infected BNs (not PVGs) triggered strong airways eosinophilia and exaggerated type1 interferon gene signatures, comparable to virus-associated exacerbations in human atopic asthmatics.

Conclusion: Intrinsic, and particularly acquired defects in anti-viral defence mechanisms triggered by co-exposure to aeroallergen, contribute to hypersusceptibility to infection-associated airways inflammation characteristic of the Th2high immunophenotype. These findings provide a plausible rationale for therapeutic targeting of aeroallergen-specific immunity in human atopics for prevention of virus-associated severe asthma exacerbations.

Viral activation of RIG-I and STING pathways can induce necroptotic cell death

Schock, S., Chandra, N., Coscoy, L., Winoto, A.
UC Berkeley, Molecular and Cell Biology, Berkeley, United States

Necroptosis is a form of necrotic cell death that requires the activity of the death domain-containing kinase RIP1 and its family member RIP3. Necroptosis only occurs in apoptotic resistant cells and when RIP1 is de-ubiquitinated to form a complex with RIP3. Necroptosis may play a role in host defense through the release of inflammatory danger signals. We thus hypothesized that some viruses can induce necroptosis. We report here that among six different viruses surveyed, two of them, are capable of inducing necroptosis in the murine fibrosarcoma L929 cell line, especially when caspases are also inhibited. We found that one of the viruses induces cell death through the STING DNA sensor pathway in a TNF-dependent manner. In contrast, the other virus induces death through a TNF-independent manner. Knockdown of the RNA sensing molecule RIG-I or the RIP1 de-ubiquitin protein, CYLD but not STING, rescued cells from necroptosis induced by the latter virus. Mutant virus lacking some of the non-essential viral proteins is partially defective in its necroptotic activities. Together, these data identify viruses capable of programmed necrosis with divergent molecular pathways leading to death.

Characterising nAb responses and B cell phenotypes in early primary HCV infection

Wu, B.-R., Walker, M.R., Eltahla, A., Lloyd, A.R., Bull, R.A.
University of New South Wales, Inflammation and Infection Research Centre, School of Medical Sciences, Faculty of Medicine, Sydney, Australia

Development of early and broad neutralising antibodies (nAbs) has recently been associated with clearance of hepatitis C virus (HCV) infections. However, it is unclear what factors are associated with the differential development of nAb responses in individual subjects. Successful nAb responses are derived from a robust B cell maturation and differentiation pathway. There is existing evidence to indicate that B cell development is skewed in late chronic HCV infection, with increasing immature and tissue-like B cells. In the present study, we aim to understand the correlation between HCV-specific B cell phenotypes, and the timing and breadth of nAbs in primary infection. Early incident subjects with peripheral blood mononuclear cells (PBMCs) and plasma were collected fortnightly over 24 weeks before clearance (n=7) or chronicity (n=7) is resolved. Neutralisation activity was determined against autologous HCV pseudoparticles (HCVpp) and a library of heterologous HCVpp representing all genotypes. A multichannel flow cytometric analysis is being performed to identify B lymphocyte subpopulations in the longitudinally-collected samples, using add some key markers. To-date, nAb responses targeting autologous virus have been measured in one subject that spontaneously cleared HCV. nAbs were detectable from 5 days post-infection (DPI) and gradually increased before

peaking at ~58 DPI and then persisted after clearance. The peak in nAb correlated with a decrease in viral load and subsequent clearance, suggesting nAbs contributed to clearance. We hypothesise that HCV-induced B cell skewing will be observed in those who become chronically infected and cause the loss of nAb responses thereby contributing to viral persistence.

Abrogation of the interferon response promotes more efficient human cytomegalovirus replication

McSharry, B.P.¹, Forbes, S.K.^{1,2}, Ashley, C.¹, Avdic, S.¹, Randall, R.E.³, Wilkinson, G.W.G.⁴, Abendroth, A.¹, Slobedman, B.¹

¹University of Sydney, Infectious Diseases and Immunology, Sydney Medical School, Sydney, Australia, ²Westmead Institute for Medical Research, Centre for Virus Research, Sydney, Australia, ³University of Saint Andrews, School of Biology, Saint Andrews, United Kingdom, ⁴Cardiff University School of Medicine, Department of Medical Microbiology, Cardiff, United Kingdom

Human cytomegalovirus (HCMV) is a ubiquitous virus that is associated with severe morbidity and mortality in immunocompromised individuals and is the major infectious cause of birth defects in the developed world. Interferons (IFNs) are innate immune cytokines known to play a crucial role in controlling cytomegalovirus replication exemplified by the number of virally encoded gene products that limit the production of and/or the action of IFNs. However to our knowledge the effect of disabling the IFN response on HCMV replication has not been previously investigated. The effect of such an abrogation of the interferon response on HCMV infection and replication was examined using primary human fibroblast cell lines expressing either the V protein of Parainfluenza type V or the nPro protein of Bovine Viral Diarrhoea Virus that block the response to or the production of type I IFNs, respectively. In these IFN-defective cell lines, although there was no enhancement of the efficiency of initial infection, a number of different HCMV strains (both UL128L⁺ and UL128L⁻) produced significantly larger plaques compared to control cells. The virus also spread and replicated more rapidly than in parental fibroblasts demonstrating the key role of IFN- β in controlling viral replication. In addition, these cell lines facilitated the study of IFN stimulated gene (ISG) upregulation/induction post HCMV infection identifying ISGs directly regulated by HCMV independently of interferon e.g. ISG15. These cell lines demonstrate the vital role of IFNs in controlling HCMV replication and provide useful tools to further investigate the IFN response to HCMV.

Varicella zoster virus ORF63 protects cells from staurosporine-induced apoptosis

Gerada, C., Steain, M., McSharry, B., Slobedman, B., Abendroth, A.
The University of Sydney, Infectious Diseases and Immunology, Camperdown, Australia

Varicella zoster virus (VZV) is a human alphaherpesvirus that causes varicella (chickenpox) during primary infection.

During varicella, VZV establishes life long latency in the dorsal root ganglia and can later reactivate to cause herpes zoster (shingles). The mechanisms by which VZV establishes latency and can later reactivate to cause herpes zoster are not fully understood; however it has been suggested that viral inhibition of neuronal apoptosis plays an important role. Apoptosis is a critical component of the intrinsic, innate and adaptive immune response to viral infection, as it allows for rapid elimination of infected cells without causing excessive inflammation. We have previously shown that VZV ORF63 can inhibit neuronal apoptosis, however the mechanism of action is unknown. To study the effects of VZV ORF63 on the apoptosis pathway, human foreskin fibroblasts (HFFs) were transduced with a novel lentivirus encoding VZV ORF63, with expression and functionality of ORF63 confirmed via western blotting and immunofluorescence assay (IFA) analysis. Apoptosis was induced through treatment with a protein kinase inhibitor, staurosporine, and the percentage of apoptotic cells was determined via the detection of cleaved caspase 3 (CC3) and DNA fragmentation (TUNEL) by IFA. Comparison of ORF63 expressing HFFs to parental transduced HFFs revealed a statistically significant reduction in CC3 and TUNEL positive cells with ORF63 expression. Together these data indicate that VZV ORF63 protects HFFs from staurosporine-induced apoptosis. Furthermore, this work validates a model that could be applied to determine the mode of action of VZV ORF63 in the protection of neurons from apoptosis.

p62/sequestosome-1 supports dengue virus replication by inactivating NF- κ B-mediated IL-6 production

Chang, C.-P.^{1,2}, Li, C.-H.¹, Lin, Y.-S.^{1,2}

¹National Cheng Kung University, Department of Microbiology & Immunology, Tainan, Taiwan, Republic of China, ²National Cheng Kung University, Center of Infectious Disease and Signaling Research, Tainan, Taiwan, Republic of China

Dengue is a re-emerging disease which is endemic in more than 100 countries. Due to global warming effects, the dengue virus (DV) threat is broadening in the world. The symptoms are febrile illness called dengue fever to dengue haemorrhagic fever and dengue shock syndrome. A recent study showed that DV infection is able to reduce an autophagy adaptor protein p62, which may facilitates DV replication. However, our data here indicate that p62 seems to be required for DV replication. Compared to WT MEF cells, less virus proteins, released DV particles and DV RNA were detected in DV-infected p62-deficient MEF cells. Significant decreased DV protein translation was also observed in p62 knockdown DV-replicon stable expressing cells. This facilitating role of p62 to DV replication is not limited in MEF cells but also in hepatocytes and monocytes. There were no differences in virus cell binding, endocytosis, interferon activation and autophagy induction between DV-infected WT and p62-deficient cells. However, DV triggered high NF- κ B phosphorylation and nuclear translocation in p62-deficient cells. The reduced DV replication can be rescued by inactivation of NF- κ B with inhibitor BAY 11-7082 in p62-deficient cells. Moreover, we found that NF- κ B responsible cytokine

IL-6 was highly produced in DV-infected p62-deficient cells. Blocking IL-6 by neutralizing antibody can rescue DV replication in p62-deficient cells. In addition, recombinant IL-6 inhibits DV replication in vitro. Our findings uncover a new role of p62 in facilitating DV replication via inactivating NF- κ B-mediated IL-6 and also provide a potential therapeutic target for dengue infection.

Antigen-presenting cell-like differentiation of microglia retard dengue virus-induced acute viral encephalitis

Lin, C.-F.^{1,2}, Tsai, T.-T.¹, Chen, C.-L.³

¹Taipei Medical University, Department of Microbiology and Immunology, Taipei, Taiwan, Republic of China, ²Taipei Medical University, Graduate Institute of Medical Sciences, Taipei, Taiwan, Republic of China, ³Taipei Medical University, Translational Research Center, Taipei, Taiwan, Republic of China

Mosquito-borne four serotypes of dengue virus (DENV) cause 390 million infections annually. Dengue patients may progress to severe dengue hemorrhagic fever/dengue shock syndrome (DHF/DSS), which can be fatal. Patients who succumb to DHF/DSS frequently present early altered neurological consciousness as similar with acute viral encephalitis acquired through an unknown mechanism. Here, we report that encephalitic DENV-infected mice exhibited progressive hunchback posture, limbic seizures, limbic weakness, paralysis, and lethality 7 days post-infection. These symptoms were accompanied by CNS inflammation, neurotoxicity, and blood-brain barrier destruction. Microglial cells surrounding blood vessels and injured hippocampus regions were activated by DENV infection. Pharmacologically depleting microglia unexpectedly increased viral replication, neuropathy, and mortality in DENV-infected mice. DENV infection increased expression of antiviral cytokines and infiltration of CD8 positive cytotoxic T lymphocytes (CTLs) in a microglia-dependent manner. DENV infection prompted antigen-presenting cell-like differentiation of microglia, which in turn stimulated CTL proliferation and activation. These results suggest that microglial cells are key factors in facilitating antiviral immune responses against DENV-induced acute viral encephalitis.

659
Bromodomain-containing protein 3 (BRD3) selectively promotes IFN- β production via recruiting IRF3/p300 complex to the IFN- β promoter in macrophages

Wang, C., Ren, W., Sun, D., Cao, X.

Chinese Academy of Medical Sciences, Institute of Basic Medical Sciences, Beijing, China

Bromodomain containing protein 3 (BRD3) is a family member of bromodomain and extraterminal motif proteins (BETs) which function as protein scaffolds, mitotic bookmarks, cell cycle regulators and transcription regulators. However, the function of BRD3 in innate immune response remains unclear. Here we find that BRD3 is ubiquitously expressed in immune organs and immune cells, indicating that BRD3 might participate in

the regulation of innate immune response. The expression level of BRD3 is significantly down-regulated in macrophages upon stimulation with LPS or viruses. BRD3 knockout cells show significantly decreased production of IFN- β after LPS challenge and virus infection. However, the production of TNF- α and IL-6 is not affected. Importantly, we find BRD3 can bind to IRF3 and p300, and maintains the stability of IRF3/p300 complex upon virus infection. In addition, BRD3 recruits IRF3/p300 complex to the promoter of IFN- β , and enhances the acetylated histone3/histone4 promoter of IFN- β , leading to the promotion of type I interferon production. Therefore, our work reveals BRD3 as a selective positive regulator of innate IFN- β production, providing new mechanistic insight into the molecular mechanism for efficient activation of the innate immune response.

Plasma expression profile and potential function of HCMV-encoded microRNAs in oral lichen planus patients

Zhang, C.¹, Ding, M.¹, Wang, X.², Wang, C.¹, Zen, K.³, Zhang, C.³

¹Jinling Hospital, Nanjing University School of Medicine, Clinical Laboratory, Nanjing, China, ²Nanjing Stomatological Hospital, Medical School of Nanjing University, Oral Medicine, Nanjing, China, ³Nanjing University, Life Sciences, Nanjing, China

Background: Oral lichen planus (OLP) is a T-cell-mediated autoimmune disease. The aetiology and molecular mechanisms of OLP remain unclear. Human cytomegalovirus (HCMV) infection is a causal factor in the development of various diseases, but the clinical relevance of HCMV in OLP has not been investigated. We examined HCMV-encoded miRNA expression profiles in plasma from OLP patients to reveal a potentially novel aetiology of OLP.

Methods and results: Twenty-three HCMV-encoded miRNAs were initially measured using RT-qPCR in a cohort of 21 OLP patients and 18 healthy controls. Five upregulated miRNAs in OLP patients, hcmv-miR-UL112, hcmv-miR-UL22a-5p, hcmv-miR-UL148D, hcmv-miR-UL36-5p and hcmv-miR-UL59, were confirmed in an additional cohort of 41 OLP patients and 33 controls. The levels of most of these miRNAs correlated significantly with anti-HCMV IgG concentrations in OLP patients. Additionally, by using a combination of luciferase reporter assays and western blotting, we demonstrated that cytomegalovirus UL16-binding protein 1, a molecule that mediates the killing of virus-infected cells by natural killer cells, is a direct target of hcmv-miR-UL59.

Conclusion: We report for the first time a distinct circulating HCMV-encoded miRNA profile and identify a novel HCMV miRNA-based immunoevasion strategy in OLP. Our results suggest a possible involvement of HCMV in the aetiology of OLP.

661

The primary immune response to vaccinia virus vaccination includes cells with a distinct cytotoxic effector CD4 T cell phenotype

Munier, C.M.L.¹, Bailey, M.¹, Ip, S.¹, Xu, Y.¹, Alcantara, S.², Liu, S.M.³, van Bockel, D.¹, Suzuki, K.^{1,4}, Cooper, D.A.^{4,5}, Kent, S.J.^{2,6,7}, Zaunders, J.J.^{1,4}, Kelleher, A.D.^{1,4}, PHIIDO Study Group

¹The Kirby Institute, UNSW Australia, Immunovirology and Pathogenesis Program, Sydney, Australia, ²Peter Doherty Institute, University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ³The Garvan Institute, Sydney, Australia, ⁴St Vincent's Hospital, Sydney, Australia, ⁵The Kirby Institute, UNSW Australia, Sydney, Australia, ⁶Alfred Health, Central Clinical School, Monash University Melbourne, Melbourne Sexual Health Centre and Department of Infectious Diseases, Melbourne, Australia, ⁷ARC Centre of Excellence in Convergent Bio-Nano Science and Technology, University of Melbourne, Melbourne, Australia

Smallpox was eradicated by global inoculation with vaccinia virus (VV). Robust VV-specific CD4 T cell responses during primary infection are likely to be essential to controlling VV replication. Although there is increasing interest in cytolytic CD4 T cells across a range of viral infections, the importance of these cells during acute VV infection is not understood. We undertook a detailed functional and genetic characterization of human VV-induced CD4 T cells during acute infection. VV-specific T cells were identified by up-regulation of activation markers *ex vivo* and through cytokine and co-stimulatory molecule expression during short *ex vivo* cultures. Thirteen days following VV inoculation, CD38^{high}CD45RO⁺ CD4 T cells were purified and analysed by microarray, quantitative RT-PCR and flow cytometry. We compared analyses of VV-specific CD4 T cells to studies on 12 subjects with primary HIV infection (PHI). A median 11.9% of CD4 T cells were CD38^{high}CD45RO⁺ at day 13 post-VV inoculation, compared to 3.0% prior to inoculation and 10.4% during PHI. Activated CD4 T cells had an up-regulation of genes related to cytolytic function, including Granzymes K and A, Perforin, Granulysin, granule marker TIA-1, and Rab27a. No difference was seen between CD4 T cell expression of perforin or TIA-1 in response to VV and PHI, however Granzyme K was more dominant in the VV response. We conclude that CD4 CTL are prominent in the early response to VV. Understanding the role of CD4 CTL in the generation of effective anti-viral memory may help develop more effective vaccines for diseases such as HIV.

662

Altered neutrophil trafficking and viral pathogenicity resulting from genetic reassortment of influenza A virus PA and NA genes

Dlugolenski, D.¹, Tompkins, M.², Tripp, R.²

¹Deakin University, School of Medicine, Waurn Ponds, Australia, ²University of Georgia, Infectious Diseases, Athens, United States

Reverse zoonosis of the 2009 pandemic H1N1 virus into swine was identified soon after introduction into humans, and continued reassortment of the 2009 pandemic H1N1 influenza A virus (IAV) with current circulating strains of swine IAV has been observed. H3N2 variant (H3N2v) viruses resulted from introduction of the pandemic H1N1 M gene into triple reassortment internal gene (TRIG) swine IAV resulting in zoonotic transmission with enhanced morbidity. However, these viruses failed to transmit from human-to-human. Therefore, we sought to establish the pathogenic potential

of reassortment between current circulating strains of swine IAV and the pandemic H1N1 virus. Reassortants had altered pathogenic phenotypes linked to introduction of the swine PA and NA into pandemic H1N1. In mice, the swine H1N2 PA and NA mediated increased MIP-2 expression early post-infection resulting in substantial pulmonary neutrophilia with enhanced lung pathology and disease. These results show the potential for continued reassortment of the 2009 pandemic H1N1 virus with endemic swine IAV, and the potential for reassortants to have increased pathogenicity linked to the swine NA and PA genes which are associated with increased MIP-2 expression and pulmonary neutrophil trafficking.

663

Biodegradable therapeutic nanoagents for influenza A virus by blocking viral entry via sialic receptor-targeting 3-aminophenylboronic acid

Yun, D.¹, Kim, H.-O.¹, Na, W.², Yeom, M.², Lim, J.-W.¹, Kim, J.¹, Chun, H.¹, Park, G.¹, Song, D.², Haam, S.¹

¹Yonsei University, Chemical and Biomolecular Engineering, Seoul, Korea, Republic of, ²Korea University College of Pharmacy, Sejong, Korea, Republic of

Influenza A virus (IAV) causes recurrent respiratory epidemics not only in humans but also birds and other mammals, threatening millions of lives every season. Due to the frequent gene reorganization or mutation of IAV, conventional therapeutic agents which are mostly neuraminidase (NA) inhibitors cause tolerance problems and side effects. Thus, development of biocompatible therapeutics free from resistance problems, types of virus as well as unwanted toxicity should be essential. In this study, we developed mucus-penetrating biodegradable nanoparticles (MPBNs) consisting of chitosan coated sialic receptor-targeting 3-aminophenylboronic acid (APBA) conjugated with Hyaluronic acid (HA) and poly (lactic-co-glycolic acid) (PLGA). MPBNs showed effective virus therapy by competitively blocking cellular infiltration of IAV as targeted cellular binding available nanoplatform *in vitro*. These results indicate that MPBNs with an easy administration method through mucous membrane could be an efficient treatment for various influenza viruses.

664

Frequency and phenotype alterations in monocyte subsets from dengue patients: a main contribution of the non-classical subset

Naranjo-Gomez, J.-S.¹, Castillo, J.², Restrepo, B.³, Rojas, M.^{1,4}, Velilla, P.², Castaño, D.¹

¹Universidad de Antioquia, Facultad de Medicina, Instituto de Investigaciones Médicas, Grupo de Inmunología Celular e Inmunogenética, Medellín, Colombia, ²Universidad de Antioquia, Facultad de Medicina, Departamento de Microbiología y Parasitología, Grupo Inmunovirología., Medellín, Colombia,

³Instituto Colombiano de Medicina Tropical, Sabaneta, Colombia,

⁴Universidad de Antioquia, Unidad de Citometría de Flujo, Sede de Investigación Universitaria, Medellín, Colombia

About ten percent of patients with dengue virus develop severe manifestations, which can lead to death. It has been proposed that monocytes and their products must participate in severe dengue development. Considering that exist three different functional monocyte subsets (classical, intermediate and non-classical), they could be differentially involved in the immunopathogenesis. A flow cytometric approach was performed to evaluate in monocytes activation markers (CD86/CD68/HLA-DR/CD64), and molecules allowing interaction with endothelium (CD11a/CD11b/CD18/CD54), in 57 dengue patients.

An increased expression per cell of CD64, CD86, and CD54 was found on classical subset and of CD11b, CD18, CD54, CD64, and CD86 on intermediate subset, only in 4-7 days of illness without changes in the number of monocytes, compared to healthy controls. At day 8, the expression of these molecules decrease, except for CD64, indicating that these subsets may contribute with the immune responses to dengue mainly during the first days of illness.

It was observed a lower number of no-classical monocytes, with high expression of CD11b, CD54, CD68, CD64, CD86 and HLA-DR during illness evolution in particular, in dengue patients with alarm signs. Only this monocyte subset had augmented the percentage of TNF- α cells *ex vivo*. These results suggest that no-classical monocytes in dengue patients remain active and capable to interact with the endothelium during all days of illness; considering, these results were associated with severe manifestations, those changes could be evaluated in the future as prognostic tools.

665

Dietary fatty acids alter T cell affinity for antigen and decrease anti-viral immunity

Kolawole, E.M., Evavold, B.D.

Emory University, Microbiology and Immunology, Atlanta, United States

There has been much investigation into the influence of dietary fatty acids with regard to modulation of immune function. Omega-3 polyunsaturated fatty acids have been shown to exert beneficial anti-inflammatory effects for both chronic and acute inflammatory disease. Based on studies suggesting incorporation of omega-3 fatty acids into lipid membranes, we assessed whether omega-3 fatty acids modulates T cell responses by altering the two dimensional membrane microenvironment of the TCR. Using the novel two dimensional (2D) micropipette adhesion frequency assay we determine T cell affinity for antigen on a single cell basis. Our data indicates that dietary fish oil reduces antigen affinity in T cell receptor transgenic cells. Moreover, we observed a decrease in the frequency of antigen specific (gp33) T cells by both tetramer and micropipette at peak anti viral immunity to lymphocytic choriomeningitis (LCMV) infection. These data indicate that a diet rich in omega-3 fatty acids decrease T cell affinity and expansion to viral antigen.

666

Novel role for galectin-9 as a potent inhibitor of human cytomegalovirus infection

Machala, E.A., McSharry, B.P., Abendroth, A., Slobedman, B. University of Sydney, Infectious Diseases and Immunology, Sydney, Australia

Human cytomegalovirus (HCMV) is a large double stranded DNA virus of the herpesvirus family. While HCMV infection is generally asymptomatic in the immunocompetent, HCMV can have devastating consequences in immunocompromised individuals. Galectins are a family of cellular proteins characterised by the presence of a carbohydrate recognition domain. Members of this widely expressed protein family have been demonstrated to exert profound effects on host-pathogen interactions. Two of the best studied galectins, galectin-1 (Gal-1) and galectin-9 (Gal-9), have been implicated in a number of immune regulatory processes, and specific roles these for galectins in modulating both anti-viral immunity and regulating direct host-virus interactions have also recently emerged. Previous HCMV infection studies from the Slobedman laboratory have established potent upregulation of Gal-9 at the total protein level, dependent on the anti-viral cytokine IFN- β . The potential for galectins to directly modulate infection has not previously been studied in the context of HCMV. Infection studies utilising recombinant protein treatment, revealed Gal-9, but not Gal-1, as an anti-viral lectin that potently inhibited HCMV infection. Furthermore Gal-9 mediated inhibition of infection was carbohydrate recognition domain-dependent and blocked by anti-Gal-9 specific antibodies. Temperature-shift studies, separating the binding and entry stages of infection, identified Gal-9 specific inhibition as mediated primarily at the level of viral entry, and appeared to be dependent on binding to the virion rather than interacting with cellular ligands. This study provides the first evidence of a novel role for Gal-9 as an anti-viral, IFN- β induced protein, that exerts a profound inhibitory effect on HCMV infection.

667

Influenza-specific antibody-dependent phagocytosis

Ana-Sosa-Batiz, F.¹, Vandervan, H.¹, Jegaskanda, S.¹, Johnston, A.², Rockman, S.^{1,3}, Laurie, K.⁴, Barr, I.⁴, Reading, P.^{1,4}, Lichtfuss, M.¹, Kent, S.J.¹

¹Peter Doherty Institute for Infection and Immunity at The University of Melbourne, Microbiology and Immunology, Melbourne, Australia, ²Monash Institute of Pharmaceutical Sciences, Monash University, Drug Delivery, Disposition and Dynamics Laboratory, Parkville, Australia, ³bioCSL Ltd, Parkville, Australia, ⁴WHO Collaborating Centre for Reference and Research on Influenza (VIDRL), Melbourne, Australia

Immunity to human influenza virus infection is only partially understood. Broadly reactive non-neutralizing antibodies may assist in reducing disease but have not been well characterized. Non-neutralizing antibodies have the potential to bind conserved regions of hemagglutinin (HA). Some of these antibodies can engage Fc receptor CD32 of effector cells and mediate antibody-dependent phagocytosis (ADP).

We measured internalization of opsonized, influenza protein-coated fluorescent beads and live influenza virus into a monocytic cell line to study antibody-dependent phagocytosis against multiple influenza HA subtypes. We analyzed influenza HA-specific ADP in healthy human donors, in preparations of intravenous immunoglobulin (IVIG), and following influenza infection of humans and macaques.

We found that both sera from healthy adults and IVIG preparations had broad ADP to multiple seasonal HA proteins. Many sera and all IVIGs also had weak cross-reactive ADP to non circulating HA proteins. Macaques experimentally infected with H1N1 and H3N2 viruses developed robust ADP. Further, the influenza virus phagocytosed in an antibody-mediated manner had reduced infectivity *in vitro*. Humans recently infected with H1N1 had a rise in ADP functional activity in sera to both homologous and heterologous HA proteins and influenza viruses.

Influenza infection in humans and macaques leads to the development of influenza-specific ADP that can clear influenza viruses. Repeated exposure of humans to multiple influenza infections likely leads to the development of ADP that is cross-reactive to strains not previously encountered. Further analyses of the protective capacity of broadly reactive influenza-specific ADP is warranted.

668

The salmon pathogenic viruses IPNV, ISAV and SAV are differentially recognized by RIG-I-like receptors and induce different immune responses in a salmonid cell-line

Nerbøvik, I.-K.G., Solheim, M.A., Eggsetøl, H.Ø., Rønneseth, A., Jakobsen, R.A., Wergeland, H.I., Haugland, G.T. University of Bergen, Bergen, Norway

In fish, the type I interferons (IFNs) and their antiviral effect are well described, but less is known about the involvement of the RIG-I-like family receptors (RLRs) upon infection with whole viruses and the pro-inflammatory response during virus infection. Therefore, we infected a salmonid cell line, TO-cells, with infectious pancreatic necrosis virus (IPNV), infectious salmon anaemia virus (ISAV) and salmonid alphavirus (SAV) and monitored the responses of the RLRs RIG-I, MDA5 and LGP2 during infection. RIG-I, followed by LGP2, was highest upregulated by IPNV and ISAV at 1 and 4 days post infection, respectively, which correlates with the replication pattern of the viruses. During SAV infection, the opposite was observed, LGP2 was expressed significantly higher than RIG-I and MDA5. Furthermore, we investigated the innate immune responses by measuring the production of IFNs and pro-inflammatory cytokines at the transcriptional level. Among the interferons, IFN α was highest upregulated during infections with all viruses. Unexpectedly, the responses of pro-inflammatory cytokines upon infection with IPNV and ISAV were profoundly different from the SAV infection. During infection with the two aforementioned, TNF α 1 and α 2 was highly upregulated, while during SAV infection these cytokines were down-regulated. Similarly, one of the three IL12p40 homologues, IL12p40c, was down-regulated during SAV infection but not during infection with IPNV and ISAV.

Knowledge of virus recognition and the innate and adaptive immune responses during infection make the basis for development of prophylactic and preventive control measures and may help elucidate why and how some viruses can escape the immune system.

West Nile virus (WNV) belongs to the Japanese encephalitis virus (JEV) serocomplex of *Flaviviridae* family, which causes fatal encephalitis / meningitis mostly in the elderly. Currently, there is no specific therapeutics or vaccine for human use, thus, its development is urgent. Previously, we have reported that WNV-neutralizing antibodies are induced in some individuals immunized with inactivated JEV vaccine. And we have developed immunospot array assay on a chip (ISAAC) technology using microwell-array chip, which enables direct identification of antigen specific antibody-secreting cells from human peripheral blood lymphocytes (PBLs) and rapid cloning of antibody cDNA, leading to efficient and rapid production of human monoclonal antibodies (HuMoAbs). In the present study, we applied the ISAAC technology to establish WNV-neutralizing HuMoAbs from the PBLs of individuals vaccinated with inactivated JEV. As a result, we established three WNV E protein - specific HuMoAbs with high binding avidity as well as WNV-neutralizing activity. Competitive binding assay indicated no epitope sharing. Next, we examined protective effect of these HuMoAbs against WNV infection in vivo. WNV were inoculated to the C57BL/6 mice, to which HuMoAb was administrated subcutaneously on the day of WNV inoculation and 24 hours later, followed by monitor of their mortality and morbidity. Administration of the WNV-neutralizing HuMoAbs clearly postponed manifestation of the symptoms, indicating that these WNV-neutralizing HuMoAbs are protective against WNV infection. This is the first report that WNV-neutralizing HuMoAbs derived from JEV- vaccinated human can exert protection against WNV infection in vivo. Analysis of their epitopes is now under way.

PTD fused Mx1 enhances protection against influenza virus infection

Jung, H.E., Lee, H.K.

Korea Advanced Institute of Science and Technology (KAIST), GSMSE, Daejeon, Korea, Republic of

Dynamine-like GTPase Mx1 is an intracellular antiviral protein that is induced by type I and type III interferons. A deficiency in the antiviral Mx1 protein increases susceptibility to influenza infection because the protein serves as a restriction factor and inhibits viral replication by blocking the transcription of viral RNA. Hence, although commercially manufactured anti-influenza drugs were primarily developed for inhibition of neuraminidase or the M2 protein, Mx1 could be another efficient target of antiviral therapy. To improve the delivery of Mx1 into cells, a polyarginine protein transduction domain (PTD) was fused to the C-terminus of Mx1. The engineered Mx1 was efficiently internalized in MDCK cells. Following influenza infection, viral replication and viral RNA expression levels in the infected cells were inhibited by treatment with the engineered Mx1. Further, intranasal administration of the engineered Mx1 improved the survival of mice infected with the PR8 influenza virus strain. These data reveal that engineered cell permeable Mx1 could be a novel therapeutic agent against mucosal influenza virus infection.

671

HCMV glycoprotein gp39 downregulates host antiviral response

Choi, H.J., Park, A., Lee, S., Park, B.

Yonsei University, Seoul, Korea, Republic of

Human cytomegalovirus (HCMV) infects a large of percentage of the population worldwide and causes chronic infection. Type I interferon (IFN) response establishes an antiviral state in infected cells. However, it remains unclear how HCMV has evolved to evade the innate immune system for persistence. Here, we show that HCMV infection inhibits IFN- β induction during early and late times post-infection, when diverse viral genes are expressed. In particular, we identify HCMV glycoprotein gp39 that suppresses HCMV-induced IFN- β response. Localization of gp39 in the endoplasmic reticulum (ER) and mitochondria, important platforms for innate immune response, may be associated with its function in subverting host defense. Our finding provides a novel mechanism to understand HCMV pathogenesis and immune surveillance.

672

Amphiphilic antiviral delivery nanocarrier possessing cell-targeting phenylboronic acid functional groups for virus therapy

Kim, H.-O.¹, Chun, H.¹, Na, W.², Yeom, M.², Lim, J.-W.¹, Yun, D.¹, Kim, J.¹, Park, G.¹, Song, D.², Haam, S.¹

¹Yonsei University, Chemical and Biomolecular Engineering, Seoul, Korea, Republic of, ²Korea University College of Pharmacy, Sejong, Korea, Republic of

Influenza, one of the most contagious diseases, has caused seasonal epidemics and pandemics being a consistent concern for global health. Despite laudable advances in antiviral agents and drugs, the vast majority of them have shown limited efficacy due to non-specificity and low viability in physiological or endosomal environment, especially in the case of intracellular drug. A nano platform, consisting of phenylboronic acid (PBA) pendant group polymer which has sialic acid-targeting property, gained greater access to the intracellular space transporting antivirals within the host cell. Amphiphilic copolymers made of pPhe-b-mPEG-PBA formed polymersomes which encapsulated hydrophilic antiviral agents in the core and hydrophobic drugs in the exterior layer. Combination of antiviral drug delivery using amphiphilic nanocarrier and cell-targeting functional group gives a better chance to improve transfection and intracellular distribution efficiency of therapeutic substances.

Characterisation of the antibody response to hepatitis C virus by infected individuals

Allan, J.¹, Felsberger, G.¹, Silvia, L.^{2,3}, Hayley, C.⁴, Flexman, J.³, Watson, M.⁴

¹University of Western Australia, School of Medicine and Pharmacology, Perth, Australia, ²University of Western Australia, Pathology and Laboratory Medicine, Perth, Australia, ³Royal Perth Hospital and PathWest Laboratory Medicine, Perth, Australia, ⁴Murdoch University, Institute for Immunology and Infectious Diseases, Centre for Clinical Immunology & Biomedical Statistics, Perth, Australia

Hepatitis C virus (HCV) is a blood borne pathogen which is responsible for life long, chronic infection of the liver. It is expected that the optimal HCV vaccine will contain both cell mediated immunity and antibody stimulating epitopes. Our aim is to characterise antibodies against HCV elicited by infection that are genotype cross-reactive and infection neutralising *in vitro*.

Previously we have reported that 98% of a cohort of 100 chronic hepatitis C patients responded by ELISA to g2 (JFH-1) HCV prior to treatment. Analysis by denaturing western blot in a subset of this cohort revealed that each person recognised HCV core antigens but this was not found for the viral envelope glycoprotein, E2, which is the target of many infection neutralising antibody responses. Neutralisation of JFH-1 HCV infection of Huh7 cells *in vitro* was also common amongst the entire cohort irrespective of whether patients were infected with genotype 1, 2, 3 or 4 HCV. The presence of antibody to E2 has been tested by ELISA in a subset of patients using recombinant E2 for genotypes 1, 2, 3 and 4 produced in mammalian cells. Cross-reactivity of the antibody response between genotypes was common while the strength of the response to E2 was not directly related to the infecting HCV genotype. This information has been used to select donors whose HCV reactive B cells are captured in a modified ELISPOT for isolation of immunoglobulin sequences for diagnostic and vaccine development purposes.

674

Characterisation of human CD14⁺ monocytes following Varicella-Zoster virus infection

Kennedy, J., Steain, M., Slobedman, B., Abendroth, A. University of Sydney, Infectious Diseases and Immunology, Sydney, Australia

Primary infection by Varicella-Zoster Virus (VZV) is presumed to involve transfer of virus from regional lymph nodes to peripheral blood mononuclear cells (PBMC) in support of dissemination throughout the host. The role CD14⁺ monocytes provide in this interplay is not fully elucidated and is a subject of conflicting reports. Here we demonstrate VZV infects CD14⁺ monocytes extracted from human blood, with 30% of cells expressing viral antigen within 24 hours of infection. CD14⁺ monocytes from at least 6 independent donors were co-cultured with VZV infected human fibroblasts and assessed by flow cytometry for viral antigen expression. By 24 hpi 20-60% of CD14⁺ monocytes were viral antigen positive. By immunofluorescence assays (IFA) CD14⁺ monocytes exhibited immediate-early, early and late VZV antigens; a full cascade of viral gene expression and hallmark of Herpesvirus infection. Concomitant with viral antigen expression, cell-surface analysis of monocytes revealed a trend of decreased cell-surface HLA-ABC at 72 hpi and statistically significant decreases in HLA-DR at 48 and 72 hpi. Interestingly the decrease in these cell markers coincided with a significant decrease in cell-surface CD14 at 72 hpi. These cellular changes may indicate infected monocytes are undertaking a polarising or differentiation event. Of publications that have previously investigated PBMC tropism, many have focused heavily on non-monocyte populations such as B and T lymphocytes or used less stringent indicators of infection. Thus this is the first demonstration of the full cascade of VZV gene expression during infection of human peripheral blood CD14⁺ monocytes.

Immunostimulation reduces the severity of Influenza infection during pregnancy

Lauzon-Joset, J.-F., Scott, N.M., Mincham, K.T., Study, M., Holt, P.G., Strickland, D.H.

Telethon Kids Institute, University of Western Australia, Subiaco, Australia

Introduction: Pregnancy is associated with a heightened susceptibility to many pathogens and more severe clinical symptoms. The only preventive treatment currently available is vaccine, but the breadth of potential coverage is limited by vaccine availability. To circumvent this limitation, we were interested by a new class of treatment: the immunostimulation. Immunostimulation has been previously shown to limit infection severity, it had never been tested during pregnancy. As a proof-of-principle, we investigated the efficacy of an immunostimulant (OM-85) to protect from Influenza infection in a mouse model.

Methods: BALB/c mice were time-mated and fed OM-85 once a day from gestational day (GD) 0.5 until GD8.5. Mice were infected with a low dose of H1N1 influenza A virus (mouse adapted PR8 strain) at GD9.5 (corresponding to mid-late gestation). Disease

severity was assessed daily and the immune response was assessed at GD17.5 by flow cytometry in the airway tissues.

Results: The severity of Influenza infection was increased in pregnant mice compared to non-pregnant controls. In both pregnant and non-pregnant mice, Influenza infection was associated with an increased accumulation in the airway tissues of plasmacytoid dendritic cells and activated T cells, whereas the recruitment of inflammatory dendritic cells and granulocytes was only observed in pregnant mice. Interestingly, OM-85 preventive treatment did not have any adverse effect and it was able to normalize the inflammatory response to Influenza back to the level of non-pregnant.

Conclusions: Overall, we showed that OM-85 treatment prevent influenza-induced pregnancy complications by reducing inflammatory cell recruitment in the airways.

676

Tregs influence kinetics of immunodominant antiviral CD8+ T cell responses

Chadderton, J.¹, L. La Gruta, N.^{1,2}

¹Peter Doherty Institute for Infection and Immunity at The University of Melbourne, Melbourne, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia

CD4+ regulatory T cells play a well characterised role in preventing autoimmune diseases where inflammatory immune responses have the potential to cause significant damage to the host, however their role in the regulation of T cell responses during viral infection is much less clear.

Previous studies have shown that removing or depleting regulatory T cells can modulate the antiviral CD8+ T cell immunodominance hierarchy by permitting the activation of low avidity CTLs that would normally be suppressed. The consequences of removing regulatory T cells may alternatively be beneficial in allowing increased numbers of CD8 T cells to participate in the immune response following vaccination. Thus we are studying the role of Treg cells in regulating both immunodominant and subdominant responses to influenza in C57Bl6 mice and asking whether removing Tregs during the acute antiviral response significantly alters CD8+ T cell responses and consequently influenza pathogenesis during infection. Experiments indicate that Tregs can respond during viral infection both in the lungs and periphery. Studies initially using PC61 antibody depletion suggest the size of NP₃₆₆ and PA₂₂₄ populations as well as the kinetics of the CD8 response are influenced by the presence of Tregs and this has been further confirmed using an influenza infection model in Treg depleted B6.Foxp3.GFP.DTR mice. This study is relevant to immunosuppressed individuals or those on immune therapy whose CD8+ T cells responses to acute viral infection may be significantly altered.

677

CD160 plays a protective role during chronic HIV-1 infection and is critical to CD8+ T cell differentiation through T-bet pathway

Zhang, A.¹, Xu, J.¹, Zhang, L.¹, Qiu, C.¹, Qiu, C.¹, Wang, Y.², Ye, L.³, Li, T.⁴, Zhang, X.¹, Fu, Y.-X.⁵, Xu, J.¹

¹Fudan University, Shanghai Public Health Clinical Center, Shanghai, China, ²Shanghai CDC, AIDS Department, Shanghai, China, ³Third Military Medical University, Chongqing, China, ⁴Peking Union Medical College Hospital, Beijing, China, ⁵University of Texas Southwestern Medical Center, Dallas, United States

The role of CD160 during chronic HIV-1 infection remains controversial. Here we show that CD160 plays a protective role during chronic HIV-1 infection by enhancing CD8+ T cell functions through T-bet pathway. CD160+CD8+ T cells were enriched primarily in HIV-1+ slow progressors and their frequencies correlated with CD4 counts and inversely with plasma virus loads. CD160+CD8+ T cells were highly poly-functional and proliferative, which was further corroborated in a chronic LCMV infection in mouse model; triggering CD160 enhanced CD8+ T cell cytotoxicity and IFN- γ production in the context of HIV-1 antigen stimulation. Genetic ablation of CD160 resulted in the loss of T-bet expression in CD8+ T cells during chronic LCMV infection and thereby impaired CD8+ T cell functions and proliferation, and attenuated the containment of viral replication. Overall, we identified a novel CD160/T-bet pathway which plays a protective role during chronic infection through regulating CD8+ T cell function and proliferative capacity. These data suggest that CD160 represents a potential target for immune intervention in chronic infection.

678

Retinoic acid regulates immune responses by promoting IL-22 production and modulating S100 protein in viral hepatitis

Sun, J.¹, Liang, Y.¹, Jie, Z.¹, Yi, P.¹, Tang, H.², Soong, L.¹, Cong, Y.¹, Zhang, K.²

¹University of Texas Medical Branch, Microbiology and Immunology, Galveston, United States, ²University of Texas Medical Branch, Pharmacology and Toxicology, Galveston, United States

The effector T cell responses promote viral clearance and disease resolution in viral hepatitis, but can also mediate tissue damage; however, much less is known as to how the liver protects itself against the injury. In this study, we have revealed a retinoic acid (RA)-mediated, hepatoprotective mechanism in adenovirus-induced hepatitis in mice. We found that RA treatment promoted hepatoprotective cytokine IL-22, but inhibited the pro-inflammatory cytokine IL-17, from gd T and double-negative T cells, and that the hepatic IL-17 and IL-22 production were regulated via the mTOR/PI3K signaling pathway. Moreover, we found that RA modulated the magnitude of antigen-specific T cell responses via down-regulating dendritic cell (DC) co-stimulatory molecule expression and its migratory capacity. Mechanistically, RA treatment inhibited calcium-binding S100 family proteins (S100A4/6/10) and the NF κ B/ERK signaling pathways on DCs. The inhibition of novel S100A4 resulted

in impaired DC migration from inflamed tissues to lymph nodes for T cell priming. Collectively, our study has revealed a previously unappreciated role and molecular mechanism of RA in modulating immune responses and protecting the liver from viral hepatitis.

679

Highly cytotoxic effector CD8⁺ T cells in influenza A virus infection

*Kim, J., Lee, J., Lee, H., Kim, A.-R., Shin, E.-C.
KAIST, Daejeon, Korea, Republic of*

Influenza A virus is controlled by adaptive immune system in which cytotoxic CD8⁺ T cells target the cells with infection. However, it has been also reported that excessive activation of effector CD8⁺ T cells is harmful by destroying infected alveolar epithelial cells. With this study, we investigated CD8⁺ T cell responses in a mouse influenza model, using highly replicating and slowly replicating influenza A virus. Although influenza-specific CD8⁺ T cells were similar in frequency, effector T cells with same antigen specificity display significantly different function and phenotype during highly and slowly replicating virus infection. We found that effector CD8⁺ T cells from the highly replicating influenza-infected lungs exerted strong cytotoxicity and distinct phenotype. In contrast, effector CD8⁺ T cells with same antigen specificity presented intermediate cytotoxicity with IFN- γ secretion in the slow-replicating influenza-infected lungs. Interestingly, depletion of CD8⁺ T cells rescued survival during infection with highly replicating virus. These results indicate that cytotoxic effector CD8⁺ T cells are dominated in lungs during highly replicating influenza virus infection and they may contribute to lung injury.

680

Lowering of influenza viral infectivity by using polypyrrole/polyaniline co-polymerized nanocomplex through control of cellular reactive oxygen species (ROS)

Kim, J.¹, Kim, H.-O.¹, Lim, J.-W.¹, Yun, D.¹, Chun, H.¹, Park, G.¹, Na, W.², Yeom, M.², Song, D.², Haam, S.¹

¹Yonsei University, Chemical and Biomolecular Engineering, Seoul, Korea, Republic of, ²Korea University, Pharmacy, Sejong, Korea, Republic of

Influenza A viral infection induces intracellular ROS generation to contribute to the virus propagation. In cytoplasm, ROS is generated by NADPH oxidase (Nox) whose expression is induced RNA and proteins in endocytosed virus through NADPH+O₂ (NADP⁺)+(H⁺)+2(O₂⁻). Plenty of ROS play a part in cell signal transduction to induce viral replication. The results of this study suggest that polypyrrole/polyaniline co-polymerized nanocomplex (PASome) has ROS controllability to block the viral replication. The ROS controllability comes from a character of Polypyrrole and polyaniline to be absorbing-emitting the hydrogen ion or electron by oxidizing-reducing themselves. As an antiviral agent, PASome has some strengths : it could be applied to all types of influenza A virus without the need to be modified or newly developed, and viruses don't acquire a

drug-resistance. We used a biocompatible amphiphilic polymer as template to form nanocomplex and to have the surface modified nanocomplex is bio-affinitive and stable in water. Thus we made effective ROS controllable nanocomplex to be suited for a medical application on a body. Furthermore, PASome could be applied to prevent or cure ROS-induced diseases like inflammation, arteriosclerosis, and cancer.

681

The time-interval between infections and viral hierarchies are determinants of viral interference following influenza virus infection in a ferret model

Laurie, K.¹, Guarnaccia, T.^{1,2}, Carolan, L.¹, Horman, W.^{1,3}, Yan, A.³, Aban, M.¹, Petrie, S.³, Cao, P.³, Heffernan, J.^{3,4}, McVernon, J.^{3,5}, Mosse, J.², Kelso, A.⁶, McCaw, J.^{3,5}, Barr, I.¹

¹WHO Collaborating Centre for Reference and Research on Influenza (VIDRL), Melbourne, Australia, ²Federation University Australia, School of Applied and Biomedical Sciences, Gippsland, Australia, ³University of Melbourne, Melbourne, Australia, ⁴York University, Mathematics and Statistics and York Institute for Health Research, Centre for Disease Modelling, Toronto, Canada, ⁵Royal Children's Hospital Murdoch Childrens Research Institute, Melbourne, Australia, ⁶Formerly of WHO Collaborating Centre for Reference and Research on Influenza (VIDRL), Melbourne, Australia

Epidemiological studies suggest that following infection with influenza virus, there is a short period of time during which the host experiences a lower susceptibility to infection with other influenza viruses. This viral interference appears to be independent of the antigenic similarities between the two viruses. In this study, we used the ferret model of human influenza to systematically investigate viral interference and the role it plays in determining the outcome of consecutive infections. Ferrets were first infected then challenged 1 to 14 days later with pairs of influenza A (H1N1) pdm09, A (H3N2) and B viruses that were circulating in humans in 2009 and 2010. Challenge outcomes varied depending on the virus combination and time-interval between primary infection and challenge. Infection with A (H1N1) pdm09 virus was observed to prevent or delay infection with an influenza B or A (H3N2) virus. Infection with an A (H3N2) virus sometimes prevented infection with A (H1N1) pdm09 virus. Infection with an influenza B virus delayed the subsequent infection with either A (H1N1) pdm09 or A (H3N2) viruses. Co-infections occurred when short periods (1 or 3 day intervals) separated infections. Overall, these data indicate that the time-interval between infections and the sequential combination of viruses presented are important determinants of the degree of viral interference. Influenza viruses appear to have an ordered hierarchy according to their ability to block/delay infection, which may contribute to the dominance of different viruses often seen in an influenza season. Exploiting mechanisms that induce this temporary immunity may provide novel vaccine or therapeutic strategies to overcome influenza and other respiratory diseases.

682

Immune recognition of respiratory syncytial virus (RSV) antigens and epitopes*Borochova, K.¹, Niespodziana, K.², Focke-Tejkl, M.², Valenta, R.²**¹Medical University of Vienna, Vienna, Austria, ²Medical University of Vienna, Division of Immunopathology, Department of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria*

Background: HRSV is an important causal agent of severe respiratory tract infections in children, elderly and immune compromised persons. There is still no active vaccine available for HRSV and there is a lack of serological diagnostic tests based on defined viral antigens and epitopes.

Materials and methods: The HRSV envelope proteins F and G were expressed in insect cells as C-terminally hexahistidine-tagged recombinant proteins and purified by Nickel-affinity chromatography. The purity and identity of both proteins were analysed by SDS-PAGE followed by Western-blotting using a monoclonal anti-His-tag antibody and mass spectrometry, whereas the correct folding was confirmed by circular dichroism analysis. Furthermore, synthetic peptides spanning the surface proteins were produced by solid phase synthesis. Enzyme-linked immunosorbent assay (ELISA) was used to investigate the occurrence of F- and G-specific as well as epitope-specific antibodies in healthy adult individuals.

Results and conclusion: We expressed and purified recombinant F and G proteins in very good yields. When we performed preliminary immunoassays, we found an interesting fine specificity of isotype and subclass specific immune responses. F protein was predominantly recognized by IgG1 whereas G protein reacted additionally with IgG4 by the tested subjects. Furthermore, recombinant intact F protein was exclusively recognized by the commercially available Palivizumab, a monoclonal antibody currently used for the prevention of severe HRSV infections in high risk infants. Our results suggest that recombinant HRSV-derived envelope proteins and their epitopes may be useful for the diagnosis and monitoring of HRSV infections.

683

Effect of HBV-induced IL-23 on the biological behavior of hepatocarcinoma cells*Jiang, Q.¹, Ma, S.¹, Guo, Z.¹, He, Q.¹, Sun, Y.¹, Zhu, H.¹, Chen, R.¹, Ning, Q.², Cai, X.³, Lei, P.¹, Shen, G.¹**¹School of Basic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Immunology, Wuhan, China,**²Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Infectious Disease, Wuhan, China,**³Wuhan General Hospital of Guangzhou Military, Wuhan, China*

Chronic infection with HBV is one of the major risk factors for development of HCC.

Published reports and our previous studies have indicated that HBV infection may induce the expression of IL-23, which exerts two-way regulation in carcinogenesis.

However, the reports about direct effects of IL-23 on tumor cells are rare and contradictory.

In present study, It was confirmed that HBV drove infected hepatoma cells to produce more inflammatory cytokines, especially IL-23. Furthermore, IL-23 had effects on the malignant properties of hepatoma cells in a concentration-dependent manner. At low concentration (0-20ng/ml), hrIL-23 could increase the proportion of stem/progenitor cells, promote proliferation and colony formation, reduce apoptosis and induce motility and invasivity of them. During exploration for the underlying mechanisms, HNF4a, which plays an important role in liver development and hepatocyte function, was found to be downregulated in HBV-infected hepatoma cells. Its expression was also decreased in cells treated by HepG2.215 culture supernatant, which could be abolished by supplement of anti-IL-23p19 Ab. Meanwhile, HNF4a level gradually decreased as hrIL-23 concentration increased in a certain range. Hence, it is speculated that HBV related IL-23 might regulate malignant properties of hepatoma cells through attenuation of HNF4a. The findings suggested that IL-23 could promote the development of HCC at a certain concentration, which might be potential targets of interventional strategies for treating hepatitis B patients.

684

Influence of ectromelia virus infection on mitochondrial morphology and function in murine L929 fibroblast cell line*Gregorczyk, K.P.¹, Wyzewski, Z.¹, Szczepanowska, J.², Bossowska, M.¹, Mielcarska, M.¹, Struzik, J.¹, Szulc-Dabrowska, L.¹**¹Warsaw University of Life Sciences-SGGW, Faculty of Veterinary Medicine, Department of Preclinical Sciences, Warsaw, Poland,**²Nencki Institute of Experimental Biology, Department of Biochemistry, Laboratory of Bioenergetics and Biomembranes, Warsaw, Poland*

Ectromelia virus (ECTV), like other orthopoxviruses, affects mitochondria-associated processes including apoptosis. However, little is known about the impact of ECTV infection on morphology and functional status of mitochondria. In the present study we show that in infected L929 cells mitochondria gather around the viral factories, indicating a role for mitochondria during ECTV replication and/or morphogenesis. Therefore, maintaining mitochondrial functionality may be an important feature of ECTV survival, presumably, preservation of mitochondrial ability to produce ATP required in the viral replication process. Analysis of selected electron chain transport proteins, representing OXPHOS complexes, revealed no significant changes in their levels between control and infected cells. Moreover, the amount of chaperones (Hsp60, Hsp10) engaged in the maintenance of proper mitochondrial function increased during ECTV infection. On the other hand, virus infected cells displayed degradation of the mitochondrial network and increased level of reactive oxygen species (ROS). Extensive fragmentation of mitochondria resulted in decrease of mitochondrial mass. Furthermore, we observed increase of Fis1 and decrease of Opa1 proteins, responsible for mitochondrial fission and fusion, respectively. Also we found that in ECTV-infected cells the mitochondrial membrane potential was reduced, suggesting the induction of apoptosis. Interestingly, ECTV does not trigger apoptosis in the first 24 hours of

replication in L929 fibroblasts. Taken together, our results allow us to hypothesize that during ECTV infection mitochondria may engage the autophagy (mitophagy) process in order to protect infected cells from apoptosis and promote viral replication. Work supported by Grant No.2011/03/B/NZ6/03856 from National Science Centre, Poland.

Leucocyte subsets in the fibroblast activation protein deficient mouse with influenza infection

Tan, S.-Y.^{1,2}, Chowdhury, S.^{2,3}, Weninger, W.^{1,2,4}, Gorrell, M.^{2,3}

¹Centenary Institute, Immune Imaging Program, Newtown, Australia, ²University of Sydney, Medical School, Sydney, Australia, ³Centenary Institute, Molecular Hepatology Laboratory, Newtown, Australia, ⁴Royal Prince Alfred Hospital, Department of Dermatology, Camperdown, Australia

Fibroblast activation protein (FAP), a serine protease with both post-proline dipeptidyl peptidase and endopeptidase activities, is highly upregulated in reactive stromal cells in embryogenesis, wound healing, fibrosis, tissue remodelling, inflammation and cancer. FAP⁺ stromal cells are thought to have a non-redundant, suppressive role in adaptive immunity. FAP might be involved via cleavage of its physiological substrates α 2-antiplasmin and neuropeptide Y. However, whether FAP itself exerts immunosuppressive functions in an inflammatory milieu, such as infection, is not known. We found that the major populations of leukocytes were unaltered in FAP-deficient mice; including splenic CD11c⁺ dendritic cells, CD19⁺ B cells, CD4⁺ and CD8⁺ T cells, CD25⁺CD44^{int} regulatory, CD25⁻CD44⁻ naive and CD25⁻CD44^{hi} activated subsets of CD4⁺ T cells, CD44⁺ and CD62L⁺ subsets of CD8⁺ T cells, and CD11b⁺Ly6G⁺ neutrophils. Although FAP expression was upregulated in the lungs and draining lymph nodes of influenza-infected mice, genetic ablation of FAP did not aggravate morbidity or mortality. In infected mice, FAP deficiency did not alter antigen-specific T cell proliferation or cytokine (IL-2 and IFN- γ) production or differentiation into CD44⁺CD62L⁻ effector T cells by donor OT-I cells. Anti-influenza antibody levels were unaltered in the absence of FAP. We conclude that FAP is dispensable for anti-influenza immunity.

686

ADAMTS7: an essential enzyme for adaptive immunity

McMahon, M.¹, Ye, S.¹, Dlugolenski, D.^{1,2}, Tripp, R.², McCulloch, D.¹, Stambas, J.¹

¹Deakin University, Geelong, Australia, ²University of Georgia, Athens, United States

Clearance of influenza virus infection requires an effective and targeted immune response. Extracellular matrix (ECM) enzymes, such as the ADAMTS (A disintegrin-like and metalloproteinase with thrombospondin-1 motifs) family play a significant role in ECM remodelling. ECM remodelling facilitates immune cell migration, cell adhesion and cleavage of ECM proteins. ADAMTS7, a relatively uncharacterised metalloproteinase, has recently been found to play a role in influenza virus replication *in vitro*. To further validate these results, we assessed the

immune response in influenza-infected *Adamts7*^{-/-} mice. Upon infection, *Adamts7*^{-/-} mice displayed increased weight loss and virus titres at various time points post infection. This correlated with lower influenza-specific CD8⁺ T cell numbers at day 7 and 10 post infection. Moreover, secondary challenge with influenza virus resulted in increased weight loss and a diminished recall of influenza-specific CD8⁺ T cell immunity in *Adamts7*^{-/-} mice. These results suggest that ADAMTS7 expression is essential for optimal clearance of virus infection.

687

Intrahepatic CXCL-10 is strongly associated with markers of liver fibrosis in HIV-HBV co-infection

Crane, M.¹, Tennakoon, S.¹, Harman, A.², Torresi, J.³, Avihingsanon, A.⁴, Lewin, S.¹

¹Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Westmead Institute for Medical Research, Sydney, Australia, ³Austin Hospital, Melbourne, Australia, ⁴Chulalongkorn University, Bangkok, Thailand

Liver disease progression is accelerated in HIV-HBV co-infection. HIV infection is associated with increased microbial translocation and chronic immune activation. We hypothesised that in HIV-HBV co-infection enhanced hepatic production of the chemokine CXCL-10 accelerates progression of liver disease. Liver biopsies and plasma were collected from co-infected patients naive to anti-retroviral therapy (ART; n=37) and from uninfected controls (n=8). Liver biopsies were analysed for CXCL-10, CXCR3, IFN α and - γ mRNA (qPCR). Plasma CXCL-10, sCD14 and CCL-2 were quantified by ELISA. Liver fibrosis was assessed by Fibroscan. Human hepatoma cell lines; HepG2, AD43 (HBV-negative) and AD38 (HBV-infected) were treated with IFN γ or IFN α and lipopolysaccharide (LPS) or PamCys (Invivogen) alone or in combination with HBsAg, HBeAg or HIV gp120 or following infection with HIV NL4.3 or vsv- pseudotyped NL4.3. Levels of CXCL-10 in the supernatant were measured by ELISA. Liver stiffness (kPa) was significantly correlated with intrahepatic CXCL-10 mRNA (p=0.017, r²=0.404), CXCR3 (p=0.0185 and IFN γ 0.0349). Intrahepatic CXCL-10 significantly correlated with intrahepatic CXCR3 (p=0.0005, r²=0.231), ALT (p=0.0055, r²=0.267), AST (p=0.001, r²=0.379) and circulating CXCL-10 (p=0.0047, r²=0.0218). *In vitro*, CXCL-10 production was increased 3 fold in HBV infected cells compared to HBV negative cells and vsv-pseudotyped HIV infection ablated CXCL-10 production. No effect of HIV or HBV proteins was observed. Intrahepatic markers of immune activation (CXCL-10, CXCR3 and IFN γ) were significantly associated with liver stiffness in HIV-HBV co-infected patients prior to ART. CXCL-10 and IFN γ should be considered as potential future targets to reduce liver stiffness in HIV-HBV co-infection.

Varicella zoster virus inhibits necroptosis in HT-29 adenocarcinoma cells

Steain, M., McSharry, B., Avdic, S., Slobedman, B., Abendroth, A. University of Sydney, Infectious Diseases and Immunology, Sydney Medical School, Sydney, Australia

Varicella zoster virus (VZV) is the herpesvirus responsible for varicella and herpes zoster. Herpesviruses encode inhibitors of cell death pathways, including necroptosis. In cells expressing receptor interacting protein (RIP) 3, necroptosis can occur following death receptor signaling if caspase 8 activity is compromised. The impact of VZV on necroptosis has yet to be investigated. To address this we infected the necroptosis susceptible HT-29 cell line with VZV. Mock and VZV-infected HT-29s were treated with TNF (T), the smac mimetic BV-6 (S) and the pan-caspase inhibitor z-vad-fmk (V) to induce necroptosis and cell death was assessed by measuring ATP levels. Following the induction of necroptosis a significantly higher proportion of VZV-infected cells survived versus mock-infected cells (69% vs. 39%). IFA staining for VZV and phosphorylated mixed lineage kinase like protein (p-MLKL), which is induced during necroptosis, was also performed following T+S+V treatment. Phosphorylated-MLKL was readily observed in mock cells, however within the VZV-infected culture, p-MLKL was predominantly seen in uninfected bystander cells, and rarely within VZV antigen positive cells. Together these data suggest that VZV inhibits necroptosis. The ribonucleotide reductase (R1) encoded by herpes simplex virus (HSV)-1 and 2, encodes a RIP homotypic interaction motif (RHIM), which is essential for blocking necroptosis. VZV R1 shares homology with the C-terminus of HSV R1, however lacks the RHIM domain. We have identified a RHIM-like sequence within a capsid gene of VZV and are undertaking studies to determine if this viral gene product is responsible for the observed block in necroptosis mediated by VZV.

Characterisation of the phenotypic profile of antigen specific cytotoxic T cell responses during primary HCV infection

Rasoli Pirozyan, M.¹, Leung, P.¹, Eltahla, A.¹, Rizzetto, S.¹, Nguyen, O.², Kedzierska, K.², Lloyd, A.¹, Bull, R.¹, Luciani, F.¹

¹University of New South Wales, Faculty of Medicine, School of Medical Sciences, Sydney, Australia, ²The University of Melbourne, Peter Doherty Institute for Infection and Immunity, Parkville, Australia

CD8+ T cells (CTLs) play a pivotal role in protection from viral infections. Several viruses infecting humans, such as HIV and HCV develop chronic infection, which are characterised by both immune escape and CTL exhaustion. TCR diversity and impaired differentiation are known to be associated with immune escape and exhaustion of CTLs, but the timing and mechanisms of these impairments remains unclear.

Exhaustion and differentiation profiles as well as TCR diversity, were assessed in unique longitudinal blood samples from primary HCV infection. Multicolor flow cytometry was employed for phenotypic characterisation of Antigen (Ag)-CTLs via activation, differentiation and inhibitory molecules. Single cells were sorted and analysed for transcriptomic profile (SmartSeq2) and TCR diversity using a novel computational workflow.

The majority of Ag-CTLs responses identified via IFN- γ ELSPOT were also characterised by a dominant population

of terminally differentiated effector memory cells (CCR7^{low}CD45RO^{high}KLRG1^{high}CD127^{low}), and elevated expression of co-inhibitory markers (PD-1, 2B4 and CTLA4) targeting both conserved as well as escaped HCV variants at the peak of immune response (as early as 70-90 days post infection). However, evidence of long-term central memory subpopulations with moderate IFN- γ production was identified in a subset of responses. There was an association of viral escape with the magnitude (IFN- γ production) of the response and ongoing diversification of TCR clonotypes, suggesting ongoing evolution of CTLs in response to prolonged viral exposure. These findings support the model of early onset of exhaustion, which compromises the successful establishment of a long-term memory repertoire in chronic HCV infection.

Induction of CD137 expression by Epstein-Barr Virus facilitates immune escape of infected cells

Wu, M.^{1,2}, Schwarz, H.^{1,2}

¹National University of Singapore, Immunology Programme, Singapore, Singapore, ²National University of Singapore, Department of Physiology, Singapore, Singapore

The tumour necrosis factor (TNF) receptor family member CD137 (4-1BB, TNFRSF9) is a co-stimulatory molecule expressed on activated T cells. Its ligand CD137L (4-1BBL, TNFSF9) is constitutively expressed on most antigen-presenting cells (APCs), and reverse signalling through CD137L augments the activity of APCs. Previous studies in our lab had shown that ectopic CD137 expression on Hodgkin and Reed Sternberg (HRS) cells in Hodgkin lymphoma leads to a downregulation of surface CD137L on surrounding APCs, thus reducing T cell co-stimulation by CD137 and IFN- γ secretion, and enabling an escape of HRS cells from a Th1 immune response. Several intracellular pathogens are also known to induce CD137 expression and it has been reported that CD137 expression is induced in Epstein-Barr Virus (EBV)-positive cells from patients with EBV-positive T or NK cell lymphoproliferative diseases. In this study, we show that CD137 expression is upregulated shortly after nucleofection of mRNA encoding the EBV latent membrane protein 1 (LMP1) in peripheral T cells isolated from healthy donors and persists for several hours even after LMP1 expression has diminished. Furthermore, co-culture of these CD137-induced T cells with various CD137L-expressing monocytic and B cell lines leads to a decrease in surface CD137L expression on the cell lines. Our data suggests that similar to HRS cells, intracellular pathogens, such as EBV, utilise ectopic CD137 expression as a means to downregulate CD137L on APCs in order to evade a Th1 immune response.

RNF122 suppresses antiviral type I interferon production by targeting RIG-I CARD to mediate RIG-I degradation*Jiang, M., Wang, W., Liu, S., Zhang, S., Liu, W., Ma, Y., Zhang, L., Zhang, J., Cao, X.**Chinese Academy of Medical Sciences, Institute of Basic Medical Sciences, Beijing, China*

As a cytoplasmic innate sensor for viral RNA, retinoic acid-inducible gene-I (RIG-I) is tightly regulated to avoid over activation and prevent excessive inflammation reactions. Post-translational modifications, particularly ubiquitination, are crucial for regulation of RIG-I activity. Increasing evidence suggest that E3 ligases play important roles in the regulation of various cellular processes, including cell proliferation and antiviral innate immune signaling. Here we report that RING finger protein 122 (RNF122), an E3 ubiquitin ligase, interacts with mouse RIG-I as demonstrated through screening the RIG-I-interacting proteins in RNA virus-infected cells using mass spectrometry. The transmembrane (TM) domain of RNF122 associates with the caspase activation and recruitment domains (CARDs) of RIG-I; this interaction effectively triggers RING finger domain of RNF122 to deliver the Lys-48-linked ubiquitin to the Lys115 and Lys146 residue of RIG-I CARDs and promote RIG-I degradation, resulting in a marked inhibition of RIG-I downstream signaling. Deficiency of RNF122 selectively increases RIG-I-triggered production of type I IFNs and proinflammatory cytokines in response to RNA virus infection both in vitro and in vivo, and RNF122-deficient mice exhibits longer survival after lethal VSV infection than control groups. Thus, we demonstrate that RNF122 acts as a selective negative regulator of RIG-I mediated antiviral innate responses by targeting CARDs of RIG-I.

692

Dengue virus (DENV) inhibition of NETs is independent of neutrophil IL-8 synthesis*Moreno-Altamirano, M.M.B., Nava-Pérez, T.M., Rodríguez-Espinosa, O., Santiago-Ojeda, I.P.**Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Immunology, Mexico City, Mexico*

Introduction: Dengue is a disease caused by any of four serotypes of dengue virus (DENV-1, -2, -3 or -4). There is a striking correlation between increased serum levels of IL-8 and severe DHF. IL-8 stimulates the formation of neutrophil extracellular traps (NETs). Although the role of NETs in dengue patients, if any, is currently unknown, Since activated neutrophils produce IL-8 and this has proved to be an inducer of NETs.

The aim of this work was to explore if DENV-2 down-modulates the PMA-induced production of IL-8 and formation of NETs. Material and methods: neutrophils (PMN) were obtained from peripheral blood of healthy donors using heparin as anticoagulant and gradient centrifugation on Polymorphprep. The Neutrophils were recovered and resuspended in DMEM medium. For the formation of NETs and IL-8 detection, neutrophils (5X10⁵) were seeded on 6 well culture plates. Neutrophil were 8 hours incubated with 100 ng/mL PMA, with DENV and with PMA

plus DENV. After incubation, 50ul of supernatant was collected and the cytokines analyzed by using the human CBA kit (BD) PMN were fixed with 4% paraformaldehyde for 20 min, washed and stained with DAPI, mounted on Vectashield and observed by the fluorescence microscopy.

Results: showed that in vitro DENV-2 triggers the neutrophil production of IL-8. Thus, we propose that neutrophils should also been considered as an important source of IL-8 and that the mechanism(s) by which DENV-2 inhibits NET formation is independent of the synthesis of IL-8 by neutrophils. MMBMA and TMNP are supported by SIP 20150448/20161048.

Enhancement of interferon and antiviral activities by staphylococcal enterotoxin superantigens and their mimetic peptides in vitro and in vivo*Mujtaba, M.¹, Johnson, H.²**¹Florida Gulf Coast University, Biological Sciences Department, Fort Myers, United States, ²University of Florida, Microbiology and Cell Science, Gainesville, United States*

The staphylococcal enterotoxins are a causative agent of food poisoning and have been implicated in other pathologies. They are classified as superantigens due to their potent stimulation of the immune system resulting in T cell activation and prodigious cytokine production. If superantigen activation of T cells and resulting cytokine production can be controlled, then the superantigen's beneficial properties can be harnessed. This study examined the ability of superantigens and their mimetic peptides to induce antiviral activity in vitro and in vivo. The superantigens SEA and SEB induced an antiviral activity in cells and prevented encephalomyocarditis (EMC) virus infection of L929 mouse cells in tissue culture. Furthermore, prophylactic treatment of mice in vivo with intraperitoneal injections of superantigens SEA and SEB prevented EMC virus lethality in 80% of the mice as compared to the control saline treated groups in which EMC virus was lethal to all mice. It was found that superantigens do not directly prevent EMC viral infection in mice, but rather indirectly via inducing IFN-gamma production in cells. Furthermore, development of a library of superantigen mimetic peptides showed one peptide (SEA3) having superantigen-like activity without the associated toxicity in vitro. If the negative side effects of superantigens can be eliminated then the beneficial effects of superantigens can be harnessed for prophylactic and therapeutic treatment of viral infections.

Regulatory role of neutrophils in the inflammatory responses to paramyxovirus infection in mice*Cheemarla, N., Banos-Lara, R., Guerrero-Plata, A.**Louisiana State University, Department of Pathobiological Sciences, Baton Rouge, United States*

Neutrophils are the most abundant leukocytes (50% to 70%) in humans and are the first immune cell population recruited to the sites of infection. They are known to act in the first line of innate immune defense against invading pathogens, and more recently, to playing a crucial role in orchestrating adaptive immune responses. However, the role of neutrophils in the control of adaptive immune response during respiratory viral infections is still largely unknown. In order to elucidate the role of neutrophils in respiratory antiviral defense, we employed an experimental mouse model of human metapneumovirus (hMPV) infection. HMPV is a member of the Paramyxoviridae family, and a leading respiratory pathogen causing severe symptoms such as bronchiolitis and pneumonia in the young, elderly and immunocompromised patients. Our findings demonstrate that neutrophils are rapidly recruited in high numbers to the lungs of infected mice (>80%) during the acute phase of infection. Specific depletion of neutrophil *in vivo* using a monoclonal antibody and simultaneous infection with hMPV exhibited significantly higher levels of inflammatory cytokines, pulmonary inflammation and severe clinical disease compared to hMPV-infected competent mice. Interestingly, the lack of neutrophils altered the T cell responses in the lung, particularly the $\gamma\delta$ -T-cell subset. Finally, we also observed that the recruitment of neutrophils to the lung was controlled by the expression of the hMPV attachment protein. These novel findings demonstrate that neutrophils regulate T cell responses and are critically important for the control of the hMPV-induced inflammatory responses in the respiratory tract.

Reshaping of the host immunopeptidome during virus infection*Croft, N.¹, Smith, S.², Wu, T.¹, Guan, J.³, Flesch, I.², La Gruta, N.³, Tschärke, D.², Purcell, A.¹*

¹Infection and Immunity Program, Monash Biomedicine Discovery Institute and Department of Biochemistry and Molecular Biology, Monash University, Biochemistry and Molecular Biology, Melbourne, Australia, ²Australian National University, John Curtin School of Medical Research, Canberra, Australia, ³University of Melbourne, Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia

With the advent of rapid high-resolution mass spectrometry, our knowledge of the diversity of MHC-peptides presented on the surface of cells - the immunopeptidome - is becoming ever more complete. Our previous analyses have focused on the identification and quantification of virus-derived MHC-bound peptides presented during infection. However, in addition to substantial changes in the immunopeptidome elicited by viral peptides we have also observed changes in the host immunopeptidome generated by altered self-peptide

presentation.

We present data on the infection of cells with either of two different viruses (vaccinia virus, a large double-stranded DNA virus; and influenza A virus, a small single-stranded RNA virus) and find that the host immunopeptidome is reshaped following infection, with both the loss of many constitutively presented MHC-bound peptides and the subsequent gain of expression of previously undetected peptides. We describe data on the origin of these virus-induced self-peptides and discuss the clear implications in their potential autoreactivity as T cell targets.

Evaluation of antiviral activity of *Carica papaya* aqueous leaf extract and its role in platelet augmentation*Sharma, N., Mishra, K.P., Ganju, L., Singh, S.B., Immunomodulation DIPAS, DRDO, Immunomodulation, Delhi, India*

Aim: Dengue disease is characterized by marked decrease in platelet count which is life threatening. We investigated the anti-viral activity of aqueous extract of *Carica papaya* (CP) leaves against dengue virus (DENV) and its effect on platelet augmentation.

Methods: Antiviral activity of CP in DENV infected THP-1 cells was determined by immunoblotting and flow cytometry. Its effect on platelet augmentation in cyclophosphamide induced thrombocytopenic rats was also examined. The rats were divided into four groups, normal control, thrombocytopenic control, thrombocytopenia induced rats in which CP dose was given prophylactically and in fourth group CP dose was given therapeutically after establishment of thrombocytopenia.

Results: CP significantly decreases the expression of envelope and NS1 protein in DENV infected THP-1 cells. Significant decrease in intracellular viral load by CP confirmed its antiviral activity. Platelet count of blood from retro orbital plexus of rats was examined at different time interval of 1st, 4th, 7th, 11th and 14 th day of study. Average platelet count in normal rats was $6.25 \times 10^5/\mu\text{l}$ on day 1. Platelet count in second group started to fall after Day 3 and remarkable thrombocytopenia developed after day 7 ($2.51 \times 10^5/\mu\text{l}$). However in third group interestingly, there was only mild decrease ($4.21 \times 10^5/\mu\text{l}$) even after day 7 and on day 11 it reaches normal level ($7.13 \times 10^5/\mu\text{l}$). CP also increases platelet count in the fourth group ($6.98 \times 10^5/\mu\text{l}$) at day 14.

Conclusion: Our findings suggest that CP can be a potent antiviral agent as it helps in platelet augmentation and exhibits excellent antiviral activity against DENV.

697

Conjugated bilirubin regulates CD4+T effector cell and T regulatory cell function through outside-in and inside-out mechanisms: intracellular signalling and HAV receptor on cell surface*Corral-Jara, K.F.¹, Trujillo-Ochoa, J.L.², Realpe, M.³, Panduro, A.⁴, Gomez-Leyva, J.F.⁵, Rosenstein, Y.⁶, Roman, S.¹, Fierro, N.A.²*

¹Universidad de Guadalajara, Biología Molecular, Guadalajara, Mexico, ²Universidad de Guadalajara, Fisiología, Guadalajara, Mexico, ³Universidad de Guadalajara, Medicina Veterinaria,

Guadalajara, Mexico, ⁴Universidad de Guadalajara & Hospital Civil de Guadalajara Fray Antonio Alcalde, Clinicas Medicas, Guadalajara, Mexico, ⁵Instituto Tecnológico de Tlajomulco, Tlajomulco, Mexico, ⁶Universidad Nacional Autónoma de México & Instituto de Biotecnología, Cuernavaca, Mexico

We recently reported an immune-modulatory role of conjugated BR (CB) in Hepatitis A virus (HAV) infection. During HAV infection, the immune response relies on CD4+ T cells and may also be affected by the interaction of HAV with its cellular receptor (HAVCR1/TIM-1) expressed on T cell surface. Moreover, a six-amino-acid insertion (157insMTTVP) in *HAVCR1/TIM-1*, has been associated with the development of severe HAV infection. However, how BR may affect T cell function to define the clinical course of the disease has not been determined.

Herein, when CB was used to stimulate peripheral T lymphocytes (TLs) from healthy donors *in vitro*, changes in the degree of intracellular tyrosine phosphorylation relative to the concentration of CB were found. When side-by-side comparison between TLs from healthy and HAV-seropositive patients was conducted, changes in the degree of CREB, CD3e and Syk phosphorylation relative to discrete changes in CB levels were found. An increased activity of Tregs along with a Th17 cytokine profile and elevated proportion of Tregs expressing HAVCR1/TIM-1 on the cell surface were found in those patients which exhibited higher levels of CB. Moreover, a low frequency of the 157insMTTVP insertion in *HAVCR1/TIM-1* gene was found in patients and healthy donors suggesting that mild HAV-related disease is not associated with this mutation. Our data revealed that during HAV infection, CB plays a role in defining T cell function by modulating intracellular pathways and by inducing changes in the function of Tregs in a mechanisms related to expression of HAVCR1/TIM-1 on the cell surface.

698

Effect of oxidative stress and rhinovirus infection on mitochondrial/endoplasmic reticular function in human primary bronchial epithelial cells

Pathinayake, P.S.¹, Hsu, A.C.-Y.¹, Parsons, K.¹, Loo, S.-L.¹, Fricker, M.¹, Wood, L.G.¹, Hansbro, P.¹, Wark, P.A.B.^{1,2}

¹Priority Research Center for Asthma and Respiratory Disease and Hunter Medical Research Institute, University of Newcastle, New Lambton Heights, Australia, ²John Hunter Hospital, Department of Respiratory Medicine, New Lambton Heights, Australia

Asthma is characterized by chronic airway inflammation and increased susceptibility to virus infections, such as Rhinovirus (RV), consequently the airway epithelium is exposed to high levels of oxidative stress. The Mitochondria play a central role in cellular metabolism and the immune response to virus infections. While mitochondrial dysfunction has been described in many chronic inflammatory diseases, little is known about its role in airway diseases.

Here we assessed the impact of the exposure of cigarette smoke, hydrogen peroxide (H₂O₂), tunicamycin (ER stress) and human rhinovirus infection (RV-1B) on mitochondrial function of human primary bronchial epithelial cells (pBECs) grown at the air liquid interface or submerged culture system. Mitochondrial functions were assessed by Seahorse XF⁹⁶ analyzer and

measuring cytochrome-C release. Pro-inflammatory cytokines were measured to evaluate the level of inflammation.

Infection with RV-1B demonstrated a reduced mitochondrial respiration and increased proton leak. This is accompanied with increased pro-inflammatory cytokines. Exposure of 1% CS increased the mitochondrial oxygen consumption rate, increased cytochrome-C release and increased virus replication compared with untreated cells. Induction of ER stress also increased the mitochondrial respiration. Exposure of 0.2mM H₂O₂ completely arrested the mitochondrial respiration with or without infection.

Taken together these results demonstrate that exposure of cigarette smoke or other forms of oxidative and ER stress change the mitochondrial function leading to impaired immune responses.

699

The E3 ligase FBXW7 stabilizes RIG-I to mediate antiviral immunity by targeting SHP2 for ubiquitination and degradation

Song, Y.¹, Liu, Y.¹, Lai, L.¹, Zhang, Y.², Chen, Z.², Cao, X.³, Wang, Q.¹
¹Zhejiang University School of Medicine, Institute of Immunology, Hangzhou, China, ²Zhejiang University School of Medicine, Hangzhou, China, ³Chinese Academy of Medical Sciences, Beijing, China

RIG-I serves to detect viral RNA in cytosol and trigger a type I interferon-mediated response that protects the host against viral infection. Viruses can evade the host recognition by degradation of RIG-I or interference of the RIG-I signaling to establish persistent infections. However, the mechanisms how host cells stabilize RIG-I protein for avoiding its degradation is largely unknown. We report here that the E3 ubiquitin ligase FBXW7 stabilizes RIG-I to mediate antiviral immunity by targeting SHP2 for ubiquitination and degradation. The Lysm⁺FBXW7^{fl/fl} mice showed impaired antiviral ability when challenged with vesicular stomatitis virus (VSV) but not DNA virus. FBXW7 deficient macrophages showed a decrease in RIG-I protein level, produced less IFN- β and IFN- α 4 and downregulated the activation of NF- κ B, IRF3, AP-1 upon VSV and H1N1 infection. FBXW7 translocates from the nucleus into the cytoplasm upon VSV stimulation to interact with SHP2 and mediated the degradation and ubiquitination of SHP2, thus protecting RIG-I from degradation. The stabilization of RIG-I was enhanced in SHP2 deficient macrophages. Furthermore, we detected a significantly lower level of FBXW7 mRNA in peripheral blood mononuclear cells (PBMCs) from 70 cases of children with RSV infection when compared to that in PBMCs from control healthy children. Taken together, our results have identified the E3 ligase FBXW7 as an important interacting partner for RIG-I, which is crucial for the stability of RIG-I and RIG-I-triggered type I IFN production. These findings provide insights into the novel function of FBXW7 in antiviral immunity and its related clinical significance.

700

Differentiation by cytokine signatures of acute hepatitis in Mexican population. The diagnostic value for independent, and HAV/HEV co-infection

Realpe, M.¹, Copado-Villagrana, E.D.², Meraz-Medina, T.³, Panduro, A.^{4,5}, Fierro, N.A.^{6,7}

¹Universidad de Guadalajara, Medicina Veterinaria, Guadalajara, Mexico, ²Universidad de Guadajara, Guadalajara, Mexico, ³Universidad Politecnica de la Zona Metropolitana de Guadalajara, Tlajomulco de Zuñiga, Mexico, ⁴Universidad de Guadalajara, Guadalajara, Mexico, ⁵Hospital Civil de Guadalajara Fray Antonio Alcalde, Servicio de Biología Molecular, Guadalajara, Mexico, ⁶Universidad de Guadalajara, Fisiología, Guadalajara, Mexico, ⁷Hospital Civil de Guadalajara Fray Antonio Alcalde, Unidad de Inmunovirología, Servicio de Biología Molecular, Guadalajara, Mexico

Hepatitis A virus (HAV) and hepatitis E virus (HEV) are the major causes of acute viral hepatitis worldwide. HAV infection use to resolve spontaneously whereas HEV infection initially defined as self-limiting, can take chronic courses under certain circumstances. Despite a major outbreak of HEV in Latin America occurred in Mexico, no information about incidence of single or co-infection has been available periodically for these two hepatotropic viruses. The detection of soluble immune mediators involved in specific immune responses against each of these viruses could provide valuable diagnostic tools.

The frequency of single and double infection was retrospectively analyzed in serum samples from Mexican patients clinically diagnosed with acute hepatitis. A total of 131 samples (seronegative for HBV and HCV), 8 without a known aetiological agent, and 30 samples from healthy individuals were screened for anti-HEV IgM and anti-HAV IgM. In addition, common and unique cytokines were identified by multiplexed immune assays. HAV-HEV co-infection, HEV- and HAV-single infections, and infections with no aetiological agent were found in 54%, 3%, 37% and 6% of the samples, respectively. IL-10 and IL-17 were commonly modulated in patients. A reduced secretion of cytokines was found in HEV-infected and HAV-HEV co-infected patients as compared to HAV single infection. Levels of IL-12, IL-13, IFN-gamma, and IL-4 were higher ($p < 0.05$) in HAV-positive samples as compared with other groups. Altogether, data highlighted the presence of HEV single infection and HAV-HEV co-infection in Mexico and revealed a virus-specific induction for specific host cytokines during acute viral hepatitis.

701

Regulation of innate immune cell activation and the type I IFN response by interleukin enhancer binding factor 3 (ILF3) during HIV-1 infection

Nazitto, R.^{1,2}, Johnson, J.S.², Amon, L.², Aderem, A.^{1,2}

¹University of Washington School of Medicine, Immunology, Seattle, United States, ²Center for Infectious Disease Research, Immunology, Seattle, United States

Type I interferon (IFN) acts as a potent antiviral weapon. Almost all cells can produce type I IFN, but innate immune cells, such as myeloid dendritic cells (DCs), play key roles in IFN signaling

as they are positioned to “sense” pathogens and program adaptive immune responses. It is critical that we understand IFN regulation, since dysregulation occurs in disorders such as autoimmune disease, cancer, and chronic infections. In particular, HIV-1 is known to evade early detection in myeloid DCs, but as the disease progresses, IFN responses become exacerbated and correlate with the degree of pathogenesis. To uncover new regulatory nodes of IFN signaling, we have infected human monocyte-derived DCs (MDDCs) with HIV-1, and computationally analyzed the transcriptome. Here we describe that Interleukin Enhancer Binding Factor 3 (ILF3) acts as a negative regulator of HIV-driven innate immune responses. ILF3 is known to play roles in stress responses and regulation of host mRNA and miRNA processing in ribonucleoprotein (RNP) complexes. Knockdown of ILF3 in MDDCs led to increased basal activation and significantly potentiated maturation and IFN production during HIV-1 infection. By blocking reverse transcription during ILF3 knockdown, we inhibited maturation in response to HIV-1, supporting the hypothesis that viral DNA is sensed by MDDCs. Through combinatorial knockdown of ILF3 and cGAS, an innate intracellular DNA sensor, we abolished the activation phenotype and HIV-mediated induction of IFN. This work uniquely links host RNA processing complexes to modulation of innate antiviral responses, signaled through nucleic acid sensors of the myeloid immune compartment.

702

Modulation of MHC class I expression by human cytomegalovirus encoded IL-10

Avdic, S., Ariyakumar, G., McSharry, B.P., Steain, M., Abendroth, A., Slobedman, B.

The University of Sydney, Discipline of Infectious Diseases and Immunology, Camperdown, Australia

Human cytomegalovirus (HCMV) infection induces both innate and adaptive immune responses, and whilst these responses ultimately lead to the resolution of productive infection, the clearance of replicating virus can take weeks or months. The capacity of HCMV to interfere with immune-mediated clearance is likely due to viral genes that target host immune responses, including a viral homolog of human interleukin-10 (hIL-10), termed cmvIL-10, which exerts a number of immunomodulatory functions.

We explored the impact of cmvIL-10 on MHC Class I (MHC I) expression by CD14⁺ monocytes. We included examination of NLRC5, a cellular protein which has recently been reported to play an important role in transactivation of MHC I genes. Whilst cmvIL-10 did not significantly alter surface expression of MHC I by freshly isolated CD14⁺ monocytes, transcription of NLRC5 and a range of genes associated with the MHC I antigen presentation pathway (HLA-A, HLA-B, B2M and LMP2) were significantly downregulated. These data indicate that cmvIL-10 may not rapidly alter constitutively expressed cell-surface MHC I, but may rather impair newly synthesized MHC I. To address this, we used LPS to stimulate surface MHC I by CD14⁺ monocytes in the presence of cmvIL-10. This analysis revealed inhibition of upregulation of surface MHC I protein as well as inhibited transcription of NLRC5 and MHC I associated genes.

Thus, cmvIL-10 can impair the MHC I biosynthesis pathway, including a key regulator of this pathway, NLRC5. These findings provide evidence of an additional mechanism by which HCMV may restrict immune recognition and virus clearance.

703

MiR-22 promotes porcine reproductive and respiratory syndrome virus replication by targeting the host factor heme oxygenase-1

Xiao, S., Wang, X., Ni, H., Li, N., Yan, Y., Zhou, E.-M.

Northwest A&F University, College of Veterinary Medicine, Yangling, China

Porcine reproductive and respiratory syndrome virus (PRRSV) is one of the most economically important viruses affecting the swine industry worldwide. Our previous research showed that PRRSV down-regulates the expression of heme oxygenase-1 (HO-1), a pivotal cytoprotective enzyme, post-infection and overexpression of HO-1 inhibits PRRSV replication. MicroRNAs (miRNAs) regulate gene expression at the posttranscriptional level and have recently been demonstrated to play vital roles in pathogen-host interactions. We have previously shown that miRNA miR-24-3p promotes PRRSV replication through the suppression of HO-1 expression. Given that multiple miRNAs can regulate expression of the same gene, we postulated that there may be other miRNAs modulating HO-1, and by doing so, regulate PRRSV replication. Using bioinformatic prediction and experimental verification, we demonstrate that HO-1 expression is regulated by miR-22. A direct interaction between miR-22 and HO-1 mRNA was confirmed using a number of approaches. miR-22 can downregulate HO-1 expression by directly targeting its 3' untranslated region. Suppression of HO-1 expression by miR-22 facilitates PRRSV replication. Collectively, these results suggested that miR-22 promotes PRRSV replication through suppression of HO-1 expression, which not only provides new insights into virus-host interactions during PRRSV infection, but also suggests potential new antiviral strategies against PRRSV infection.

This study was supported by National Natural Science Foundation of China (31472173 31430084), Northwest A&F University talent special fund (Z111021201) and Fundamental Research Fund (QN2013028).

Bim deficiency prevents PD-1 mediated T cell attrition and rescues CD8 T cell exhaustion

Preston, S., Toe, J., Cooney, J., Pellegrini, M.

Walter and Eliza Hall Institute of Medical Research, Infection and Immunity, Parkville, Australia

Several host factors impede immunity to chronic infections including PD-1, CTLA-4 and type I interferons. These factors contribute to the exhaustion and attrition of virus specific T cells. During infection of mice with chronic LCMV docile the relative amounts of pro- and anti- apoptotic proteins are altered to favour the death of virus specific T cells. We show that loss of the pro-apoptotic protein Bim is sufficient to prevent the death of PD-1^{hi} virus specific T cells during chronic LCMV

infection. We found that conditional knock out mice deficient for Bim in their virus specific CD8 T cells had 10-40 fold more virus specific T cells compared to controls. These Bim deficient T cells were able to kill target cells as well as maintain their capacity to produce TNF α and IFN γ despite high expression of PD1. These findings are the first to demonstrate that keeping T cells alive, via inhibition of intrinsic apoptosis, rescues not only the quantity but also the quality of the T cell response. However, despite the ability of Bim deficient T cells to persist and retain immunological function their proliferative potential is impaired and this is not due to PD-1 signalling. Our data suggest that a PD-1-independent checkpoint blocks the proliferative capacity of pathogen specific T cells if they have escaped exhaustion/deletion. This work provides novel insights into the mechanisms of T cell death during chronic infections and could contribute significantly to development of immune modulating therapies that are desperately needed in many chronic overwhelming infections.

705

Universal and heterologous CD8⁺ T cell immunity to influenza viruses

Koutsakos, M.¹, Gras, S.², Rossjohn, J.², Nguyen, O.¹, Kedzierska, K.¹

¹Peter Doherty Institute, University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia,

²Biomedicine Discovery Institute, Monash University, Infection and Immunity Program & Department of Biochemistry and Molecular Biology, Clayton, Australia

Influenza A and B viruses (IAV and IBV, respectively) remain a global health threat due to the occurrence of annual epidemics and the imminent emergence of novel pandemics. Thus, a CD8⁺T cell-inducing vaccine that can provide universal immunity across all influenza viruses would be of great health benefit. However, despite the breadth of work being done on immunity to IAVs, clinically relevant IBVs are greatly understudied. Here, to determine any cross-reactivity between IAVs and IBVs, we examined the conservation of known IAV CD8⁺T cell epitopes in IBV strains and identified a set of highly conserved epitopes. We found that a HLA-A02:01-restricted peptide from the PB1 protein (PB1₄₁₃₋₄₂₁ NMLSTVLGV) was 100% conserved in >99% of all human and avian influenza viruses. This A2/PB1₄₁₃₋₄₂₁ induces polyfunctional (IFN- γ , TNF and CD107a) responses in CD8⁺T cell lines from HLA-A2⁺ healthy donors, although appears to be subjected to a competition from the IAV A2/M1₅₈₋₆₆ epitope, at least in some donors. This first potential evidence of immunodominance in humans has implications for human CTL vaccines. We are further investigating the quality of the A2/PB1₄₁₃₋₄₂₁ response by determining the functional avidity of A2/PB1₄₁₃₋₄₂₁-specific CD8⁺T cells. Using a multiplex, paired single-cell PCR for TCR α repertoire, we have also determined the clonotype composition of A2/PB1₄₁₃₋₄₂₁ CD8⁺T cells. We are now evaluating the magnitude, quality and protective capacity of the A2/PB1₄₁₃₋₄₂₁ response in humanized HHD-A2 mice infected with IAV and IBV. Our studies demonstrate the potential for universal and protective CD8⁺ T cell-mediated immunity across IAV and IBV viral strains.

706

TIPE2 negatively regulates hepatitis by inducing HBV-infected hepatocytes apoptosisCui, J.¹, Hu, Y.², Lian, K.³, Chen, Y.⁴, Liu, S.⁵¹Shandong University Medical of Sciences, Ji'nan, China, ²Binzhou Medical University, Department of Pathophysiology, Yantai, China, ³Shandong University School of Medicine, Ji'nan, China, ⁴University of Pennsylvania, Philadelphia, United States, ⁵Shandong University, Immunology, Ji'nan, China

Apoptosis, or type = 1 * ROMAN I programmed cell death (PCD), is considered as a controlled process of cell death involved in homeostasis. During HBV infection the apoptosis of infected-hepatocytes is very important for eliminating viruses. But the mechanism is not clear. Tumor necrosis factor- α -induced protein-8 like-2 (TNFAIP8L2, TIPE2) is a newly identified protein of TNFAIP8 family which can promote Fas/Fas Ligand (FasL)-induced apoptosis. Using gene expression microarray analysis, we found that TIPE2 deficiency could regulate the expression of apoptosis associated genes in liver tissues from hepatitis B mice models. TIPE2 protein was detected in TUNEL staining positive hepatocytes in HBV-infected C57 mice. Interestingly, the TIPE2 expressed hepatocytes were just the HBV infected cells. Furthermore, TIPE2 could upregulate the mRNA levels of FasL, Bim and TNFRsF1b which could promote cells death, when TIPE2 was transfected into HepG2 cells *in vitro*. As a result, TIPE2 overexpression cells showed a higher number of apoptotic cells and increased level of cleavage caspase3 compared to controls. Those results indicate that TIPE2 may participate in HBV infection by regulating apoptosis of virus-infected hepatocytes.

707

MNV manipulation of the host immune response

Fritzlar, S., Mackenzie, J., Mackenzie Lab

Peter Doherty Institute, University of Melbourne, Microbiology and Immunology, Melbourne, Australia

Human Noroviruses are highly infective, single stranded RNA (ssRNA) viruses and the major cause of non-bacterial gastroenteritis worldwide. Due to the lack of a small animal or tissue culture model for Human Noroviruses, mechanisms of norovirus infections are so far poorly understood and drug treatments as well as efficient vaccines remain to be developed. With the discovery of the Murine Norovirus (MNV) and the introduction of an effective model for norovirus infection and replication, knowledge about infection mechanisms and its impact on the host immune response has progressed. We have recently discovered that MNV inhibits important effectors of the innate immune response, critical in controlling viral replication and systemic spread. We have observed that infection with MNV induces increased transcription of cytokines such as TNF α , IFN β and IL-6, however only a minimal amount of these cytokines is secreted into the culture medium. This observed manipulation of cytokine production obviously affects the autocrine and paracrine activity of these important immune mediators. We have observed that the virus-induced intervention is at the translation level as constitutive secretion is not impeded in MNV-infected cells. In addition, we have observed that MNV

interferes with the presentation of antigens on the surface of infected cells. We have shown that MNV-infected DCs and macrophages have a reduced surface expression of MHC class I proteins. Overall our observations indicate that MNV has a large array of strategies to avoid immune-mediated detection and clearance.

708

Quantitative shifts in the influenza immunopeptidome reveal the relative contributions of direct and cross-presentation to the induction of T cell mediated antiviral immunityWu, T.¹, Guan, J.², Croft, N.P.¹, Tschärke, D.C.³, La Gruta, N.L.², Purcell, A.W.¹¹Monash University, Infection and Immunity Program & Department of Biochemistry and Molecular Biology, Melbourne, Australia, ²University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ³Australian National University, Research School of Biology, Canberra, Australia

T cell immunity directed against conserved epitopes from internal influenza proteins provides an alternative vaccination strategy to current antibody-based vaccines. However, the development of suitable peptide-based vaccines is currently limited by our incomplete understanding of the factors that control the relative immunogenicity of T cell epitopes. CD8+ T cells eradicate influenza virus through recognition of viral peptides in complex with major histocompatibility complex class I molecules that are presented on the surface of infected cells and professional antigen presenting cells.

We used a comprehensive mass spectrometry approach to identify and quantify naturally presented influenza epitopes following direct infection and cross-presentation of viral antigen *in vitro* and correlate this to the CD8+ response *in vivo* in C57/BL6 mice. In total, 22 viral peptides were identified including the two known immunodominant epitopes (NP₃₆₆₋₃₇₄ and PA₂₂₄₋₂₃₃), 11 known subdominant epitopes and 8 novel peptides. After direct infection of two murine cell lines, NP₃₆₆₋₃₇₄ abundance was the highest, whereas PA₂₂₄₋₂₃₃ abundance was the lowest, despite the co-dominant response to these epitopes during primary infection in mice. However, cross presentation data showed a 5-fold increase in PA₂₂₄₋₂₃₃ abundance, whilst the majority of other epitopes presented in lower abundance compared to direct presentation. This study provides novel insights into the relationship between peptide abundance and virus-specific CD8+ immunodominance hierarchies, with data suggesting that cross presentation may differentially affect the immunogenicity of influenza epitopes. This insight into the quantitative profiling of direct and cross-presented epitope abundance holds promise to optimise future antiviral vaccination strategies.

709

Methyltransferase Dnmt3a upregulates HDAC9 to deacetylate TBK1 for activation of antiviral innate immunity*Li, X.^{1,2}, Zhang, Q.^{2,3}, Wang, Q.¹, Cao, X.^{1,2,3}*¹Zhejiang University School of Medicine, Hangzhou, China,²Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, ³Second Military Medical University, Shanghai, China

Epigenetic regulation of innate immunity needs further identification. Dnmt3a, a *de novo* DNA methyltransferase, is highly expressed in terminally differentiated macrophages, however, its role in innate immunity remains unknown. Here we report that deficiency of Dnmt3a selectively impairs PRR (Pattern Recognition Receptor)-triggered TBK1-dependent production of IFN α / β but not proinflammatory cytokine TNF α and IL-6. Dnmt3a-deficient mice exhibit more susceptibility to virus challenge than littermate controls. Although Dnmt3a does not directly regulate IFN α / β transcription, Dnmt3a strengthens TBK1/IRF3-initiated IFN α / β production by maintaining high expression of HDAC9 through antagonizing H3K27me3 at distal promoter of HDAC9. HDAC9 directly maintains deacetylation status of TBK1 at Lys241, enhancing TBK1 kinase activity. Our data add mechanistic insights into crosstalk of epigenetic regulation and posttranslational modification in regulation of innate signaling and activation of antiviral innate immune response.

710

Spatiotemporal dynamics of innate immunity and lung pathogenesis during influenza virus infection*Jiang, X., Duan, E., Lu, C., Orian, J., Chen, W.**La Trobe Institute for Molecular Science, Melbourne, Australia*

Excessive pro-inflammatory immune responses are believed to contribute to lung pathogenesis during highly pathogenic influenza A virus (IAV) infections. Innate immune cells such as neutrophils and monocytes have been attributed both protective as well as pathological roles in the development of influenza-induced lung disease. However, current study methodologies such as flow cytometry and gene expression arrays require tissue digestion, which removes critical spatial information about influenza virus infection and clearance dynamics.

We utilize confocal imaging to study the spatial and temporal kinetics of influenza infection in mice following sublethal compared to lethal influenza virus infections. 2D and 3D imaging of influenza virus propagation and inflammatory immune cell recruitment revealed that the PR8 influenza virus infection produced a more diffuse and deeper spread in the lung parenchyma, even with lower initial viral doses compared to X-31. Critically, this pattern of virus infection was spatially associated with the formation of multiple foci of inflammatory innate immune cells. Investigation of influenza virus infection kinetics using the MyD88^{-/-} immunocompromised mouse model further showed that a lack of early inflammatory immune cell foci correlated with increased virus spread, triggering a paradoxical increase in inflammatory lung tissue responses

at day 6 and onwards post-infection. Altogether, our results demonstrate the importance of a spatiotemporal investigation of inflammatory immune cell responses during pathogen infection.

711

Critical role of pDC in regulating gene expression and innate immune responses to human rhinovirus*Xi, Y.¹, Bosco, A.², Upham, J.W.^{1,3}*¹University of Queensland, Translational Research Institute, Lungand Allergy Research Centre, Woolloongabba, Australia, ²The

University of Western Australia, Telethon Kid's Institute, Perth,

Australia, ³Princess Alexandra Hospital, Department of Respiratory Medicine, Woolloongabba, Australia

Human rhinoviruses (HRV) are innocuous viruses in healthy people, but often trigger asthma exacerbations and this has been attributed to a defective type I interferon (IFN-I) response in asthma. We have previously shown that in HRV-stimulated peripheral blood mononuclear cell (PBMC), plasmacytoid dendritic cells (pDC) are responsible for more than 90% of IFN- α production, but the role of pDC in regulating gene expression patterns is unknown. In this project, we have further investigated the role of pDC using gene expression microarray. PBMC and pDC depleted PBMC were isolated from healthy volunteers (n=15) and cultured \pm HRV16 for 24h. HRV stimulated gene expression was determined using Illumina Human HT-12 microarrays: 3856 differentially expressed genes were identified when comparing pDC depleted PBMC versus intact PBMC. pDC depletion led to major changes in upstream regulators, many of which play an important role in IFN-I synthesis. RV16 stimulation triggered upregulation of 597 genes and downregulation of 236 genes; 70-80% of these appeared to be pDC dependant. Using RT-PCR and/or ELISA, we confirmed changes in the expression of selected key genes: pDC depleted PBMC expressed significantly lower *CD303*, *IL-27*, *IL-15RA*, *IRF7*, *EBI3*, *IFI27*, *IL-6*, and *IFN- γ* than PBMC. Adding recombinant *IL-27*, *IL-6*, *IL-15* and *IFN- β* to pDC-depleted cultures was able to successfully 'rescue' the IFN- α response.

In conclusion, we have demonstrated that HRV16 triggered immune response is highly regulated by pDC. The key changes in gene expression provide an important basis for developing novel therapies targeting anti-viral immunity in asthma.

Immunity to Viruses

Immune responses to oral polio vaccine (OPV) in patients with X-linked agammaglobulinemia (XLA)

Wu, Y.¹, Mao, H.W.², Chan, S.M.¹, Lam, K.T.¹, Tu, W.¹, Lau, Y.L.¹

¹University of Hong Kong, Paediatrics and Adolescent Medicine, Hong Kong, Hong Kong, ²HKU-ShenZhen Hospital, ShenZhen, China

Background: XLA is characterized by impaired antibody response resulting from Bruton's tyrosine kinase (BTK) mutation. Unlike other primary immunodeficiency with no predisposition to extraordinary risk of viral infection, XLA renders a unique susceptibility to enteroviruses infection including poliovirus. OPV can induce paralytic poliomyelitis in XLA patients. Of great public concern is that the attenuated OPV can persist and revert to a virulent form in these patients, which renders a high risk of reintroducing virulent poliovirus into general population. It is known that BTK is involved in toll-like receptor 3 (TLR3) signaling, and TLR3-mediated type I IFN responses play critical roles in host protection against poliovirus. However, whether XLA patients have impaired type I IFN responses to OPV are not clear.

Hypothesis: BTK mutations in XLA impair TLR3-mediated type I IFN response, leading to the unique susceptibility to poliovirus in XLA patients.

Method: To investigate the response of XLA patients to OPV, monocyte derived macrophages (MDM) from XLA patients and healthy controls were infected with OPV Sabin strain 1 (OPV1). Further to examine the role of BTK in OPV infection, MDM from healthy controls were infected with OPV1 in the presence or absence BTK inhibitor.

Result: IFN-alpha production was measured by ELISA. OPV virus replication and IFN-inducible gene expressions including Mx1, Mx2, OAS1 were detected by qPCR. Results were compared between XLA patients and healthy controls

Conclusion: This study investigated the immune response of XLA patients to OPV and helped to reveal the role of BTK to control OPV infection.

Immunosuppression

713

Ultraviolet-B irradiation of the skin for alteration of immunophenotype and functional responses in clinically isolated syndrome

Jones, A.P.¹, Kermod, A.G.^{2,3,4}, Nolan, D.^{3,5}, Lucas, R.M.^{1,6}, Hart, P.H.¹

¹Telethon Kids Institute, The University of Western Australia, Perth, Australia, ²Centre for Neuromuscular and Neurological Disorders, Western Australian Neuroscience Research Institute, The University of Western Australia, Sir Charles Gairdner Hospital, Perth, Australia, ³Institute for Immunology & Infectious Disease, Murdoch University, Perth, Australia, ⁴Sir Charles Gairdner Hospital, Department of Neurology and Clinical Neurophysiology, Perth, Australia, ⁵Royal Perth Hospital, Immunology Department, Perth, Australia, ⁶Australian National University, Canberra, Australia

Multiple sclerosis (MS) is an autoimmune disease characterised by demyelination in the CNS. T cells play a crucial role in the development of MS, with evidence of a T helper (Th)1/Th17 skewed phenotype, impaired regulatory T cell (Treg) function, and increased circulating follicular helper T cells (Tfh). Low exposure to ultraviolet-B radiation (UVB) is a strong MS environmental risk factor. UVB is immunosuppressive; inducing Treg and downregulating Th1/Th17 pathways. Due to the therapeutic use of UVB in psoriasis we are investigating its efficacy as a therapy in a neurological autoimmune condition.

We have a world first, NHMRC-funded, randomised controlled trial of narrowband UVB phototherapy for Clinically Isolated Syndrome - a first and single demyelinating event suggestive of MS. The hypothesis is that UVB phototherapy will slow or prevent the progression to MS via immunosuppression. Participants are randomised to receive, or not, 24 sessions of UVB phototherapy over 8 weeks. In addition, all participants receive vitamin D supplementation to control for the independent effects of vitamin D. Blood is collected at seven time points over the 12 month follow-up for measurement of serum 25(OH)D3 and bio-banking of peripheral blood mononuclear cells. Neurological examination and MRI scans are conducted to monitor clinical progression. Here we present longitudinal analysis of Th, Treg and Tfh phenotypes in n=12 participants and an equivalent number of age- and sex-matched controls. This study will inform on the biomarkers of progression of disease from a pre-MS condition, as well as the mechanisms by which UVB may be immunoregulatory.

714

Solar-simulated ultraviolet radiation alters the formation of cell membrane-derived microvesicles in mouse plasma and skin draining lymph nodes

Ferguson, A.L.¹, Halliday, G.M.², Grau, G.E.R.³, Byrne, S.N.^{1,2}

¹University of Sydney, Cellular Photoimmunology Group, Infectious Diseases and Immunology, Sydney Medical School, Camperdown, Australia, ²University of Sydney, Dermatology Research Laboratories, Sydney Medical School, Camperdown, Australia, ³University of Sydney, Vascular Immunology Unit, Discipline of Pathology, Sydney Medical School, Camperdown, Australia

The ultraviolet (UV) radiation contained in sunlight is a powerful modulator of adaptive immune responses. UV can suppress immune responses both locally at the cutaneous site of exposure as well as systemically to affect distant organs and tissues. Modulation of immunity in this way partly explains how UV contributes to the development of skin cancer as well as protects from some autoimmune diseases like multiple sclerosis. We hypothesised that one way UV may be affecting immunity in distant tissues is by altering the number and type of microvesicles (MVs). MVs are cell membrane-derived vesicles that are involved in intercellular communication and are associated with diseases such as MS, cancer, diabetes and infections. MVs were isolated from peripheral blood as well as the lymph nodes that drain UV-exposed back skin (inguinal). Using a combination of fluorochrome conjugated antibodies together with flow cytometry we were able to identify the cellular origin of the MVs. We have discovered that exposure of mice to an immune suppressive dose of UV significantly alters the production and systemic circulating levels of microvesicles (MVs). Understanding the mechanisms by which UV affects immune responses in distant tissues will enable us to develop therapies that harness the power of UV to halt disease progression while eliminating any harmful side-effects.

715

4-Methoxy TEMPO attenuates murine experimental colitis

Chami, B., Vallejo, A., Jeong, G., Varda, A., Witting, P
The University of Sydney, Sydney, Australia

Inflammatory bowel disease (IBD) is a chronic inflammatory condition, where MPO-mediated oxidative damage plays an important role in exacerbating tissue injury.

Aim: To test whether the MPO-inhibitor, 4-Methoxy TEMPO (MetT), can ameliorate the course of colitis.

Methods: Experimental colitis was induced in C57BL/6 mice by administering 3% v/v dextran-sodium-sulphate (DSS) in drinking water ad libitum over 9 days with mice also administered (i.p. injection) MetT (15mg/Kg) or vehicle control (10% DMSO+90% PBS) twice daily during DSS challenge.

Results: MetT attenuated bodyweight loss (50%, $p < 0.05$, $n=6$) and improved clinical score

(53%, $p < 0.05$, $n=6$) at day 9 of DSS challenge and inhibited the DSS-mediated increase in serum lipid hydroperoxide. Analysis of the inflamed colon revealed that damage to gut tissues and several inflammatory, including Ly6C⁺ monocytes and Ly6G⁺ neutrophils, were markedly decreased in MetT-treated mice. Constitutively expressed IL-10 (an anti-inflammatory cytokine) was significantly reduced in the colon of DSS-challenged mice; MetT-treated mice showed a trend to increased IL-10 expression. Levels of MPO were decreased in MetT-treated mice with DSS-induced colitis; likely a consequence of reduced neutrophil motility. Notably, crypt integrity was negatively correlated to MPO⁺ labelling ($p=0.011$, $n=24$), suggesting that increased MPO levels were associated with increased severity of colitis. MetT protected against MPO-producing neutrophil oxidative damage in a myocytes in an in vitro co-culture system.

Conclusion: MetT significantly reduced the severity of

experimental colitis, though it remains unclear whether MetT actions were mediated via inhibition of MPO or anti-inflammatory pathways, or both.

716

Utilizing quantitative methods to study the interaction of immunosuppressive drugs in combination

Lye, B.K.^{1,2}, Heinzl, S.^{1,2}, Kan, A.^{1,2}, Hodgkin, P.D.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²The University of Melbourne, Medical Biology, Parkville, Australia

When naive T cells become activated, they undergo antigen-specific clonal expansion where their survival, proliferation and differentiation are governed by the antigenic signal, cytokines and co-stimulatory molecules received. This response is manipulated clinically by immunosuppressive drugs (ISDs). While the molecular targets of most ISDs are known, a comprehensive understanding of the kinetic changes on proliferation and survival is lacking and hence, predicting synergistic effects is difficult. Here, we utilize quantitative methods to investigate the effects of ISDs on CD8⁺ T cell activation, survival and proliferation in vitro. We report discrete effects that enable unique quantitative descriptions of each ISD that can be utilised for predicting combination therapies. Rapamycin and Mycophenolic acid lengthen division times and consequently reduce the number of division rounds cells undergo before they stop dividing. In contrast, Dexamethasone selectively affected survival, causing increased cell loss over time with unaffected division parameters. When combined, each drug acted independently, allowing net effects to be accurately predicted and their synergies evaluated. Examples include combining drugs affecting division times (Rapamycin and Mycophenolic acid) and survival (Dexamethasone), with progressively less cells undergoing fewer divisions. Interestingly, quantitative analysis of drugs affecting the same parameter such as Rapamycin and Mycophenolic acid showed that the effects of these drugs followed a simple rule of addition. Thus, we demonstrate that quantitative analysis of the effects of ISDs on T cell proliferation kinetic parameters to each fate provides a powerful platform to understand and potentially predict drug synergy.

717

Residential memory regulatory T cells function on immune responses to influenza A virus infection

Lu, C.

La Trobe University, Biochemistry and Genetics, Melbourne, Australia

Recent studies on Tregs responses to influenza A virus (IAV) infections demonstrated that Tregs can be activated during IAV infection, thereby modulating antiviral immune response. Whereas the suppressive function of Tregs that have experienced primary IAV infection remain largely unexplored. To our observation in A/PR8/H1N1 infected C57BL/6 mouse model, there are a certain number of IAV infection experienced Tregs maintaining their residence in mediastinal lymph node (MedLN)

and lung. Moreover, Tregs that have experienced primary IAV infection show more rapid accumulation in bronchotracheo alveolar lavage (BAL), MedLN and lung during secondary infection when compared to naïve Tregs. Subsequently, MedLN and lung residential memory Tregs (RM Tregs) are expanded following by examining their function on immune responses to IAV infection. The expanded RM Tregs interact with bone marrow (BM) DCs resulting in downregulation of B7 molecules on DCs. RM Tregs interfere with antigen-presentation through downregulation of B7 molecules, therefore limiting memory CD4⁺ and CD8⁺ T cell responses. In contrast, blocking CTLA-4 on RM Tregs results in robust memory responses stimulated by DCs presenting IAV-antigens. Our results thus reveal that RM Tregs are more IAV-reactive and suppressive than naïve Tregs and their immunosuppression on IAV-induced immune responses may partially exert via CTLA4-B7 interaction.

718

Translocation and dissemination of commensal bacteria as a source of infection after stroke

Wong, C.¹, Stanley, D.², Mackin, K.³, Lyras, D.³, Prakash, M.⁴, Nurgali, K.⁴, Hill, M.⁵, Moore, R.⁶

¹Monash University, Medicine, Melbourne, Australia, ²Central Queensland University, Rockhampton, Australia, ³Monash University, Melbourne, Australia, ⁴Victoria University, Melbourne, Australia, ⁵University of Calgary, Calgary, Canada, ⁶RMIT, Melbourne, Australia

Stroke is highly prevalent and is one of the leading contributors to morbidity and mortality worldwide. Despite the debilitating neurological deficits, bacterial pneumonia occur frequently and contributes significantly to disease mortality. Prophylactic administration of broad non-specific antibiotics may appear to be a viable option for treatment, but a recent large clinical trial did not support this. Most importantly, the source of infection post-stroke is unclear to date. In this study, we found the majority of the microorganisms detected in the blood of infected stroke patients were commensal bacteria which normally reside in the intestinal tracts. Using a mouse model of stroke, we found that post-stroke infection was only observed in mice born and raised in specific pathogen free facilities, and not germ free. Using high throughput 16S rRNA gene amplicon sequencing and relevant bioinformatics tools, the predicted source of bacteria forming the microbial community in the lungs (most clinically relevant site) of post-stroke mice was indeed the host small intestine. Additionally, stroke-induced gut barrier permeability preceded the dissemination of orally-inoculated bacteria to peripheral tissues. Taken together, we have identified an important source of infection after stroke that have been overlooked. Importantly, the findings of this study clearly indicate that stroke induces a rapid and aberrant intestinal response, permitting selective commensals to breach the gut epithelial barriers and contribute to the development of infectious complications following stroke.

719

A two factor-cocktail: potential substitute for mesenchymal stromal cells in suppressing graft versus host disease

Fan, X.B.¹, Guo, D.Y.¹, Yap, C.S.¹, Bari, S.², Cheung, A.³, Li, S.³, Hwang, W.^{3,4,5}

¹Singapore General Hospital, Department of Clinical Research, Singapore, Singapore, ²National University of Singapore, Department of Pharmacy, Singapore, Singapore, ³Duke-NUS Graduate Medical School, Cancer & Stem Cell Biology, Singapore, Singapore, ⁴Singapore General Hospital, Department of Hematology, Singapore, Singapore, ⁵Singapore Cord Blood Bank, Singapore, Singapore

We identified two mesenchymal stromal cells (MSCs)-derived factors exhibited synergistic immunomodulation effect in mixed lymphocyte reaction. This two factor-cocktail (2F, patent pending) also showed excellent *in vivo* immunosuppressive effect in ameliorating graft versus host disease (GVHD) symptoms and improving survival. A moderate and severe GVHD animal model was created by injecting 200×10⁶cells/kg and 400×10⁶cells/kg of cryopreserved human PBMCs into NSG mice respectively. Four consecutive treatments were given on day-10, day-14, day-17 and day-21 post-transplantation. In moderate GVHD model, the immunosuppressive effect was comparable to BM-MSCs and single factors. However, in severe GVHD model, it exhibited excellent immunosuppressive effect as it could improve mice 36-day survival from 19.0% with severe symptoms to 61.9% with mild symptoms ($p < 0.01$). It was significantly better than BM-MSCs (8.3%, $p < 0.001$) and Cyclosporine A (26.1%, $p < 0.05$). Synergistic effect was again observed between those two factors (Factor-A, 18.2%; Factor-B, 9.1%; $p < 0.05$). The 2F cocktail treatment could elevate human regulatory T cells but also cytotoxic T lymphocytes (CTLs) and T helper 1 (Th1) cells. Meanwhile, it could increase anti-inflammatory cytokine IL-10 and pro-inflammatory cytokines IFN- γ , IL-8, MIP-1 β and MCP-1 in the circulation. These results indicated the 2F cocktail suppressed immune reaction probably through M2 macrophages and regulatory T cells. In conclusion, the efficacy of a novel identified 2F cocktail was validated in an *in vivo* GVHD model. It demonstrated a robust immunosuppressive effect and kept the development of GVHD under control. The 2F cocktail is a potential chemically defined substitute for MSC in GVHD therapy.

720

Metabolic alarmins train monocyte tolerance

Uhle, E., Lichtenstern, C., Weigand, M.A.

Heidelberg University Hospital, Department of Anesthesiology, Heidelberg, Germany

The induction of tolerance is a crucial negative feedback mechanism of activated innate immune cells to counteract activation. The phenomenon of tolerance has been described for a variety of ligands (PAMPS, DAMPS and cytokines) and their corresponding pattern recognition receptors, with endotoxin tolerance being the most prominent one. During inflammation, metabolism of myeloid cells is shifted to aerobic glycolysis, resulting in a rapid energy provisioning necessary to fuel the

immune response. As a by-product, the reactive dicarbonyl compound methylglyoxal is formed, resulting subsequently in the generation of Advanced Glycation Endproducts (AGEs) by reacting with lipids and proteins. In recent studies, we were able to prove elevated levels MG as well as AGEs in both sterile (trauma) and infectious (sepsis) systemic inflammation.

To shed light on the consequence of its presence during disease, we performed in vitro experiments using the monocytic cell line MonoMac 6 and primary human monocytes. After priming of the cells with AGEs, we found a diminished cytokine response upon restimulation with both AGEs and LPS. The observed anergy was neither associated with a changed expression of the involved pattern recognition receptors TLR4 and RAGE, nor with increased cell death or cell cycle variations. It actually was associated with altered levels of intracellular TNF-alpha, despite no changes in the expression of the corresponding gene were measurable. In conclusion, we are able to prove a dual effect of AGEs: initially they act as pro-inflammatory mediators, secondarily training monocytes to a state of cross- and self-tolerance.

721

Phenotypic characterization of LAG-3 expressing cells

Okazaki, I.-M., Okazaki, T.

Tokushima University, Institute for Genome Research, Tokushima, Japan

The activation of lymphocytes is tightly controlled by stimulatory and inhibitory co-receptors in addition to antigen receptors. These co-receptors provide not only a second signal for activation but also a balanced network of positive and negative signals to optimize immune responses against pathogens while limiting immune responses to self. We have been focusing on inhibitory co-receptors, PD-1 and LAG-3, which synergistically regulate T cell activation and autoimmunity. Although accumulating evidence suggests that LAG-3, a type I transmembrane protein with structural similarity with CD4 inhibits activation of T cells, the actual role of LAG-3 is still enigmatic. In this study, we tried to identify cell populations on which LAG-3 functions by single-cell gene expression analysis.

We selected 192 genes based on microarray analyses of bulk LAG-3 expressing cells, analyzed the expression levels of these 192 genes in each LAG-3 expressing cell using BioMark HD system (Fluidigm), and performed the hierarchical clustering analysis. We analyzed LAG-3 expressing cells induced by antigen immunization and those emerged upon autoimmunity. We found that LAG-3 expressing cells were heterogeneous in both conditions but apparently distinct cell populations were increased between two conditions. These results suggest that LAG-3 can regulate the function of variable cell types and that it may regulate the function of specific cell populations in the suppression of autoimmunity.

722

Globo-H ceramide induced T cell immunosuppression via A2A receptor (A2A-R) and cAMP/PKA pathway

Cheng, J.-Y., Wang, S.-H., Hung, J.-T., Yu, A.L., Yu, J.

Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China

Globo-H ceramide (GHCer), the most prevalent antigen in epithelial cancers, is a hotly pursued target for cancer immunotherapy. Previously, we demonstrated that uptake of GHCer shed from cancer cells by endothelial cells promoted angiogenesis via binding of GHCer to TRAX, with consequent release of PLCb1 to trigger Ca²⁺ mobilization. In contrast, uptake of GHCer by lymphocytes significantly suppressed their activation via down-regulation of Notch1 signaling mediated by increased expression of *ID3* and *egr2/3* controlled *itch*. However, the link between GHCer and transcriptional regulation of *ID3/Itch* remains unclear. Here we provided the first evidence for GHCer induced immunosuppression through recruiting TRAX-KIF2A complex to A2A-R, thereby activating A2A-R signaling, which inhibits immune responses. We found that treatment of Jurkat cells, a human T-ALL cell line, with GHCer increased cAMP and CREB activity as determined by cAMP ELISA and CREB reporter assay, respectively, both of which were significantly blocked by pretreating cells with protein kinase A (PKA) inhibitor, H89, or A2A-R antagonist. Since A2A-R is known to be activated by binding to TRAX-KIF2A complex, we used Biacore system with immobilized TRAX on sensor chip CM5 to determine the binding of GHCer to TRAX. At concentrations of 9.77 nM to 5 mM, GHCer bound to TRAX with fast association rate, followed by slow dissociation ($K_D \sim 4.09 \times 10^{-8}$ M). Using immunoprecipitation and Mass Spectrometry, we showed that GHCer formed a complex with TRAX through its lipid-tail, which facilitated the recruitment of A2A-R to TRAX-KIF2A complex through its carbohydrate-head, with ensuing A2A-R signaling and immunosuppression.

Pathogen non-specific bystander T cells were attenuated upon infection with malaria parasites

Suzue, K.¹, Amano, H.², Taniguchi, T.¹, Shimokawa, C.¹, Olia, A.¹, Onishi, R.¹, Hisaeda, H.¹

¹Gunma University Graduate School of Medicine, Department of Parasitology, Maebashi, Japan, ²Gunma University Graduate School of Medicine, Department of Dermatology, Maebashi, Japan

When infected with malaria parasites, infected host falls into immunosuppression state. As a result, allergic symptoms such as atopic dermatitis and contact hypersensitivity (CHS), autoimmune symptoms such as experimental autoimmune encephalomyelitis and collagen-induced arthritis, as well as the course of *Listeria* and *Leishmania* infection, were dramatically changed upon infection with malaria parasites. Our group has been reported that blood ATP concentration is markedly elevated concomitant with malaria parasite infection. Extracellular ATP and its metabolites are known to modulate immune response. Here we show that the extracellular ATP induced by the infection with malaria parasite modulates bystander immune

responses. To examine the role of extracellular ATP on bystander immune suppression, we monitored serum ATP concentration of *Plasmodium yoelii*-infected mice and parasite-non-specific T cell response. The serum ATP concentration was correlated with parasite rate, on the other hand, it was inversely correlated with T cell response and the outcome of CHS. Next, to examine the relationship between serum ATP and the outcome of DNFB-induced CHS, malaria parasite-infected mice were injected with carbenoxolone, an inhibitor for putative ATP secretion channel pannexin-1. Mice infected with malaria parasites showed milder outcome of CHS and relatively lower DNBS-specific T cell response than non-infected control mice. However, when injected with carbenoxolone, the suppressive effect of malaria infection on CHS outcome was diminished. These results suggested that the ATP, induced by malaria parasite infection, elicited bystander immune suppression.

724

Human fibroblastic reticular cells of secondary lymphoid organs regulate T cell activation and proliferation through four overlapping mechanisms

Knoblich, K.¹, Siew, S.M.-L.¹, Parekkadan, B.², Turley, S.³, Fletcher, A.¹
¹University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom, ²Massachusetts General Hospital and Harvard Medical School, Center for Engineering in Medicine and Surgical Services, Boston, United States, ³Genentech, Department of Cancer Immunology, South San Francisco, United States

Fibroblastic reticular cells (FRCs) residing in secondary lymphoid organs are phenotypically and functionally distinct myofibroblasts of mesenchymal origin. Investigations into their role and function have yielded high impact findings regarding their manifold roles as immune regulators. FRCs provide pivotal regulation of lymphoid cells, particularly effector T cells. In mice, FRCs enable T cell activation but suppress effector T cell proliferation and acquisition of effector function, primarily through nitric oxide release, presumably to avoid damage to lymphoid organ infrastructure during an immune response. Accordingly, transfer of ex-vivo expanded mouse FRCs to models of severe inflammation prevents pathology and mortality, suggesting therapeutic potential. However, human FRCs are almost entirely unstudied. Here we show that primary human FRCs from lymph nodes and tonsils shut down human T cell proliferation through multifaceted mechanisms that are nitric oxide independent. Suppression was robust, dose-dependent and MHC independent. Specifically, human FRCs concomitantly utilised TGF β R, A2AR, PGE2 and IDO pathways to suppress both the proliferation and activation of human T cells and to alter their cell cycle and apoptotic properties. Signalling through these pathways increased LAG-3 expression by T cells in the presence of FRCs, while inhibition reversed FRC-mediated immunosuppression of T cell proliferation. FRCs were distinct from mesenchymal stromal cells and did not show trilineage potential in in vitro assays. These results show, for the first time, that human FRCs actively suppress the proliferation of human T cells and define the mechanisms at play, with implications both biological and therapeutic.

725

Soluble CD52 is a negative regulator of innate immune cell-driven inflammation

Rashidi, M., Bandala-Sanchez, E., Zhang, Y., Ngui, K., Neale, A., Lawlor, K., Wentworth, J.M., Vince, J., Harrison, L.C.
 Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia

Background: We showed that CD52, a glycosylphosphatidylinositol (GPI)-anchored cell surface glycopeptide, is released upon activation of T cells and suppresses bystander T cells via interaction with the sialic acid-binding immunoglobulin-type lectin 10. Whether soluble CD52 also influences innate immune function remains unexplored and is the focus of this study.

Methods: Human and mouse monocytes, dendritic cells and macrophages were cultured with different concentrations of CD52-Fc or control Fc in the presence of Toll-like receptor (TLR) and TNF receptor (TNFR) ligands for 24h at 37° C and the inflammatory response assessed using NF- κ B activation assays and cytokine ELISAs. Gene targeting of CD52 in the mouse was performed on a C57BL/6 background by homologous recombination of lox-p sites flanking exon 2. Mice were administered CD52-Fc or control Fc (i.v.), then LPS (i.p.), and assessed after 5 h.

Results: CD52-Fc potently inhibited cytokine secretion by different innate immune cells induced by a range of inflammatory stimuli, including both TLR and TNFR ligands, by inhibiting NF- κ B and ERK transcription factor activation. When injected into mice, CD52-Fc blunted the hypothermic and cytokine response to LPS. Moreover, the decrease in body core temperature and the increase in cytokine production upon LPS injection were more pronounced in CD52 knockout mice compared to wild-type littermates.

Conclusion: Our findings demonstrate the suppressive effect of CD52 on innate immune cell-driven inflammation and its potential as a therapeutic candidate for hyper inflammatory conditions such as septic shock.

726

Involvement of caveolin-1 in quercetin-induced Nrf2 activation

Matsushima, M., Kusatsugu, Y., Oyabu, S., Ochi, H., Atsumi, K., Ogasawara, N., Takemura, K., Kawabe, T.
 Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan

Quercetin is one of the flavonoids and has a wide variety of cytoprotective effects. We previously reported that quercetin exerted anti-allergic, anti-oxidant, and anti-fibrotic activities via heme oxygenase (HO)-1 activity. However, the mechanisms how quercetin can induce HO-1 to exhibit cytoprotective effects are poorly understood. We focused on cell membrane, the first line to interact with extracellular environment. Cell membrane has lipid rafts and caveolae, a subset of rafts which participate in the regulation of many cellular functions. Recent studies demonstrated that flavonoids including quercetin have a suppressive effect on the accumulation of lipid rafts. Moreover,

Caveolin-1 (Cav-1), a structural protein component of caveolae, has been reported to interact with Nrf2 and inhibited the expression of antioxidant enzymes, such as HO-1. In this study, we investigated the mechanisms underlying the induction of HO-1 by quercetin, focusing on lipid rafts and Cav-1. We found that quercetin changed lipid raft formation in NIH3T3 cells. Cav-1 was located in cell membrane with Nrf2 under resting condition, and Cav-1-Nrf2 complex was translocated to cytosol and nucleus after quercetin treatment. Treatment with M β CD induced HO-1 expression as much as quercetin. Quercetin dose-dependently increased the phosphorylation of Cav-1, ERK and JNK. These results suggested that the disruption of lipid rafts by quercetin would translocate Cav-1 and Nrf2 from cell membrane and to nucleus, leading to HO-1 induction.

727

Soluble-CD40L, and/or CD40L-Ig could beneficially modulate disturbed costimulatory signaling between APCs and CD4+T cells

Royan, A.¹, Fazal, N.²

¹Chicago State University, College of Pharmacy, Chicago, United States, ²Chicago State University, Chicago, United States

Immunosuppression is a dreadful phenomenon in burn-septic patients. Although loss of T cell function that contributes to immunosuppression has been known in both burn-septic animal models and in patients, little is known about therapeutic approaches that could protect injured hosts from these conditions with high risks of morbidity and mortality. In a well-published rat model of burn and (Cecal-Ligation and Puncture)-CLP injury (Fazal, et al, 2006), we documented CD4+ T cell dysfunction and intestinal pathology (damaged microvascular/endothelial and mucosal/epithelial barrier). However, such concurrent T cell dysfunction and intestinal morbidity is not accompanied by any substantial mortality

(< ~20 %) in animals with burn or CLP alone. We designed studies to evaluate the tenet that T cell dysfunction and APC dysfunction are intimately linked in the pathogenesis of burn and/or sepsis injuries, such that injury-caused defective APCs can injure healthy T cells and defective T cells so generated can injure healthy APCs through disturbed signaling between the two immune cell systems. Such derangements could well be related to altered interactions between costimulatory ligands-receptors of APCs and T cells. In this series of experiments, we investigated whether costimulatory agonists, e.g., soluble-CD40L, and/or CD40L-Ig could beneficially modulate disturbed costimulatory signaling between APCs and CD4+T cells, or protect against APC's intracellular pathogenic mechanism developing after burn and/or CLP, could alleviate risks for morbidity and mortality in the burn and/or CLP injuries. Our results showed a partial reversal of immune suppression in these burn-injured animals leading to elimination of morbidity and mortality.

728

Plant-derived heme-oxygenase 1 (HO-1) inducers modulate maturation and pro-inflammatory functions in human dendritic cells and macrophages

Campbell, N., Basdeo, S., Mahon, O., Fletcher, J., Dunne, A.

Trinity College Dublin, Biochemistry & Immunology, Dublin, Ireland

The stress response protein Heme-Oxygenase 1 (HO-1) has been identified as an important immunomodulator which is highly upregulated during inflammation. HO-1 catalyses the conversion of free heme to biliverdin, liberating carbon monoxide. Biliverdin is subsequently converted to bilirubin and all three products exhibit potent anti-inflammatory activity in various animal models of disease. The plant-derived polyphenolic compounds carnosol and curcumin induce the expression of HO-1 in many different cell types, and are considered potential anti-inflammatory compounds.

We have examined the effects of carnosol and curcumin in human monocyte-derived dendritic cells (DCs) and macrophages. Treatment of DCs with either compound inhibited LPS-induced expression of the maturation markers CD40, CD80, CD83 and CD86 and reduced the production of the pro-inflammatory cytokines IL-12 and IL-23, resulting in an impaired ability of treated DCs to stimulate allogeneic CD4+

T cells. Carnosol and curcumin treatment restored the phagocytic capacity of LPS-stimulated DCs, and this effect was blocked by addition of the HO-1 inhibitor, SnPP. Reduced activation of NF κ B in response to LPS was also observed in carnosol and curcumin treated DCs. Thus, carnosol and curcumin appear to maintain DCs in an immature, tolerogenic state and this effect may be mediated by HO-1. Macrophages treated with carnosol or curcumin demonstrated reduced expression of M1-associated genes, indicating that carnosol and curcumin may act to polarise macrophages towards an anti-inflammatory or tolerogenic phenotype. In summary, this study confirms that carnosol and curcumin have significant immunomodulatory effects in human innate cells and may have potential as treatments for inflammatory disease.

729

Pre-malignant immune suppressive environment is dependent on HPV16E7-Rb interaction induced epithelium hyperplasia

Kuo, P., Tuong, K., Mattarollo, S., Frazer, I.

University of Queensland Diamantina Institute, Brisbane, Australia

Vaccines are available to prevent infection with cervical cancer-causing Human Papilloma Virus (HPV) 16 and 18. However, treatment for persisting HPV infection, the precursor to cancer, is still lacking. Using a transgenic mouse, which expresses the HPV16 viral oncoprotein E7 under the control of keratinocyte 14 promoter (K14E7), a chronic infection model that resembles cervical intraepithelial neoplasia grade 3 (CIN3) has been established. K14E7 skin is hyperproliferative, induced by the interaction between E7 and retinoblastoma protein (Rb), and is associated with an increased lymphocytic infiltration. Previous studies found an immune suppressive environment in HPV16E7-expressing skin, and this local immune suppression

limits transgenic skin graft rejection. To establish whether the expression of viral oncoprotein, or E7-Rb interaction induced hyperplasia, is responsible for the suppressive environment, we used an Rb mutation transgenic mouse model (K14E7Rb9), where the interaction of E7 and Rb is disrupted but normal Rb functions are preserved. K14E7Rb9 mice had, normal skin thickness, normal lymphocyte subpopulations and normal cytokine secretions, as found in wild type C57 and in contrast to K14E7 mice. Expression of E7 limited the effective immune response after OVA immunisation and induced multiple co-inhibitory markers, CTLA4 and PD-1, suggesting possible T cell exhaustion. RNAseq data revealed that chemokine and receptor pathways were highly correlated with E7-induced hyperplasia, which might account for lymphocyte recruitment to the skin. The K14E7Rb9 mouse enables differentiation of the non-Rb associated effects of E7 expression from the E7-induced hyperplasia, which induces locally immunosuppressive inflammation.

730

The role of IL-4 in the development and function of regulatory T cells induced by B cells (Treg-of-B cells)

Lin, S.-Y., Chiang, B.-L.

National Taiwan University, College of Medicine, Graduate Institute of Immunology, Taipei, Taiwan, Republic of China

Naïve B cells could act as antigen-presenting cells to induce a subpopulation of Foxp3⁺ regulatory T cells, called Treg-of-B cells. Naïve B-cell-primed T cells is through cell-cell contact and independent of IL-10. The suppressive function of Treg-of-B cells partly requires close cell-cell proximity. Therefore, Treg-of-B cells is a population different from natural Treg cells (nTreg) and Type 1 regulatory T cells (Tr1). Recent studies have demonstrated that Treg-of-B cells could be developed as a therapeutic approach against transplant rejection, allergy and rheumatological diseases. However, the previous studies showed that the differentiation of Treg-of-B cells involved STAT6 phosphorylation and IL-4 secretion, the transcription factor and cytokine of Th2 cells. Hence, we hypothesized that naïve T-B cells co-culture might lead to two different populations. One differentiates to Th2 cells and the other to T cells with regulatory activities. This study was performed to examine the role of IL-4 signaling pathway in the development and function of Treg-of-B cells. We supposed that neutralizing IL-4 would produce higher purity of Treg-of-B cells and enhance regulatory function, in order to improve current therapeutic approaches.

731

Inhibition of T cell activation by human LAG-3

Kajihara, T., Sugiura, D., Maruhashi, T., Okazaki, I.-M., Okazaki, T.

Institute for Genome Research Tokushima University, Tokushima, Japan

Inhibitory co-receptors regulate the activation of lymphocytes by dampening antigen receptor signaling. Because of the recent success of tumor immunotherapy targeting CTLA-4 and PD-1, inhibitory co-receptors are attracting high attention of

researchers in various fields. However, the precise mechanisms of inhibition and the interplay among multiple co-receptors are not fully understood.

We previously reported that the synergistic regulation of T cells by PD-1 and LAG-3 is critical for the regulation of autoimmunity. In this study, we analyzed the inhibitory capacity of human LAG-3 using mouse T cell hybridoma cells. Although the inhibitory function of mouse LAG-3 was readily observable, we could not observe the inhibitory effect of hLAG-3. We found that hLAG-3 soluble protein could bind to mouse antigen presenting cells and that the cytoplasmic region of hLAG-3 could suppress TCR signaling when fused with the extracellular region of mLAG-3. Unexpectedly, the expression level of hLAG-3 was much lower than that of mLAG-3 when their transcriptions were driven by retroviral LTR. When we increased the expression level of hLAG-3 by using a stronger promoter, substantial inhibitory effect was observed. We also found that two independent intracellular regions were required for the inhibitory activity of LAG-3 and that the relative contribution of these regions was different between human and mouse LAG-3. These results indicate that mouse ligand and signaling intermediates are cross-reactive to hLAG-3 and that the amount is critical for the inhibitory effect of LAG-3.

732

Context-dependent inhibition of antigen-specific T cell activation by LAG-3

Maruhashi, T., Okazaki, I.-M., Sugiura, D., Okazaki, T.

Institute for Genome Research, Tokushima University, Tokushima, Japan

Stimulatory and inhibitory co-receptors play fundamental roles in the regulation of the immune system. We have been analyzing the inhibitory co-receptor, PD-1 which is especially important for the regulation of autoimmunity and tumor immunity as evidenced by the spontaneous development of autoimmune diseases in PD-1 deficient mice and the recent success of PD-1 blocking antibody in the treatment of various cancer patients. Recently, we found that PD-1 collaborates with another inhibitory co-receptor LAG-3 in the regulation of autoimmunity. Mice deficient for LAG-3 and PD-1 died of autoimmune myocarditis by 5 weeks of age on BALB/c background, and LAG-3 deficient NOD mice developed accelerated type 1 diabetes, indicating the critical regulatory role of LAG-3 in preventing autoimmunity.

Although accumulating evidence suggests that LAG-3, a type I transmembrane protein with structural similarity with CD4 is a critical regulator of T cells, its precise mechanism remains elusive. In this study, we tried to unravel the inhibitory mechanisms of LAG-3 against the antigen-dependent activation of T cells. By testing various cell lines overexpressing MHC class II and CD80 as antigen presenting cells, we found that some cell lines could not support inhibitory function of LAG-3 although they can activate TCR. By retroviral expression cloning, we identified a gene that endowed antigen presenting cells the capacity to support the inhibitory function of LAG-3. These results suggest that LAG-3 inhibits antigen-specific T cell activation in a context-dependent manner.

733**Status of immune system of patients with breast cancer in different stages***Bagina, U.S., Kovchur, P.I., Volkova, T.O.**Petrozavodsk State University, Petrozavodsk, Russian Federation*

Recent reports provide evidence that malignant tumors growth correlates with significant deviations in various components of the immune system. It is also well recognized that two possible effects of the immune system components on the tumor are either promoting or down-regulating tumor growth. To investigate connection between T cells and different stages of oncogenesis, specifically breast cancer, we assessed ratio of T cells. The goal of these studies was to investigate a possibility of using T-cell markers as prognostic parameters. In these studies, we used samples from patients with different stages of advanced breast cancer supported by histology analysis. The subsets of mononuclear cells in the peripheral blood were determined using antibodies to CD3, CD4, CD8, CD16, CD20, CD25, and CD95 antigens. We observed non-significant increase of CD16+ cells along with decrease of CD3+ and CD4+ T cells in patients with stage I breast cancer. At the same time, the percentage of CD8+ cells is increased thus suggesting a helper's effect. The percentage of CD3 CD4+ cells further decreases with progression of the disease in patients with stage II tumor. In contrast, the percentage of CD4+CD25+ (Treg) cells increases from 4% in normal controls to ~8% in stage III patients. These data allow for preliminary conclusions that using of T-cell markers for diagnosis of breast cancer might be promising and is worth continuation. Our long-standing goal is to improve the accuracy of diagnosis based on individual immunological pattern (or "portrait") of the patient. Project was supported by the grant №1713.

734**Erythroblasts (Er-suppressor cells) - a new type of suppressor cells that inhibit immune response***Kozlov, V.**Research Institute of Fundamental and Clinical Immunology, Laboratory of Clinical Immunopathology, Novosibirsk, Russian Federation*

In the literature, there is evidence of a pronounced immunosuppressive effect of stress, which stimulate erythropoiesis (erythropoietin, induction of phenylhydrazine anemia, high altitude hypoxia, hemorrhage). It was shown that the transfer of spleen cells from these experimental animals inhibits the production of antibodies in recipients. It turned out discovered that erythroblast cells have the immunosuppressive effect, and they were designated as Er-suppressor cells. It was found that erythroblasts express several cytokines, which are able to be responsible for immunosuppressive effect, including TGF- β . In addition, the erythroblasts have a cytotoxic effect in vitro on some tumor cells. It is assumed that reduced suppressor activity of erythroblasts is one of the mechanisms of autoimmune diseases development, for example. It was also shown that cells of embryonic liver transferring to the recipient mice also suppress the production of antibodies. It is likely that

the suppressor cells of erythroid origin are a major cause of the impossibility of immunogenesis in embryonic liver. Where, according to some authors, B cells are presented, but antibody forming cells completely absent. Perhaps Er-suppressor cells with cytotoxic effects are responsible for the lack of tumor growth during embryonic development.

735**Monocytic myeloid-derived suppressor cells from females, but not males, alleviate CVB3-induced myocarditis by increasing regulatory and CD4⁺IL-10⁺ T cells***Yue, Y., Xiong, S.**Soochow University, Suzhou, China*

Coxsackievirus group B type 3 (CVB3) is a common etiologic agent of viral myocarditis and often causes sexually dimorphic myocarditis with increased incidence and mortality in male. So far, the underlying mechanism for the high male prevalence is not well elucidated. In this study, we deciphered the role of myeloid-derived suppressor cells (MDSCs) in the gender bias in murine CVB3-induced myocarditis by comparing their frequencies, subsets as well as immune suppressive functions. We found that much more myocardial MDSCs were enriched in infected females than males, with dramatically higher percentage ratio of CD11b⁺Ly6G⁻Ly6C^{high} monocytic subset (M-MDSCs) to CD11b⁺Ly6G⁺Ly6C^{low} granulocytic subset (G-MDSCs). Interestingly, more potent suppression on T cell proliferation was also evidenced in female-derived M-MDSCs. Consistently, adoptive transfer of female- but not male-derived M-MDSCs efficiently alleviated CVB3-induced myocarditis in male recipient mice, and this protection could be ascribed to the increased induction of regulatory and CD4⁺IL-10⁺ T cells. Our study suggested that myocardial MDSCs were distinctively induced not only in quantities but also in phenotypes and immune suppressive functions in CVB3-infected males and females; and female-derived more suppressive M-MDSCs contributed to their insensitivity to CVB3-induced myocarditis.

736**Redox regulation of the critical immunoregulatory enzyme indoleamine 2,3-dioxygenase 1***Yeung, A.W.S.¹, Lim, Y.J.¹, Glaros, E.¹, Hastad, M.¹, Dang, L.¹, Freewan, M.¹, Orfi, L.^{2,3}, Keri, G.^{2,4}, Szabadkai, I.², Terentis, A.C.⁵, King, N.J.C.⁶, Witting, P.K.⁶, Thomas, S.R.¹**¹University of New South Wales, School of Medical Sciences, Sydney, Australia, ²Vichem Chemie Research Ltd., Budapest, Hungary, ³Semmelweis University, Department of Pharmaceutical Chemistry, Budapest, Hungary, ⁴Semmelweis University, Department of Medical Chemistry, Budapest, Hungary, ⁵Florida Atlantic University, Department of Chemistry and Biochemistry, Boca Raton, United States, ⁶University of Sydney, Charles Perkins Centre, Discipline of Pathology, Sydney, Australia*

The heme enzyme indoleamine 2,3-dioxygenase 1 (IDO1) is a critical immune regulatory enzyme capable of signalling for immune suppression in diverse pathological settings including chronic inflammation, infection and cancer. During inflammation, IDO1 is expressed within activated innate immune cells that can

produce the reactive oxygen species (ROS) hydrogen peroxide (H_2O_2) and hypochlorous acid (HOCl) by the oxidative enzymes NADPH oxidase (Nox) and myeloperoxidase (MPO), respectively. We recently reported that H_2O_2 inhibits recombinant IDO1 dioxygenase activity by engaging the enzyme's heme peroxidase activity resulting in oxidative self-inactivation (*JBC* 2013;288:1548). To investigate if Nox-derived H_2O_2 or MPO-derived HOCl also control cellular IDO1 activity, we studied IFN- γ -stimulated human monocytes that co-express IDO1, Nox and MPO. Stimulation of monocytes with PMA increased cellular production of both H_2O_2 and HOCl that coincided with the post-translational inhibition of IDO1 activity. The ability of PMA to inhibit IDO1 was abrogated by inhibition of Nox-derived H_2O_2 production with the PKC inhibitor Bisindolylmaleimide or the flavoprotein oxidase inhibitor diphenyliodonium, but not by inhibition of MPO-derived HOCl with 4-aminobenzoic acid hydrazide. Interestingly, IFN- γ -stimulated human monocytes not only expressed the traditional phagocytic Nox isoform Nox2 but also the more recently discovered Nox4 isoform. While selective Nox4 inhibition reduced cellular H_2O_2 production by ~50%, it did not reverse the inhibitory activity of PMA on IDO1, suggesting that Nox2 but not Nox4-derived ROS control IDO1 activity. These studies establish that Nox-derived ROS controls IDO1 activity in innate immune cells and provide important new insights into the redox control of IDO1's immune regulatory actions.

737

The effect of Wuzhi capsules on tacrolimus pharmacokinetics in renal transplant recipients

Li, Y., Chen, J., Yan, L., Ren, J., Shi, Y., Wang, L.

West China Hospital of Sichuan University, Chengdu, China

Objective: Wuzhi capsules (WZCs), a traditional Chinese medicine, which was used in renal transplant recipients to increase the concentration of tacrolimus, while the role of this drug on tacrolimus pharmacokinetics is still unknown.

Patients and methods: A total of 175 kidney transplantation recipients were included in this study, including three groups: Wuzhi group (used immediately after surgery, n=86), control group (always without use, n=40) and self-control group (used from two weeks after surgery, n=32). We measured the renal function and tacrolimus concentrations (7 days, 14 days, 21 days and 28 days after surgery). Additionally CYP3A5 and ABCB1 genotypes of each patient were analyzed.

Results: The mean dose and weight adjusted C₀ in the group with Wuzhi capsules was higher than the controls in the first month after transplant (P < 0.05). For the self-control group, we found their Tac dose and weight adjusted C₀ increased significantly after using Wuzhi capsules (P < 0.05). Multiple binary logistic regression analysis was carried out to assess the baseline clinical covariates (CYP3A5 and ABCB1 genotypes, age, gender, BMI of donors and recipients, HLA, PRA, dialysis time, coinfection with HBV). No modification appeared on the association between Wuzhi capsules and increased C₀. On the other side, there were no differences in the renal functions during those groups.

Conclusions: Wuzhi capsules have strong influence on

tacrolimus pharmacokinetics in the early period after transplantation and the same clinical outcome. This approach can reduce the economic burden of the recipients and maybe reduce tacrolimus-related toxicity.

738

Anti-inflammatory activities of dangyuja (*Citrus grandis* Osbeck) on 12-O-tetradecanoylphorbol-13-acetate (TPA) induced skin inflammation

Herath, K.H.I.N.M.¹, Bing, S.J.¹, Cho, J.¹, Kim, A.², Kim, G.-O.³, Lee, J.-C.³, Lee, Y.¹

¹Jeju National University, Department of Veterinary Medicine, Jeju-si, Korea, Republic of, ²Jeju National University, Advanced Convergence Technology & Science, Jeju-si, Korea, Republic of, ³Jeju Diversity Research Institute, Seoqwoo-si, Korea, Republic of

Dangyuja (*Citrus grandis* Osbeck), which is widely used in traditional medicine for its potent anti-inflammatory effect is a citrus cultivated in South Korea. In this study, we examined the anti-inflammatory effect of 80% ethanol extract of *Citrus grandis* Osbeck (ECGO) on mouse edema model induced by 12-O-tetradecanoylphorbol acetate (TPA). For *in vitro* assays, murine splenocytes stimulated with concanavalin A (Con A) were treated with ECGO and evaluated for T cell population and production of inflammatory cytokines IL-2, IL-4 and IFN- γ . For *in vivo* assays, TPA-challenged mice ear skin were treated with ECGO topically and potent anti-inflammation of ECGO was assessed by edema induction, myeloperoxidase (MPO) activity, immunohistochemical localization of inducible nitric oxide (iNOS), cyclooxygenase (COX)-2, CD3⁺ T cells, F4/80⁺ macrophage and infiltration of inflammatory cytokines IL-1 β and TNF- α to the site of inflammation. ECGO-treated Con A-stimulated splenocytes showed a significant reduction in CD44/CD62L⁺ T cell population and a marked decrease in the production of inflammatory cytokines IL-2 and IFN- γ . Interestingly, topical treatment of ECGO significantly decreased the edema induction and MPO activity. Decreased expression of iNOS, COX-2, IL-1 β and TNF- α and suppressed homing of CD3⁺ T cells and F4/80⁺ macrophages to the site of inflammation further evinced the potent anti-inflammatory effect of ECGO. ECGO's anti-inflammatory activity disclosed in this study emphasizes the possibility of developing *Citrus grandis* Osbeck fruit extract as an alternative therapeutic agent for inflammatory edema. This work was supported by High Value-added Food Technology Development Program, Ministry of Agriculture, Food and Rural Affairs.

739

Exhausted T cell signature enriched in HPV16 E7 mouse model and cervical intraepithelial neoplasia grade III

Tuong, Z.K., Kuo, P., Sinha, R., Tolley, L., Frazer, I.

UQDI, TRI, Brisbane, Australia

Background: High-risk human papillomavirus (HPV) infection is involved in the development of precancerous cervical intraepithelial neoplasia (CIN) and persistent lesions can eventually lead to cervical cancer. Overcoming immune cell

exhaustion is a highly topical field of research in immunology and the ability to target and reinvigorate exhausted T cells is a promising immunotherapy for a wide range of cancers. We have an established transgenic (K14 promoter) mouse model (C57.K14E7) of epithelial premalignancy in skin expressing HPV E7 oncoprotein (in keratinocytes) whereby the C57.K14E7 skin is hyperplastic and has increased immune cell infiltrate associated with a strong immunosuppressive microenvironment.

Aim: To define the transcriptome of the C57.K14E7 skin.

Method: Here we performed state-of-the-art RNA-seq deep-sequencing analysis coupled with Gene Set Enrichment Analysis and curated a set of ~300 upregulated genes as a 'K14E7' transcriptional signature.

Results: We show that this signature is significantly enriched in human CIN3 cohorts specifically. Furthermore, we show that C57.K14E7 skin express high levels of multiple co-inhibitory molecules by qPCR and FACS analysis and both C57.K14E7 skin and human CIN3 cohorts are significantly enriched for 'exhausted' CD8+ and/or CD4+ T cell gene signatures.

Conclusions: These results suggest that high-risk HPV exploit immune cell exhaustion during infection and future work should be directed towards the development of immune checkpoint blockade-based strategies for immunotherapy in HPV-related CIN.

740

Identification of early myeloid progenitors as immunosuppressive cells

Pu, S.¹, Qin, B.¹, He, H.², Zhan, J.¹, Wu, Q.^{1,3,4}, Zhang, X.¹, Yang, L.^{1,3}, Lin, W.^{1,3}, Qu, C.², Zhou, Z.^{1,3,4}

¹Guangxi Normal University, School of Life Sciences, Guilin, China, ²Chinese Academy of Medical Sciences & Peking Union Medical College, State Key Laboratory of Molecular Oncology, Cancer Hospital/Institute, Beijing, China, ³Guangxi Normal University, Guangxi Universities Key Laboratory of Stem Cell and Biopharmaceutical Technology, Guilin, China, ⁴Guangxi Normal University, Research Center for Biomedical Sciences, Guilin, China

Background: Hematopoiesis in stress often exerts myeloid-biased alternations, resulting in accumulation of distinct myeloid lineages including early myeloid progenitors within the compartment of hematopoietic stem/progenitor cells (HSPCs). Despite growing evidence suggesting a crucial role for HSPCs in immunosurveillance, precise function of the specific myeloid progenitor subpopulations remains unclear.

Methods: Tumor model was established via injecting s.c. C57BL/6 mice with Lewis lung carcinoma (LLC) cells. We examined HSPC populations for their suppressive capabilities using T-cell proliferation assays. Gene expression was assessed by RT-PCR, and the levels of NO were determined with Greiss reagents.

Results: We show here that murine granulocyte/macrophage progenitors (GMPs) and common myeloid progenitors (CMPs) freshly isolated from tumor-bearing or naïve animals are capable of inhibiting polyclonal stimuli- and alloantigen-induced T cell proliferation, with tumor host-derived cells having elevated activities. Strikingly, both GMPs and CMPs even display much stronger suppressive capacity than the classical

myeloid-derived suppressive cells. Analysis of GMPs indicates that these cells express iNOS and can secrete high levels of NO. Further studies using iNOS specific inhibitors reveal that the immunosuppression of GMPs is, to a large extent, NO-dependent. Early myeloid progenitors can also efficiently induce regulatory T cell development. During tumor progression, GMPs but not CMPs are markedly expanded within both the bone marrow and blood of mice.

Conclusions: Together, these studies demonstrate that early myeloid progenitors can act as immunosuppressive cells in addition to being hematopoietic precursors. Our finding provides a unique insight into the functional diversity and plasticity of early myeloid progenitor cells.

Tolerance

741

Understanding how infection of the thymus renders newly differentiated T cells tolerant to mycobacteria-specific antigens

Cerqueira-Rodrigues, B.^{1,2}, Nobrega, C.^{1,2}, Barreira-Silva, P.^{1,2}, Serre-Miranda, C.^{1,2}, Correia-Neves, M.^{1,2}

¹Life and Health Sciences Research Institute (ICVS), School of Health Sciences, University of Minho, Braga, Portugal, ²ICVS/3B's-PT Government Associate Laboratory, Braga/Guimaraes, Portugal

In mouse models of *Mycobacterium avium* systemic infection, bacteria colonize the thymus, the central organ for T cell differentiation, rendering newly generated T cells tolerant to mycobacterial peptides, but not unrelated proteins, indicating a pathogen-specific T cell tolerance.

Several mechanisms can be envisaged to explain this infection-induced T cell tolerance such as antigen-specific T cell deletion, increased frequency/activity of antigen-specific regulatory T cells (Tregs) and/or generation of anergic T cells. Our goal is to explore which of these mechanisms is/are responsible for such tolerance.

Infection of P25 T cell receptor (TCR) transgenic mice, a model where the vast majority of T cells recognize the Ag85 mycobacterial peptide, revealed no major alterations either on the total number of thymocytes, or on the proportion of the four main thymic cell populations, upon systemic infection. Making use of the P25-RAG-GFP mouse model, in which the recent thymic emigrants express GFP, we observed no difference in the number of exported newly generated mycobacteria-specific T cells (GFP⁺CD4⁺). Chimeric mice, transferred with a 10/90 mixture of P25/WT bone-marrow, revealed no differences between mycobacteria-specific and WT T cell differentiation. In addition, infection did not promote an obvious increase of Tregs, anergic T cells or T cells expressing a non Ag85-specific TCR.

Presently, we are testing the ability of these mycobacteria-specific T cells to confer protection upon *de novo* infection, analyzing molecular changes acquired on differentiating T cells and Treg suppressor ability acquired after infection, in order to understand the mechanism(s) responsible for infection-induced tolerance.

742

Understanding the impact of patient-derived mutations on CTLA-4 expression and functionKennedy, A.¹, Hou, T.¹, Grimbacher, B.^{1,2}, Ikemizu, S.³, Walker, L.¹, Sansom, D.¹¹University College London, Institute of Immunity and Transplantation, London, United Kingdom, ²Universitätsklinikum Freiburg, CCI-Center for Chronic Immunodeficiency, Freiburg, Germany, ³Kumamoto University, Division of Structural Biology, Kumamoto, Japan

CTLA-4 maintains a critical immune checkpoint and is involved in the function of regulatory T cells. Mice lacking CTLA-4 die soon after birth of profound lymphoproliferation and fatal autoimmunity. Recently we and others have reported individuals with heterozygous (autosomal dominant) mutations in CTLA-4 who suffer from an immune dysregulation syndrome with wide ranging autoimmune features. In many cases these patients are identified as having immunodeficiency due to problems with class switched antibody production. Despite evidence for impaired CTLA-4 function, the impact of the various mutations identified are mostly not understood and may provide new information on the requirements for CTLA-4 function. To address this, we cloned and expressed CTLA-4 proteins based on a spectrum of mutations identified in patients. All missense mutations studied so far were capable of generating an expressed full length protein. We therefore performed a series of flow cytometric and microscopic analyses comparing the expression location, protein trafficking and ligand binding properties of each mutant. This reveals a number of discrete phenotypes of differing severity ranging from partial loss of ligand binding and failure to traffic correctly through to complete failure of the protein folding. This analysis may be used to predict the severity of different mutations, help immunological detection and possibly inform treatment strategies for these individuals.

743

Effect of probiotic (Lactobacillus Reuterii) administration on regulatory T cell in SLE with mild manifestation

Mulya, D.

Gadjah Mada University, Internal Medicine, Yogyakarta, Indonesia

Background: In patient with Systemic Lupus Erythematosus (SLE) there are abnormality on T cell lymphocyte, including defect in regulatory T cells both in number and function. Giving probiotic (Lactobacillus reuterii) is expected to stimulate immune response by increasing the number of regulatory T cells and decreasing IL 6 production.

Method: Thirty SLE patients with mild manifestation, were given Lactobacillus reuterii (15 people) and placebo (15 people) for 8 weeks. We then analyzed the level of CD4+CD25+FoxP3+ and IL 6 before and after exposure.

Result: Administration of Lactobacillus reuterii for 8 weeks brought statistically significant improvement on CD4+CD25+Foxp3+ level (1,38%±8,36% VS 3,17%±3,71%; P=0,007; CI -3,91 - -0,74). There were decreased level of IL 6 in Lactobacillus reuterii group (4,76±5,75 pg/ml VS 3,71±3,36 pg/

ml; P=0,25; CI -0,83 - 2,9) and the placebo group (2,6±2,02 pg/ml VS 2,07±2,39 pg/ml; P=0,35; CI -0,57 - 1,5). However at the end of study those changes didn't make statistically significant difference on CD4+CD25+Foxp3+ and IL 6 level between two group.

Conclusion: A significant increase of CD4+CD25+Foxp3+ were found after 8 weeks Lactobacillus reuterii administration.

744

Loss of TACI expression allows self-reactive MZ B cells to escape deletion but not energyLim, E.X.¹, Figgett, W.A.¹, Brink, R.², Mackay, F.¹¹Peter Doherty Institute for Infection and Immunity at The University of Melbourne, Department of Microbiology and Immunology, Carlton, Australia, ²The Garvan Institute of Medical Research, Darlinghurst, Australia

B cell-activation factor of the TNF family (BAFF) overexpression is known to subvert B cell tolerance, where self-reactive B cells are allowed to mature rather than being deleted. Transmembrane activator and cyclophilin ligand interactor (TACI) is a receptor for BAFF and loss of TACI protects against autoimmune manifestations mediated by excess BAFF. To further investigate the role of TACI in B cell self-tolerance, we crossed TACI^{-/-} mice onto switched-HEL (Sw_{HEL}) mice, whereby the BCR of B cells are modified to recognize hen egg lysozyme (HEL). We generated bone marrow chimeras using HEL-transgenic hosts (sHEL-Tg) reconstituted with Sw_{HEL} or TACI^{-/-}Sw_{HEL} BM to track the fate of anti-HEL self-reactive B cells in the presence or absence of TACI expression. Flow cytometry gating on HEL-binding B cell populations revealed skewing to a high proportion of TACI^{-/-} HEL-specific marginal zone (MZ) B cells remaining, compared to the TACI-sufficient Sw_{HEL}^osHEL-Tg control group in which mature HEL-specific B cells are efficiently deleted. In vitro BCR stimulation of splenic B cells with soluble HEL suggested that although the absence of TACI allowed HEL-binding B cells to escape deletion, the consequence of this breach of tolerance may be mitigated by the B cells being rendered anergic, as indicated by the failure to up-regulate CD86. TACI is expressed highly on MZ B cells and is where self-reactive B cells normally accumulate. These results suggest that loss of TACI is required for tolerance via self-reactive MZ B cell deletion, but is not required for tolerance via self-reactive B cell anergy.

745

Neonatal tolerance to proinsulin is sufficient to prevent autoimmune diabetes*Jhala, G.^{1,2}, Chee, J.¹, Trivedi, P.¹, Selck, C.¹, Gurzov, E.¹, Graham, K.^{1,2}, Thomas, H.^{1,2}, Kay, T.^{1,2}, Krishnamurthy, B.^{1,2}*¹St. Vincent's Institute of Medical Research, Immunology and Diabetes Unit, Fitzroy, Australia, ²The University of Melbourne, Department of Medicine, Fitzroy, Australia

All individuals are born with a certain level of self-tolerance to tissue specific antigens partly due to presentation of self-antigens in the thymus. Those with genetic predisposition, who may have less robust self-tolerance, develop autoimmune disease. Augmenting the level of antigen-specific tolerance may prevent autoimmunity. We aimed to define whether augmentation of pre-existing tolerance for a limited period could be effective. For this, we expressed two different autoantigens, proinsulin and islet-specific glucose-6-phosphatase catalytic subunit-related protein (IGRP) in the antigen presenting cells (APCs) of autoimmune diabetes-prone non-obese diabetic (NOD) mice during defined periods and tracked self-antigen specific T cells. Proinsulin expression from birth until weaning was sufficient to completely protect NOD mice from diabetes, insulinitis and development of insulin autoantibodies. Insulin-specific T cells were significantly diminished (424 ± 50 vs. 181 ± 24), were naïve and did not express IFN γ ($14\% \pm 1.7$ vs. $4\% \pm 0.9$) when challenged. We tracked IGRP specific CD8⁺ T cells in NOD mice expressing IGRP in APCs. When IGRP was expressed until weaning, IGRP specific CD8⁺ T cells were not detected later in life (1797 ± 786 vs. 50 ± 4). Thus, islet specific auto-reactive T cells are uniquely produced in early life. Our finding that a brief exposure to proinsulin confined to neonatal life in NOD mice imparts long lasting protection from diabetes leads us to suggest that neonatal life is a vulnerable period for the escape of insulin-specific T cells. Therapies bolstering proinsulin antigen presentation during early life in high-risk human subjects may provide the best chance of prevention of diabetes development.

746

Does dendritic-cell targeted antigen expression induce both T and B cell tolerance?*Brooks, J.¹, Al-Kouba, J.¹, Davies, J.², Wells, J.¹, Steptoe, R.¹*¹University of Queensland Diamantina Institute, University of Queensland, Woolloongabba, Australia, ²Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia

Autoimmune and allergic diseases often involve an interplay of T and B cell responses and develop, potentially, through failure of tolerance in or between these compartments. Transgenic expression of antigen is robustly tolerogenic. Restricting antigen expression to dendritic cells (DC) or other antigen-presenting cells (APC) is equally tolerogenic, induces central and peripheral T-cell tolerance and prevents the development of autoimmune and allergic disease. The mechanisms through which DC- or APC-targeted antigen expression prevents disease development remain unclear. We asked whether DC, as specialized APC for T cells, might prevent disease purely through

induction of T-cell tolerance. To define the effects of targeted antigen expression, we aimed to compare models where OVA expression is restricted to DC (11c.OVA), MHC class II+ APC (MII.OVA) or expressed ubiquitously (actin.OVA). 11c.OVA and MII.OVA mice express a truncated form of OVA (OVA₁₃₉₋₃₈₆) and when immunized with full-length OVA mount strong T-cell and IgG1, 2a & 2b responses that appear to be directed against the unexpressed (aa1-138) portion of OVA. In contrast, actin.OVA mice that express full-length OVA have significantly dampened IgG and T cell responses. To define whether this reflects the effects of antigen targeting, expression level or the fragment of OVA expressed, we produced recombinant OVA₁₃₉₋₃₈₆ using *Escherichia coli* expression and his-tag purification. Studies underway will reveal the effects of targeted antigen expression using this recombinant protein. We conclude these transgenic models will be unique and valuable tools for defining T and B cell tolerance.

747

Semi-mature dendritic cell generation by targeting acetyl-CoA carboxylase in the lipid metabolism process*Kim, J.-S., Thuy, N.P., Park, C.G.**Seoul National University College of Medicine, Seoul, Korea, Republic of*

The adoptive transfer of tolerogenic dendritic cells has great potential for treating autoimmune diseases and for preventing transplant rejection. In this study, we developed a novel method for generating tolerogenic semi-mature dendritic cells by targeting lipid metabolism pathway. Immature dendritic cells (imDCs) from C57BL/6 mice were generated by 8-day culture of the bone marrow-derived dendritic cell (BMDC) precursors in the presence of GM-CSF and IL-4. imDCs were matured with LPS in the presence or absence of CP-640186 (CP), an acetyl-CoA carboxylase (ACC) inhibitor for 24hr. Phenotypic and functional characteristics of BMDCs were examined for identifying the role of lipid metabolism pathway during DC maturation. ACC inhibition by CP-640186 resulted in decreased accumulation of neutral lipid in LPS-treated DCs. Expression level of costimulatory molecules including CD80, CD86 and CD40 and MHC II was greatly down-regulated by dose-dependant manners. Coincidentally, the secretion of pro-inflammatory cytokines (IFN- γ , IL-6, IL-12p70) was suppressed. Expression of CCR7, a mature DC homing receptor, was decreased. On the contrary, expression of CCR5, a receptor largely expressed in immature DCs, was reversely increased. Antigen uptake capacity was greatly increased in the presence of CP-640186 by a dose dependant manner. DCs generated in the presence of CP-640186 greatly down-regulated the CD4⁺T cell proliferation by an antigen-specific manner. In conclusion, these data demonstrated that semi-mature DCs can be generated by targeting acetyl-CoA carboxylase in the lipid metabolism pathway. We suggested here novel target for the induction of metabolism based-dendritic cell tolerance for preventing transplant rejection and treating autoimmune diseases.

748

In vitro induction of serial transfer of allospecific suppression potential in human peripheral T cells*Uchida, K., Negishi, N., Bashuda, H., Kawai, F., Okumura, K., Habu, S. Juntendo University, Atopy Research Center, Tokyo, Japan*

Background: We have achieved clinical operational tolerance in transplantation via adoptive transfer of the ex vivo induced donor specific anergic cells. This accomplishment have proposed the life period of the anergic cells and maintenance mechanism or immunological tolerance. Based on the infectious tolerance concept, we have hypothesized naïve T cell inherit allospecific suppressive function when coexisted with the transferred anergic cells

Material and methods: Donor specific anergy in recipient PBMC was induced in mixed lymphocyte culture with irradiated donor PBMC in the presence of anti-CD80/86 antibodies. These generated anergy recipient cell were transferred into the next MLC to determine whether they have potential to sequentially transfer their suppressive function into new alloreactive PBMC. To distinguish the anergy and new naïve recipient cell after co-culture, new PBMC were labeled with CFSE.

Result: The proliferation and IL-2 expression of the recipient T cells were significantly suppressed under anti-CD80/86 blockade in the first MLR with significant increase of CD4⁺CD25⁺Lag3⁺FOXP3⁺ cells. These induced 1st anergic PBMC provided the donor-specific suppression activity to new naïve activated recipient cells with significant expansion of CD4⁺CD25⁺Lag3⁺ cells and low IL-2 expression. Moreover, such anergy status transferred into the third MLR recipient cells.

Conclusion: These results indicate the in vitro induced allospecific anergic T cells by blocking the 2nd TCR signal generate T cells with potential to suppress another activated T cells, suggesting the serial induction of allo-specific tolerance that may be promise. This observation established inheritance of allospecific suppressive function in human supporting immune tolerance.

749

Ndfip1 limits autoreactive CD8⁺ T cell responses to high dose antigen*Wagle, M.V.¹, Goodnow, C.C.^{1,2,3}, Parish, I.A.¹**¹Australian National University, John Curtin School of Medical Research, Canberra, Australia, ²Garvan Institute of Medical Research, Immunology, Darlinghurst, Australia, ³University of New South Wales, St. Vincents Clinical School, Sydney, Australia*

As thymic selection is not a perfect process, peripheral tolerance mechanisms have evolved to inactivate rogue self-reactive T cells that escape into the periphery. While the molecular pathways that enforce CD4⁺ T cell peripheral tolerance are well studied, relatively little is known about the molecular basis of CD8⁺ T cell tolerance. Ndfip1 is a key immunoregulatory adaptor molecule required for the function of inhibitory ubiquitin ligases such as Itch, and Ndfip1 loss severely disrupts CD4⁺ T cell peripheral tolerance. In this study, we examined the role of Ndfip1 in CD8⁺ T cell peripheral tolerance using the transgenic RIP-OVAhi model of CD8⁺ T cell tolerance. In this model, ovalbumin (OVA)

is expressed as a neo-self-antigen within the insulin-producing pancreatic islet β -cells, and transfer of ovalbumin (OVA)-specific OT-I CD8⁺ T cells into RIP-OVAhi mice leads to OT-I tolerance. Surprisingly, Ndfip1 deficient OT-I cells were tolerised normally in the RIP-OVAhi model, with the transferred cells failing to cause diabetes. However, in the context of higher antigen doses within a peptide anergy model, Ndfip1 deficient OT-I cells displayed elevated expansion relative to their wild-type counterparts, and acquired effector function through enhanced Granzyme B expression and downregulated CD62L. Moreover, boosting antigen doses in the RIP-OVAhi model by peptide injection allowed mutant but not wild-type OT-I cells to breach tolerance and cause diabetes. Collectively, these data suggest that Ndfip1 regulates peripheral CD8⁺ T cell tolerance, but only in the context of high antigen doses.

750

Involvement of TIGIT in serial transfer of anergy status in T cells*Negishi, N.¹, Uchida, K.¹, Sato, T.², Kametani, Y.³, Okumura, K.¹, Habu, S.¹**¹Juntendo University Graduate School of Medicine, Atopy (Allergy) Reserch Center, Tokyo, Japan, ²Tokai University School of Medicine, Department of Immunology, Isehara, Japan, ³Tokai University School of Medicine, Department of Molecular Life Science, Isehara, Japan*

The term “infectious tolerance” was referred to the serial suppression process in which anergy status is transferred from the anergic T cells to newly stimulated naïve cells. To confirm this phenomenon precisely, we established the in vitro experimental system, in which OVA specific TCR transgenic (TCR-Tg) mice that react super-antigen, TSST-1, through the TCR- β chain. The spleen cells from TCR-Tg mice receiving TSST-1 administration became anergic status restimulation of OVA/TSST-1. The induced 1st anergy T cells showed to induce newly stimulated naïve T cells to be the 2nd anergy T cells when both were co-cultured with OVA. And the 2nd anergy T cells also had a similar character. To elicit molecular mechanism of the anergic status transfer, we compared molecules between the anergy and activated T cells by flow-cytometric and microarray comparison of gene expression. Among the different expression molecules, we have focused TIGIT as a responsible molecule for serial transfer of the anergic status. TIGIT has been reported to function as the co-inhibitory molecules. TIGIT is negative in naïve status but expressed by stimulation. Then, we examined the time course of TIGIT-expression and -intensity in stimulated naïve T cells with or without anergy T cells. When naïve T cells were co-cultured with anergy T cells, stimulated naïve T cells showed higher and earlier TIGIT expression in comparison to that of their single culture without the anergy cells. Based on these results, we will discuss how TIGIT is linked to suppressing activation of stimulated naïve T cells.

751

Modified signaling cascades in DAMP-tolerized human phagocytes

Freise, N., Ortkras, T., Vogl, T., Roth, J., Austermann, J.
University Hospital Muenster, Institute of Immunology, Münster, Germany

Background: Sepsis is still associated with high mortality and develops in two phases, an early strong inflammatory phase and a secondary hypo-reactive state which is called endotoxin-tolerance. We recently demonstrated that the DAMP (Damage associated molecular pattern) proteins S100A8/S100A9 are able to induce a Toll-like receptor 4 (TLR4) dependent hypo-responsiveness in phagocytes under sterile conditions, a mechanism called stress-tolerance (Austermann et al. Cell Rep. 2014). The goal of the present study was to analyse molecular mechanisms underlying stress-induced tolerance in phagocytes.

Methods: We investigated the impact of different kinase signaling pathways in the S100A8/S100A9 induced stress-tolerance of human monocytes. Impaired activity of kinases and the influence of kinase inhibitors on target proteins were analysed by western blot and ELISA. Protective effects of inhibitors *in vivo* were tested using the D-Gal model of septic shock.

Results: Activity of GSK-3 is down-regulated during S100-induced tolerance of human monocytes. Accordingly, endogenous NF- κ B antagonists I κ B α and BCL-3, two known targets of GSK-3, are up-regulated in tolerant monocytes. *In vivo* data show a protective effect of pharmacological tolerance induction by the use of the GSK-3 inhibitor CHIR99021 on the survival rate of mice during septic shock.

Conclusion: The inactivation of the GSK-3 and the resulting accumulation of I κ B α in tolerant human monocytes interfere with the translocation of the active transcription factor NF- κ B to the nucleus. *In vivo* data indicate that inhibiting GSK-3 and thus imitating a natural protective mechanism of the immune system could be used as a treatment in sepsis patients.

752

Antigen-decorated engineered red blood cells as a novel immune tolerance-inducing agent

Pishesha, N., Bilate, A., Wibowo, M., Lodish, H., Ploegh, H.
Massachusetts Institute of Technology/Whitehead Institute for Biomedical Research, Cambridge, United States

Currently available therapies for autoimmune diseases are traditional immunosuppressive medications, exposing patients to higher risks of opportunistic infection and other discomforts. Immunoregulatory modalities, which are able to prophylactically educate or therapeutically re-educate the immune system to induce antigen-specific tolerance are desirable. Here we employed engineered red blood cells carrying desired synthetic or natural antigens to induce long term, drug-free, specific immunotolerance while maintaining immune competence. Utilizing genetic engineering and Sortase A-mediated protein modification strategies, we generated both mouse and human red blood cells covalently carrying the desired antigens. Covalent conjugation allows precise quantification of antigens

attached and sortagging method robustly attaches consistent amount of various antigens. These modification strategies do not inflict any damage to the red blood cells as the engineered red blood cells can circulate *in vivo* with normal half-life. As a proof of concept using the ovalbumin-specific T cell receptor transgenic mouse models, we found that administration of red blood cells that carry the relevant peptide epitopes leads to induction of tolerance, as inferred from the drastic reduction in number of adoptively transferred CD4⁺ and CD8⁺ T cells. We further illustrate the tolerance-induction capacity of these engineered red blood cells to a model of autoimmune diseases, experimental autoimmune encephalitis (EAE), a mouse model for multiple sclerosis, we showed that myelin oligodendrocyte glycoprotein (MOG)-decorated red blood cells could suppress, or at least delay the onset of, the disease. We have therefore highlighted the potential of hijacking the natural properties of red blood cells to curb autoimmune diseases.

753

Dexamethasone and MPLA treatment of monocyte-derived dendritic cells from rheumatoid arthritis patients induce transcriptional modulation of genes related to cell recruitment, signaling and metabolism

García-González, P.A.^{1,2}, Schinnerling, K.^{1,2}, Sepúlveda, A.³, Ubilla-Olguín, G.^{1,2}, Soto, L.⁴, Neira, O.⁵, Medhi, A.M.⁶, Nel, H.J.⁶, Catalán, D.^{1,2}, Thomas, R.⁶, Verdugo, R.A.³, Aguilón, J.C.^{1,2}

¹Universidad de Chile, Immune Regulation and Tolerance Research Group, Programa Disciplinario de Inmunología, ICBM, Santiago, Chile, ²Millennium Institute on Immunology and Immunotherapy, Santiago, Chile, ³Universidad de Chile, Chilegenómico, Programa de Genética Humana, ICBM, Santiago, Chile, ⁴Universidad de Chile, Unidad del Dolor, Hospital Clínico de la Universidad de Chile, Santiago, Chile, ⁵Hospital del Salvador, Sección de Reumatología, Santiago, Chile, ⁶University of Queensland Diamantina Institute, Translational Research Institute, Queensland, Australia

Background: Despite growing interest in tolerogenic dendritic cells (tolDCs) as target for immunotherapy in autoimmunity, the molecular mechanisms driving differentiation of tolDCs towards a regulatory phenotype are poorly understood. We studied the transcriptional pattern of tolDCs from healthy subjects (HC) and rheumatoid arthritis patients (RA), modulated with dexamethasone (Dex) and activated with monophosphoryl lipid A (MPLA) (DM-DCs), to identify molecular regulators and pathways related with tolerogenicity.

Methods: Genome-wide transcriptional profiling of DM-DCs, Dex-modulated DCs (D-DCs), MPLA-matured DCs (M-DCs) and untreated DCs from HC and RA, was performed with Illumina HumanHT-12 v4 BeadChip Array. Differentially expressed (DE) genes were determined using a false discovery rate of 0.5 and a 1.5 fold change, compared to untreated DCs. Functional enrichment and pathway overrepresentation was performed using Ingenuity Pathway Analysis. Expression of genes of interest was confirmed through qPCR.

Results: Dex and MPLA exert a distinctive effect on DCs transcriptional program, which is similar on RA and HC. 814 DE transcripts were identified in DM-DCs, further grouped according to expression patterns, exhibiting downregulation of

maturation/inflammation-associated genes and upregulation of tolerance-related genes. Functional and pathway analysis revealed enrichment of genes involved in cellular movement, cell-to-cell signaling and interaction, and metabolism, particularly ROS production and zinc homeostasis; predicting the activation of chemotactic responses and proliferation of regulatory cells.

A network of gene-gene interactions, including potential transcriptional factors involved, was constructed.

Conclusion: DM-DCs exhibit a particular transcriptional programming in response to Dex and MPLA, supporting a regulatory profile on these cells.

Support: Fondecyt-Chile 1140553 and MIII P09/016-F.

754

Liver sinusoidal endothelial cells induce the tolerogenic and regulatory feature of autoreactive CD4⁺ recent thymic emigrants

Ge, Q., Xu, X., Wang, K., Zhang, S.

Peking University Health Science Center, Beijing, China

Mechanisms of peripheral tolerance play a critical role in preventing T cells that escape from negative selection in the thymus from initiating autoimmune reactions. The purpose of this study was to investigate the tolerance of recent thymic emigrants (RTEs) in the liver. We found that a fraction of CD4⁺ RTEs were retained in the liver independent of the secondary lymphoid organs. Following transfer into RAG^{-/-} recipients, CD4⁺ liver RTEs induced more severe organ-specific inflammation and cell infiltration than lymph node RTEs, indicating that more autoreactive RTEs were retained in the liver. Compared to RTEs from the lymph nodes, more CD4⁺ RTEs from the liver acquired activated phenotype (CD44^{hi}CD62L^{lo}CXCR3^{hi}PD-1^{lo}Foxp3⁻) with high expression of LAG3, FasL, IL-10, and IFN- γ . These liver RTEs also acquired regulatory functions as they could suppress the proliferation of naïve T cells *in vitro*. We further found that liver sinusoidal endothelial cells could induce the tolerogenic and regulatory phenotype of liver RTEs via cellular interaction. The expression of MHC, Aire, and Notch all contributed to RTEs' acquisition of liver tolerance. These results suggest that the liver is the first checkpoint in the periphery to filter, retain, and enforce tolerance to autoreactive CD4⁺ thymic emigrants that escape from negative selection.

⁶University of Adelaide, Adelaide, Australia, ⁷Queensland University of Technology, Brisbane, Australia

Established memory T cell responses represent a key hurdle to both protein and tissue replacement therapies as well as the application of tolerogenic immunotherapies in general. Targeting expression of antigen to antigen-presenting cells is a powerful means to induce T-cell tolerance. We have shown previously that genetic targeting of antigens to DC and other APC inactivates memory CD4⁺ and CD8⁺ T cells, but we now show this can be exploited for induction of therapeutic tolerance to 'turn-off' established but unwanted T-cell responses. We have combine the approaches of targeted antigen expression and bone marrow (BM) / hematopoietic stem cell transplantation under immune-preserving conditions to show antigen-specific, therapeutic termination of memory CD4⁺ and CD8⁺ T-cell responses. This approach has the capacity to turn off the pathogenic T-cell responses that underlie autoimmune rejection of antigen-expressing pancreatic islet transplants and Th2-mediated airways inflammation. Associated with this immune-related pathology related to these responses, such as airways inflammation and hyper-responsiveness is prevented or ameliorated. Immunological mechanisms associated with reversal of established memory T-cell responses by BM transfer under immune preserving conditions appear to be deletion and induction of unresponsiveness through T-cell 'adaption'. Refinement of BM-mediated gene therapy for tolerance such as this could lead to development of highly-effective therapies for T-cell mediated pathologies.

756

Determining the molecular factors that control apoptotic cell disassembly

Tixeira, R.¹, Nedeva, C.¹, Atkin-Smith, G.¹, Phan, K.¹, Puthalakath, H.¹, Herold, M.², Hulett, M.¹, Poon, I.¹

¹La Trobe Institute for Molecular Science, Biochemistry, Melbourne, Australia, ²Walter & Eliza Hall Institute, Melbourne, Australia

Apoptosis is a key process in maintaining homeostasis in the body. Clearance of apoptotic cells is important, as inefficiency is linked to various diseases including autoimmune and inflammation. Numerous cells types are involved in the clearance of apoptotic cells including professional phagocytes namely, macrophages and dendritic cells, and non-professional phagocytes such as fibroblasts and epithelial cells. To achieve timely cell clearance, apoptotic cells undergo regulated disassembly. This apoptotic cell disassembly (ACD) process involves a series of coordinated morphological changes such as membrane blebbing (circular bulges of the plasma membrane), apoptopodia formation (string-like membrane extensions), and fragmentation to generate apoptotic bodies. Inhibitor based assays have shown Rho Kinase 1 (ROCK1) and P21 activated kinase 2 (PAK2) are involved in membrane blebbing, while Pannexin 1 (PANX1) is a negative regulator of apoptotic body formation. However, specific roles of these proteins in ACD are not well defined as most studies are based on pharmacological approaches. Moreover, how ACD could aid efficient cell clearance is also not well understood. Here, using CRISPR technology- based gene

disruption in Jurkat T cells as a model system; we are able to confirm that ROCK1 is important for membrane blebbing, while loss of PAK2 shows no phenotypic changes to ACD. Disruption of PANX1 leads to enhanced ACD. Furthermore, engulfment assays using dendritic cells and macrophages derived from peripheral blood monocytes show a preference for apoptotic bodies over apoptotic whole cells. These data suggests that apoptotic cell disassembly is a regulated process, which may have implication on efficient cell clearance.

757

Tyrosine phosphatase SHP-1 as a critical switch in altering the sensitivity of Tcon cells to Treg mediated suppression

Mercadante, E., Lorenz, U.

University of Virginia, Carter Immunology Center and Department of Microbiology, Immunology and Cancer Biology, Charlottesville, United States

Immune tolerance requires a balance between T cell activation and regulatory T cell (Treg)-mediated suppression. While the number and functionality of Treg cells are known to influence immune responses, resistance of conventional T (Tcon) cells to Treg-mediated suppression can also contribute to autoimmunity. However, how Tcon resistance is modulated is poorly understood and here through several observations, we demonstrate a novel role for SHP-1 in regulating Tcon susceptibility to suppression. First, genetic ablation of SHP-1 specifically in T cells leads to resistance of Tcon cells to Treg-mediated suppression. Second, in a complementary approach, inhibiting the enzymatic activity of SHP-1 through sodium stibogluconate (SSG or Pentostam) also confers resistance to wild type Tcon cells indicating a

T cell intrinsic mechanism. Third, T cells deficient in SHP-1 protein or activity are hyper-responsive to TCR-mediated stimulation, as evidenced by hyper-proliferation. Fourth, in the absence of SHP-1 activity, a higher percentage of the T cell population respond to stimulation suggesting that SHP-1 regulates the threshold that separates response versus no response. Finally, analysis of downstream signaling events indicates altered activation of AKT under conditions of SHP-1 deficiency, consistent with resistance to Treg-mediated suppression. Collectively, these genetic and pharmacological approaches reveal a novel role for the signaling protein SHP-1 in regulating suppression of Tcon cells by Treg cells. Since resistance to Treg-mediated suppression is increasingly linked to the pathogenesis of autoimmune diseases, our data are relevant for autoimmunity, for potential new therapeutic options, and for tumor immunity where Treg cells hinder a productive immune response.

Relevance of immunomodulatory factors in HSCT: HLA-G as a biomarker for graft versus host disease

Kanga, U.¹, Mourya, M.¹, Seth, T.², Chowdhury, K.¹, Mitra, D.K.¹, Coshic, P.³, Mahapatra, M.²

¹All India Institute of Medical Sciences, Transplant Immunology and Immunogenetics, New Delhi, India, ²All India Institute of Medical Sciences, Hematology, New Delhi, India, ³All India Institute of Medical Sciences, Transfusion Medicine, New Delhi, India

Introduction: HLA-G is a non-classical HLA-class I molecule with immunosuppressive property. Through interaction with receptors ILT2, ILT4 and KIR2DL4 on several immune cells, HLA-G mediates a micro-environment that induces tolerance. miRNAs interact with polymorphic sites in the HLA-G 3'UTR region and control post transcriptional regulation.

Material and methods: The present study was conducted on patients with leukaemia and aplastic anaemia who underwent Hematopoietic Stem Cell Transplantation (HSCT). We investigated HLA-G 3'UTR region- exon 8-14pb INDEL polymorphism and SNPs (miRNA interaction sites). Additionally, the levels of soluble HLA-G, Treg cell frequency and levels of Th1 (IL-2, IL-17, TNF- α , and IFN- λ) and Th2 cytokines (IL-4 and IL-10) were evaluated at pre and post transplant time points (days 15, 30, 90 and at GvHD).

Results: The Kaplan Meier analysis revealed that recipients with 14bp ins/ins genotype had lower incidence of GvHD in comparison of those with 14bp del/del genotype. The incidence of GvHD was higher in recipients with HLA-G 3'UTR +3027 CC, +3035CC other SNP genotypes. Of the 7 UTR haplotypes in North Indians, UTR1 and UTR 3 were associated with GvHD. The soluble HLA-G1/G5 levels, Treg cell frequency and Th2 cytokines levels were significantly lower at the time of GvHD, whereas levels of Th1 cytokines were higher.

Conclusion: HLA-G 3'UTR polymorphism impacts the soluble HLA-G levels that create an immunosuppressive micro-environment, modulates Treg cell frequency and Th1/Th2 cytokine balance and all this correlates with manifestation of GvHD and impacts transplant outcome. We propose HLA-G molecule as possible biomarker for predication of GvHD.

Checkpoints for autoreactive B cells in peripheral blood of lupus patients assessed by flow cytometry

Jeganathan, V.¹, Malkiel, S.², Wolfson, S.², Manjarrez Orduño, N.², Marasco, E.², Aranow, C.², Mackay, M.², Gregersen, P.², Diamond, B.²
¹The Feinstein Institute for Medical Research, Bronx, United States,
²The Feinstein Institute for Medical Research, Manhasset, United States

Antibodies to nuclear antigens (ANA) are diagnostic in several autoimmune disorders, yet failure to achieve B cell tolerance in these diseases is still poorly understood. Although secreted ANA detected by an indirect immunofluorescent assay (IFA) are the gold standard for autoreactivity, there has been no convenient assay to measure the frequency of circulating B cells that recognize nuclear antigens (ANA + B cells) in patients. Our aim was to generate an assay to easily identify these B cells and to examine its utility in a study of autoreactive B cells in Systemic Lupus Erythematosus (SLE). We developed and validated a novel flow cytometry-based assay that identifies ANA + B cells using biotinylated nuclear extracts, and used it to examine B cell tolerance checkpoints in peripheral blood mononuclear cells (PBMCs) obtained from SLE patients and healthy controls (HCs). We show progressive selection against ANA + B cells as they mature from transitional to naïve to CD27 + IgD - memory cells in both healthy subjects and SLE patients; however SLE patients failed to anergize ANA + naïve B cells to

the same extent as healthy individuals. We also show anergy induction is restored in SLE patients treated with belimumab, an inhibitor of B cell-activating factor (BAFF). This assay will enable studies of large populations to identify potential genetic or environmental factors affecting B cell tolerance checkpoints in health and disease and permit monitoring of the B cell response to therapeutic interventions.

Antigen-specificity of superior dominant encephalitogenic peptide confers inductivity, stability and hybrid signatures to CD69⁺CD103⁺ subset of Treg responsible for sustainable inhibition of CNS autoimmune diseases

Lin, Y.^{1,2}, Miyake, S.³, Yamamura, T.¹

¹National Institute of Neuroscience, National Center of Neurology and Psychiatry, Immunology, Tokyo, Japan, ²National Center Hospital, National Center of Neurology and Psychiatry, Neurology, Tokyo, Japan, ³Juntendo University Graduate School of Medicine, Immunology, Tokyo, Japan

Targeted monoclonal antibodies have dramatically improved the therapeutic efficacy for some autoimmune diseases, however, it is insufficient to completely inhibit disease activity and differs depending on the disease. Regulatory cells therapy is promising, but the heterogeneity influencing the stability and complications due to non-specific suppression are problematic. By focusing on experimental autoimmune encephalomyelitis (EAE), previously, we demonstrated that sensitization of superior dominant peptide sustained remission due to induction of CD69⁺CD103⁺ (DP)-subset of regulatory T cells (Treg) after EAE peak.

DP-subset of Treg was most potent, expressing maximum Treg-compatible markers, and harbored multiple hybrid signatures corresponding to each phase of EAE. DP-subset preferentially infiltrated into the central nervous system without loss of Foxp3 expression by retaining low IL-6R expression.

Furthermore, the DP-subset of Treg acquired high antigen-specificity that in turn maintained the hybrid signatures and IL-6R^{low} fraction, accounting for the stability. Antigen-specificity and hybrid signatures of Treg were also detected in CD69⁺CD103⁺ (103SP)-subset. Unlike the DP-subset, 103SP-subset expressed high IL-6R and also harbored the non-Treg fraction, exhibiting plasticity for the down-regulation of Foxp3 under inflammatory condition. TCR stimulation without proper antigen was unable to sustain hybrid signatures and increased the non-Treg fraction involved in EAE relapse.

Only for the superior dominant peptide, sensitization led to the suppression of the reactivity to other encephalitogenic peptides in a tissue-specific manner, unlike tolerance induction inhibiting in a peptide-specific manner. Such suppression was detected under non-EAE condition and in EAE-affected mice.

This mechanism can be used for alternative therapy to resolve the problems described here.

P2X7 polymorphisms and the role of P2X7 in graft-versus-host disease

Adhikary, S.^{1,2}, Geraghty, N.^{1,2}, Belfiore, L.^{1,2}, Alexander, S.³, Sluyter, R.^{1,2}, Watson, D.^{1,2}

¹University of Wollongong, Wollongong, Australia, ²Illawarra Health and Medical Research Institute, Wollongong, Australia, ³The Children's Hospital at Westmead, Westmead, Australia

The P2X7 receptor has been implicated in the development of graft-versus-host disease (GVHD). The human *P2RX7* gene is highly polymorphic and P2X7 activity can be altered by single nucleotide polymorphisms (SNPs). We investigated donor human peripheral blood mononuclear cells (hPBMCs) for their *P2RX7* genotype and activity. The *P2RX7* gene was sequenced from genomic DNA from thirteen human donors. Seven known *P2RX7* gene SNPs including three gain-of-function and four loss-of-function P2X7 SNPs were found. The SNPs identified accounted for the five known haplotypes of the *P2RX7* gene (*P2X7-1* (wildtype), *P2X7-2*, *P2X7-3*, *P2X7-4*, and *P2X7-5*). Similar P2X7 activity was observed between CD3⁺, CD3⁺CD4⁺ and CD3⁺CD8⁺ T cells within each donor. However, high P2X7 activity was observed in T cells from donors with gain-of-function *P2RX7* SNPs and haplotypes *P2X7-2*, *P2X7-4* and *P2X7-5*. Low P2X7 activity was observed in T cells from donors with loss-of-function SNPs and haplotype *P2X7-3*. hPBMCs from a *P2X7-2* haplotype donor were injected into NODSCIDIL-2Rg^{null} (NSG) mice and the effect of P2X7 blockade (with Brilliant Blue G, BBG) on the development of GVHD was examined. NSG mice injected with hPBMCs and BBG or saline (control) showed similar levels of hPBMC engraftment (predominantly T cells). Similar CD4⁺ and CD8⁺ T cell engraftment and intracellular IFN-gamma was observed in spleens. Both BBG and control mice developed GVHD. However BBG-injected mice demonstrated reduced serum IFN-gamma compared to control mice. This warrants further investigation into the role of P2X7 donor genotypes and P2X7 blockade on the development of GVHD in this humanised mouse model.

762

The ligands of translocator protein (TSPO) inhibit human Th1 responses and prevent the rejection of murine skin allografts

Wu, C.¹, Zhang, Y.², Yu, S.², Yang, B.²

¹Institute of Immunology, Department of Immunology, Guangzhou, China, ²Institute of Immunology, Zhongshan School of Medicine, Guangzhou, China

The translocator protein (TSPO) may impact inflammatory and immune responses. However, the exact actions of TSPO on Th1 cell responses *in vitro* and *in vivo* are still unclear. In the current study, we found that TSPO ligands, FGIN1-27 and Ro5-4864, both suppressed the production of IFN- γ in a dose- and time-dependent manner, but only Ro5-4864 suppressed TNF- α production by human PBMCs after stimulation. FGIN1-27 inhibited the production of IFN- γ by memory CD4⁺ T cells and

the differentiation of naïve CD4⁺T cells into Th1 cells. In addition, TSPO ligands inhibited mixed lymphocyte reactions by human or murine cells. After the transplantation of allogeneic murine skin, injection of TSPO ligands prevented graft rejection and resulted in reduced levels of IFN- γ as measured *ex vivo* compared to the control. FGIN1-27 suppressed cell cycle, cell proliferation and activation of CD4⁺T cells. TSPO ligands also inhibited expression of the corresponding transcriptional factors including T-bet, pSTAT1, pSTAT4 and pSTAT5. Taken together, our data suggest that TSPO ligands inhibit Th1 cell responses and may be novel therapeutic drugs for the treatment of autoimmune diseases and prevention of transplant rejection.

Chitosan encapsulated superparamagnetic iron oxide (SPIO) nanoparticles facilitating the graft tracking and immunosuppression in allo-transplantation

Shen, C.-R.^{1,2}, Wu, S.-T.¹, Liu, H.-Y.¹, Wang, J.-J.¹, Tsai, Z.-T.², Juang, J.-H.^{1,2}, Liu, C.-L.³

¹Chang Gung University, Taoyuan, Taiwan, Republic of China,

²Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China, ³Ming Chi University of Technology, New Tpei, Taiwan, Republic of China

In vivo imaging, being non-invasive, quantitative, and repetitive, of targeted macromolecules have recently attracted widespread interests. In particular, the use of superparamagnetic iron oxide (SPIO) leads to the combination of high spatial resolution of magnetic resonance (MR) imaging and the high specificity of magnetic markers. We had developed and demonstrated SPIO coated with γ -ray irradiated chitosan (CSPIO) as a great MR T2 contrast agent for grafted islet tracking. In this study, we intend to equip the CSPIO with immunosuppressive characteristics, and apply in allo-transplantation. After evaluating the transfecting efficiency of different CSPIO preparations, the CSPIO (HSPIO) encapsulated with a quaternized chitosan, N-[(2-hydroxy-3-trimethylammonium) propyl] chitosan chloride (HTCC), appeared to demonstrate a better potential to deliver gene expression. The transfecting efficiency of HSPIO could be even elevated by supplying poly-L-lysine (PLL) or lipofectamine, and such had no influence on cell growth and viability. In fact, the relaxivity of the HSPIO equipped with the reporter genes was also assessed, and no change was obtained on the T1 and T2 signals in MR imaging. It indicated that the interaction or intracellular uptake of such HSPIO with the cells resulted in the target gene expression. Finally, the utilization of IL-10 gene resulted in the satisfied amount of IL-10. Now the application of the HSPIO equipped with IL-10 is being tested for allo-transplantation. We anticipate that the newly developed contrast agents would not only benefit for graft tracking but also reducing immune rejection in cell or tissue transplantation.

764

Fetal in-utero hepatocyte transplantation for immunodeficiency disease: a systematic review of case reports

Chibueze, C.E.¹, da Silva Lopes, K.¹, Ota, E.¹, Enosawa, S.², Umezawa, A.²

¹National Research Institute for Child Health and Development, Health Policy, Setagaya-ku, Japan, ²National Research Institute for Child Health and Development, Department of Reproductive Biology, Center for Regenerative Medicine, Setagaya-ku, Japan

Background: Fetal in-utero hepatocyte transplants for the treatment of prenatally diagnosed immunodeficiencies affords immune manipulation parallel to ongoing maturity without a need for immunosuppression and its attendant side effects. To evaluate available evidence on in-utero hepatocyte transplantation, we conducted a systematic review.

Methods: We searched multiple database for ongoing trials, case reports, published and unpublished studies on in-utero hepatocyte transplantation. Titles and abstracts were screened and ineligible studies excluded. Full texts were then evaluated for inclusion independently by two authors, eligible articles were then retrieved and data extracted and summarised.

Results: 2 studies conducted in 2 countries, France (1993) and Sweden (2002) were eligible for inclusion, this included 5 fetuses (2 SCID (severe combined immunodeficiency syndrome), 1 BLS (bare lymphocyte syndrome), 2 Thalassemia major). Hepatocytes were gotten from either dead or viable foetuses with ages ranging from 7 - 11.5 weeks. Fresh and cryopreserved hepatocytes at 0.02×10^9 at >78% viability were transplanted at 14 - 28 gestational weeks through the umbilical vein (3) and intraperitoneum (2). Reported outcomes included engraftment (5), immune reconstitution (4), live births (4), partial improvement in symptoms (3) or complete recovery (1), death (1). Due to evident heterogeneity between studies and a lack of detailed information, a meta-analysis was not possible.

Conclusions: Fetal in utero hepatocyte transplants provide a promising alternative to fetal abortions, as they result in partial or incomplete reconstitution of T cells usually prior to birth and exclude possible transplant rejection.

Allele mismatch at the HLA-A locus is associated with high risk of relapse in unrelated umbilical cord blood transplantation

Chen, D.-P.^{1,2}, Tseng, C.-P.^{1,2}, Chang, S.-W.³, Wang, W.-T.¹, Jaing, T.-H.⁴

¹Chang-Gung Memorial Hospital, Laboratory Medicine, Taoyuan, Taiwan, Republic of China, ²Chang-Gung University, Taoyuan, Taiwan, Republic of China, ³Chang-Gung University, Clinical Informatics and Medical Statistics Research Center, Taoyuan, Taiwan, Republic of China, ⁴Chang Gung Children's Hospital, Department of Pediatrics, Taoyuan, Taiwan, Republic of China

Allogeneic hematopoietic stem cell transplantation is effective in the treatment of hematologic malignancy. Owing to the tolerance of immune reaction caused by one or two mismatched alleles in the HLA gene and the difficulty in finding matched HLA between donor and patient, unrelated umbilical cord blood transplantation (UUCBT) offers an attractive venue for

treatment of patients with rare HLA types. Nevertheless, which allele mismatch is relevant to the occurrence of graft-versus-host disease and relapse in UUCBT has not yet been unveiled. In this study, the HLA alleles in the HLA-A, -B, -C and -DR loci for 116 pairs of donor/patient undergone UUCBT with a minimum of one year follow-up were analyzed using the sequence-specific oligonucleotide probe method. Chi-square test was then used to compare the number of mismatched and non-mismatched donor-recipient pairs, the number of mismatched alleles, and the number of mismatched antigens at the HLA-A, -B, -C, and -DR loci. Our data revealed that both the number of mismatched donor-recipient pairs (P -value = 0.0182) and the number of mismatched alleles (P -value = 0.0253) at the HLA-A locus were significantly associated with the occurrence of relapse. The recipients with mismatched alleles were 2.2 times more likely to relapse when compared to those without mismatched alleles. Hence, matching of HLA-A alleles between recipient and donor is crucial to reduce the risk of relapse in UUCBT.

766

Swine SIRP α (CD172) protein has specific IgV residues associated with recognition of human CD47 and can bind human CD47 *in vitro*

Powell, E.J.¹, Boettcher, A.¹, Cunnick, J.¹, Loving, C.L.², Tuggle, C.K.¹

¹Iowa State University, Ames, United States, ²USDA-ARS-NADC, Food Safety and Enteric Pathogens, Ames, United States

Superior success in human hematopoietic cell (hHSC) engraftment in the non-obese diabetic (NOD) mouse is due, in part, to the ability of the signal-regulatory protein α (SIRP α , CD172) receptor to recognize human CD47. Such binding causes an inactivation signal to be transduced into host SIRP α + cells, preventing phagocytosis and killing of graft cells. Pigs are more similar in size and physiology to humans than mice; therefore, a severe combined immunodeficient pig model for hHSC transplant research is under development. This includes evaluating the human CD47 interaction with porcine SIRP α to assess the potential for human-pig xenograft tolerance. Porcine SIRP α shares specific residues necessary for binding with the NOD mouse SIRP α and human SIRP α that are not found in human SIRP β or normal mouse SIRP α (not able to bind). Specifically, porcine SIRP α IgV, the domain critical for recognition of human CD47, contains twelve of nineteen residues that have been identified as significant for binding. To test the hypothesis that similarities between swine and NOD mice SIRP α are sufficient for binding to human CD47, we used flow cytometry to determine if recombinant human CD47 chimeric protein (hCD47Fc) could bind to swine peripheral blood mononuclear cells (PBMCs) *in vitro*. We also examined if cells bound by hCD47 were SIRP α +, which would be indicative of hCD47 binding to porcine SIRP α . Preliminary results indicate hCD47Fc does bind to SIRP α + porcine monocytes. This interaction suggests that SIRP α + porcine macrophages may tolerate human CD47+ cells, and further work underway to evaluate this interaction.

767

Cytokine release syndrome in haploidentical stem cell transplantation in children with non-malignant disease: higher incidences of infusion-related febrile reaction but no acute graft-versus-host disease

Yeap, F.^{1,2}, Francisco, K.^{1,2}, Villegas, M.^{1,2}, Tan, P.-L.^{1,2}

¹Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore,

²Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Haploidentical SCT provides an important alternative for treating patients requiring an urgent SCT but with no HLA-matched donor available. However CRS is a feared complication in haploidentical SCT. We attempted to determine the incidence of CRS in pediatric patients with non-malignant conditions undergoing haploidentical SCT and its prognostic impact.

Our review consisted of 5 patients with non-malignant conditions (1 SCID, 1 ALD, 3 HLH), with 3 patients requiring a 2nd transplant. Patients were aged between 6 months to 15 years. All received myeloablative conditioning for their first transplant except 1 who became too septic. The mean CD34 cell dose was $26.9 \times 10^6/\text{kg}$ ($5.07\text{-}39.44 \times 10^6/\text{kg}$). These were all T cell depleted (CD3/CD45 RA depleted or TCR $\alpha\beta$ depleted). CRS was observed in 7 out of 8 transplants and 5 were grade 2 and above. 3 patients had grade 4 CRS; 2 required dual inotropic support and 1 had raised intracranial pressures and was given tocilizumab.

Six out of 8 cases met the criteria for IRFR and all except 1 developed engraftment syndrome. The median time for developing engraftment syndrome was +11 (9-13) days. Stem cell dose did not seem to influence the risk of CRS and we did not observe a correlation in the height of C-reactive protein or procalcitonin with the severity of CRS. With increased IRFR and ES seen in our small review of children compared to that previously reported,^{1,2} it was interesting that only 1 developed chronic graft-versus host-disease suggesting that GVHD may be dependent on the underlying disease.

768

Impact of CD99 on T cell immune response following an allogeneic skin transplantation

Nam, G., Choi, E.Y.

Seoul National University College of Medicine, Biomedical Science, Seoul, Korea, Republic of

CD99 is expressed on most hematopoietic cells and has been intensively studied in leukocyte migration. However, its role has rarely been investigated in T cell-mediated immune response. Since allogeneic skin transplantation is a useful tool for studying the outcome of T cell immune response, we transplanted allogeneic BALB.B donor skin to wild type or CD99-deficient B6 recipient mice to examine the effect of the absence of CD99 on T cell reactivity during allogeneic graft rejection. We found that the progression of graft rejection based on the assessment of graft scores was delayed and median graft survival time was increased in CD99-deficient recipient mice, indicating the involvement of CD99 in allogeneic graft rejection. Contrary

to previous reports that blockade of CD99 stopped leukocyte transmigration, CD99-deficient CD8 T cells were able to migrate to the allograft antigen sites. However, the absence of CD99 in allo-antigen-specific CD8 T cells resulted in slower activation and weaker immune response than in CD99-sufficient CD8 T cells, suggesting that delayed graft rejection in CD99-deficient host was due to the insufficient activation of allo-reactive CD8 T cells, rather than inhibited migration. Results presented here provide new insight into CD99 as a regulator of T cell activation and its effector function following allogeneic tissue transplantation.

Analysis of immune recovery following allogeneic stem cell transplantation

de Silva, H.¹, French, R.^{1,2}, Korem, M.^{3,4}, Paukovics, G.¹, Orłowski, E.¹, Curtis, D.^{5,6}, Spencer, A.^{5,6}, Avery, S.⁶, Patil, S.⁶, Morrissey, O.^{3,4}

¹Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ²Monash University, Department of Immunology and Pathology, Melbourne, Australia, ³Monash University Central Clinical School, Department of Infectious Disease, Melbourne, Australia, ⁴Alfred Health, Central Clinical School, Monash University Melbourne, Melbourne, Australia, ⁵Australian Centre for Blood Diseases, Monash University, Melbourne, Australia, ⁶Malignant Haematology and Stem Cell Transplantation Service, Alfred Health, Melbourne, Australia

Introduction: Allogeneic stem cell transplantation (SCT) is used to cure haematological malignancies but immune recovery is necessary to prevent infection. Data on immune responses in the current era of allogeneic SCT are limited.

Methods: Since Feb 2015, 18 allogeneic SCT recipients had blood collected at baseline, 3, 6, 9 months post-SCT for analysis by lymphocyte proliferation assays, Th1, Th2, Th17 cytokines in serum and culture supernatant, and immunophenotyping of T, B, NK, monocyte and neutrophil cell subsets.

Results: Median age of patients was 46 years, 65% were male and 50% had acute leukaemia. Baseline total white cell count was below normal in 37%, and 33%, 28% and 61% respectively had decreased baseline absolute neutrophil, monocyte and lymphocyte counts.

Median percent values for neutrophils (54%), monocytes (5.9%), T (14%) and NK cells (4.1%) were within normal range at baseline but B cells (0.7%) were decreased. At 3-months (n=6), neutrophils (68%), monocytes (8.3%) and NK cells (13%) were above baseline whereas B and T cell recovery was slower with only smaller increases by 6-months in median percent B (1.2%) and T cells (16%) respectively, (n=5).

Proliferative responses to mitogen decreased from baseline to 6-months (median stimulation-index 55 vs. 20) and antigen-specific responses were not seen until 9-months post-SCT. Th1, Th2, Th17 cytokines were detected in cell cultures following stimulation. Apart from CD40L (median=311pg/ml) serum had very low cytokine levels.

Conclusions: This pilot demonstrates the kinetics of immune recovery in the 9-months post allogeneic SCT. Further analysis in a larger cohort is required.

770

Differential modulation of IL-12 family cytokines in islet graft rejection

Chen, H.-Y.¹, Chou, F.-C.², Sytwu, H.-K.^{1,2}

¹National Defense Medical Center, Graduate Institutes of Life Sciences, Taipei, Taiwan, Republic of China, ²National Defense Medical Center, Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan, Republic of China

The relative contribution of T helper 1 (Th1) and T helper 17 (Th17) cells in graft rejection is inconclusive, based on evidence provided by different T cell-related cytokine-deficient animal models and graft types. We used novel antigen-presenting cell-specific IL-12p35 knockout (KO), IL-23p19 knockdown (KD) and IL-27p28 KD strategies to investigate T cell differentiation in islet graft rejection. In vitro dendritic cell-T cell coculture experiments revealed that dendritic cells (DCs) from IL-12p35 KO and IL-23p19 KD mice showed reduced ability to stimulate interferon- γ and IL-17 production by T cells, respectively. To further explore the T cell responses in islet graft rejection, we transplanted islets into streptozotocin-induced diabetic NOD/SCID recipient mice with IL-12-, IL-23-, or IL-27-deficient backgrounds and then challenged them with BDC2.5TCRtg T cells. The survivals of islet grafts were significantly prolonged in IL-12p35 KO and IL-23p19 KD recipients, compared with the control recipients. T cell infiltrations and Th1 cell populations were also decreased in the grafts, correlating with prolonged graft survival. Our results suggest that IL-12 and IL-23 promote and/or maintain Th1 cell-mediated islet graft rejection. Thus, blockade of IL-12 and IL-23 might act as therapeutic strategies for reducing rejection responses.

771

Investigating the role of NK cells in regulating donor cell engraftment, rejection and the graft-versus tumour effect

Davis, J.^{1,2,3,4}, Jiao, Y.^{2,5,6}, Belz, G.^{5,7}, Koldej, R.^{1,2,3,4}, Huntington, N.^{5,7}, Ritchie, D.^{1,2,3,4,8}, Transplantation, NK cells

¹The Royal Melbourne Hospital, The ACRF Translational Research Laboratory, Melbourne, Australia, ²University of Melbourne, Department of Medicine, Melbourne, Australia, ³The Peter MacCallum Cancer Centre, Cancer Immunology Research, Melbourne, Australia, ⁴University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia, ⁵Walter and Eliza Hall Institute of Medical Research, Molecular Immunology Division, Melbourne, Australia, ⁶Tsinghua University, School of Medicine, Beijing, China, ⁷University of Melbourne, Department of Medical Biology, Melbourne, Australia, ⁸The Royal Melbourne Hospital, Department of Clinical Oncology and Haematology, Melbourne, Australia

Allogeneic haematopoietic stem cell transplantation (allo-HSCT) is used to treat a range of haematological malignancies through an immunological anti-tumor effect. Allo-HSCT is limited by significant toxicity related to conditioning intensity, opportunistic infection, graft failure, and graft-versus host disease. Allo-HSCT outcome is dependent on immunological recovery, reducing toxicity and reliable and rapid marrow recovery. Natural killer (NK) cells contained within the donor

graft have been implicated in both the benefit and toxicity of allo-HSCT. The role of recipient NK cells in allo-HSCT outcome has not been explored. Using mouse models, we explored the manipulation of recipient NK cells on donor engraftment and the ability to exploit NK cell deficiencies to alter conditioning and donor T cell doses.

We used MHC-mismatched mouse models (BALB/c (H2K^d) into C57BL/6 (H2K^b)). Wild type (WT), perforin-deficient (PD) or NK-deficient (Mcl1^{fl/fl} Ncr1-Cre) (MCL) recipient mice received 2 x 600 rad before iv injection of 7.5^{×10⁶} donor BM + 1^{×10⁶} T cells. Compared to WT recipients, both PD and MCL mice had accelerated expansion of donor-derived T cells, rapid differentiation to effector memory T cell subtypes, and elevated pro-inflammatory serum cytokine levels (MCP-1, IFN γ and IL-6) resulting in a higher rate of fatal GVHD. In PD and MCL-1 recipients, reduction of irradiation doses to 800 rad was sufficient to achieve long-term engraftment, whereas WT mice rejected the graft.

These findings indicate that manipulation of recipient NK cell function can be utilized to lower conditioning intensity and promote engraftment. Exploration on how these findings impact on GVT is ongoing.

772

Migration of allogenic T cells in the small intestine during graft-versus-host disease

Ottmueller, K.^{1,2}, Brede, C.¹, Friedrich, M.³, Mokhtari, Z.¹, Thusek, S.¹, Amich, J.¹, Brandl, A.¹, Jordán-Garrote, A.-L.¹, Kalleda, N.¹, Miller, M.⁴, Figge, M.T.⁵, Heinze, K.³, Beilhack, A.^{1,2}

¹University Clinic Wuerzburg, Wuerzburg, Germany, ²Graduate School of Life Sciences, University of Wuerzburg, Wuerzburg, Germany, ³Rudolf Virchow Center, University of Wuerzburg, Wuerzburg, Germany, ⁴Washington University School of Medicine, St. Louis (MO), United States, ⁵Hans Knoell Institute (HKI) Jena and Friedrich Schiller University Jena, Jena, Germany

Hematopoietic cell transplantation is a powerful treatment against hematologic malignancies. However, it is often hampered by the complication of graft-versus-host disease (GvHD), where alloreactive donor T cells attack healthy host tissues. Strikingly, only three specific target organs are infiltrated during acute GvHD: Beside liver and skin, the gut is a primary target organ of GvHD.

During priming of naive donor T cells in secondary lymphoid organs, upregulation of CCR9 on alloreactive donor T cells plays a pivotal role in their subsequent extravasation into the lamina propria of the small intestine where their vigorous inflammatory response destroys the host tissue. Infiltration occurs by both CD4 and CD8 conventional T cells, but also by populations of regulatory T cells and Th17 cells. However, the timing and proportion of these populations, as well as the basis for selective organ infiltration and guidance within the tissue are not well understood.

In the course of GvHD, we find increased intestinal CCL25 expression, which is an attractant for CCR9+ donor T cells. *In vivo* two-photon microscopy revealed that infiltration of CD4 T cells into the small intestine precedes CD8 T cell infiltration. These cells are influenced by the collagen network and migrate in a directed manner, confirming that after extravasation, T cells

are guided within the tissue towards a source of gradient such as chemokines. Manipulating this driving force is a promising strategy to avert GvHD without affecting beneficial anti-leukemogenic T cell toxicity.

773

Transplantation equals organ and resident immune cell transfer

Prosser, A.¹, Larma, I.², Huang, W.H.³, Liu, L.¹, Nanayakkara, C.¹, Lu, B.⁴, Kallies, A.⁵, Lucas, M.⁶

Transplantation of solid organs entails transplantation of immune cells residing within the organ, such as regulatory T cells, conventional effector T cells as well as circulating and tissue-resident memory cells. The fate and function of these cells after transplantation, however, is unknown.

Congenetic mice receive an orthotopic syngeneic liver transplant and organs (graft liver, spleen, LN and bone marrow; BM) are harvested at Day 1 and Day 14 post transplantation. The tissue homogenates are analysed for the presence of tissue resident T cells (Trm), innate lymphoid cells (NK and NKT), naive, central and effector memory CD8 and CD4 T cells by multi-parameter flowcytometry.

Shortly after transplantation, grafted livers are rapidly infiltrated by recipient lymphoid cells which consist predominantly of CD8⁺ T cells, some of which gain phenotypic characteristics of Trm cells by Day 14. In addition, there is an apparent expansion of donor cells with a Trm phenotype post transplantation. The numbers of donor and recipient conventional liver NK cells increase over time whereas donor NKT cell numbers remain stable and recipient NKT cells infiltrate the liver. Donor tissue resident immune cells that can be found at small numbers in LN, spleen and BM post transplantation surgery are maintained at low frequency over the study period.

Immune resident cells within organs are readily transferrable and are maintained within the new host. Recipient cells also contribute to the replenishment of the resident immune cell pools. The extent and quality of the cellular components transferred via the graft may influence transplantation outcome.

Estudios Avanzados, CINVESTAV, México DF, Mexico

Allogeneic hematopoietic stem cell transplantation (AHSCT) is used in patients with hematologic diseases; however, there are difficulties for the transplant to be successful: having a good mobilization of HSC and other cells, having a success graft, and no graft versus host disease (GVHD) develops. This work focused on the response to the HSC mobilization on donors, monitoring post-transplant patients, and the correlation of the data with the success or failure of the transplant by searching biomarkers to avoid GVHD. A panel of inflammatory biomarkers in healthy individuals, donors mobilized with Filgrastim® (G-CSF) and patients undergoing AHSCT were assessed by flow cytometry. At first, it was studied the donors after mobilize HSC, to know if this process induces a specific profile. An increase of cells with inflammatory profile CD8+IFN γ + ($p < 0.01$), CD4+IFN γ + ($p < 0.001$) and CD8+IL17+ ($p < 0.05$) as well as regulatory profile CD8+IL10+ ($p < 0.01$) were observed. So it was decided to make a correlation between patients who developed acute GVHD (aGVHD) and the percentages of IFN γ + T-cells that were infused. Patients which developed an aGVHD had received higher percentages of CD8+IFN γ + (Tc1) T-cells; however, this observation was not statistically significant. Patients were divided into 3 groups: with aGVHD, with controlled aGVHD, and without GVHD. In these cases the Tc1 ($p < 0.01$) and CD8+IL17+ T-cells (Tc17) ($p < 0.05$) are important in the development of GVHD. Moreover CD8+FoxP3+ Treg cells ($p < 0.01$) contribute in the process of regulating inflammation; so, these 3 subpopulations can be used as predictive biomarkers of GVHD.

775**Non-invasive prediction of renal transplant rejection using FOXP3 mRNA expression analysis in peripheral blood and urine: a prospective study**

Barabadi, M.¹, Keshavarz Shahbaz, S.¹, Hosseinzadeh, M.¹, Foroughi, F.², Nafar, M.³, Amirzargar, A.A.^{1,4}

¹Tehran University of Medical Sciences, Department of Immunology, Tehran, Iran, Islamic Republic of, ²Tehran University of Medical Sciences, Department of Immunology, School of Public Health, Tehran, Iran, Islamic Republic of, ³Shahid Labbafinejad Medical Center and Shahid Beheshti University of Medical Sciences, Chronic Kidney Disease Research Center and Department of Nephrology, Tehran, Iran, Islamic Republic of, ⁴Tehran University of Medical Sciences, Molecular Immunology Research Center, Tehran, Iran, Islamic Republic of

Background: FOXP3+ Regulatory T cells play a crucial role in immune response to rejection and the induction of allograft tolerance. This study focuses on the blood and urinary FOXP3 mRNA expression in renal transplant recipients, as an important factor in the development and function of regulatory T cells. We hypothesized that due to its regulatory function, FOXP3 gene expression alterations in patients undergoing renal transplantation can be used as an immunodiagnostic tool in predicting graft outcome.

Methods: we analyzed peripheral blood mononuclear cell and urinary FOXP3 mRNA expression in 212 blood and 159 urine samples taken from 53 kidney transplant recipients

in a prospective cohort study within first 6 months post transplantation. Measurements were performed using Taqman mRNA assay. Moreover, Receiver operating characteristic (ROC) analysis was performed to distinguish allograft dysfunction from well-functioning grafts.

Results: The expression level of transcription factor FOXP3 in patients developing allograft dysfunction ($n=25$) 6 months post-KTx was higher ($p < 0.001$) compared with well-functioning group ($n=27$). Analysis of receiver operating characteristic curves could discriminate graft dysfunction from normal functioning group by calculating the optimal FOXP3 mRNA cutoff value.

Conclusion: Results presented here provide the evidence that high expression of FOXP3 in blood and urine from kidney transplant recipients appears to be a useful non-invasive diagnosis of allograft dysfunction and graft outcome assessment.

Keywords: Kidney Transplantation, FOXP3, acute rejection.

776**Allogeneic transplantation associated 'Cytokine Storm' leads to early death in chemo-conditioning based murine model of graft versus host disease (GVHD)**

Mehta, M.^{1,2}, Majumdar, A.¹, Kumar, R.³, Gota, V.²

¹Bombay College of Pharmacy, Department of Pharmacology and Toxicology, Mumbai, India, ²Advanced Center for Treatment, Research and Education in Cancer, Department of Clinical Pharmacology, Navi-Mumbai, India, ³Tata Memorial Hospital, Department of Pathology, Mumbai, India

Background: The extent of release of pro-inflammatory cytokines and subsequent damage to target organs of GVHD following allogeneic transplantation in Busulfan - Cyclophosphamide conditioning based murine model was profiled.

Methods: Recipient Balb/c mice were treated with Busulfan (80mg/kg/4days) followed by Cyclophosphamide (100mg/kg/2days). On "Day 0" recipient mice were transplanted with 20*10⁶ bone marrow and 30*10⁶ spleen cells from MHC mismatched donor C57BL/6 mice. Non transplanted mice served as chemo-controls. At pre-defined time interval, mice were sacrificed and major internal organs were subjected for pathological evaluation. Serum cytokines were analyzed using Luminex xMAP platform.

Result: Levels of IFN-Gamma, TNF-Alpha, IL-4, IL-5, IL-1 Beta, IL-2, IL-10 and IL-17 were increased by 292, 2.89, 2.40, 2.84, 2.21, 2.96, 6.47 and 2.83 folds respectively compared to chemo-control group after transplantation. IL-6, IP-10 and IL-12 p70 remained unaffected. Aberrant rise of pro-inflammatory cytokines were accompanied by inflammatory changes in recipient's Liver, Skin and Gut. Liver was characterized by lobular inflammation and peri-portal and central vein chronic inflammation. Chronic active colitis with surface ulceration, crypt abscess, apoptosis and sloughing of epithelial lining revealed the damage in Gut. Inflammation along with apoptotic keratinocytes in epidermis and basal cell vacuolization were observed in Skin. Median survival of transplanted mice was 9 days compared to 15 days of chemo-control group [Hazard Ratio = 4.06 (3.39 - 39.75)].

Conclusion: Aberrant rise in levels of pro-inflammatory

cytokines leads to severe inflammatory changes and subsequent damage in target organs of GVHD and thus associated with early mortality in mice following allogeneic transplantation.

777

Sterile inflammation in grafted organs and its systemic side effects

Larma, I.¹, Nanayakkara, C.², Prosser, A.², Huang, W.³, Liu, L.², Lucas, M.⁴

¹University of Western Australia, Centre for Microscopy, Characterization and Analysis, Nedlands, Australia, ²University of Western Australia, Medicine and Pharmacology, Nedlands, Australia, ³University of Western Australia, School of Surgery, Nedlands, Australia, ⁴University of Western Australia, Pathology and Laboratory Medicine, Nedlands, Australia

Sterile inflammation within grafted solid organs is an unavoidable technical consequence of transplantation. The corollaries of this early inflammation affect graft survival and the recipient's health overall.

We use a murine cardiac syngeneic transplant model in order to understand local and systemic cellular dynamics without adaptive responses to foreign tissue. Mice receive a graft heart besides their native heart. Hearts, draining lymph nodes (LN), spleen and bone marrow (BM) are analysed by multi-parameter flow-cytometry at day 1 (D1; n=6) or day 7 (D7; n=7) post-transplant.

The grafts increase in size at D1 due to an influx of monocytes (CD11b⁺CD11cLy6C⁺MHCII⁻), granulocytes (SSC^{high}CD11b^{high}Ly6G^{high}) and T cells accompanied by a proportional decrease of NK and B cells. These changes persist at D7 to a lesser extent. Native hearts show a lesser influx of neutrophils (but not monocytes) at D1 with an increase in ST2⁺CD3⁻NK⁻B220⁻CD11b⁻ cells on D1 and D7.

Draining LN and spleen show an immediate decrease in T, NK cells and pDCs while B cells and neutrophils (LN only) increase. In the BM T and NK cells increase overtime, while the proportion of B cells reduces by D7. There is an apparent early reduction in granulocytes and monocytes that is followed by an increase of these cells by D7.

Key changes occur predominantly within 24 hours post transplantation and are dominated by neutrophils and monocytes/macrophages. Understanding the nature and triggering of these early infiltrates after organ transplantation will contribute to new therapeutic developments extending graft longevity and reducing systemic side effects.

778

New method of allogeneic hematopoietic stem cell transplantation: hematopoietic stem cell transplantation plus thymus transplantation for intractable diseases

Hosaka, N.^{1,2}

¹Kansai Medical University Kori Hospital, Neyagawa, Japan,

²Kansai Medical University, Hirakata, Japan

Although allogeneic hematopoietic stem cell transplantation (allo-HSCT) has become a valuable strategy for intractable diseases, a number of problems remain to be resolved. We have

developed a new HSCT method, HSCT + thymus transplantation (TT), which induces elevated T cell function with mild graft-versus-host disease (GVHD) in comparison to conventional HSCT alone and HSCT + donor lymphocyte infusion (HSCT + DLI) in mice. This method leads to improvement of immune function and the ability of engraftment. The results indicated that this method is effective for treatment of several intractable diseases and conditions, such as autoimmune diseases in aging, advanced malignant tumors, exposure to supralethal irradiation, multiple organ transplantation from different donors, and type 2 diabetes mellitus, for which conventional methods are ineffective. Our findings suggest that allo-HSCT + TT is preferable to conventional allo-HSCT alone or allo-HSCT + DLI. This method may become a valuable next-generation HSCT technique for clinical use.

779

Identification of naturally presented allopeptides using immunoproteomics to determine their role in T cell cross-reactivity

Mifsud, N.^{1,2}, Rowntree, L.², Nguyen, O.³, Schittenhelm, R.¹, Illing, P.¹, Kotsimbos, T.^{2,4}, Purcell, A.¹

¹Monash University, Infection and Immunity Program, Monash Biomedicine Discovery Institute, Clayton, Australia, ²Monash University Central Clinical School, Melbourne, Australia, ³Peter Doherty Institute for Infection and Immunity at The University of Melbourne, Parkville, Australia, ⁴Alfred Hospital, Melbourne, Australia

Cross-reactive anti-viral memory T cells constitute a significant proportion of the alloresponse and potentially play a role in mediating adverse clinical outcomes in HLA mismatched allografts. Additionally, chronic DNA viruses including cytomegalovirus (CMV) contribute to significant post-transplant morbidity and mortality. We have identified CMV-reactive (HLA-A*02:01-NLVPMVATV) CD8⁺ T cells with a unique TCR signature (TRAV3TRAJ31_TRBV12-4TRBJ1-1; OTN5) that cross-react against specific HLA-B27 allomorphs with a defined hierarchy (B*27:09>B*27:07>B*27:05). This observation combined, with the failure of OTN5 to recognise TAP-deficient B27⁺ APC, highlights the peptide dependence of the allorecognition. However, the identity of the HLA-B27 restricted peptide(s) is unknown. In this study, we undertook an immunoproteomics approach for allopeptide identification. HLA B27-peptide complexes were captured by immunoaffinity chromatography from individual C1R-B27 transfectants (C1R-B*27:01, -B*27:02, -B*27:07 or -B*27:09), the bound peptide ligands were isolated and fractionated by RP-HPLC. An immunoreactive peptide fraction, common to all C1R-B27 transfectants, was identified by screening with SKW3 cells expressing the cross-reactive OTN5 TCR (SKW3.OTN5). Sequencing of the peptides within this fraction by mass spectrometry (LC-MS/MS) yielded 2646 unique B27-restricted peptides. Of these, a subset of 136 peptides were synthesised and either pooled (groups of 8-11 peptides) or individually tested to measure functional reactivity by SKW3.OTN5 cells. Whilst preliminary investigations have not as yet confirmed the presence of the allopeptide(s) within the first wave of selected peptides, this study demonstrates the

potential of immunoproteomics to identify naturally presented peptides in the context of specific HLA allomorphs in order to determine their role in mediating T cell cross-reactivity.

780

Induction of transgene-specific immunological tolerance by hematopoietic microchimerism using gene-modified bone marrow transplantation in a gene therapy setting

Boyer, O.^{1,2}, Bourdenet, G.¹, Cohen, J.L.³, Mingozi, F.^{4,5}, Martinet, J.^{1,2}

¹Normandy University, Inserm U 905, Rouen, France, ²Rouen University Hospital, Department of Immunology, Rouen, France, ³UPEC, Inserm U 955, Creteil, France, ⁴Genethon, Evry, France, ⁵UPMC, Inserm U 974, Paris, France

Introduction: Gene therapy is a promising treatment option for hemophilia. Replacement therapy is hampered by a risk of immunization against recombinant coagulation factors and immune response against the transgene product is an obstacle to gene therapy. Induction of hematopoietic chimerism is a potent way for inducing immunological tolerance in experimental solid organ transplantation, including grafting of alloantigen expressing gene-modified syngeneic bone marrow. **Objective:** To elicit transgene-specific immunological tolerance by inducing a hematopoietic microchimerism in a gene therapy setting.

Material and methods: We developed lentiviral vectors encoding a strong immunogene composed of an immunodominant peptide of ovalbumin (OVA) linked to a MHC class I - beta-2-microglobulin fusion protein (LV-OVA), or factor IX cDNA under a pgk promoter (LV-FIX). C57BL/6 mice (Ly5.2) were lethally (10 Gy) or sub-lethally (5 Gy) irradiated and reconstituted with LV-transduced congenic Ly5.1 bone marrow cells.

Results: Less than 1% bone marrow microchimerism was sufficient to tolerize the CD8+ T cell compartment towards OVA and to allow persistent transgene expression after in vivo gene transfer. We could prevent the anti-FIX humoral response and achieve persistent production of circulating FIX after LV-mediated gene transfer in vivo.

Conclusion: This work provides proof of concept that inducing hematopoietic microchimerism by bone marrow transplantation under sub-lethal conditioning using gene-modified cells confers tolerance to a gene therapy product. This opens perspectives for further preclinical evaluation of a dual gene therapy approach using the same vector.

781

Extracellular ATP as an early danger signal initiating allograft rejection

Amores-Iniesta, J., Martínez, C.M., Barberà-Cremades, M., Baroja-Mazo, A., Pelegrin, P.

Murcia's Biomedical Research Institute (IMIB-Arrixaca), Murcia, Spain

The immune system is activated in response to foreign non-self components that represent a danger to the host, such as pathogenic microorganisms. However, harmful agents for the host could also be of endogenous origin and activate immunity,

leading to 'sterile' inflammation. A challenging unexplored scenario for this model is the activation of the immune system in allogeneic transplantation, where a strong Th1 destructive immune response is developed against 'sterile' foreign non-self but 'not-dangerous' tissue grafts. Here we found that in allotransplants extracellular ATP concentration increase, suggesting that this nucleotide acts as an early endogenous danger signal released after innate sensing of allogeneic tissues. Antigen-presenting cells recognizing non-self antigens are responsible for the early elevation of extracellular ATP. In this process, P2X7 receptor plays a key role and activates the Nucleotide oligomerization domain-, Leucine-rich repeat-, and Pyrin domain-containing 3 (NLRP3) inflammasome. Furthermore, NLRP3 inflammasome induces the release of interleukin (IL)-18 that establish a Th1 response against the allotransplant via interferon- γ (IFN- γ) production. P2X7 receptor pharmacological inhibition, or genetic deficiency of P2X7 receptor or NLRP3 inflammasome resulted in a delayed graft rejection without complete immune paralysis. These data clarify the function of danger signals during non-self and 'non-dangerous' immune activation and have important implications for transplantation medicine, as pharmacological targeting of P2X7 receptor could improve the development of graft tolerance.

782

Stem cell and novel biologic therapies to improve functional outcomes in limb transplantation

Salgar, S.¹, Kniery, K.²

¹Madigan Army Medical Center, Clinical Investigation, Tacoma, United States, ²Madigan Army Medical Center, Surgery, Tacoma, United States

Introduction: Vascular composite allotransplantation (VCA) such as limb and face require successful nerve regeneration and reinnervation of graft for optimal functional outcome.

Materials and methods: We investigated whether mesenchymal stem cells (MSCs), Granulocyte-Colony Stimulating Factor (G-CSF), and Dihexa can improve sensory and motor functional recovery in rat sciatic nerve transection repair and limb transplant models. Surgical procedures were performed under general anesthesia. Bone marrow derived syngeneic MSCs (5x10⁶), G-CSF (50 μ g/kg), (Dihexa 2 mg/kg) or Vehicle were administered topically and i.v./i.p. The motor function was assessed by walking track analysis and sensory function by cutaneous reaction test.

Results: Ex vivo expanded MSCs were CD29+, CD90+, MHC Class I+, CD34-, CD31-, Class II-, and pluripotent. At two weeks post-nerve repair, total sensory nerve function in all groups was ~1.5 on a scale of Grade 0-3 (0=No function; 3=Normal); however, peroneal nerve function ranged 2.6-3.0. By 4 weeks total sensory function was 2.2 \pm 1.0, 2.0 \pm 1.2, 2.2 \pm 1.1 and 1.8 \pm 1.3 in MSC, G-CSF, Dihexa and Vehicle groups, respectively. At 10 weeks, sensory function (~3) was restored to normal in all groups (n=8/group). Sciatic function index (SFI) a measure of motor function (0=normal function; -100=nonfunctional) during 5-16 weeks was markedly improved in G-CSF (-40 to -26) compared to MSC (-93 to -66), Dihexa (-85 to -57) or Vehicle (-110 to -45) group. In limb transplants, sensory function ranged 0.8-1.3 by

8 weeks, and 1.5-2.0 by 16 weeks post-surgery. Majority of the transplants (~60%) developed flexion-contractions.

Conclusions: MSC, G-CSF and Dihexa appear to promote functional recovery in VCA.

Treg

783

ST2-expressing regulatory T cells in the colon express the repair mediator, Amphiregulin

Chomka, A.¹, Krausgruber, T.², Powrie, F.¹

¹University of Oxford, The Kennedy Institute of Rheumatology, Oxford, United Kingdom, ²CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria

Tissue-specific regulatory T cells (Tregs), in contrast to their lymphoid counterparts, develop specific adaptations enhancing their survival and function. Tregs are enriched in the intestinal lamina propria and represent a key immune cell type that controls the intestinal homeostasis. Recently we have identified a sizeable population of Tregs in the colon expressing the interleukin 33 (IL-33) receptor, ST2. We showed that these cells respond to the alarmin, IL-33, which is released by cells upon tissue damage.

To further characterize this population, we compared the mRNA expression profile of murine colonic ST2-expressing Tregs (ST2+) to colonic Tregs that do not express ST2 (ST2-). Amphiregulin, an EGF-like growth factor previously shown to be important for repair mechanisms, was significantly enriched among the ST2+ colonic Tregs. Amphiregulin was also significantly more abundant in the whole colonic tissue compared to lymphoid tissues, i.e. the spleen and the mesenteric lymph nodes. Finally, to investigate a direct link between IL-33 and the expression of Amphiregulin by Tregs, we performed both *in vitro* and *in vivo* experiments, which confirmed that upon IL-33 signalling in Tregs Amphiregulin production was substantially increased.

Together, these results highlight that intestinal Tregs, similarly to other tissue-specific Tregs, have a distinct phenotype and function. Through the enhanced production of Amphiregulin, ST2+ Tregs may represent a specialised population capable of mediating repair functions.

784

Maternal dietary fiber intake during pregnancy affects on Foxp3⁺Treg differentiation in the thymus of offspring

Nakajima, A., Kaga, N., Miyake, S., Habu, S.

Juntendo University, Tokyo, Japan

Maternal diet intake during pregnancy is thought to be crucial for developing immune system of offspring. Recent studies have also shown that short-chain fatty acids (SCFAs), metabolites of dietary fiber have a potential role in inducing regulatory T cells (Tregs) in the gut. Moreover, accumulating evidence suggests that thymus-derived Tregs (tTregs) are important in suppressing immune response and homeostasis. Based on these evidences, we examined whether SCFAs metabolized in mother's gut influence on the development of tTregs in

offspring. For this purpose, purified high soluble fiber diet (HFD) or no fiber diet (NFD) was fed to mothers during pregnancy and then tTregs of offspring were analyzed. We then observed increased frequency of tTregs in the offspring born from HFD-fed mice when compared with those born from NFD-fed mice. In addition, SCFAs could also increase the number of tTregs in fetal thymus organ culture (FTOC) system. To address the mechanism by which SCFAs increase tTregs in offspring, we focused on the involvement of thymic microenvironment such as thymic epithelial cells (TECs). Given that the transcription factors Aire and Fezf2 especially expressed in TECs are related not only to negative selection of T cells but also to induction of tTregs, we analyzed the expression of Aire and Fezf2 in TECs. As expected, the expression of these genes was increased by SCFAs treatment in FTOC.

These results suggest that SCFAs, metabolites of commensal bacteria from mother's gut could affect Tregs development in the thymus of offspring.

785

In follicular regulatory T cells NFAT2 is essential for homing to germinal centers

König, A.¹, Vaeth, M.¹, Müller, G.², Stauss, D.², Dietz, L.¹, Klein-Hessling, S.¹, Serfling, E.¹, Lipp, M.², Berberich, I.³, Berberich-Siebelt, F.¹

¹Institute of Pathology, Julius-Maximilians-University, Wuerzburg, Germany, ²Max-Delbrück-Center for Molecular Medicine (MDC), Department of Tumor Genetics and Immunogenetics, Berlin, Germany, ³Institute for Virology and Immunobiology, Julius-Maximilians-University, Wuerzburg, Germany

The humoral immune response represents one arm of adaptive immunity and is based on antibody-secreting plasma cells. Plasma cells, which secrete class-switched antibodies with high affinity, are the product of the germinal center reaction (GCR). The GCR depends on CD4⁺CXCR5⁺ follicular T helper cells (T_{FH}), while it is controlled by CD4⁺CXCR5⁺Foxp3⁺ follicular regulatory T cells (T_{FR}). Expression profiling revealed high expression of the 'Nuclear Factor of Activated T cells 2' (NFAT2) in follicular T cells, covering T_{FH} as well as T_{FR} cells. Therefore, we chose to investigate the role of NFAT2 in those two follicular T-cell subsets. The ablation of *Nfat2* in all T cells, but also in Foxp3-expressing cells only, led to an increase in the GCR. This effect was due to an impaired homing of the T_{FR} population to the B cell follicle, because T_{FR} cells specifically failed to upregulate the homing receptor CXCR5. In T_{FR} cells - in contrast to T_{FH} cells - 'B lymphocyte-induced maturation protein' (Blimp-1) is highly expressed in line with being a hallmark of effector Tregs. Our data indicated that, similar as in plasma cells, Blimp-1 represses the expression of *Cxcr5* in T_{FR} cells and that this is a direct effect. However, it supports the recruitment of NFAT2 to *Cxcr5* by protein-protein interaction, by those means cooperating with NFAT2 for transactivation of *Cxcr5*. In sum, NFAT2 is essential for overcoming Blimp-1-mediated repression of *Cxcr5* and therefore for homing of T_{FR} cells, which control the GCR, an essential part of the humoral immune response.

786

IL-10 produced by B cell-induced regulatory CD4⁺Foxp3⁺ T cells via the activation of c-Maf*Chien, C.-H., Chiang, B.-L.**College of Medicine, National Taiwan University, Taipei City, Taiwan, Republic of China*

The role of B cells in the development of interleukin (IL)-10-producing regulatory T cells and Foxp3⁺ regulatory T cells have been emphasized recently. Previously, we demonstrated that the antigen-presenting splenic B cells converted naïve CD4⁺CD25⁻ T cells into CD4⁺CD25⁺ T cells with regulatory function without the expression of Foxp3. Here, we investigated the effect of OVA₃₂₃₋₃₃₉ peptide-presenting splenic B cells on the naïve DO11.10 splenic CD4⁺CD25⁻ T cells. We found that the levels of IL-10 and IL-4 increased gradually during the 3 rounds of B-T coculture. After 3 rounds of B-T coculture, B cell-induced CD4⁺CD25⁺ T cells increased the IL-10-producing population, the production of IL-10, the expression of c-Maf, and the expression of inducible T-cell co-stimulator (ICOS) as well as cytotoxic T-lymphocyte-associated protein 4 (CTLA4). We found that the major IL-10-producing population was confined to the c-Maf-expressing population in the B cell-induced regulatory T cells. By the blockade assay, not only IL-10 also CTLA4 played the roles in the suppressive mechanism of the B cell-induced regulatory T cells. We also found that the induction mechanism largely depended on cell-cell contact mechanism. These results suggested that the antigen-presenting B cells promote the development of IL-10-producing regulatory T cells via the activation of c-Maf.

787

The phenotype, functions and cytokine properties of 5-Azacytidine (5AzaC) induced Treg-like FOXP3⁺ CD4⁺ T cells*Benfatto, C.¹, Seidl, T.¹, Perez Abellan, P.¹, Chung, S.S.¹, Ellis, R.², Mufti, G.¹, Thomas, N.S.B.¹, Kordasti, S.¹**¹King's College London, Haematological Medicine, London, United Kingdom, ²NIHR GSTFT/ KCL, Biomedical Research Centre, London, United Kingdom*

Myelodysplastic Syndrome (MDS) is a group of premalignant diseases characterised by ineffective erythropoiesis. Expansion of CD4⁺CD25^{hi}CD127^{low}FOXP3⁺ (Tregs) is one of the characteristic features of high risk MDS. Although the only curative treatment is bone marrow transplantation, treatment with the hypomethylating agent 5AzaC can enhance life expectancy. It has been shown by our group that following treatment with 5AzaC, the absolute number of Tregs is reduced.

This study focuses on the FOXP3⁺ T cells ("Treg-like" cells) derived from 5AzaC treated Tconv (CD4⁺CD25⁻). We wanted to investigate whether the features of this subpopulation were still Tconv or whether they polarised to another population. We have analysed the cell surface protein phenotype, functional analysis and cytokine secretion of "Treg-like" cells compared with Tregs, Tconv and Th-17 derived from a Th-17 polarising environment (*in-vitro* culture with IL-1b, IL-6 and IL-2).

Our data demonstrate: 1) "Treg-like" cells show an increase in secretion of IL-17 and expression of FOXP3 and have no significant immunosuppressive properties; 2) the ability of Tregs

to polarise towards Th-17; 3) the Treg-specific demethylated region (TSDR) within the FOXP3 gene in "Treg-like" cells is fully methylated compared with Tregs. Changes in the methylation status of the FOXP3 downstream genes of Tconv (+/- 5AzaC) versus Tregs from healthy donors are now being analysed. We used a mass-cytometry technology (CyTOF) to characterise the cell surface protein phenotype of "Treg-like" cells.

The phenotype and the methylome analysis will give an improvement in understanding how these "Treg-like" cells develop, behave and their potential use in therapy.

788

The complementary role of FOXP3⁺ regulatory T cells and Tr1 cells in the maintenance of tolerogenic immune modifying nanoparticle (TIMP) peripheral tolerance*Podojil, J.R.¹, Getts, D.R.¹, Miller, S.D.²**¹Cour Pharmaceuticals Development Co, Chicago, United States,**²Northwestern University Feinberg School of Medicine, Chicago, United States*

Tolerogenic Immune Modifying Nanoparticles (TIMP) encapsulating self-antigens (TIMP) are highly effective for the prevention and treatment of autoimmunity. TIMP(PLP₁₃₉₋₁₅₁) treatment of naïve SJL/J mice totally abrogates the induction of PLP₁₃₉₋₁₅₁/CFA-induced R-EAE in an antigen-specific manner via synergistic mechanisms. First, deletion/inactivation of Tregs by treatment of with anti-CD25 at the time of tolerance partially reversed the protective effect of TIMP(PLP₁₃₉₋₁₅₁), and transfer of purified splenic

T cells from TIMP(PLP₁₃₉₋₁₅₁)-treated mice protects recipient SJL/J mice from PLP₁₃₉₋₁₅₁/CFA-induced EAE. Second, administration of TIMP(PLP₁₃₉₋₁₅₁) to 5B6 (PLP₁₃₉₋₁₅₁-specific) TCR transgenic mice was found to lead to the significant expansion of both antigen-specific Foxp3⁺ iTregs and Lag3⁺, IL-10⁺ Tr1 cells. Third, the supplementation of rIL-2 to *ex vivo* recall cultures from TIMP(PLP₁₃₉₋₁₅₁)-treated mice partially restored the proliferative response indicating a role for anergy. To test the effects of TIMP on regulation of previously activated T cells, we showed that administration of TIMP(p31) to NOD.SCID recipients of activated BDC2.5 TCR transgenic T cells (specific for the chromogranin A p31 mimotope peptide) led to long-term prevention from induction of T1D. TIMP(p31) infusion was dependent on the activation of Foxp3⁺ Tregs which acted to regulate the trafficking of the effector BDC2.5 T cells to the pancreas and causing their retention in the spleen of the recipient mouse. Tolerance was reversed by treatment with either anti-PD-1 or anti-CTLA-4. These findings indicate a role for Tregs, Tr1 cells, and T cell anergy in TIMP-induced tolerance.

789

The role of regulatory T cells in T cell recovery under severe lymphopenic conditions in hemoblastosis patients*Batorov, E., Tikhonova, M., Kryuchkova, I., Batorova, D.,**Sergeevicheva, V., Sizikova, S., Ushakova, G., Gilevich, A., Ostanin, A., Chernykh, E.**Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation*

Introduction: Well-timed T-cell reconstitution is crucial for early restoration of anti-infectious and anti-tumor immune response. Homeostatic proliferation is important for the restoration of T cell count in immune competent host during the 1st year following autologous hematopoietic stem cell transplantation (AHSCT). Mature T cells involved in expansion may be sensitive for the balance between signals that mediate proliferation or suppression, e.g. from regulatory T cells (Tregs). We have investigated dynamics of CD4+FOXP3+ Tregs recovery following AHSCT and possible relationship between Tregs and clinical outcomes.

Patients and methods: 109 hemoblastosis patients underwent AHSCT in 2009-2014. The content of circulating CD4+FOXP3+ Tregs has been evaluated using flow cytometry before AHSCT, at the day of engraftment, and following 6 and 12 months.

Results: relative count of Tregs restored rapidly, reached initially high level at the time of engraftment, and then subsequently decreased for a year until it lowered to healthy donors' values. CD4+FOXP3+ Tregs at the time of engraftment were increased in patients with relapse or progression of disease during 6 and 12 months following AHSCT compared to non-relapsed patients. (12.1±5.6% vs. 7.3±3.9%; pU=0.016, and 10.7±5.0% vs. 6.9±3.7%; pU=0.024; data as Mean ± SD).

Conclusions: Our data of Tregs reconstitution may confirm the earlier assumption that the presence of Tregs during the period of immune recovery preserves optimal T cell receptors diversity. But excess of these cells leads to the inhibition of proliferative activity and immune response and is associated with early relapse.

790

Inhibins regulate peripheral Treg induction through modulation of dendritic cell function

de la Fuente Granada, M.¹, Olguin Alor, R.¹, Bonifaz Alfonso, L.², García-Zepeda, E.A.¹, Soldevila, G.¹

¹Instituto de Investigaciones Biomedicas, Universidad Nacional Autónoma de México, Immunology, Mexico, Mexico, ²Hospital de Especialidades, Centro Médico Nacional 'Siglo XXI', Unidad de Investigación Médica en Inmunoquímica, Mexico, Mexico

Inhibins and Activins, members of the Transforming Growth Factor b superfamily, participate in the immune system as key regulators of several cellular functions. Despite some reports indicating that Activins may regulate DC maturation and function, the role of Inhibins in these processes remains elusive. Here, we investigated the role of Inhibins in DC maturation and function and its impact in Treg induction. Analysis of mature Inha-/- BMDCs obtained after lipopolysaccharide stimulation (mBMDC) showed a significant reduction in the surface expression of MHC II and CD86 (a semi-mature phenotype), and a concomitant increase in PD-L1, compared to WT mBMDC, suggesting a tolerogenic phenotype. In addition, the Inha-/- mBMDC showed reduced migration towards CCL19 and CCL21 by *in vitro* chemotaxis and *in vivo* adoptive competitive transfer assays. In addition, mBMDC from Inha-/- displayed reduced capacity to induce proliferation of allogeneic CD4+ naïve T cells. This correlated with an increased induction of iTregs (CD25+Foxp3+) from CD4+ naïve T cells in the presence of

TGFb, as well as with increased absolute numbers of iTregs and nTreg (CD4+CD25+Foxp3+Helios- and Helios+, respectively) in peripheral lymph nodes of 4 week-old Inha-/- mice compared to WT. Interestingly, Inha-/- T cells showed a reduced induction of Tregs in the absence of APCs, suggesting an intrinsic role of Inhibins in the differentiation of T cells. Our data demonstrate for the first time a direct role of Inhibins in the regulation of DC mediated functions and point out the importance of Inhibin signaling to maintain the balance between inflammation and tolerance.

791

TET2 and TET3 play essential roles in Treg-specific DNA demethylation and Treg stability

Nakatsukasa, H., Yoshimura, A.

Keio University School of Medicine, Department of Microbiology and Immunology, Tokyo, Japan

It has been shown that DNA demethylation of Treg-specific demethylation regions (TSDRs) during Treg development plays essential roles in stable Foxp3 expression. Although DNA demethylating enzymes, ten-eleven translocation (TET) family proteins have been proposed to be involved in the DNA demethylation of TSDRs, actual contribution of TET family proteins in Treg stability and function remain to be elucidated. To investigate the role of TET proteins in Tregs, we generated Treg-specific Tet-deficient mice by crossing *Tet2^{flf}* and/or *Tet3^{flf}* mice with *Foxp3^{YFP-Cre}* mice. In Treg-specific *Tet2*- and *Tet3*-single KO mice, Treg development was normal and these mice did not show any spontaneous immunological diseases. While *Foxp3^{YFP-Cre}+Tet2^{flf}Tet3^{flf}* (FDKO) mice died at an average of 20 weeks of age with abnormal expansion of T cells. TSDRs of FDKO Tregs were hyper-, but not completely, methylated compared with WT Tregs, indicating that there are Tet2/3 dependent and independent mechanisms for TSDR demethylation. Treg transfer experiments into *Rag*-deficient mice revealed that Foxp3 expression in FDKO Tregs were more unstable than that in WT Tregs. In aged FDKO mice, both Foxp3⁺ and Foxp3⁻ T cells were expanded and produced high levels of IL-17, suggesting that the accumulation of exFoxp3 cells in FDKO mice. These data indicate that Tet2/3 are redundantly involved in TSDR demethylation and are important for the stability and homeostasis of Tregs.

792

Regulatory T cell-dendritic cell interactions in the prevention of graft-versus-host disease

Bolton, H.^{1,2}, Pijning, A.¹, Terry, A.^{1,2}, Shklovskaya, E.^{1,2}, Zhu, E.^{1,3}, Fazekas de St Groth, B.^{1,2}

¹Centenary Institute, T Cell Biology, Camperdown, Australia, ²University of Sydney, Department of Dermatology, Camperdown, Australia, ³Childrens Medical Research Institute, Westmead, Australia

Regulatory T cells (Tregs) improve immune reconstitution after bone marrow transplant (BMT) by promoting a more diverse TCR repertoire and reducing the incidence of graft-versus-host disease (GVHD). How Tregs mediate these effects is unknown.

Using a mouse model of lymphopaenia-induced proliferation (LIP), we have shown that selective reconstitution of the Treg compartment inhibits spontaneous T cell proliferation in response to endogenous antigens, with T cells instead undergoing slow homeostatic division to repopulate the host with a diverse repertoire of naïve T cells. Inhibition of LIP in this model was primarily mediated via CTLA-4-dependent downregulation of CD80/CD86 on DCs. Importantly, the level of CD80/CD86 expressed by DCs was determined by the ratio of Tregs:DCs, suggesting that normalising the Treg:DC ratio rather than the Treg:Tcell ratio may be more important in promoting optimal immune reconstitution during lymphopaenia.

We tested the clinical relevance of these findings in situations in which treatment renders patients transiently lymphopaenic. Using an allogeneic BMT model, we have shown that the elevated DC costimulation in irradiated mice can be reduced by selective Treg-reconstitution of either donor-type Tregs or host-type Tregs. Critically, Treg-reconstitution of BMT recipients prior to transfer of conventional T cells was associated with complete protection against T cell-mediated GVHD, whereas Tregs co-transferred with conventional T cells provided minimal protection. These results indicate that optimal immune recovery from lymphopaenia should aim to achieve early Treg-reconstitution prior to transfer of conventional T cells.

793

High regulatory T-cell predicts low CD4 recovery, and is associated with exacerbated CD4 turnover and inflammation in HIV-patients at risk of low CD4 recovery

Rosado-Sánchez, I.¹, Álvarez-Ríos, A.I.², Herrero, I.¹, Beltrán-Debón, R.³, Rafii-El-Idrissi, M.¹, Ruiz-Mateos, E.¹, Blanco, J.⁴, Vidal, F.³, Leal, M.¹, Pacheco, Y.M.¹

¹IBiS-HUVR, Seville, Spain, ²HUVR, Seville, Spain, ³Joan XXIII Hospital, Tarragona, Spain, ⁴IrsiCaixa, Barcelona, Spain

Peripheral Treg expansion has been associated with low CD4 T-cell counts, particularly in HIV-infected subjects. Our group and others have associated higher Treg frequency to HIV-infected patients with low CD4 recovery after antiviral-treatment (cART). However, this association has been found from post-treatment analysis, when their CD4 counts are significantly lower than any control group, thus it cannot be discarded that this feature could be simply a consequence of such low CD4 recovery.

To overcome this limitation, we analyzed before-to-cART matched samples (also by CD4 counts). In the Spanish CoRIS cohort, we selected samples of HIV-subjects starting cART with < 200 CD4/μL and achieving < 250 CD4/μL on cART (LR patients). Additionally, as control, we selected samples of HIV-subjects starting cART with < 200 CD4/μL but achieving ≥250 CD4/μL. We studied levels of pro-inflammatory biomarkers, cellular turnover and Treg frequencies.

We found that despite similar CD4 counts, LR patients showed an increased Treg frequency before-to-cART. Our results also showed elevated levels of pro-inflammatory biomarkers and exacerbated CD4 turnover. Moreover, these parameters were associated with Treg. Eventually, we performed a multivariate analysis to predict patients at risk

of low CD4 recovery. After adjusting, only Treg frequency was independently associated.

Conclusions: Before-to-cART, LR patients showed specific alterations despite similar CD4 counts. Multivariate analysis indicates that Treg could be used to early detect HIV-patients at risk of low CD4 recovery. Treg accumulation in this scenario could be due to exacerbated CD4 turnover and inflammation, and could play a pivotal role in low CD4 recovery.

794

The lymphoproliferative disorder from depletion of regulatory T cells (Tregs) occurs independently of commensal microbial and dietary antigens and accompanies robust peripheral Treg generation

Yi, J.^{1,2}, Lee, J.^{1,2}, Han, D.¹, Surh, C.^{1,2,3}

¹Academy of Immunology and Microbiology, Institute for Basic Science, Pohang, Korea, Republic of, ²POSTECH, Department of Integrative Biosciences and Biotechnology, Pohang, Korea, Republic of, ³Division of Developmental Immunology, LIAI, San Diego, United States

Thymic regulatory T cells (tTregs) have been regarded as an important regulator of self-tolerance. However, the mechanism how tTregs prevent autoimmunity remains elusive. Since negative selection is believed to eliminate most of auto-reactive thymocyte clones in the thymus, molecular mimicry between foreign-antigens (Ags) and self-Ags has been proposed as possible explanation for most of autoimmune diseases. By utilizing Foxp3-diphtheria toxin receptor (Foxp3-DTR) mice, one group previously tested the role of Ags from intestinal microbiota for induction of lymphoproliferative disorder by depleting Tregs in germ-free (GF) Foxp3-DTR mice and found that lymphoproliferative disorder occurred unabated. In order to test the role of food Ags in inducing lymphoproliferative disorder upon Treg depletion, we generated Ag-depleted Foxp3-DTR bone-marrow chimeras in GF RAG-1 KO host mice that were raised with an ultra-filtered, elemental antigen-free (AF) diet. Strikingly, the AF Foxp3-DTR chimeras displayed equally strong lymphoproliferative disorder upon Treg depletion indicating that foreign Ags are not required for induction of this disease. In addition, we have discovered that the majority of effector CD4 T cells that emerge after Treg depletion originates from a small fraction of naïve CD4 T cells and display Th1 characteristics. More interestingly, the generation of effector CD4 T cells was accompanied with robust conversion of effector CD4 T cells into peripheral Tregs (pTregs). Such a transition applied to a significant fraction of effector CD4 T cells that display a high TCR affinity to self and also required the presence of IL-2. Our findings suggest existence of a strong homeostatic mechanism.

795

Immunomodulatory functions of *Lactobacillus casei* surface proteins induced in interaction with intestinal epithelial cells

Keto, J., Ritamo, I., Haiko, J., Impola, U., Wacklin, P., Partanen, J., Valmu, L., Mättö, J., Lähteenmäki, K.

Finnish Red Cross Blood Service, Medical Services, Helsinki, Finland

T cell subtypes are critical in determination of the immunological balance in the intestine. Intestinal microbiota affects development and maturation of immunological cells. Many *Lactobacillus* species are considered beneficial for intestinal health, and knowledge of their potential effects on immune cell populations could lead to development of therapeutic applications for intestinal disorders. We have previously shown that *Lactobacillus casei* promotes maturation of regulatory T cells (CD4+CD25+FoxP3+) and induction of IL-10 in peripheral blood mononuclear cells (PBMC) more efficiently after cultivation with intestinal epithelial cells than after standard laboratory culture conditions (MRS broth)(Tiittanen et al.,2013,PlosOne,8(11),e78420).

In the current work, we completed a mass spectrometric characterization of the surface proteome of *Lactobacillus casei* ATCC334 with bacteria derived either from HT-29 intestinal epithelial cells or from MRS broth. The results indicated significant culture condition-dependent alterations in the bacterial surface proteome. We are currently analysing potential immunomodulatory effects of selected *Lactobacillus* proteins affected by epithelial cell cultivation. T cell population and cytokine profiling is performed after co-culture of PBMC with recombinant *L. casei* proteins and, for comparison, *Escherichia coli* lipopolysaccharide (LPS). Our initial results suggest similarities in PBMC responsiveness induced by LPS and *L. casei* glyceraldehyde-3-phosphate dehydrogenase (GAPDH), whereas two *L. casei* proteins with yet unknown function promote more immunosuppressive responses. Expression of these proteins was highly induced on the surface of bacteria cultivated with epithelial cells. The results suggest that simulation of bacterial contact with intestinal epithelium can be a valuable tool for identification and production of *Lactobacillus* proteins for therapeutic use.

796

T cell tuning to self-reactivity generates a population of resting naïve Tregs that sensing recent activation of T conventional cells

Lee, J.Y.^{1,2,3}, Kim, J.H.^{1,2}, Yi, J.^{1,2}, Surh, C.^{1,2,4}

¹Institute for Basic Science, Pohang, Korea, Republic of, ²POSTECH, Pohang, Korea, Republic of, ³Division of Developmental Immunology, San Diego, United States, ⁴La Jolla Institute for Allergy and Immunology, Division of Developmental Immunology, San Diego, United States

Thymic selection of regulatory T cells (Tregs) is known to require a relatively strong TCR affinity for self-antigens (Ags). High affinity to self-Ags, however, does not induce all mature Tregs to eventually acquire effector/memory phenotype in the periphery and the mechanism regulating this peripheral differentiation remains elusive. Recently, it has been reported that Ly6c is expressed on naïve-phenotype Tregs and Ly6c⁺ Tregs exhibit impaired suppressive activity. However, the physiological significance of Ly6c⁺ Tregs and the factors regulating Ly6c⁺ Treg homeostasis are poorly understood. Based on the aforementioned findings, it has been deduced that Ly6c expression is associated with peripheral TCR tuning. Indeed, the Ly6c expression was found to inversely correlate

with the TCR signaling strength of Tregs, and Ly6c⁺ Tregs did not respond to self-Ags. We found that the proportion of naïve and effector Treg subsets changed dynamically depending on the age of mice. The proportion of Ly6c⁺ Tregs gradually increased from the perinatal periods to young adult age, but declined slowly with aging. The reduction of Ly6c⁺ Tregs in aged mice appears to be due to activation-induced down-regulation of Ly6c. Because effector T conventional (Tconv) cells are known to accumulate with aging, we speculated that the cytokines generated from effector Tconv cells are essential for awakening of resting Ly6c⁺ Tregs to transition into effector Tregs. Indeed, Ly6c⁺ Tregs underwent strong proliferation under conditions with elevated effector T cell. Therefore, our findings reveal novel characteristics of resting Tregs and suggest a new model of Tconv cell-Treg homeostasis.

797

Requirement of full TCR repertoire for regulatory T cells to maintain intestinal homeostasis

Nishio, J.¹, Baba, M.¹, Atarashi, K.², Tanoue, T.², Negishi, H.¹, Yanai, H.^{1,3}, Habu, S.⁴, Hori, S.⁵, Honda, K.², Taniguchi, T.^{1,3}

¹Institute of Industrial Science, The University of Tokyo, Molecular Immunology, Meguro, Japan, ²RIKEN Center for Integrative Medical Sciences (IMS-RCAI), Laboratory for Gut Homeostasis, Yokohama, Japan, ³Max Planck-The University of Tokyo Center for Integrative Inflammation, Meguro, Japan, ⁴Juntendo University, Department of Immunology, Bunkyo, Japan, ⁵RIKEN Center for Integrative Medical Sciences (IMS-RCAI), Laboratory for Immune Homeostasis, Yokohama, Japan

The regulation of intestinal homeostasis by the immune system involves the dynamic interplay between gut commensal microbiota and resident immune cells. It is well known that a large and diverse lymphocyte antigen receptor repertoire enables the immune system to recognize and respond to a wide range of invading pathogens. There is also an emerging appreciation for a critical role the T cell receptor (TCR) repertoire serves in the maintenance of peripheral tolerance by regulatory T cells (Tregs). Nevertheless, how the diversity of the TCR repertoire in Tregs affects intestinal homeostasis remains unknown. To address this question, we studied mice whose T cells express a restricted TCR repertoire. We observed the development of spontaneous colitis, accompanied by the induction of T helper type 17 (Th17) cells in the colon that is driven by gut commensal microbiota. We provide further evidence that a restricted TCR repertoire causes a loss of tolerogenicity to microbiota, accompanied by a paucity of peripherally derived, Helios-negative Tregs and hyperactivation of migratory dendritic cells. These results thus reveal a new facet of the TCR repertoire in which Tregs require a diverse TCR repertoire for intestinal homeostasis, suggesting an additional driving force in the evolutionary significance of the TCR repertoire.

798

Enhanced stability of the Foxp3 expression by forced expression of TET DNA demethylase catalytic domain in iTregs

Someya, K., Yoshimura, A.

Keio University School of Medicine, Microbiology and Immunology, Tokyo, Japan

Induced regulatory T cells (iTregs) are generated from naive T cells in the presence of transforming growth factor- β (TGF- β). Since iTregs can be produced in a large quantity *in vitro*, these cells are expected to be clinically used as an inducer of tolerance in various immunological diseases. However, unlike Tregs developed in the thymus, Foxp3 expression in iTregs is unstable and iTregs tend to become effector

T cells due to the lack of epigenetic modifications of Treg-specific demethylation regions (TSDRs). To facilitate demethylation in TSDRs, we have tried to overexpress the catalytic domain (CD) of the ten-eleven translocation (TET) protein, which catalyzes the steps of the iterative demethylation of 5-methylcytosine (5mC). By using retroviral gene transfer, we introduced the catalytic domain of the TET1 protein (TET1CD) or constitutively active form of STAT5a-TET1 CD fusion protein (STAT5aCA-TET1CD). We expected a specific recruitment of TET1CD to intronic element, CNS2 region, of the Foxp3 gene, since STAT5 has been shown to bind to CNS2. Unexpectedly, not only STAT5a-TET1CD expression but also TET1CD alone were sufficient for the introduction of demethylation of CNS2 in iTregs, and expression of Foxp3 was more stable in iTregs expressing TET1CD or STAT5aTET1CD than in control iTregs. TET1CD-iTregs exhibited stronger suppression activity in inflammatory bowel disease (IBD) and graft-versus-host disease (GVHD) models in mice. Our data suggest that induction of TET enzymes in iTregs would be an effective method for immunotherapy.

799

T_{FR} cells regulate the germinal center to prevent the emergence of self-reactive and IgE-producing plasma cells

Gonzalez-Figueroa, P.¹, Papa, I.¹, Fernandez de Canete Nieto, P.¹, Roco, J.¹, Watchirs Connolly, L.¹, Dent, A.², G Vinuesa, C.¹

¹John Curtin School of Medical Research, Australian National University, Dept of Immunology and Infectious Disease, Canberra, Australia, ²Indiana University School of Medicine, Dept of Microbiology and Immunology, Indianapolis, United States

Stringent selection is required in the germinal center (GC) to ensure self-reactive B cells and IgE-expressing B cells are not selected as long-lived, high affinity plasma cells that may otherwise trigger autoimmune diseases or allergic reactions respectively. While B follicular helper T (T_{FH}) cells have been shown to be required for GC B cell selection, T follicular regulatory (T_{FR}) cells have been suggested to curtail GC reactions in response to both foreign and self-antigens. Whether T_{FR} cells play an important or selective role in preventing pathogenic antibody responses, as opposed to simply accelerating the demise of GC reactions, remains unclear. Here, we have taken advantage of mice that selectively lack T_{FR} cells and show that, in the absence of immunization, T_{FR}-deficient mice consistently

and spontaneously develop anti-nuclear autoantibodies characteristic of lupus, by 8 weeks of age. Furthermore, T_{FR} cell deficiency leads to spontaneous formation of GCs, hypergammaglobulinemia and high titres of total IgE. When immunized with protein antigens or sensitised to food allergens such as peanut extracts, T_{FR}-deficient mice develop exaggerated IgE responses, without marked differences in IgG production. Together, our results demonstrate that T_{FR} cells are actively involved in the suppression of self-reactive B cell clones and are critical to prevent the emergence of IgE-producing plasma cells. These findings suggest that manipulation of T_{FR} cells or their products may constitute the basis of powerful therapies against the growing numbers of autoantibody-mediated diseases, allergies and food intolerances.

800

Optimized whole blood flow cytometry assay that improves separation of Foxp3+ and Foxp3- cells using 3G3 monoclonal antibody

Jinoch, P., Prouza, M., Tvarůžková, J., Benko, M., Suchánek, M.

EXBIO, Vestec u Prahy, Czech Republic

The central feature of the regulatory T cells (Treg) characterization is to detect the transcription factor Foxp3. The recommended flow cytometry staining protocols are usually optimized for a specific Foxp3 antibody clone and may differ depending on the character of the sample (whole blood vs. Ficoll-Hypaq purified PBMCs). Previously published data showed that Foxp3 staining with antibody clone 259D provides better separation of Foxp3+ and Foxp3- cells than clone 3G3. The results were the same for all tested commercial permeabilization buffer sets. In our study we demonstrate that the 3G3 staining combined with sample permeabilization with anionic detergents resulted in comparable signal to noise ratio and yield of Foxp3+ cells as obtained with the 259D and commercially available reagents. Based on this observation we developed a new Treg staining assay that defines Tregs as the CD4+CD25+Foxp3+ cells. The procedure uses the 3G3 clone and allows detection of other Treg markers such as Helios. We evaluated the protocol by measuring the proportion of Helios+ and Helios- Treg cells in umbilical cord blood and human adult blood. As expected the Helios-Foxp3+ events represented approximately one third of adult blood Tregs and were absent from the cord blood Tregs. The developed assay introduces a new tool for examining the quality and quantity of Tregs in the fields of rheumatology, organ transplantation and reproductive medicine.

801

The transcriptional regulator, IRF4 is essential for the development of follicular T regulatory cells

Teh, P.P.^{1,2}, Vasanthakumar, A.^{1,2}, Tellier, J.^{1,2}, Sidwell, T.^{1,2}, Thelemann, C.¹, Nutt, S.^{1,2}, Kallies, A.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²University of Melbourne, Department of Medical Biology, Parkville, Australia

Follicular T regulatory (Tfr) cells are a specialised subset of

regulatory T (Treg) cells that display an effector phenotype and are found within the B-cell follicles of germinal centres (GC). Tfr cells play an important role in regulating humoral immunity by limiting GC formation and shaping affinity maturation of B cells during antigenic stimulation. Like their conventional counterparts, follicular T helper (Tfh) cells, Tfr cells express high levels of CXCR5 and PD-1, and rely on the expression of Bcl6 for their development. However, it remains unclear what signals or transcription factors other than Bcl6 drive Tfr cell development. Mice with a Treg-specific deletion of the transcription factor interferon regulatory factor (IRF) 4 develop severe immune pathology with large GC and increased antibody serum titres. Therefore, we hypothesised that IRF4 is involved in the development of Tfr cells. Indeed, using an IRF4-reporter mouse, we found that Tfr cells express an increased amount of IRF4. Furthermore, conditional deletion of IRF4 showed that Tfr cells strictly depend on IRF4. After viral infections, mice with IRF4-deficient Treg cells show a significant increase in Tfh cell numbers and form larger GC compared to their wild-type littermates. Importantly, we show that IRF4-deficient Treg cells were unable to induce the Tfr-specific transcriptional program, and demonstrate that multiple molecules required for Tfr development and function are regulated by IRF4. Our work provides fundamental insights into the essential role of IRF4 for the development of Tfr cells. This knowledge may help to develop protocols to further advance vaccination strategies.

802

Characterisation and selection of highly suppressive alloantigen specific regulatory T cells from umbilical cord blood

Srivastava, S.^{1,2}, Navarrete, C.^{1,2}, Girdlestone, J.^{2,3}

¹NHS Blood and Transplant, Histocompatibility and Immunogenetics Research, London, United Kingdom, ²University College London, London, United Kingdom, ³NHS Blood and Transplant, Stem Cells and Immunotherapies, Oxford, United Kingdom

Ex-vivo expanded polyclonal CD4⁺CD25⁺FoxP3⁺ Regulatory T cells (Treg) have been used successfully in clinical trials to manage acute graft versus host disease (aGvHD). However pre-clinical data indicate that alloantigen specific Tregs (Ag-Tregs) are more efficient compared to polyclonal Tregs in suppressing allospecific responses. As limited cell numbers and phenotypic stability prevent the full clinical integration of Tregs, alternative and more directed strategies are required. In this study we have generated, expanded and characterised Ag-Tregs from umbilical cord blood (UCB).

CD4⁺CD25⁺ cells were directly isolated from UCB mononuclear cells using anti-CD25 magnetic beads. Ag-Tregs were generated by stimulating Tregs for 2 rounds with allogeneic monocyte derived dendritic cells (MDDCs) + IL-2. Phenotypic characterisation, including expression of FoxP3, was conducted by flow cytometry. Tregs were isolated with magnetic beads and tested for allospecificity using autologous UCB CD4⁺CD25⁻ cells co-cultured with the same allogeneic MDDC or a 3rd party stimulator.

Freshly isolated UCB Tregs show limited functional capacity

compared to adult Tregs, but improved following activation. Allostimulation of UCB Tregs resulted in a 62±34 fold expansion with Tregs providing effective suppression towards the alloantigen compared to a 3rd party stimulator. Characterisation of Ag-Tregs revealed the presence of a CD25^{high}CD45RO⁺CD39⁺ sub-population that expressed increased FoxP3, CTLA-4 and HELIOS. CD39⁺ Ag-Tregs showed improved suppression compared to total Ag-Tregs and CD39⁻ Ag-Tregs, with >50% suppression maintained at a 1:256 ratio.

The naivety of UCB Tregs can be advantageous for the development, expansion and selection of highly suppressive allospecific Tregs that could potentially be used in immunotherapy.

803

IgG4 induced by regulatory T cells inhibits *in vitro* haemolysis and inversely correlates with clinical anaemia in infants

Gbenoudon Satoguina, S.J.¹, Tamadaho, R.¹, Adanho, C.¹, Vikou, R.¹, Biaoou, O.¹, Layland, L.², Hoerauf, A.²

¹University of Abomey Calavi, Biochemistry, Cotonou, Benin,

²Institute of Med. Microbiology, Immunology and Parasitology, IMMIP. Medical Faculty, University of Bonn, Bonn, Germany

Background: We previously showed regulatory T cells induced during chronic diseases and responsible for regulatory isotype IgG4 switch. IgG4 was induced by Tr cells from naïve and from memory B cells by mechanisms including IL-10, TGF-beta and receptor/ligand GITR and GITRL. IgG4 has neutralizing role and may capture antigen to prevent binding immune-active antibodies like IgG1 and IgG3. However, unlike other isotypes, IgG4 lacks physiological role. Here we demonstrate that IgG4 inhibits *in vitro* haemolysis induced artificially by homologous IgG1/IgG3 enriched human sera. Concordantly, we demonstrate that increasing IgG4 levels regulate actively inflammation and prevent anaemia in children with chronic malaria.

Hypothesis: We hypothesized that tolerance to parasite antigen, e.g. malaria parasite antigens, will involve active regulatory molecules to prevent severe disease, e.g. severe malaria. Therefore, if coinfecting with Tr and IgG4 inducing nematodes like hookworm, malaria induced clinical anaemia will be alleviated.

Objectives: We aim to show that IgG4 modulates clinical inflammatory events like anaemia.

Methods: Ex vivo and *in vitro* analysis, flow cytometry and ELISA on samples from children, 0-7 years with severe or asymptomatic malaria, were used and we measure specific IgG, isotypes IgG1-4, total protein, cytokines and Hb levels.

Results: We found severe anaemia prevalence in infants with single inflammatory infection compared to those with mixed infections, ($p < 0.0001$). The isotype IgG4 levels were highest with the increasing Hb levels. Using *in vitro* experience, IgG4 prevents haemolysis ($p=0.002$), while IgG1-IgG3 accelerate cell-lysis ($p=0.014$).

In conclusion, IgG4 modulates immune response and prevents inflammation induced burst of red-blood-cells.

804

Pten-Foxo1 signaling prevents autoimmunity by reinforcing maintenance of T_H1 and T_{FH} responses*Shrestha, S.^{1,2}, Chi, H.^{1,2}*¹St. Jude Children's Research Hospital, Immunology, Memphis, United States, ²University of Tennessee Health Science Center, Memphis, United States

Regulatory T cells (Tregs) modulate the immune response to self-antigens, and dysfunctional Treg function can trigger autoimmune diseases. Although the transcriptional and epigenetic programs regulating Treg function have been extensively studied, the signaling and metabolic pathways underlying Treg stability and function are not fully understood. We have recently found that the phosphatase PTEN controls mTORC2 activation and metabolism within Tregs. In the absence of PTEN, mTORC2 function and glycolytic metabolism are elevated, and Treg stability and functional diversity are impaired. These alterations result in the development of a lymphoproliferative disease, spontaneous follicular T helper cell and germinal center B cell responses, and systemic autoimmunity characterized by elevated levels of autoantibodies. Mechanistically, hyper-activation of mTORC2 signaling in Pten-deficient Tregs suppresses the function of the transcription factor, Foxo1. Indeed, restoration of Foxo1 function in Pten-deficient Tregs ameliorates the autoimmune disease features described above. Our results establish PTEN-mTORC2-Foxo1 signaling axis is critical for controlling Treg stability and function necessary to prevent autoimmunity.

805

Phosphorylation of Akt and Foxos induced by TGF- β negatively regulates the differentiation of induced regulatory T cells*Nagai, S.¹, Kurebayashi, Y.², Baba, Y.², Minowa, A.², Azuma, M.¹, Yoshimura, A.^{2,3}, Koyasu, S.^{2,4}*¹Tokyo Medical and Dental University (TMDU), Tokyo, Japan, ²Keio University School of Medicine, Shinanomachi Shinjuku-ku, Japan, ³CREST JST, Tokyo, Japan, ⁴Laboratory for Immune Cell System, RIKEN Center for IMS, Yokohama, Japan

TGF- β plays the pivotal role of preventing uncontrolled immune responses that result in lethal autoimmunity through inducing thymic development of naturally occurring regulatory T cells (nTregs) and peripheral differentiation of induced regulatory T cells (iTregs). Foxo transcription factors (Foxos) positively regulate this process to induce the expression of *Foxp3* gene by direct interaction with its promoter region. In the meanwhile, the function of Foxos are negatively regulated by PI3K/Akt signaling, which is activated by TGF- β in many kinds of cells. However, the role of TGF- β on Akt activity and its downstream substrates, including Foxos in CD4⁺ T cells, is still not clear. In this study, we demonstrate that TGF- β selectively induces Akt phosphorylation in a time-dependent manner in CD4⁺ T cells, resulting in the phosphorylation and inhibition of Foxos, which negatively regulates the differentiation of iTregs. The phosphorylation of Foxos induced by TGF- β required class I_A PI3K activity, and the deletion of p85 α , a regulatory subunit of class

I_A PI3K, increased the differentiation of iTreg but not of nTreg. These results indicate a novel negative regulatory mechanism involving Akt and Foxos in the iTreg differentiation process.

806

A novel human T cell expansion technology for affordable cell therapy*Harding, F.¹, Delalat, B.¹, Guundsambuu, B.², Pardo, E.³, Huttmacher, D.³, Voelcker, N.¹, Barry, S.C.^{2,4}*¹CRC for Cell Therapy Manufacturing, Future Industries Institute, Adelaide, Australia, ²Molecular Immunology, Robinson Research Institute, Adelaide, Australia, ³CRC for Cell Therapy Manufacturing, Institute of Health and Biomedical Innovation, Brisbane, Australia, ⁴Women's and Children's Health Network, Gastroenterology, Adelaide, Australia

The demand for affordable cell therapy is rapidly rising, and the clinical imperative for tailored therapies with few side effects has placed cell therapy at the vanguard of modern medicine. While there is early promise for the use of T cells in cell therapy, the cost of manufacturing remains a hurdle to the wide scale use of cell therapy. The unmet need includes tolerisation in solid organ transplantation, prevention of graft vs. host disease in bone marrow transplantation autoimmune disease and cancer immunotherapy, which together account for thousands of patients a year who could benefit from cell therapy. In order to address this we are developing functionalised smart surface technologies that can be use in large scale expansion of T cells for clinical use. We have combined melt electrospin 3D scaffold production, epoxy plasma polymerisation and biological stimulation of T cells using surface immobilised antibodies to develop a T cell expansion platform that is scalable and affordable. Pilot data on this smart surface technology will be presented showing its ability to expand CD4⁺ T cells, regulatory T cells and CD8 T cells, giving utility for several immunotherapy approaches. We will present data on robust expansion of relevant human T cell subsets including CD8 T cells/CAR-T cells, CD4 T Cells and regulatory T cells.

807

A new biomarker of stable regulatory T cell function which has diagnostic utility in type 1 diabetes*Mohandas, A.¹, Hill, D.¹, Hope, C.¹, Pederson, S.¹, Walsh, J.¹, Grose, R.², Zola, H.², Couper, J.³, Krumbiegel, D.², Sadlon, T.⁴, Barry, S.C.^{1,4}*¹Molecular Immunology, Robinson Research Institute, Adelaide, Australia, ²Leukocyte Biology, WCHRI, Adelaide, Australia, ³Diabetes and Endocrinology, WCHN, Adelaide, Australia, ⁴Women's and Children's Health Network, Gastroenterology, Adelaide, Australia

Natural Treg express the transcription factor FOXP3, but isolation using FOXP3 is not tractable for functional assays or for cell enrichment. A cell surface surrogate for FOXP3 is hence required. As part of a program to develop better biomarkers of immune homeostasis and its breakdown in disease, and also for immunotherapy, In search of a biomarker surrogate for FOXP3, we mined for up-regulated novel surface proteins(1),

and Peptidase Inhibitor 16 (PI16) was identified. Analysis of resting and stimulated Treg and Thelper cells demonstrated that PI16 was readily detectable on the surface of resting nTreg. In conjunction with CD25+, PI16 is expressed on both resting and stimulated FOXP3+ cells. Detailed characterisation of PI16+ve Treg cells reveals an antigen experienced memory phenotype. PI16+ CD25+ cells are highly suppressive *in vitro* and preliminary data suggest that they may be more potent than the CD25+ Treg pool. Importantly, stimulation of CD25-Thelper cells, which substantially up regulates CD25 expression and transiently induces FOXP3, does not induce detectable expression of PI16, suggesting that PI16 is able to segregate Treg subsets, as it is not expressed on CD25- derived iTreg. When a cohort of 30 type 1 diabetes samples were analysed for PI16+ Treg FOXP3 expression, we observed a significant decrease in FOXP3 expression levels in t1d, suggesting a loss of functional fitness in these Treg. We propose that PI16 identifies functional FOXP3+ve Treg and FOXP3-ve Thelper subsets with clinically relevant functional capacity in humans.

Regulatory T cells induced by B cells as a potent therapeutic approach for osteoporosis

Chen, S.-Y., Chiang, B.-L.

National Taiwan University College of Medicine, Graduate Institute of Clinical Medicine, Taipei City, Taiwan, Republic of China

Bone destruction in the metabolic bone diseases, including rheumatoid arthritis and osteoporosis, are triggered by activated immune responses. Regulatory T cells (Tregs) have been found to maintain immune homeostasis and self-tolerance. In addition to the regulatory activity, recent data demonstrated that Tregs suppressed the osteoclastogenesis both *in vitro* and *in vivo*, suggesting the different function of Tregs in protecting bone loss. Treg-of-B cell is a type of induced Tregs that could be generated by naïve B cells and possesses the immunosuppressive effect. In our previous study, mice of collagen induced arthritis receiving LAG3+ Treg-of-B cell treatment showed reduced osteolysis and tartrate-resistant acid phosphatase (TRAP) expression in the hind footpads. Hence, in this study, we aim to investigate the protective role of Treg-of-B cells in the animal model of osteoporosis. First, we perform the *in vitro* culture system to clarify the suppressive effect of Treg-of-B cells in osteoclastogenesis. Further, we develop the optimal potential iTreg-based therapy for ovariectomized mice as an osteoporosis model by adoptively transferring Treg-of-B cells. The osteoclastogenic factors and immunological parameters will be evaluated after mice are sacrificed. We hope this work not only enlighten the role and mechanisms of Treg-of-B cells in osteoclastogenesis, but also facilitate exploring novel regulatory T-cell-based therapies for controlling the bone loss in the metabolic bone diseases.

809

Study on the role of galectins in the regulatory function of T-reg-of-B cells

Tsai, Y.C., Yang, C.C., Chiang, B.L.

Graduate Institute of Immunology, College of Medicine, National Taiwan University, Taipei, Taiwan, Republic of China

Regulatory T cells induced by B cells (Treg-of-B) are a subpopulation of regulatory T cells. They are different from other regulatory T cells on the expression of the major genes and cytokine functions. Different from natural regulatory T cells, T-reg-of-B cells are Foxp3 negative, and they are CD25 positive while type 1 regulatory T cells (Tr1 cells) are CD25 negative. However, T-reg-of-B cells suppressive function is not clearly understood, so we aim to further investigate the mechanisms how T-reg-of-B cells modulate immune responses. Galectins are b-galactoside proteins, and there are many researches showing that galectins play the roles in both innate and adaptive immunity. In this study, we assayed the suppressive function of Treg-of-B by T cell suppressive assay and checked the galectins gene expression of T-reg-of-B cells by real-time PCR and showed that galectin-2 is highly expressed in T-reg-of-B cells. We also checked galectin-2 expression at protein level by Western blot. We further tested the suppressive function with the addition of recombinant galectin-2. The results showed that the proliferation of either CD4+CD25- T cells was decreased in the presence of galectin-2. It suggested that galectin-2 might play a role in the regulatory function of Treg-of-B cells.

810

Characterization of a novel mouse IL-33R (ST2)-specific monoclonal antibody

Wu, X., Ernst, D., Ejrnaes, M., Zhou, J.C., Kempton, L., Waterman, P.
BD Biosciences, R&D, San Diego, United States

Interleukin-33 (IL-33) is a novel and an unconventional member of IL-1 family. It is a ligand for IL-33R (ST2). The IL-33R exists in either a type I transmembrane or soluble glycoprotein form. These IL-33R forms are encoded by the *Il1rl1* (Interleukin-1 receptor-like 1) gene which belongs to the IL-1 Receptor family within the Ig superfamily. The IL-33R is expressed by subsets of T cells, including Th2-like cells and subset of regulatory T cells, and some innate lymphocytes, eosinophils, basophils, and mast cells. The IL-33/IL-33R (ST2) signaling has been studied in a wide range of inflammation, immunity and allergy for its crucial role in immune responses and tissue homeostasis. In order to further characterize the nature of cells that express IL-33R, we have developed a monoclonal antibody, U29-93, that specifically recognizes the mouse IL-33R. This antibody was used in multicolor flow cytometric analyses of mouse T cell subsets. U29-93 was found to stain either unfixed, or fixed and permeabilized mouse splenic leucocytes. The latter cells could be co-stained with a Foxp3-specific antibody to identify mouse T regulatory cells. The results showed that a small subset of T regulatory cells obtained from either C57BL/6 or BALB/c mice expressed IL-33R. The U29-93 monoclonal antibody should be useful in studying the functions of IL-33R+ T regulatory cells and other IL-33R+ cells.

811

Foxp3⁺ regulatory T cells are maintained and induced by CD2-stimulation *ex vivo*

Kashiwakura, Y., Kanno, Y., Hashiguchi, M., Kobata, T., Kojima, H.
 Dokkyo Medical University School of Medicine, Department of Immunology, Shimotsuga, Japan

Regulatory T (Treg) cells are essential in the regulation of immune responses and the maintenance of immune homeostasis. We previously reported that CD2 was involved in the survival of peripheral Treg cells in mice. In this study, we examined whether the CD2 signaling solely affects the induction and function of Treg cells. CD48-Fc, which is composed of extra-cellular portion of murine CD48 and murine Fc γ , was used for CD2-stimulation. We found that CD2-stimuli upregulated Foxp3 expression and maintained the regulatory activity (functions) in Treg cells. Foxp3 upregulation in Treg cells is reported to be dependent on IL-2- and/or TCR-stimulation. We found that CD2-induced Foxp3 upregulation was partially dependent on IL-2. Furthermore, it was found that CD2- and TCR-stimulation synergistically increased the Foxp3 expression in Treg cells. These findings led us to examine whether the CD2-signaling is involved in generating the induced Treg (iTreg) cells. We found that CD2-stimuli induced Foxp3 expression in CD4⁺CD62L⁺CD25⁻ naïve T cells in the presence of TGF- β . It is well known that iTreg cells are induced by TCR- and/or IL-2-signaling in cooperation with TGF- β . It was confirmed that PI3K and JAK/STAT signals were involved in CD2-induced Foxp3 expression in naïve T cells by using inhibitors for these pathways. Importantly, the CD2-induced iTreg cells exerted regulatory effects on CD8⁺ T cell activation. Taken together, these results clearly suggest that CD2-stimuli complement the TCR/CD3-stimuli in Foxp3 expression and/or introduce a TCR/CD3-independent signal, which plays a key role in homeostasis and induction of Treg cells in the periphery.

45 Minute Oral**16:45:00 - 17:30:00****Computational Immunology****Every immune cell counts: The calculus behind lymphocyte decision-making**

During the adaptive immune response T and B-lymphocytes receive signals from different sources that determine the strength and type of response they follow. We are investigating how multiple signals are integrated to direct cellular decisions. Initially, following stimulation, B and T cells respond by undergoing a series of divisions before returning to a small, quiescent state. The number of divisions the clonal families undergo is directly regulated by the strength and sum of the activating stimuli. For T cells costimulation by CD28, CD27 and cytokine signals (IL-2 and IL-12) extend the number of divisions undergone. These signals combine following a rule of simple arithmetic addition. Thus, integration of multiple inputs leads to a geometric increase in the size of immune responses due to the two-fold increase with each additional division round. This mode of regulation ensures the size of the response is highly sensitive to small changes in stimulatory inputs and that many combinations of signals can be 'added' to generate a strong immune response.

T Stress**Stressed Out: A Novel Approach to Cancer Immunotherapy**

Glimcher, L.H., Weiss Dean, S.
 Weill Cornell Medical College

Cancer cells induce a set of adaptive response pathways to survive in the face of stressors due to inadequate vascularization¹. One such adaptive pathway is the unfolded protein (UPR) or endoplasmic reticulum (ER) stress response mediated in part by the ER-localized transmembrane sensor IRE1 and its substrate XBP1. We have shown that the transcription factor XBP1 promotes intrinsic tumor growth directly in the setting of triple negative breast cancer, and now have established that this signaling pathway also regulates the host anti-tumor immune response. Dendritic cells (DCs) are required to initiate and sustain T cell-dependent anti-cancer immunity. However, tumors often evade immune control by crippling normal DC function. Constitutive activation of XBP1 in tumor-associated DCs (tDCs) drives ovarian cancer (OvCa) progression by blunting anti-tumor immunity. XBP1 activation, fueled by lipid peroxidation byproducts, induced a triglyceride biosynthetic program in tDCs leading to abnormal lipid accumulation and

subsequent inhibition of tDC capacity to support anti-tumor T cells. Accordingly, DC-specific XBP1 deletion or selective nanoparticle-mediated XBP1 silencing in tDCs restored their immunostimulatory activity *in situ* and extended survival by evoking protective Type 1 anti-tumor responses. Targeting the ER stress response should concomitantly inhibit tumor growth and enhance anti-cancer immunity, thus offering a unique approach to cancer immunotherapy.

Imaging Immunity: Developing a Spatiotemporal Understanding of Host Defense and Disease

Germain, R.N.1, Laemmermann, T.1,2, Uderhardt, S.1, Liu, Z.1, Rudensky, A. Y.3,4, Levine, A. G.3,4, Li, W.1, Radtke, A.1, Yu, W.1, Pires da Silva Baptista, A.1, Gerner, M. Y.1,5

1Laboratory of Systems Biology, NIAID, NIH, Bethesda, MD USA 20892, 2Present address: Max-Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany, 3Howard Hughes Medical Institute, Memorial Sloan-Kettering Cancer Center, New York, New York, USA, 4Immunology Program, Memorial Sloan-Kettering Cancer Center, New York, New York, USA, 5Present address: Dept. of Immunology, Univ. of Washington, Seattle, WA

Background: Immune responses involve cell-cell interactions within lymphoid tissues, trafficking of activated cells to sites of effector function, and the migration of effector cells within peripheral tissues. To gain insight into the relationships among cell movement, tissue architecture, and immune function, we have used intravital multiphoton microscopy and a novel multiplex immunohistochemical method we have developed called Histo-cytometry. Observations: Migrating T cells follow stromal pathways in lymph nodes, with chemokine cues facilitating interactions among rare antigen-presenting and antigen-recognizing cells. In tissue sites, effector cells stop when they perceive antigen and undergo transient activation and cytokine release, followed by tuning of their response to existing antigen levels. Innate immune (neutrophil) responses have been dissected at the molecular level. The role of cell localization in both innate and adaptive immunity has also been addressed using Histo-cytometry. With an ability to use as many as 14 different colors and antibodies not only to surface markers but to phospho-proteins and cytokines, and also to conduct imaging in large 3D volumes in a quantitative manner, our multiplex imaging technology facilitates analysis of the phenotype, number, location, signaling state, and function of immune cells and stromal elements in infected, inflamed, or tumor sites. **Conclusion:** This talk will illustrate the power of *in situ* imaging for the acquisition of a more accurate picture of the molecular, cellular, spatial, and temporal aspects of cell function and signaling events in host immune responses. This work was supported in part by the Intramural Research Program of the NIH, NIAID.

Gut microbiota-induced Immunoglobulin G controls systemic infection by symbiotic bacteria and pathogens

Zeng, M., Cisalpino, D., Nunez, G.

University of Michigan Medical School, Pathology, Ann Arbor, United States

The gut microbiota is compartmentalized in the intestinal lumen and induces local immune responses, but it remains unknown whether the gut microbiota can induce systemic response and contribute to systemic immunity. We report that selective gut symbiotic Gram-negative bacteria were able to disseminate systemically to induce Immunoglobulin G (IgG) response, which primarily targeted Gram-negative bacterial antigens and conferred protection against systemic infections by *E. coli* and *Salmonella*, by directly coating bacteria to promote killing by phagocytes. T cells and Toll-like receptor 4 on B cells were important in the generation of microbiota-specific IgG. We identified murein lipoprotein (MLP), a highly conserved Gram-negative outer membrane protein, as a major antigen that induced systemic IgG homeostatically in both mice and humans. Administration of anti-MLP IgG conferred crucial protection against systemic *Salmonella* infection. Thus, our findings reveal an important function for the gut microbiota in combating systemic infection through the induction of protective IgG.

1998

Beneficial effect of enhancing apoptotic cell clearance *in vivo*

Ravichandran, K., Lee, C.S.

University of Virginia, Department of Microbiology, Immunology and Cancer Biology, Charlottesville, United States

Proper apoptotic cell clearance is critical for regulating the inflammatory status in tissues. Very few apoptotic corpses are seen *in vivo*, even in tissues with high cellular turnover; it is often assumed that the capacity for engulfment *in vivo* is vast. Whether apoptotic cell clearance can be enhanced *in vivo* in mammals, and whether this can provide a functional benefit is not known. Here, using complementary genetic approaches, we have revealed that enhancing apoptotic cell clearance is possible *in vivo*, and that increasing the levels of even a single receptor can be beneficial. In an acute colonic inflammation model, endogenous level of the phagocytic receptor BAI1 was progressively downmodulated. Further, BAI1-deficient mice had more pronounced colitis and lower survival with many

uncleared apoptotic corpses and inflammatory cytokines within the colonic epithelium. Mice engineered to overexpress BAI1 had fewer apoptotic cells reduced inflammation, and attenuated disease. Remarkably, transgenic BAI1 expression specifically in the intestinal epithelial cells and enhancing their phagocytic potential was sufficient to lower the colonic inflammation. In contrast, transgenic mice overexpressing a signaling-deficient BAI1 mutant did not show this benefit. Collectively, these data provide genetic evidence that boosting apoptotic cell clearance is achievable *in vivo*, with potential to regulate tissue inflammation in specific contexts.

Hobit and Blimp1 instruct a universal transcriptional program of tissue-residency in lymphocytes

Mackay, L.¹, Minnich, M.², Kragten, N.³, Seillet, C.⁴, Freestone, D.¹, Belz, G.⁴, Busslinger, M.², Shi, W.⁴, Carbone, F.¹, van Lier, R.³, Kallies, A.⁴, van Gisbergen, K.³

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Research Institute of Molecular Pathology, Vienna Biocenter, Vienna, Austria, ³Sanquin Research and Landsteiner Laboratory AMC/UvA, Amsterdam, Netherlands, ⁴The Walter and Eliza Hall Institute of Medical Research (WEHI), Melbourne, Australia

Tissue-resident memory T cells (Trm) permanently localize to portals of pathogen entry, where they provide immediate protection against re-infection. To enforce tissue retention, Trm upregulate CD69 and downregulate molecules associated with tissue egress including CCR7 and S1PR1. Although suppression of the transcription factor KLF2 in Trm prevents S1PR1-driven migration, a Trm-specific transcriptional regulator has not been identified. Here, we show that the transcription factor Hobit is specifically upregulated in Trm and together with related Blimp1, mediates the development of Trm in skin, gut, liver and kidney. Importantly, the Hobit/Blimp1 transcriptional module is also required for other populations of tissue-resident lymphocytes including NKT cells and liver-resident NK cells, all of which share a common transcriptional program that includes repression of *Ccr7*, *S1pr1*, and *Klf2*. Our results identify Hobit and Blimp1 as central regulators of this universal program that instructs tissue retention in diverse tissue-resident lymphocyte populations.

Allergy

Why do we have mast cells and IgE? Roles in enhancing host defenses against venoms

Galli, S.
Stanford University

Mast cells (MCs) and IgE are thought to promote to host resistance to certain parasites, but other beneficial functions remained obscure. Margie Profet (1991) noted that many allergens are from sources which either might (e.g., nuts, seafood) or always (e.g., venoms) contain toxins, and hypothesized that allergic reactions evolved to allow sensitized hosts to respond

quickly to, and to neutralize and/or avoid, noxious substances indicative of potentially life-threatening situations. In mammals, venoms provoke innate inflammatory responses and pathology reflecting the activities of the contained toxins. Venoms also can induce allergic sensitization and development of venom-specific IgE antibodies. MCs can be activated directly by certain venoms, and, in mice, innate functions of MCs, including degradation of venom toxins by MC-derived proteases, can enhance host resistance to the venoms of certain arthropods and reptiles (Metz et al., 2006; Schneider et al., 2007; Akahoshi, Song, et al., 2011). Mice injected with sub-lethal amounts of honeybee venom or Russell's viper venom developed specific Th2 responses which increased their survival after subsequent challenge with potentially lethal amounts of that venom (Marichal, Starkl et al., 2013; Starkl, Marichal et al., 2016). Our data indicate that IgE antibodies, FcεRI, and probably MCs contribute to such acquired resistance to these venoms. The finding that IgE-dependent immune responses against venoms can enhance survival in mice supports the hypothesis that one important function of IgE is to help to protect the host against toxic substances.

Peptide immunotherapy in allergic disease: targeting T cells to induce tolerance

Larche, M.
McMaster University

Allergen-specific T cells play a key role in the pathogenesis of allergic diseases through provision of help for allergen-specific B cells and control of inflammatory responses. Allergen immunotherapy using intact allergen proteins (given either subcutaneously or sublingually) is clinically effective and demonstrates enduring efficacy (i.e. disease modifying). However, the requirement for monthly injections or daily sublingual administration (both for three years), combined with a high frequency of local and systemic adverse events, results in poor compliance. Targeting allergen-specific T cells with synthetic peptides representing dominant T cell epitopes markedly decreases treatment times (4-8 intradermal injections), reduces adverse events and provides efficacy for at least 2 years. We have developed peptide immunotherapies for allergies triggered by cats, house dust mites and grass pollen. Each of these consists of a mixture of seven peptides containing multiple dominant T cell epitopes and each have demonstrated statistically significant improvements in rhinoconjunctivitis symptom scores in controlled allergen challenge facilities. The mechanisms of action appear to involve increased IL-10 production, intra- and inter-molecular suppression, modulation of T cell receptor signaling pathways and down-regulation of chemokine pathways. In contrast, treatment does not appear to be associated with deletion of allergen-specific T cells, nor with the induction of allergen-specific IgG (as is seen with conventional whole allergen immunotherapy). Thus, peptide immunotherapy may provide a safe, effective and disease-modifying treatment for allergic disease.

Dendritic Cells

Epigenetic regulation of dendritic cell differentiation and function

Cao, X.

Department of Immunology, Chinese Academy of Medical Sciences Beijing, China; National Key Laboratory of Medical Immunology, Institute of Immunology, Second Military Medical University, Shanghai, China.

Epigenetic modifiers play fundamental roles in defining unique cellular identity through the establishment and maintenance of lineage-specific chromatin and methylation status. Now, increasing evidence demonstrate a critical role of chromatin modifications in controlling innate immunity and inflammation via controlling chromatin status and gene expression. Dendritic cells (DCs)-initiated innate inflammatory responses and adaptive immune response are essential for host defense against invading pathogens, but can also cause harmful immunopathology once uncontrolled. So we are interested in the epigenetic regulation of DC differentiation and function, trying to understand how the epigenetic modifiers regulate the developmental programs and control the transcriptional expression of inflammatory mediators in innate immune cells including DCs. The findings about several epigenetic modifiers in the regulation of the DC-initiated innate response and inflammation will be reported.

3886

Signaling from lysosomes through the TFEB-TRPML1 axis controls the migration of dendritic cells

Lennon-Dumenil, A.-M.

Institut Curie, Paris, France

Immature dendritic cells (DCs) patrol their environment by integrating antigen uptake to cell locomotion. Microbial sensing inhibits antigen internalization and allows mature DCs adopting a fast migration mode needed for them to reach lymph nodes (LNs) where they present microbial antigens to T cells. The signal(s) that triggers such migration changes upon innate sensing remain(s) unknown. We here identify a positive signaling feedback loop from lysosomes as responsible for this switch in DC migration. It involves the release of lysosomal calcium by the channel TRPML1 that

(1) promotes the retrograde flow of Myosin II to stabilize the predominant F-actin structure required for fast DC migration and

(2) triggers the translocation to the nucleus of the lysosomal transcription factor TFEB, which maintains TRPML1 expression. Activation of the TRPML1-TFEB axis is required for DC chemotaxis and arrival to LNs in vivo. We propose that control of DC migration by signaling from lysosomes, where processing of exogenous antigens takes place, establishes a checkpoint for selective arrival to LNs of DCs capable of activating T cells.

Mapping the human dendritic cell lineage

Ginhoux, F.

Singapore Immunology Network (SigN)

Conventional dendritic cells (cDC) are professional antigen-presenting cells that orchestrate immune responses and can be classified into two functionally distinct lineages named cDC1 and cDC2. Important questions on the origins and differentiation paths of human DC populations remain elusive. Here we combine two high-dimensional technologies, single-cell mRNA sequencing and Cytometry by Time-of-Flight (CyTOF) to define and characterize DC precursors (pre-DC) present in human blood. We show that a previously underestimated pre-DC population shares surface markers with plasmacytoid DC (pDC) but has distinct functional properties that were previously attributed to pDC. Finally, we trace the origin of DCs from BM to peripheral blood and reveal that pre-DC comprise three distinct sub-populations consisting of uncommitted preDC and pre-DC subpopulations committed to the cDC1 lineage or cDC2 lineage. The discovery of multiple committed pre-DC populations present in human peripheral blood confirms the existence of DCs as a distinct hematopoietic lineage and opens promising new avenues for the therapeutic exploitation of DC subset-specific targeting.

Innate Lymphoid Cells

Complementarity and redundancy of innate lymphoid cells

Vivier, E.

Centre d'Immunologie de Marseille-Luminy (Aix-Marseille University, INSERM, CNRS)

Innate Lymphoid Cells represent an emerging population of lymphocytes. ILCs include Natural Killer (NK) cells and three main subsets, ILC1, ILC2 and ILC3. In contrast to T and B cells, ILCs do not express antigen-specific receptors derived from gene rearrangements. Besides this major difference in their recognition repertoire, ILC and T cell subsets share striking similarities as ILC1, ILC2 and ILC3 are driven by T-bet, GATA-3 and ROR γ t transcription factors, and produce IFN- γ , IL-5/IL-13 and IL-17/IL-22 respectively. In addition, NK cells are driven by Eomes and T-bet, can be cytolytic and produce IFN- γ , inasmuch as CD8 $^{+}$ T cells. These common features led to suggest that ILCs might correspond to innate counterparts of T cells. Over the course of evolution, two highly parallel systems have thus emerged in which ILCs mimic the effector profile of T cell subsets. However, it is still unclear how the innate and adaptive immune systems integrate these two arms. We will review the emerging set of data showing that ILCs and T cells can exert redundant functions in natura in humans and in models of experimental disease in mice, and discuss how the overlapping functions of ILCs and T cells contribute to the robustness of immunity and hence to the fitness of the hosts.

NKT Cells

3427

Direct analysis of natural killer T (NKT) cell responses and their interactions with APCs *in situ*

Johnson, D.N.^{1,2}, Hor, J.L.^{1,2}, Zaid, A.^{1,2}, Pellicci, D.G.^{1,2}, Uldrich, A.P.^{1,2}, Mueller, S.N.^{1,2}, Heath, W.R.^{1,2}, Godfrey, D.I.^{1,2}

¹University of Melbourne, Microbiology & Immunology, Melbourne, Australia, ²ARC Centre of Excellence in Advanced Molecular Imaging, University of Melbourne, Melbourne, Australia

NKT cells recognise glycolipids presented in complex with CD1d molecules through semi-invariant TCRs and play important roles in health and disease. While many studies have investigated NKT cells, very few have determined their location and behavior in relation to other cell types *in situ*. Developments in immunohistological techniques have allowed for the detection of up to 10 different fluorochromes. In conjunction with histocytometry, a flow-cytometry-based analysis technique, this allows detection of many different cell populations *in situ* based on coexpression of multiple markers. With the use of 8 colour histo-cytometry, including CD1d tetramers loaded with a-GalCer, we have succeeded in detecting endogenous NKT cells, and subsets defined by CD4 and CD43 expression, in various tissues including spleen, thymus, LNs, and lungs. Furthermore, we have determined their location in relation to other populations of CD4 and CD8 T cells, B cells, DCs and macrophages. NKT cells were primarily located within the T cell zone of the spleen and LN, where CD4⁺ NKT cells were more common than

CD4⁺ NKT cells. Within the thymus most cells were located within the medulla with equal proportions of both subsets. Following a-GalCer injection, a rapid expansion in the number of either subset of NKT cells was observed throughout the spleen particularly within the T cell zone.

These techniques resulted in novel insights into the location of NKT cell subsets and their interactions with other immune cells in resting and activated states, and provide a means for future investigations into the behavior of innate-like T cells.

502

Neutrophils license NKT cells to regulate self-reactive B cell responses

Hägglöf, T.¹, Sedimbi, S.K.¹, Yates, J.L.², Lanthier, P.A.², Leadbetter, E.A.³, Karlsson, M.¹

¹Karolinska Institutet, Microbiology, Tumor and Cell Biology, Stockholm, Sweden, ²Trudeau Institute, Saranac Lake, United States, ³University of Texas Health Science Center at San Antonio, San Antonio, United States

The early innate responsiveness of the immune system is not only important for quick responses against pathogens but also

to initiate and shape the subsequent adaptive response. In mice, repeated injections of IL-18, a product of inflammasome activation, give rise to a rapid inflammatory response that includes autoreactive antibody production. As this cytokine is elevated in both allergic and autoimmune inflammatory disease we investigated the origin of the B cell response and how it is regulated. We identified an influx of neutrophils to the spleen following IL-18 injections that promote the B cell response. It is known that NKT cells block this B cell response and we found that neutrophils activated NKT cells to upregulate the transcription factor GATA3 and FAS ligand. Increased expression of these molecules was abrogated in neutrophil-depleted mice. We found that FAS ligand expressed specifically by NKT cells was required to restrict B cell activation and autoantibody production. IL-18-injected mice which were depleted of neutrophils also had a dramatic increase in B cell activation, along with autoantibody production, indicating that neutrophils license NKT cells to regulate potentially harmful autoreactive B cell responses in inflammasome-driven inflammation. These findings are relevant for designing treatments of inflammatory diseases that often display lower NKT cells numbers in combination with elevated IL-18 levels.

933

Dominant iNKT cells subsets differentially control immunity to allografts according to the site of T cell priming

Jones, N.D.¹, Chadha, R.², Dempsey, C.M.¹, Besra, G.³, Wood, K.J.², Nakamura, K.¹

¹University of Birmingham, MRC Centre for Immune Regulation, Birmingham, United Kingdom, ²University of Oxford, Nuffield Department of Surgical Sciences, Oxford, United Kingdom, ³University of Birmingham, School of Biosciences, Birmingham, United Kingdom

Invariant natural killer T (iNKT) cells are a rare but evolutionary conserved population of cells that display a marked immunomodulatory capacity. Although iNKT cells have documented roles in a number of diseases their responses frequently lead to different functional consequences in distinct settings.

In this study the effect of activating iNKT cells by injection of glycolipid agonists (e.g. α GalCer) during T cell responses to allografts was determined. We found that glycolipid administration led to prolonged cardiac allograft survival in mice in the absence of other immunosuppressive agents. In clear contrast, activated iNKT cells were found to facilitate rapid skin allograft rejection. The impact of iNKT cells on rejection of these different allografts (i.e. whether they were immunosuppressive or immunostimulatory) correlated with the composition of iNKT cell subsets at the site of T cell priming. IL-17-producing

iNKT cells were dominant in lymph nodes draining skin allografts resulting in the infiltration of neutrophils into grafts and rapid rejection. In contrast, IFN γ -producing iNKT cells were more prevalent in the spleen resulting in the deletion of alloreactive effector T cells primed by intravenous administration of alloantigen.

In conclusion, we clearly demonstrate that the make-up of iNKT cell subsets in the lymphoid tissue hosting T cell priming

dictates whether iNKT cells act in an immunosuppressive or immunostimulatory manner promoting graft survival or rejection, respectively. We also provide evidence that this differential impact of iNKT cells on T cell alloresponses is mediated through effects on myeloid cells rather than on the alloreactive T cells directly.

Most studies of T cells have focused on those that respond to foreign peptides. However other T cells exist that recognise lipid antigens presented by the CD1 family. Whereas most published work focuses on CD1d and Natural Killer T cells, abundant populations of human T cells, which comprise up to 10 percent of T cells in the blood, recognize CD1a, CD1b or CD1c. Yet, little is known about their role in immunity. Notably, each CD1 molecule differs in their anatomical location, how they traffic within the cell and their expression levels on the cell surface. Moreover, each CD1 molecule possesses unique hydrophobic pockets that ultimately govern the types of lipid antigens that each CD1 molecule presents. We have produced CD1 tetramers and developed an innovative antigen discovery technique. By trapping lipid antigens in CD1-lipid-TCR complexes, we can specifically identify small molecules that ligate CD1-TCR binding. Using these unique tools, we have identified CD1 restricted T cells in healthy human blood. Moreover, we can detect CD1 restricted T cells that are specific towards Ags derived from *Mycobacterium tuberculosis*. The TCR repertoire of CD1a, CD1b and CD1c-restricted T cells is broad, thus allowing for the recognition of a broad array of antigens. We reveal the phenotypic characteristics of CD1-restricted T cells and also use CD1 mutagenesis to provide new insight into how different TCRs engages CD1-antigen complexes. Collectively, these studies will serve as a basis for future studies of lipid reactive T cells in health and disease.

iNKT mediated anti-tumoral response activated by a Th1 biased agonist

Esteban, I.¹, Alari-Pahissa, E.¹, Lauzurica, P.², Castaño, A.R.¹

¹Institute of Biotechnology and Biomedicine, Universidad Autónoma de Barcelona, Barcelona, Spain, ²Instituto de Salud Carlos III, Madrid, Spain

Activation of iNKT cells by CD1d-presented agonists is a potentially potent immunotherapeutic tool. α -galactosylceramide

(α -GalCer) is the prototypic agonist but its excessive potency with simultaneous production of pro- and anti-inflammatory cytokines hampers its use. Synthetic agonists with a modified polar head activate iNKT cells, *in vitro* and *in vivo*. Significantly, direct recognition *in vitro* does not anticipate *in vivo* functionality. We published how a weak *in vitro* agonist, HS44, induced a strong Th1 response *in vivo*, inducing an efficient iNKT cell dependent antitumor response in the B16 mouse model. A new analog induced a stronger and absolutely specific Th1 response, with no traces of Th2 cytokines or capacity to induce a Th2 response. The characteristic cytokine storm produced by α -GalCer was not induced, which translates in increased antitumor response upon, both as a preventive and therapeutic treatment, more efficiently controlling the establishment of lung metastases. Secondary transactivation of immune cells is potently induced, with strong mobilization of adaptive and innate cells. Differential efficiency to α -GalCer depending on the susceptibility of target cell to NK lysis is shown. *In vivo* depletion experiments demonstrate the involvement of NK cells and M ϕ in tumor killing, depending on the target tumor and the agonist. A massive Th1 associated chemoquine production is induced, which may underline mechanistic differences in the antitumor response between both agonists. Finally, these analogs are also recognized by human iNKT cells, also showing differences in fine specificities with differential recognition of some analogs compared to murine iNKT cells.

713

The activation of iNKT cells induces alloreactive T-cell deletion through the generation of myeloid-derived suppressor cells

Nakamura, K.¹, Dempsey, C.M.¹, Chadha, R.², Besra, G.S.³, Cunningham, A.F.¹, Jones, N.D.¹

¹University of Birmingham, Immunology and Immunotherapy, Birmingham, United Kingdom, ²University of Oxford, Nuffield Department of Surgery, Oxford, United Kingdom, ³University of Birmingham, School of Biosciences, Birmingham, United Kingdom

Invariant natural killer T (iNKT) cells are rare cells that exclusively recognise certain glycolipids (the prototypical agonist being α -galactosylceramide (α GalCer)) presented by CD1d. We and others have shown that iNKT cells are indispensable for the induction of tolerance to allografts in mouse models suggesting that iNKT cell activation may be a worthwhile adjunct strategy to promote tolerance to allografts.

In this study the effect of specifically activating iNKT cells by α GalCer injection during a T cell response to alloantigen was investigated. We found that iNKT cell activation led to the prolonged survival of cardiac allografts in mice in the absence of other immunosuppressive agents. In order to dissect how iNKT cells mediated this suppressive effect, alloreactive, TCR-transgenic T cells (TEa) were transferred to syngeneic recipients and activated by injection of alloantigen with and without concomitant injection of α GalCer. TEa T cells were initially activated and proliferated following stimulation but were subsequently deleted in the presence but not absence of activated iNKT cells. iNKT cell activation resulted in increased numbers of myeloid-derived suppressor cells (MDSC) that were also suppressive *in vitro* and *in vivo* following transfer to

secondary hosts and the depletion of these cells resulted in TEa T cell survival similar to controls. Interestingly, iNKT cell-derived IFN- γ was found to play a key role in enabling the differentiation of such MDSC.

In conclusion, we demonstrate for the first time that glycolipid-activated iNKT cells delete alloreactive effector T cells via an MDSC intermediary in a process requiring the production of IFN- γ .

Ly9 (CD229) cell surface receptor controls NKT2 cell development

Cuenca, M., Balada, M., Engel, P.

University of Barcelona, Cell Biology, Immunology and Neurosciences, Barcelona, Spain

Invariant natural killer cells (iNKT cells) are prototypical innate-like T lymphocytes implicated in several pathologies, including microbial infections, allergic diseases, autoimmune diseases, and cancer. These cells produce high amounts of cytokines and have been further classified into three categories (NKT1, NKT2 and NKT17) based on the expression of distinct transcription factors. Signaling lymphocytic activation molecule family (SLAMF) receptors and the specific adapter SLAM-associated protein (SAP) modulate the development of innate-like lymphocytes. Ly9, a SLAM family member, has been shown to act as a negative regulator of iNKT cell development in the thymus. In this study, we show that the increase in iNKT cell numbers found in the thymus of *Ly9*^{-/-} mice was due to an expansion of NKT2 cells (CD1d-tetramer⁺ PLZF^{hi} T-bet^{neg}), while thymic NKT1 (CD1d-tetramer⁺ PLZF^{neg} T-bet^{hi}) were not detected. *Ly9* absence also lead to an enlargement of the iNKT cell pool in the spleen, and in contrast to what it was observed in the thymus, NKT1 cells were present in *Ly9*^{-/-} spleen, indicating that the homeostasis of the different iNKT cell subsets may have distinct requirements depending on their tissue localization. Furthermore, *in vivo* treatment with an agonistic monoclonal antibody directed against Ly9 significantly decreased iNKT cell numbers in the spleen, and this reduction was preferentially due to a depletion of NKT2 cells. Thus, anti-Ly9 targeting could represent a novel therapeutic approach to modulate NKT cell expansion.

Wnt proteins drive the IL-12/IFN- γ -axis in response to the Natural Killer T cell antigen, α -galactosylceramide

Kling, J., Meiners, J., Blumenthal, A.

University of Queensland Diamantina Institute, Woolloongabba, Australia

Natural Killer T (NKT) cells are key regulators of immune responses in autoimmunity, infection and cancer. Upon recognition of glycolipid antigens, NKT cells rapidly produce cytokines, such as IFN- γ , thereby providing a defining cytokine milieu early during antigen challenge. NKT cell functions are critically influenced by cytokines released by antigen presenting cells (APCs), including IL-12, an established key driver of IFN- γ production. The nineteen mammalian Wnt proteins are known primarily for orchestrating cell differentiation and proliferation

during embryogenesis and tissue homeostasis. More recently, we and others have demonstrated that Wnt proteins are expressed by APCs and define inflammatory cytokine responses during infection and chronic inflammation. Our observation that NKT cells express Wnt signalling receptors, and our previous report that Wnt signalling perpetuated the IL-12/IFN- γ axis driven by antigen-recall of human T cells, led us to hypothesise that Wnt proteins contribute to IFN- γ production by NKT cells. *In vivo* challenge of mice with the glycolipid antigen, α -galactosylceramide (α -GalCer) led to differential expression of multiple Wnt ligands in liver tissue, an organ rich in NKT cells. Small molecule inhibitors that target functional bottle-necks of Wnt secretion and signalling decreased α -GalCer-induced expression of IFN- γ and IL-12p40. Moreover, reduced α -GalCer-induced IFN- γ and IL-12p40 responses were observed in mice with a myeloid-specific deletion of *Wntless*, a key chaperone in Wnt protein release. Taken together, our observations suggest that APC-derived Wnt proteins define early host responses to the NKT cell antigen, potentially by shaping the cytokine output from both APCs and NKT cells.

2377

Activity of sulfatide-reactive type II NKT cells from mouse lung

Pasquet, L., Kato, S., Xia, M., Berzofsky, J.A., Terabe, M.

NIH-NCI, Vaccine Branch, Bethesda, United States

Natural killer T cells are lymphocytes that recognize lipid antigens presented by the non-classical MHC-I molecule, CD1d. Type I NKT cells with semi-invariant TCR recognize α -galactosylceramide (α GalCer) while type II NKT cells with more diverse TCR repertoire recognize sulfatide. NKT cells are known to be frequent in the liver. By using sulfatide-loaded CD1d-tetramers, we observed that sulfatide-reactive type II NKT cells were enriched not only in the liver but also in the lung, a major site of metastasis. Type II NKT cells inhibit anti-tumor immunity, so understanding their function in lungs is critical. Here, we analyzed their activation either *in vitro* or *in vivo*. In the steady state, lung type II NKT cells expressed Granzyme A but not Granzyme B or perforin. By injecting sulfatide *in vivo*, we observed that lung type II NKT cells upregulated Granzyme A and Ki67 expression. However, it was difficult to detect responses *in vitro*, so we hypothesized that this might be due to inadequate antigen-presenting cells (APCs). Using syngeneic bone marrow-derived dendritic cells (BMDC) as APCs, *ex-vivo* stimulation of lung type II NKT cells with sulfatide induced the secretion of IFN- γ , IL-13 and IL-17. This was consistent with the expression of specific transcription factors, GATA-3 and ROR γ t by lung type II NKT cells. The ability to study responses of type II NKT cells *in vitro* can now help elucidate the mechanism by which these regulatory cells interact with other cells and modulate tumor immunity in the lung.

Hematopoietic stem cells and their progenitors critically require autophagy to promote early engraftment following allogeneic stem cell transplantation

Lineburg, K.E.¹, Leveque-El Mouttie, L.¹, Le Texier, L.¹, Bianca, T.¹, Kuns, R.¹, Lane, S.^{1,2}, Hill, G.R.^{1,2}, MacDonald, K.P.A.¹

¹QIMR Berghofer Medical Research Institute, Brisbane, Australia,

²Royal Brisbane and Women's Hospital, Brisbane, Australia

Hematopoietic Stem Cells (HSC) are critical for the success of stem cell transplantation. Autophagy is an intracellular process that has an established role in the long-term survival and function of HSCs. We investigated the contribution of autophagy to HSC in the setting of allogeneic transplantation, in which GVHD results in a T cell derived cytokine storm early post-transplant. We demonstrate increased autophagy in donor HSC and progenitor cells in the setting of GVHD compared to non-GVHD. Competitive transplant experiments of 1:1 Atg5^{-/-} fetal liver (FL) with WT FL demonstrated that autophagy deficient cells display reduced capacity to reconstitute. In an MHC mismatch model of GVHD we demonstrated that while Atg5^{-/-} cells are capable of engraftment they are overcome in the presence of alloreactive T cells and undergo primary graft failure by day 10 post-transplant while WT cells survive and engraft. We confirmed this early graft failure in a second model, using donor VAV^{cre} x Atg7^{fl/fl} mice. The essential requirement for autophagy, specifically in early progenitors and HSC, was confirmed using LysM^{cre} Atg7^{fl/fl} mice. We demonstrate that autophagy is increased in the GVHD setting and that without autophagy early myeloid precursors fail to provide short term reconstitution leading to primary graft failure and mortality. This primary graft failure can be rescued by the administration of cyclosporine, which works to dampen the T cell induced cytokine storm post-transplant. Thus intervention to increase autophagy in these cells post-transplant may improve engraftment in the clinic.

The IL-6/IL-17 pathway impairs the re-establishment of immune-equilibrium following autologous stem cell transplantation for multiple myeloma

Minnie, S.A.¹, Guillerey, C.², Chesi, M.³, Markey, K.A.¹, Gartlan, K.H.¹, Koyama, M.¹, Kuns, R.D.¹, Zhang, P.¹, Tey, S.-K.¹, Lane, S.W.⁴, Smyth, M.J.², Vuckovic, S.¹, Hill, G.R.¹

¹QIMR Berghofer Medical Research Institute, Bone Marrow Transplantation Laboratory, Brisbane, Australia, ²QIMR Berghofer Medical Research Institute, Immunology in Cancer and Infection Laboratory, Brisbane, Australia, ³Mayo Clinic, Comprehensive Cancer Center, Scottsdale, United States, ⁴QIMR Berghofer Medical Research Institute, Gordon and Jessie Gilmour Laboratory, Brisbane, Australia

Multiple Myeloma (MM) often escapes out of a long-standing monoclonal gammopathy, suggesting progression from a state of immune-equilibrium. Autologous stem cell transplant (auto-SCT) remains a standard of care for patients with MM, inducing a state of minimal residual disease and a prolonged

plateau phase of disease. We thus hypothesized that auto-SCT may overcome the acquired immune defects induced by myeloma and restore immune-equilibrium. Using a system in which B6.WT mice bearing clinically relevant Vk*MYC myeloma (Vk12653) were transplanted with syngeneic grafts, we demonstrated prolonged survival with a plateau phase when T cells were added to bone marrow (BM) grafts (BM+T vs. BM, gamma/albumin [M-band], 6 weeks post-transplantation 0.267 vs. 1.996, P=0.0008; median survival 106 vs. 58 days, P=0.0001). Myeloma 'experienced' T cells from mice in plateau phase (harvested >100 days post-transplantation) were able to transfer anti-myeloma immunity to secondary Vk*MYC-bearing recipients. This anti-myeloma immunity required both CD4⁺T and CD8⁺T cells but was independent of NKT or gd cells. T cell-mediated anti-myeloma immunity was mediated by IFN γ signalling within donor cells but was independent of perforin. Deletion of IL-6 and IL-17 within donor cells further enhanced anti-myeloma immunity (M-band, 8 weeks post-transplantation: WT vs IL-6^{-/-} donor 0.562 vs. 0.101; WT vs. IL-17^{-/-} donor 0.746 vs. 0.153; median survival was unreached at 120 days for IL-6^{-/-} and IL-17^{-/-} donor). These findings demonstrate the re-establishment of Th1-dependent immune-equilibrium after auto-SCT and highlight the opposing role of IL-6 and IL17 pathway in this process, providing a potential therapeutic strategy to improve outcomes.

Interleukin-35 mitigates development of rejection after murine pancreatic islet transplantation via regulation of Treg/Th17 ratio

Yin, Z.¹, Li, B.¹, Dongying, C.²

¹The First Hospital of China Medical University, Department of Hepatobiliary Surgery and Organ Transplantation, Shenyang, China, ²The First Hospital of China Medical University, Shenyang, China

IL-35 is a newly discovered inhibitory cytokine predominantly secreted by regulatory B (i35-Bregs) and T (iT35) cells and may have therapeutic potential in several inflammatory and autoimmune responses. The role of IL-35 in pancreatic islet transplantation (PIT) remains to be answered. To elucidate this, we investigated the kinetics of Treg/Th17 cell response in murine PIT model and measured the levels of IL-35 in human PIT patients. We found that Treg cells and pro-inflammatory (IFN- γ , IL-2, IL-17) cytokines were increased, however, anti-inflammatory (IL-10, IL-35, TGF- β) cytokines were decreased in PIT model. IL-35 administration effectively mitigated development of rejection after murine PIT, seemingly by repressing proliferation of Th17 and converting Th17 and conventional Treg cells into IL-35-yielded Treg cells, called iT35, indicating a phenotypic shift of Treg cells. Furthermore, serum IL-35 levels were decreased in human PIT patients compared to healthy controls, and in aGVHD grade 2-4 patients compared to time-matched patients with aGVHD grade 0-1. Our finding suggest that lack of IL-35 levels play a pivotal role in the development of rejection after PIT, and therapy with IL-35 should be investigated as the therapeutic strategy for PIT and other autoimmune diseases.

Calcineurin inhibitor Tacrolimus impairs host immune response against urinary tract infection by affecting TLR4 negative regulators

Emal, D.¹, Tammaro, A.¹, Jansen, M.P.¹, Teske, G.J.¹, Claessen, N.¹, Florquin, S.^{1,2}, Leemans, J.C.¹, Dessing, M.C.¹

¹Academic Medical Center, University of Amsterdam, Department of Pathology, Amsterdam, Netherlands, ²Radboud University Nijmegen Medical Center, Department of Pathology, Nijmegen, Netherlands

Background: Calcineurin inhibitor Tacrolimus (TAC), is a potent immunosuppressive drug widely used in order to prevent acute graft rejection. Long term use of TAC increases susceptibility to bacterial infections. Urinary tract infection (UTI) is the most frequent infectious complication in renal transplant patients. The mechanism by which TAC suppresses the adaptive immunity is well known. There are indication that TAC also affects innate immunity, however it remains largely unknown how TAC affects host innate immune response against UTI.

Methods: To study this, we performed experimental UTI model by intravesical inoculation of uropathogenic E.coli in female wild type mice pre-treated with TAC or vehicle (CTR).

Results: We found that TAC pre-treated mice display higher bacterial loads than CTR mice in kidney and bladder homogenates after 24 and 48 hours. However, inflammatory mediators in kidney and bladder were similar between TAC and CTR group, indicating that TAC pre-treated mice respond relatively less to E. coli than CTR mice. Indeed, granulocytes from TAC pre-treated mice phagocytize less E. coli ex-vivo compared to CTR. Furthermore, whole blood of TAC pre-treated mice release less cytokines after LPS or heat-killed E.Coli stimulus. This tolerant state can be explained by upregulation of TLR4 negative regulators (IRAKM, SOCS1, A20, ATF3, BCL3 and TRIM30A) as observed in TAC pre-treated granulocytes.

Conclusion: We show that TAC affects TLR4-mediated responses in granulocytes by enhancing expression of negative regulators. This so called TAC-induced tolerant state can explain the impaired antibacterial defense mechanism against UTI in TAC pre-treated mice.

Recipient bone marrow (BM) macrophages (Macs) are vital for haematopoietic stem cell (HSC) engraftment post autologous transplantation

Kaur, S.¹, Raggatt, L.J.¹, Jacobsen, R.N.¹, Millard, S.¹, Batoon, L.¹, Winkler, I.G.¹, Macdonald, K.P.A.², Perkins, A.C.¹, Hume, D.A.³, Levesque, J.P.¹, Pettit, A.R.¹

¹The University of Queensland, Mater Research Institute, Woolloongabba, Australia, ²Queensland Institute of Medical Research, Herston, Australia, ³University of Edinburgh, Roslin Institute, Scotland, United Kingdom

Use of BM-transplantation (Tx) in cancer treatment is constrained by substantial risks and limitations. Improvement in recovery and quality of HSC niches within BM will likely improve the BM-Tx risk-benefit ratio. BM-Macs support HSC niche homeostasis, consequently we examined whether BM-Macs play a role in Tx

success using an autologous Tx model. Recipient MacGreen mice (express GFP in myeloid cells) were lethally irradiated and transplanted with syngeneic HSC. Flow cytometry analyses of BM 2-16 weeks (wk) post-Tx confirmed more than 99% donor chimerism of monocytes and granulocytes validating ablation of recipient HSC. In contrast, GFP⁺F4/80⁺CD11b⁺Ly6G^{neg}CD169⁺VCAM-1⁺ER-HR3⁺ recipient BM-Macs were detected throughout the time-course. A significant 5.9 fold expansion of recipient BM-Macs occurred between wk 2 (4.5 x 10⁴ cells/femur) and 5 (27 x 10⁴ cells/femur) post-Tx which coincided with increased BM residence of long-term (LT) donor HSC. Recipient Macs in spleen displayed different frequency and longevity kinetics that correlated with transient post-Tx splenic extramedullary haematopoiesis. In situ, GFP⁺F480⁺ recipient BM-Macs localized to HSC niche-enriched perivascular microenvironments within both central BM and endosteal regions. We selectively depleted recipient BM-Macs using CD169-DTR mice transplanted with syngeneic ubiquitous GFP⁺ HSC. Depletion of recipient CD169⁺ Macs abated donor LT-HSC BM engraftment by 70% at 5 wk post-Tx and reduced BM reconstitution potential in competitive secondary transplants. Overall BM contains a myeloablation-resistant self-repopulating Mac subset that is necessary for efficient and/or sustained HSC BM engraftment in an autologous Tx setting. Therapeutically targeting resilient recipient BM-Macs may enhance stem cell engraftment and accelerate haematopoietic recovery post BM-Tx.

Clinical grade multipotent adult progenitor cells suppress IL-7 driven stimulation of T cells *in vivo*

Carty, F.¹, Reading, J.², Tree, T.², Ting, A.³, Stubblefield, S.³, English, K.¹
¹National University of Ireland Maynooth, Maynooth, Co. Kildare, Ireland, ²Kings College London, London, United Kingdom, ³Athersys Inc., Cleveland, United States

In the setting of transplantation, T cells are deliberately depleted to prevent allograft rejection. In the lymphopenic environment which ensues, interleukin-7 (IL-7) is abundant, and competition is low. This IL-7 activates the proliferation of effector memory T cells, which are the predominant mediators of graft rejection. Multipotent adult progenitor cells (MAPC) have been previously shown to modulate the response of T cells to IL-7, *in vitro* but not *in vivo*. Here, for the first time, we demonstrate that MAPC suppress IL-7 driven proliferation and pro-inflammatory cytokine production by both CD4⁺ and CD8⁺ T cells in the spleen. In order to further investigate the effects of MAPC in this model, 140 cell populations in the spleen were examined following IL-7 and MAPC therapy, using a 16 colour flow cytometry immunophenotyping study. MAPC enhanced the frequency of regulatory T cells and transitional 1 B cells in the spleen, however this effect was only observed when MAPC were administered intraperitoneally (i.p.), rather than intravenously (i.v.). The effects of routes of administration on the bio-distribution of MAPC in our model of homeostatic proliferation was further clarified using novel 3D whole animal Cryo-imaging technology. Following i.p. administration, MAPC reside in the omentum tissue suggesting that MAPC mediate their effects in the spleen through trophic signalling.

Furthermore MAPC delivered i.p. may have contact-driven effects on cells in the omentum. These findings support ongoing studies showing the therapeutic efficacy of MAPC in both solid organ and hematopoietic cell transplantation, elucidating novel mechanisms for their effects *in vivo*.

Monocyte derived dendritic cells promote Th polarization, while conventional dendritic cells promote Th proliferation

Chow, K.V.^{1,2,3}, Lew, A.M.^{1,2}, Sutherland, R.M.^{1,2}, Zhan, Y.^{1,2}

¹Walter & Eliza Hall Institute of Medical Research, Immunology, Parkville, Australia, ²University of Melbourne, Medical Biology, Parkville, Australia, ³Royal Melbourne Hospital, Nephrology, Parkville, Australia

Monocyte derived dendritic cells (moDCs) dramatically increase in numbers upon infection and inflammation. We found that this also occurs in response to allogeneic encounters, such as those that occur in the setting of organ transplantation. Despite their prominence in these settings, how emergent moDCs and resident conventional DCs (cDCs) divide their labor as APCs remain undefined. Since, unlike nominal antigens, transplant antigens can be recognized by direct and indirect presentation, we compared both direct and indirect antigen presentation by murine moDCs versus cDCs. We found that, despite having equivalent MHC-II expression and *in vitro* survival, moDCs were 20-fold less efficient than cDCs at inducing CD4⁺ T cell proliferation through both direct and indirect Ag presentation. Despite this, moDCs were more potent at inducing Th1 and Th17 differentiation (e.g. 8-fold higher IFN- γ , 2-fold higher IL-17A in T cell co-cultures) whereas cDCs induced 10-fold higher IL-2 production. Intriguingly, moDCs potently reduced the ability of cDCs to stimulate T cell proliferation *in vitro* and *in vivo*, partially through nitric oxide production. We surmise that such division of labor between moDCs and cDCs has implications for their respective roles in the immune response.

4353

A novel, blocking anti-CD40 monoclonal antibody prolongs non-human primate renal allograft survival in the absence of B-cell depletion or thromboembolic events

Cordoba, F.¹, Wiczorek, G.¹, Audet, M.², Schneider, M.¹, Espie, P.¹, Roth, L.¹, Heusser, C.¹, Bruns, C.¹, Patel, D.¹, Rush, J.¹

¹Novartis Institutes of Biomedical Research, Basel, Switzerland, ²Hôpital de Hautepierre, Strasbourg, France

CD40-CD154 pathway blockade using anti-CD40 antibodies has been shown to effectively prolong kidney allograft survival. However, these antibodies differed in their functional properties related to CD40 pathway activation, blockade as well as the ability to deplete CD40 expressing B cells. To address the question of the relative contribution of B-cell depletion to the efficacy of anti-CD40 blockade, we developed a novel, human Fc-silent anti-CD40 monoclonal antibody (CFZ533) that was incapable of antibody-dependent cellular cytotoxicity or complement-dependent cytotoxicity in MHC-mismatched cynomolgus monkey renal allograft transplantation. Well-

functioning allografts survived up to a pre-defined endpoint of 100 days in CFZ533-treated animals (100, 100, 100, 98, 78 days) in comparison to untreated monkeys (survival ~ 7 days; n = 9). Excellent graft morphology was observed in the CFZ533-dosed group, and the antibody suppressed a gene signature associated with acute rejection in a majority of animals. Further, CFZ533 completely disrupted splenic germinal centers in transplanted animals (indicating a full tissue pharmacodynamic effect), but failed to deplete peripheral blood B-cells depletion was only observed with the Fc-competent antibody. Importantly, CFZ533 was well-tolerated and there was no evidence of thromboembolic events. The data indicate that CD40 pathway blockade in the absence of B-cell depletion maintained very high allograft quality and function up to 100 days post-transplantation. Thus, use of the Fc-silent anti-CD40 antibody CFZ533 appears to be an attractive approach for preventing solid organ transplant rejection and treating autoimmune diseases involving T-cell-dependent humoral immune mechanisms.

Keap1 regulates Mycobacterium avium - induced inflammatory signaling in human macrophages

Awuh, J.A.^{1,2}, Haug, M.^{1,2}, Mildenerger, J.^{1,2}, Marstad, A.^{1,2}, Ngoc Do, C.P.^{1,2}, Louet, C.^{1,2}, Stenvik, J.^{1,2}, Steigedal, M.^{1,2}, Damås, J.K.^{1,2,3}, Halaas, Ø.¹, Flo, T.H.^{1,2}

¹Norwegian University of Science and Technology, Cancer Research and Molecular Medicine, Trondheim, Norway, ²Norwegian University of Science and Technology, Center of Molecular Inflammation Research, Trondheim, Norway, ³St Olavs Hospital, Infectious Diseases, Trondheim, Norway

Inflammatory signaling is a central mechanism controlling host defenses to pathogens. However, how these mechanisms are in turn controlled remains poorly understood. Invading pathogens activate cytokine production and might induce the production of reactive oxygen species (ROS) that needs to be tightly controlled in cells. Kelch-like ECH-associated protein 1 (Keap1) plays a well-established role as a sensor for ROS for the protection of cells against oxidative damage. We recently demonstrated a role of Keap1 in regulating intracellular survival of *M. avium* in primary human macrophages. Keap1 associated with mycobacteria in a time-dependent manner while siRNA-mediated knockdown of Keap1, Cul3, and Rbx1 increased *M. avium*-induced expression of inflammatory cytokines and type I interferons. Keap1-Cul3-Rbx1 facilitates ubiquitination and degradation of IKK β and thus terminating IKK activity. Keap1 knockdown led to increased nuclear translocation of transcription factors NF- κ B, IRF1 and IRF5 driving the expression of inflammatory cytokines and IFN β . Finally, increased inflammatory responses in Keap1-silenced cells contributed to decreased intracellular growth of *M. avium* in primary human macrophages. Taken together we propose that Keap1 acts as a negative regulator for controlling inflammatory signaling in *M. avium*-infected macrophages. Although this might be important to avoid sustained or overwhelming inflammation, a negative consequence could be facilitated growth of pathogens within macrophages. Using

different ligands and other heat-killed bacteria we have new evidence that this mechanism is not specific for mycobacterial infections but rather an NF- κ B driven mechanism. Our results indicate that altered Keap1 gene expression may also have vital clinical implications for other inflammatory conditions.

A dominant-negative mutation in TNFR1 results in increased susceptibility to pulmonary tuberculosis infection

Saunders, B.M.¹, Huch, J.², Whittle, B.³, Chan, B.², Cornall, R.⁴, Goodnow, C.^{5,6}, Britton, W.J.^{2,7}

¹University of Technology Sydney, School of Life Sciences, Broadway, Australia, ²Centenary Institute, Tuberculosis Research Program, Newtown, Australia, ³Australian National University, John Curtin School of Medical Research, Australian Phenomics Facility, Canberra, Australia, ⁴Oxford University, Nuffield Department of Medicine and Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, ⁵John Curtin School of Medical Research, Australian National University, Immunogenomics Laboratory, Canberra, Australia, ⁶Garvan Institute of Medical Research, Immunogenomics Laboratory, Darlinghurst, Australia, ⁷University of Sydney, Department of Immunology and Infectious Diseases, Sydney Medical School, Sydney, Australia

Tuberculosis remains a major global health challenge, interestingly only 10% of infected individuals progress to active disease and genetic variation contributes to this increased susceptibility. To examine this further, we undertook an unbiased genetic screen using pulmonary *M. tuberculosis* infection of mice following ENU mutagenesis. We identified a pedigree of mice (WT-007) with markedly increased susceptibility to *M. tuberculosis* infection. Deep sequencing identified a genetic variant in the extracellular domain of TNF receptor 1 (TNFR1) as the causative mutation. In humans this identical mutation results in the auto-inflammatory condition TNF receptor-associated periodic syndrome (TRAPS). In contrast to TNFR1 deficient mice, this mutation has a dominant-negative effect, as both homozygous and heterozygous mice displayed a gene dose-dependent increase in susceptibility to *M. tuberculosis* infection characterised by hyper-inflammation, failure to control bacterial growth and markedly reduced survival. This was associated with reduced circulating sTNFR1 levels, increased pro-inflammatory cytokine expression and dysregulated cellular recruitment. *M. tuberculosis*-infected mutant mice developed a robust antigen-specific T cell response, however this was insufficient to control the infection. Infection of 007-RAG^{-/-} chimeric mice demonstrated that expression of the TNFR1 mutation by both haemopoietic and stromal cells contributed to the phenotype of the 007 mice. Furthermore, while plasma sTNFR2 levels were elevated in the WT-007 mice, the hyper-inflammation and susceptibility were independent of TNFR2 expression. These data indicate that functional TNFR1 is critical to regulate TNF-induced inflammation and control of intracellular pathogens. Further, individuals with the TRAPS signalling defect may be at increased risk from intracellular pathogens.

Cathelicidin insufficiency in patients with fatal leptospirosis

Lindow, J.^{1,2}, Wunder, E.^{1,2}, Popper, S.³, Min, J.-N.², Mannam, P.², Srivastava, A.², Yao, Y.², Hacker, K.^{1,2}, Raddassi, K.², Lee, P.², Montgomery, R.², Shaw, A.², Hagan, J.⁴, Araújo, G.¹, Nery, N.¹, Relman, D.³, Kim, C.⁵, Reis, M.¹, Ko, A.^{1,2}

¹Fiocruz, Salvador, Brazil, ²Yale University School of Medicine, New Haven, United States, ³Stanford University, Stanford, United States, ⁴Centers for Disease Control and Prevention, Atlanta, United States, ⁵University of California, San Francisco, United States

Leptospirosis is an important zoonotic cause of morbidity and mortality worldwide due to life-threatening manifestations of Weil's disease and pulmonary hemorrhage syndrome. The role that the host response plays in disease progression and high case fatality (>10-50%) observed for these severe disease forms is poorly understood. We conducted a multiparameter investigation of patients with acute leptospirosis to identify mechanisms associated with case fatality. Whole blood transcriptional profiling revealed fatal cases had lower expression of the antimicrobial peptide, cathelicidin, and chemokines, but more abundant pro-inflammatory cytokine receptors (IL-18R and IL-1R2). In contrast, survivors generated strong adaptive immune signatures, including transcripts relevant to antigen presentation and immunoglobulin production. In an independent cohort (23 survivors, 22 deceased), low serum cathelicidin and RANTES levels during acute illness were independent risk factors for higher bacterial loads ($P=0.005$) and death ($P=0.04$), respectively. Additionally, administration of cathelicidin prior to lethal *Leptospira* infection in an experimental animal model of leptospirosis significantly increased survival and decreased bacterial loads. Together, these findings indicate that the host response plays a central role in disease progression during severe leptospirosis. Poor outcomes are associated with the inability to mount an immune response that controls systemic bacterial loads and the development of aberrant pro-inflammatory responses. Furthermore, the specific antimicrobial peptide, cathelicidin, is a key factor in mounting an effective bactericidal response against the pathogen and may represent a new therapeutic approach for leptospirosis.

Structural basis of mycobacterium tuberculosis lipid antigen-CD1b complex recognition by T cell receptor

Gras, S.^{1,2}, Shahine, A.¹, Tan, L.¹, Van Rhijn, I.^{3,4}, Moody, D.B.³, Rossjohn, J.^{1,2,5}

¹Monash University, Infection and Immunity Program, Clayton, Australia, ²Monash University, Australian Research Council Centre of Excellence for Advanced Molecular Imaging, Clayton, Australia, ³Harvard Medical School, Division of Rheumatology, Immunology and Allergy, Boston, United States, ⁴Utrecht University, Department of Infectious Diseases and Immunology, Utrecht, Netherlands, ⁵Cardiff University School of Medicine, Institute of Infection and Immunity, Cardiff, United Kingdom

Recently, we have identified CD1b-reactive T cells recognising mycobacterium tuberculosis lipid antigen, namely glucose monomycolate (GMM) using tetramer staining (Van Rhijn et al.,

2013, *Nature Immunology*). We have isolated two sub-families of CD1b-GMM reactive T cells, exhibiting either high or low affinity. Sequence analysis of those high and low affinity TCRs, revealed a skewed TCR repertoire with a TRAV1-2 bias usage characteristic of the high affinity TCRs while a TRAV17 bias usage characterised the low affinity TCRs (Van Rhijn et al., 2014, *Journal of Immunology*).

Surprisingly the TRAV1-2 high affinity TCRs have a nearly invariant CDR3a sequences composed mainly of germline residues, therefore we named those receptors germline-encoded mycolyl-reactive or GEM TCRs. We have shown that the GEM TCRs exhibit an unusually high affinity of $\sim 1 \mu\text{M}$ for CD1b-GMM.

To further understand the molecular basis of CD1b-GMM recognition by TCRs, as well as to determine the role played by the different Va chains (TRAV1-2 and TRAV17) in TCR affinity, we performed a structural investigation of the CD1b-GMM in complex with a GEM TCR. The GEM TCRs will provide insight into a simplified CD1b-specific T cell repertoire and a specific understanding of T cell immunity from tuberculosis patients.

Autoantibody production by murine B-1a cells stimulated with *Helicobacter pylori* urease through Toll-like receptor 2 signaling

Takeshita, H.¹, Watanabe, E.², Kobayashi, F.¹, Nakagawa, Y.², Yamanishi, S.¹, Norose, Y.², Shinya, E.², Kumagai, Y.², Ito, Y.³, Takahashi, H.²

¹Nippon Medical School, Departments of Microbiology/Immunology, and Pediatrics, Tokyo, Japan, ²Nippon Medical School, Departments of Microbiology and Immunology, Tokyo, Japan, ³Nippon Medical School, Departments of Pediatrics, Tokyo, Japan

Helicobacter pylori infection is associated with several autoimmune diseases, in which autoantibody-producing B cells must be activated. Among these B cells, CD5-positive B-1a cells from BALB/c mice were confirmed to secrete autoantibodies when cocultured with purified *H. pylori* urease in the absence of T cells. To determine the mechanisms for autoantibody production, CD5-positive B-1a cells were sorted from murine spleen cells and stimulated with either purified *H. pylori* urease or *H. pylori* coated onto plates (referred to hereafter as plate-coated *H. pylori*), and autoantibody production was measured by enzyme-linked immunosorbent assay (ELISA). Complete urease was not secreted from *H. pylori* but was visually expressed over the bacterium-like endotoxin. Urease-positive plated-coated *H. pylori* stimulated B-1a cells to produce autoantibodies, although urease-deficient isotype-matched *H. pylori* did not. Autoantibody secretion by B-1a cells was inhibited when bacteria were pretreated with anti-*H. pylori* urease-specific antibody having neutralizing ability against urease enzymatic activity but not with anti-*H. pylori* urease-specific antibody without neutralizing capacity. The B-1a cells externally express various Toll-like receptors (TLRs): TLR1, TLR2, TLR4, and TLR6. Among the TLRs, blocking of TLR2 on B-1a cells with a specific monoclonal antibody (MAb), T2.5, inhibited autoantibody secretion when B-1a cells were stimulated with plate-coated *H.*

pylori urease. Moreover, B-1a cells from TLR2-knockout mice did not produce those autoantibodies. The present study provides evidence that functional urease expressed on the surface of *H. pylori* will directly stimulate B-1a cells via innate TLR2 to produce various autoantibodies and may induce autoimmune disorders.

2607

Inhibition of TLR signaling by a bacterial protein containing immunoreceptor tyrosine-based inhibitory motifs

Yan, D.¹, Wang, X.², Luo, L.³, Cao, X.⁴, Ge, B.²

¹Fudan University, Department of Immunology, Shanghai, China, ²Clinical and Translational Research Center, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China, ³Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences & Shanghai Jiaotong University School of Medicine, Shanghai, China, ⁴National Key Laboratory of Medical Immunology and Institute of Immunology, Second Military Medical University, Shanghai, China

The protein Tir (translocated intimin receptor) in enteric bacteria shares sequence similarity with the host cellular immunoreceptor tyrosine-based inhibition motifs (ITIMs). Despite the importance of Tir in pedestal formation, relatively little is known about the role of Tir and its ITIMs in the regulation of the host immune response. Here we demonstrate that Tir from enteropathogenic *Escherichia coli* (EPEC) interacted with the host cellular tyrosine phosphatase SHP-1 in an ITIM phosphorylation-dependent manner. The association of Tir with SHP-1 facilitated the recruitment of SHP-1 to the adaptor TRAF6 and inhibited the ubiquitination of TRAF6. Moreover, the ITIMs of Tir suppressed EPEC-stimulated expression of proinflammatory cytokines and inhibited intestinal immunity to infection with *Citrobacter rodentium*. Our findings identify a previously unknown mechanism by which bacterial ITIM-containing proteins can inhibit innate immune responses.

4298

Long noncoding RNA MEG3-4 tissue specifically regulates IL-1b in pulmonary infection by repressing microRNA-138

Li, R.¹, Wu, M.²

¹University of North Dakota, Grand Forks, United States, ²University of North Dakota, Biomedical Science Department, Medical School, Grand Forks, United States

Long noncoding RNAs (lncRNAs) modulate various biological processes; however, their function in host immunity response against infection has remained elusive. Here, we identify an intergenic lncRNA MEG3 (linc-MEG3) as a tissue specific regulator for pulmonary immunity during bacterial infection. Among the 10 transcripts of linc-MEG3, transcripts 1 and 4 are main regulators due to being the most downregulated in mouse lungs after bacterial infection. Overexpression of linc-MEG3-4 in mice led to intensified inflammatory response, severe lung injury, systemic infection dissemination, and ultimately, increased mortality. Alveolar epithelial cells and alveolar macrophages (AM) were major cell populations that are targeted by linc-MEG3-4. As its 3' sequences are complementary

to microRNA-138 (miR-138), linc-MEG3-4 competitively binds miR-138 and thus releases its target IL-1b mRNA, resulting in intensified inflammatory responses. Our findings characterize linc-MEG3 as a novel pulmonary inflammatory regulator of bacterial infection through a miR-138/IL-1b/NF- κ B circuit.

FIBCD1 binds to *Aspergillus fumigatus* chitin and regulate epithelial inflammation in response to *Aspergillus fumigatus* cell wall components

Jepsen, C., Dubey, L.K., Møller, J.B., Christensen, K.B., Schlosser, A., Sørensen, G.L., Holmskov, U.

University of Southern Denmark, Odense, Denmark

Chitin is an essential cell-wall polysaccharide of fungal pathogens, that elicit pro- and anti-inflammatory responses *in vivo* and *in vitro*, but the receptors that directly interact with chitin to promote these responses are poorly understood. We have previously shown, that the membrane protein FIBCD1 expressed apically on gut epithelial cells binds crab chitin. Here we show that FIBCD1 is expressed in human airway epithelial cell and is upregulated during pulmonic *A. fumigatus* infection. We demonstrates that FIBCD1 binds to the composite cell wall extract alkaline insoluble fragment (AIF) from *Aspergillus fumigatus* (*Afu*) composed of chitin, beta-1-3-glucan and galactomannan. We show that FIBCD1 bind to *Afu* chitin but not to beta-1-3-glucan or galactomannan and that FIBCD1 recognizes chitin the rich zones like the septum, budding region, and bud scar in fungal cell wall. FIBCD1 expression inhibits AIF induces IL-8 secretion from in lung epithelial cells but it also dampens IL-8 production induced by non-FIBCD1 ligand including galactomannan, beta 1,3-glucan and TLR ligands. At the mRNA level FIBCD1 expression inhibits CCL20, GM-CSF-R-alpha, TNF-alpha TSLP Il-1b Il-8, MUC1, MUC13 MUC5AC and ZO-1, while IL-13, occludin and ICAM1 was upregulated. The anti-inflammatory role of FIBCD1 may be of benefit to the immunocompetent host as it protects against unnecessary collateral inflammation damage when the alveolar macrophages clear the opportunistic fungal pathogens. On the other hand the immunosuppressive effect of FIBCD1 may also favor *A. fumigatus* infection in the immune-compromised host.

Characterization of the Interaction between M-ficolin and the fungal polysaccharides chitin and β -1,3-glucan

Jensen, K.¹, Lund, K.P.¹, Holm, A.T.¹, Moeller, J.B.¹, Jepsen, C.S.¹, Dubey, L.K.¹, Schlosser, A.¹, Galgózy, L.^{2,3}, Thiel, S.⁴, Holmskov, U.¹, Sorensen, G.L.¹

¹University of Southern Denmark, Institute of Molecular Medicine, Odense, Denmark, ²University of Szeged, Department of Microbiology, Szeged, Hungary, ³Innsbruck Medical University, Division of Molecular Biology, Innsbruck, Austria, ⁴Aarhus University, Department of Biomedicine, Aarhus, Denmark

M-ficolin is a secreted pattern recognition molecule of the innate immune system. It binds acetylated compounds, including N-acetylglucosamine (GlcNAc), and mediates complement

activation through the lectin pathway. The polysaccharides chitin and β -glucan are key structural components of fungal cell wall and are exposed during fungal growth thereby serving as PAMPs. We investigated the possible role of M-ficolin in the recognition of, and response to, these polysaccharides. M-ficolin was immune-localized to infiltrating granulocytes and monocytes in the periphery of the aspergilloma in invasive aspergillosis. Human recombinant M-ficolin (rM-ficolin) bound to the cell wall, hyphal septae and the primary buds of the growing hyphae of *Aspergillus fumigatus* (*A. fumigatus*). rM-ficolin binding to fungal germlings, chitin, β -1,3-glucan and a standard preparation of cell wall polysaccharides of *A. fumigatus*, the alkali-insoluble fraction (AIF), showed binding in a partially inhibited by EDTA and GlcNAc when evaluated by pull-down assays. Complement activation assays showed that the interaction between M-ficolin and chitin, β -1,3-glucan and AIF mediates complement activation through the lectin pathway.

In conclusion, this study suggests a role of M-ficolin in the innate recognition of, and response to, fungal polysaccharides with novel polysaccharide PAMPs chitin and the non-acetylated β -1,3-glucan.

Src-Like adapter protein (SLAP) regulates the proliferation of mast cells *in vivo*

Sharma, N., Patel, R., McGlade, C.J.

The Hospital for Sick Children, Cell Biology, Toronto, Canada

Mast cells (MCs) are innate immune effector cells found in peripheral tissues including skin and intestine and perform the role of a sentinel for invading pathogens. Homeostatic regulation of MCs is dependent upon a receptor tyrosine kinase, c-Kit and downstream signaling axis regulating the proliferation and survival of MCs *in situ*. Src-like adapter protein (SLAP) bearing structural similarities with Src kinase except lacking the kinase domain has been previously shown to interact with c-Kit and suppress downstream signaling via regulating the receptor stabilization. Here, we report that SLAP knockout (SLAP KO) mice showed reduced mast cells in peritoneum and dermis. In addition, peritoneal MCs in SLAP KO showed reduced proliferation while similar apoptosis compared to wild-type (WT) control. In addition, mast cell progenitors in spleen and bone marrow showed equal numbers between WT and SLAP KO mice. Furthermore, bone marrow-derived mast cells (BMMCs) from SLAP KO mice showed reduced proliferation compared to WT control in response to Stem cell factor, a ligand for Kit receptor. Moreover, SLAP KO BMMCs shows reduced activation of Erk and Jnk pathways downstream of KIT receptor. Therefore, SLAP regulates the proliferation of mast cells via regulating the Kit-Erk-Jnk pathways.

The RNA-binding protein Mex-3B is required for IL-33 induction in the development of allergic airway inflammation

Yamazumi, Y.¹, Sasaki, O.², Imamura, M.², Oda, T.¹, Ohno, Y.¹, Shiozaki-Sato, Y.¹, Nagai, S.³, Suyama, S.¹, Kamoshida, Y.¹, Funato, K.¹, Yasui, T.⁴, Kikutani, H.⁴, Yamamoto, K.², Koyasu, S.⁵, Akiyama, T.¹

¹Institute for Molecular and Cellular Biosciences, The University of Tokyo, Laboratory of Molecular and Genetic Information, Tokyo, Japan, ²University of Tokyo, Department of Allergy and Rheumatology, Graduate School of Medicine, Tokyo, Japan, ³Tokyo Medical and Dental University, Department of Molecular Immunology, Graduate School of Medical and Dental Sciences, Tokyo, Japan, ⁴Osaka University, Research Institute for Microbial Diseases, Department of Molecular Immunology, Osaka, Japan, ⁵RIKEN Center for Integrative Medical Sciences, Laboratory for Immune Cell Systems, Yokohama, Japan

Allergic airway inflammation is one of the primary features of allergic asthma. Interleukin 33 (IL-33) is recognized as a key pro-inflammatory cytokine that mediates allergic airway inflammation and its expression is elevated in this condition, but little is known about the regulatory mechanisms underlying IL-33 induction. Here, we show that the RNA-binding protein Mex-3B plays a critical role in the induction of IL-33 in the development of allergic airway inflammation. We generated *Mex3b*^{-/-} mice and found that they develop significantly less airway inflammation than wild-type mice, due to reduced induction of IL-33. We further show that Mex-3B directly upregulates IL-33 expression by inhibiting miR-487b-3p-mediated repression of IL-33. Moreover, we show that inhalation of an antisense oligonucleotide targeting Mex-3B suppresses allergic airway inflammation. Our data identify a novel signaling pathway that post-transcriptionally regulates IL-33 expression and suggest that Mex-3B could be a promising molecular target for the treatment of allergic asthma.

Induction of autoimmune disease by deletion of CTLA-4 in mice in adulthood

Klocke, K.¹, Sakaguchi, S.², Holmdahl, R.¹, Wing, K.¹

¹Karolinska Institutet, MBB, Stockholm, Sweden, ²Immunology Frontier Research Center, Osaka University, Osaka, Japan

Cytotoxic T lymphocyte antigen-4 (CTLA-4) is essential for immunological (self-) tolerance but due to the early fatality of CTLA-4 knock out mice its specific function in central and peripheral tolerance and in different systemic diseases remains to be determined. Here, we further examined the role of CTLA-4 by abrogating CTLA-4 expression in adult mice and compared the resulting autoimmunity that follows with that produced by congenital CTLA-4 deficiency. We found that conditional deletion of CTLA-4 in adult mice resulted in spontaneous lymphoproliferation, hypergammaglobulinemia and histologically evident pneumonitis, gastritis, insulinitis and sialadenitis, accompanied by organ specific autoantibodies. However in contrast to congenital deficiency this was not fatal. CTLA-4 deletion induced preferential expansion of

CD4⁺Foxp3⁺ Treg cells. Yet T cells from CTLA-4 deficient iKO mice were able to adoptively transfer the diseases into T cell-deficient mice. Notably, cell transfer of thymocytes *de novo* produced myocarditis, otherwise not observed in donor mice depleted in adulthood. Moreover, CTLA-4 deletion in adult mice had opposing impacts on induced autoimmune models. Thus while CTLA-4 deficient mice had more severe collagen induced arthritis (CIA) they were protected against peptide-induced experimental autoimmune encephalomyelitis (EAE) yet onset of protein-induced EAE was only delayed. Collectively this indicates that CTLA-4 deficiency affects both central and peripheral tolerance and Treg cell-mediated suppression.

4457

Targeting citrullination with a peptidyl arginine deiminase inhibitor is associated with a shift from Th17-mediated immune responses and abrogates collagen-induced arthritis

Kawalkowska, J.¹, Quirke, A.-M.¹, Ghari, F.², Subramanian, V.³, Thompson, P.³, Williams, R.¹, Fischer, R.⁴, La Thangue, N.², Venables, P.¹

¹University of Oxford, Kennedy Institute, NDORMS, Oxford, United Kingdom, ²University of Oxford, Laboratory of Cancer Biology, Department of Oncology, Oxford, United Kingdom, ³University of Massachusetts Medical School, Biochemistry and Molecular Pharmacology, Worcester, United States, ⁴University of Oxford, Target Discovery Institute, Nuffield Department of Medicine, Oxford, United Kingdom

Citrullination is catalysed by peptidylarginine deiminases (PADs) and hypercitrullination has been reported in several inflammatory diseases including multiple sclerosis, colitis, lupus, cancer and rheumatoid arthritis. In this study we examine the therapeutic potential of a PAD inhibitor (BB-CI-amidine) in immune-mediated arthritis and its effects on T helper differentiation.

Collagen-induced arthritis was induced in DBA/1 mice by immunization with bovine type II collagen. After disease onset, mice were treated daily with vehicle or BB-CI-amidine (10 mg/kg). On day 10, mice were culled, and paws, blood and lymph nodes collected for further analysis.

Treatment of arthritic mice with BB-CI-amidine resulted in a significant reduction in clinical scores. Histological scores in joints were almost completely normalised. Unexpectedly, while pro-inflammatory cytokines (TNF- α , IL-1 β , IL-6) in serum remained unaffected by BB-CI-amidine, IL-4, IL-5 and IL-10 were significantly elevated. In line with this, IL-4⁺ Th2 cells were increased in the lymph nodes of BB-CI-amidine treated mice. Further analysis revealed a decrease in Th17 numbers in paws and lymph nodes with BB-CI-amidine. The addition of BB-CI-amidine to Th17 differentiation cultures (without APCs) lead to the inhibition of IL-17A. In addition, BB-CI-amidine reduced histone H3.2 citrullination which suggests that BB-CI-amidine may inhibit gene expression via an epigenetic mechanism.

In conclusion, BB-CI-amidine is therapeutic in CIA by inhibiting pro-inflammatory Th17-type responses. We propose that these effects are mediated by transcriptional regulation and that targeting PADs is a realistic strategy for the treatment of chronic inflammatory diseases in which PAD activity is dysregulated.

MLKL mediates programmed hepatocellular necrosis independent of RIPK3 during inflammation-dependent hepatitis

Günther, C.¹, He, G.-W.¹, Kremer, A.¹, Murphy, J.², Amann, K.¹, Vandenabeele, P.³, Linkermann, A.⁴, Krautwald, S.⁴, Neurath, M.¹, Becker, C.¹, Wirtz, S.¹

¹University Hospital Erlangen, Erlangen, Germany, ²Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ³Ghent University, Ghent, Belgium, ⁴University Hospital Schleswig-Holstein, Kiel, Germany

Although the liver is an organ of remarkable regenerative capacity, cell death related compensatory tissue injury responses commonly culminate in liver fibrosis and eventually cirrhosis, a major cause of morbidity worldwide. With regard of this vital contribution of hepatocellular death to virtually all hepatic diseases, precise mechanistic knowledge of cell death regulation is essential for the understanding of the pathophysiology of liver disease and for the development of novel therapeutic approaches.

Given that the pseudokinase mixed lineage kinase domain-like protein (MLKL) has been identified as a key mediator and potential biomarker of receptor-interacting protein kinases (RIPK)-mediated regulated necrosis (necroptosis), we investigated the role of MLKL during inflammation-dependent hepatitis. Our data demonstrate that MLKL is strongly upregulated and activated in human autoimmune hepatitis and in a murine model of inflammation-dependent hepatitis (ConA-induced hepatitis). Using genetic (*Ripk3*^{-/-}, *Mkl1*^{-/-} mice) and pharmacological approaches (necrostatin-1s) we describe that hepatocellular necrosis in experimental hepatitis is driven by a previously unrecognized pathway of RIPK1-dependent MLKL activation that occurs independent of RIPK3. Thus, depending on the physiological context, MLKL has the capacity to promote RIPK3-mediated necroptosis or alternatively triggers IFN-mediated RIPK3-independent programmed necrosis. Moreover, we provide compelling evidence that the well-known cytotoxic-activity of the proinflammatory cytokine IFN- γ in hepatic inflammation is strongly connected to induction of MLKL expression via activation of the transcription-factor STAT1.

In summary, we discovered a previously undescribed type of MLKL-dependent programmed necrosis which is executed in the absence of RIPK3 and potentially promotes the pathogenesis of severe liver diseases.

TLR9 polymorphisms induce autoimmunity in a murine model of SLE

Ruck, M.¹, Woo, J.², Laszik, Z.³, Hermiston, M.¹

¹UCSF, Department of Pediatrics, San Francisco, United States, ²UCSF, Diabetes Center, Division of Infectious Diseases, Department of Medicine, San Francisco, United States, ³UCSF, Department of Pathology, San Francisco, United States

The stochastic and heterogeneous nature of Systemic Lupus Erythematosus (SLE) supports a model whereby multiple genetic and/or environmental hits culminate in loss of tolerance

and autoantibody production. Consistent with this model, the phenotype of CD45E613R mice containing a single point mutation in the juxtamembrane wedge of CD45 depends on genetic context. Despite similar dysregulated phosphatase activity in all immune cells, CD45E613R mice on a C57Bl/6 (B6) background have no overt phenotype while BALB/c mice develop anti-double stranded (ds) DNA antibodies. An unbiased genome-wide screen for modifiers of autoantibody production between CD45E613R B6 and BALB/c mice identified two candidate loci: Wedge Associated Modifier (Wam) 1 on Chromosome (Chr) 9 encompassing *tlr9* and Wam2 on Chr 17 encompassing MHC H2. Previous work in knockouts showed the hyporesponsive BALB/c TLR9 allele permits anti-ds DNA antibodies while the B6 TLR9 allele is resistant. Here, we generate CD45E613R mice congenic for the TLR9 alleles. We demonstrate that one copy of the B6 TLR9 allele is sufficient to induce tolerance and decrease autoantibodies on the susceptible BALB/c background, while the BALB/c TLR9 allele is sufficient to induce autoantibodies and glomerulonephritis in the resistant B6 background. The signaling phenotype of the BALB/c TLR9 allele is recapitulated in B6 CD45E613R congenics and correlates with a defect in B cell tolerance prior to disease onset. These data indicate that the net signal strength between the TLR9 allele and the hyperresponsive CD45E613R mutation determines whether autoreactive B cells are deleted, resulting in tolerance, or survive, causing autoimmunity.

4481

Neuroprotection affected by immunomodulatory treatment with glatiramer acetate

Aharoni, R., Sela, M., Arnon, R.

The Weizmann Institute of Science, Immunology, Rehovot, Israel

Multiple sclerosis (MS) is an autoimmune disease of the central nervous system (CNS), involving inflammation and neurodegeneration. Treatment strategies aim to reduce the inflammation and induce neuroprotective repair processes. The therapeutic effect of Copaxone (glatiramer acetate, GA), an approved drug for MS treatment, has been attributed to a shift from inflammatory Th1 towards anti-inflammatory Th2 pathway. Using the animal model of MS, experimental autoimmune encephalomyelitis (EAE), we studied the effect of GA on cell populations relevant to pathogenesis and repair within the injured CNS, and explored whether this immunomodulatory treatment can lead to neuroprotection.

We found that the secretion of the key inflammatory factors GM-CSF and IL-17 by spleen cells from EAE-induced mice was drastically reduced following GA treatment. In the CNS of GA-treated mice, Th-17 positive cell occurrence was significantly reduced, with parallel elevation in T-regulatory cells (Tregs). Furthermore, in transgenic mice in which Tregs express diphtheria toxin receptor facilitating their selective depletion, GA was less effective in disease suppression than in wild type mice, thus supporting the role of Tregs in its therapeutic effect. The consequences of GA treatment on the CNS injury inflicted by the disease were studied *in situ* using immunohistochemistry, electron microscopy, and magnetic resonance imaging. These analyses revealed reduced demyelination and neuroaxonal damages, as well as elevation in neuroprotective

repair processes such as neurotrophic factors expression, remyelination and neurogenesis. These combined findings indicate that immunomodulatory treatment can counteract the neurodegenerative disease course, supporting a linkage between immunomodulation, neuroprotection and therapeutic activity in the CNS.

4525

Augmented activation and IL-17 production of mucosal associated invariant T cells in multiple sclerosis

Willing, A., Jäger, J., Reinhard, S., Kursawe, N., Friese, M.A.

Zentrum für Molekulare Neurobiologie, Institut für Neuroimmunologie und Multiple Sklerose, Hamburg, Germany

Multiple sclerosis (MS) is an inflammatory disease of the central nervous system involving focal T cell infiltration. The T cell derived cytokine interleukin (IL)-17 has been linked to MS pathogenesis, while the contribution of the well-characterised IL-17-producing CD4⁺ T helper (TH17) cells is controversial. Besides TH17 cells, mucosal associated invariant T (MAIT) cells produce IL-17 and carry a semi-invariant T cell receptor (TCR) recognizing bacterial and yeast antigens presented by the non-polymorphic, highly conserved major histocompatibility complex (MHC)-related protein 1 (MR1). We previously reported infiltration of MAIT cells in brain lesions and their decrease in the peripheral blood in MS. Here, we first investigated the surface expression of T cell activation markers in MS patients and healthy individuals and found a significant increase of IL-7-receptor-alpha-chain (IL-7Ra) on MAIT cells in MS, which was not observed for other T cell subsets. IL-7 is known to induce IL-17 production by CD4⁺ T cells and MAIT cells, which prompted us to investigate IL-7Ra and IL-17 expression in parallel in a second cohort of MS patients and healthy individuals. Notably, we could detect an elevated IL-7Ra surface expression on MAIT cells in MS, which correlated with an increased frequency of IL-17⁺ MAIT cells. In the same cohort IL-17⁺CD4⁺ T-cell-frequencies were not significantly different in MS patients in comparison to healthy individuals. Our findings implicate a novel role of IL-17-producing MAIT cells in MS pathogenesis driven by increased IL-7Ra expression. Factors inducing augmented MAIT cell activation in MS need to be further investigated.

Gut microbiota drives autoimmune arthritis by unleashing the Tfh response

Teng, F.¹, Klinger, C.¹, Felix, K.¹, Bradley, P.¹, Wu, E.¹, Tran, N.¹, Umesaki, Y.², Wu, H.-J.J.^{1,3}

¹University of Arizona, Immunobiology, Tucson, United States,

²Yakult Central Institute, Tokyo, Japan, ³University of Arizona, Arizona Arthritis Center, College of Medicine, Tucson, United States

Gut microbiota profoundly affects diseases, both inside and outside (systemic) the gut, but the mechanism whereby it affects systemic diseases is unclear. Little is known about whether specific microbiota influences T follicular helper (Tfh) cells, whose excessive responses inflict antibody-mediated autoimmunity. Tfh cells need to be precisely regulated to avoid

autoimmune conditions and accordingly, IL-2 has been shown to dampen Tfh response by inhibiting Tfh differentiation. Using the K/BxN autoimmune arthritis model, we demonstrated that Peyer's patch (PP) Tfh cells are required for a gut commensal, segmented filamentous bacteria (SFB)- induced systemic arthritis despite auto-antibodies being produced predominantly in systemic lymphoid tissues, not PPs. We elucidated that SFB, by driving differentiation and egression of PP Tfh cells into systemic sites, boost systemic Tfh and auto-antibody responses that exacerbate arthritis. Specifically, by using a photoconvertible transgenic mouse line, we demonstrate that SFB increase the egression of PP Tfh cells into the spleen. SFB induce PP Tfh differentiation by limiting the access of IL-2 to CD4⁺ T cells, thereby enhancing Bcl-6, a master regulator of Tfh differentiation, in a dendritic cell-dependent manner. Thus, gut microbiota remotely regulates a systemic disease by driving the induction and egression of gut Tfh cells into systemic sites. These data have strong implications for public health, as we elucidate how a generally benign gut commensal can trigger autoimmune diseases outside the gut by tipping the delicate balance of Tfh response.

MAIT cells reside in the female genital mucosa and are biased towards IL-17 and IL-22 production in response to bacterial stimulation

Gibbs, A.¹, Leeansyah, E.^{2,3}, Introini, A.¹, Paquin Proulx, D.^{2,4}, Hasselrot, K.^{1,5}, Andersson, E.⁶, Broliden, K.¹, Sandberg, J.K.², Tjernlund, A.¹

¹Karolinska Institutet, Unit of Infectious Diseases, Department of Medicine Solna, Center for Molecular Medicine, Karolinska University Hospital Solna, Stockholm, Sweden, ²Karolinska Institutet, Center for Infectious Medicine, Department of Medicine Huddinge, Karolinska University Hospital Huddinge, Stockholm, Sweden, ³Duke-NUS Graduate Medical School, Program Emerging Infectious Diseases, Singapore, Singapore, ⁴George Washington University, Department of Microbiology, Immunology and Tropical Medicine, Washington DC, United States, ⁵Danderyd Hospital, Department of Obstetrics and Gynecology, Stockholm, Sweden, ⁶Capio St. Göran Hospital, Clinical Pathology/Cytology, Stockholm, Sweden

Mucosal-associated invariant T (MAIT) cells are a novel, large innate-like T cell population that recognises microbial riboflavin metabolite antigens presented by the evolutionarily conserved major histocompatibility complex, class I related (MR1) molecules. Following microbial encounters, MAIT cells respond rapidly through cell-mediated cellular cytotoxicity, suppression of intracellular microbial growth, and secretion of pro-inflammatory cytokines. The female genital tract (FGT) mucosa is a critically important site for immune defense against microbes. The presence and role of MAIT cells in the FGT mucosa is unknown.

Here, we found that MAIT cells and MR1⁺ antigen-presenting cells were present in the upper and lower FGT, with distinct tissue localisation of MAIT cells in endometrium versus

cervix. MAIT cells from the FGT and blood displayed a distinct phenotype with expression of IL-18R α , CD127, α 4 β 7, PD-1, as well as the transcription factors PLZF, ROR γ t, Helios, Eomes, and T-bet. Their expression levels of PLZF and Eomes were lower in the FGT compared to blood. When stimulated with *Escherichia coli*, MAIT cells from the FGT displayed a bias towards IL-17 and IL-22 expression, whereas blood MAIT cells produced primarily IFN- γ , TNF, and Granzyme B. Furthermore, although both FGT- and blood-derived MAIT cells were polyfunctional following *E. coli* stimulation, deeper analyses revealed that MAIT cells displayed distinct polyfunctional profiles depending on their anatomical origin. Our data thus reveal that FGT-derived MAIT cells respond to bacterial stimuli in a fashion that is unique to the FGT, supporting their potentially important role in immunological homeostasis and control of microbes at this site.

Conditioning of lung dendritic cells by dietary vitamin A and the gastrointestinal microbiota

Ruane, D., Manzanillo, P., Zhang, H., Diehl, L., Zeng, J., Kljavin, N., Sandoval, W., Xu, M., Ghilardi, N.

Genentech, South San Francisco, United States

Vitamin A deficiency (VAD) is one of the most common micronutrient deficiencies and is associated with profound defects within the adaptive immune system. VAD individuals are especially vulnerable to morbidity and mortality caused by respiratory and gastrointestinal (GI) viral infections. However the exact mechanism by which Vitamin A regulates the antiviral response within the pulmonary compartment remains to be fully elucidated. Here we found that VAD mice have increased susceptibility to influenza infection due to defects within lung dendritic cells (LDC). LDC had decreased capacity to induce IgA isotype switching in B cells and developmental defects due to loss of signaling by all-trans-retinoic acid (RA), a Vitamin A metabolite. Furthermore, we demonstrate that conversion of Vitamin A into RA depends on the presence of intestinal microbiota, but not microbiota in general. MyD88 signaling, presumably as a result of TLR activation by microbial components, induces expression of ALDH enzymes in intestinal epithelial cells (IEC), resulting in the generation of RA. Accordingly, depletion of intestinal microbiota phenocopied Vitamin A deficiency, and restoration of RA signaling in the absence of the GI-microbiota restored host resistance to influenza. Our results identify a role for the GI-microbiota in regulating the phenotype of DCs residing at other mucosal compartments in a RA dependent manner, and thus provide a mechanistic explanation of how Vitamin A deficiency results in host susceptibility to viral pulmonary infections.

Pathogenic NK T cells attenuate clearance and exacerbate immunopathology in chlamydial infections

Armitage, C.¹, Carey, A.¹, Godfrey, D.², Beagley, K.¹

¹*Institute of Health and Biomedical Innovation, Brisbane, Australia,*

²*Australian Research Council Centre of Excellence for Advanced Molecular Imaging at the University of Melbourne, Melbourne, Australia*

Urogenital chlamydial infections continue to increase with over 100 million people affected annually, causing significant economic and public health pressures. Whilst the role of traditional MHCI and II peptide presentation is well defined in chlamydial infections, the role of lipid antigens in immunity remains unclear. Natural killer (NK) T cells are important effector cells that recognise and respond to lipid antigen during infections. Chlamydial infection of antigen-presenting cells facilitates presentation of lipid on the MHCI-like protein, CD1d, which stimulates NK T cells to respond. During urogenital chlamydial infection, wild type (WT) female mice had significantly greater chlamydial burden than CD1d $^{-/-}$ (NKT-deficient) mice, and also had significantly greater incidence and severity of immunopathology in both primary and secondary infections. WT mice had significantly more lymphocytic infiltrate and 59% more fallopian tube occlusion ($P < 0.0016$), and hence infertility, compared to CD1d $^{-/-}$ mice. Transcriptional array analysis of fallopian tubes day 6 post-infection revealed WT mice had elevated levels of IFN γ (6-fold), TNF α (38-fold), IL6 (2.5-fold), IL1 β (3-fold), and IL17 α (6-fold) mRNA compared to CD1d $^{-/-}$ mice. In infected females, both uterine and fallopian tissues had an elevated infiltration of CD4 $^{+}$ (but not CD8 $^{+}$) invariant NK T cells. Lipid mass spectrometry of infected macrophages expressing a cleavable CD1d protein revealed the chlamydial lipid profile presented to NK T cells. Taken together, these data reveal an immunopathogenic role for inflammatory NK T cells in chlamydial infections, facilitated by CD1d-restricted chlamydial lipid presentation by infected antigen-presenting cells.

PPAR γ in dendritic cells and T cells controls induction of pulmonary allergic inflammation

Nobs, S.P.¹, Schneider, C.², Van Rooijen, N.³, Kopf, M.¹

¹*ETH Zürich, Zürich, Switzerland, ²University of California, Department of Medicine, San Francisco, United States, ³Free University Medical Center, Amsterdam, Department of Molecular Cell Biology, Amsterdam, Netherlands*

Peroxisome Proliferator-Activated Receptor gamma (PPAR γ) is a well-established transcription factor which is required for development and function of alveolar macrophages. It is generally recognised as an anti-inflammatory mediator such as controlling polarization of macrophages into an anti-inflammatory or M2 phenotype. In the context of asthma PPAR γ agonists are suggested to reduce type 2 allergic airway inflammation. However, its precise role in this context and the underlying mechanism of action remains largely unclear. Using cell-type specific PPAR γ knockout mice to address the function of PPAR γ in pulmonary allergic inflammation in a more stringent manner, we could show that surprisingly specific absence of PPAR γ in either T cells or dendritic cells protected mice from ovalbumin/alum and house dust mite-induced asthma. PPAR γ was specifically required in lung DCs to polarize naive PPAR γ -sufficient

T cells towards a Th2 phenotype. Similarly, T cells lacking PPAR γ showed a cell intrinsic defect in polarization towards Th2 cells *in vivo*, while Th1 and Th17 polarization was unaffected. Thus we uncover a surprising pro-inflammatory role of PPAR γ in

pulmonary allergy, adding a novel layer of complexity to the biology of this important mediator.

Dendritic cell-intrinsic molecular chaperone grp94/gp96 is critical for maintaining gut tolerance

Liu, B.¹, Yang, Y.¹, Sun, S.², Reizis, B.³, Li, Z.¹

¹Medical University of South Carolina, Department of Microbiology & Immunology, Hollings Cancer Center, Charleston, United States,

²Medical University of South Carolina, Department of Pathology and Laboratory Medicine, Charleston, United States, ³New York University Langone Medical Center, Department of Pathology and Medicine, New York, United States

The intestinal immunity and tolerance are orchestrated by both the innate and the adaptive immune system. Dendritic cells (DCs) are professional antigen-presenting cells that play a critical role in both innate and adaptive immune response. Intestinal DCs recognize and respond to the gut microbiota through multiple pattern-recognition receptors, including TLRs and NLRs. However, how DCs maintain mucosal homeostasis remains incompletely understood. Heat shock protein grp94, also known as gp96, is an essential immune chaperone for TLRs, integrins, and other vital innate receptors. By a genetic strategy, we report here that selective deletion of grp94 from DCs in mice results in alteration of DCs and regulatory T cells in the colonic lamina propria, loss of oral tolerance, and high susceptibility to chemical-induced colitis. Strikingly, DC-specific grp94 deficient mice develop spontaneous colitis. Our findings for the first time demonstrate that DC-intrinsic grp94 plays essential roles in maintaining gut tolerance to prevent inflammatory bowel diseases, and illustrate the importance of protein homeostasis in safeguarding against immune pathology.

1458

CD4+ T cell deficiency results in blunted inflammatory response during dysbiosis-triggered colitis

Roy, U., Strowig, T.

Helmholtz Centre for Infection Research, Braunschweig, Germany

In healthy individuals the intestinal microbiota, a complex microbial ecosystem, and the host maintain a mutually beneficial homeostasis. Changes in the host's health state and environmental factors may disrupt this homeostasis, resulting in dysbiosis. In numerous animal models of human diseases dysbiotic communities can directly modulate disease severity. Our aim is to understand the role of specific components of immune system that interplay with the dysbiotic microbiota to trigger pathologic changes. To do so we study the impact of a dysbiotic community (DysM) resulting from a deficiency of the Nlrp6 inflammasome on the host resulting in increased colitis severity. Important tools are isobiotic mouse lines in which the microbiota can be manipulated at will giving us an opportunity to study the functionalities of immune pathways in homeostasis and dysbiosis.

In this model, DysM-exacerbated dextran sulfate sodium induced colitis severity was drastically decreased in T cell deficient

mice (Tcrbd^{-/-}) compared to control mice suggesting a strong involvement of T cells. Furthermore, MHC class II-restricted TCR-transgenic and CD4-deficient mice were protected supporting that antigen-specific, potentially microbiota specific, CD4+ T cells are required in this model. Along these lines we observed increases in intestinal CD45+CD4+ T cells in DysM mice including both inflammatory IL17+ and Foxp3+ T cells further supported by local increases in proinflammatory cytokines IL-6 and IL-17. Future investigations of the functions of intestinal CD4+ T cells in DysM mice will be required to advance the understanding how a dysbiotic intestinal community results in alteration of disease severity.

Functional role of intestinal dendritic cell subsets in the mucosal IgA response to rotavirus

Hütter, J.¹, Nakawesi, J.², Feng, N.^{3,4}, Greenberg, H.^{3,4}, Butcher, E.^{3,4}, Lahl, K.^{1,2}

¹Technical University of Denmark, National Veterinary Institute, Frederiksberg C, Denmark, ²Lund University, Department of Experimental Medical Science, Lund, Sweden, ³Stanford University, Stanford, United States, ⁴VA Palo Alto Health Care System, Palo Alto, United States

Rotavirus (RV) is a double-stranded RNA (dsRNA) virus that specifically infects epithelial cells of the small intestine causing severe diarrhea especially in infants under the age of 5 years. Intestinal dendritic cells play a crucial role in the recognition of mucosal pathogens but are also involved in maintaining tolerance toward commensal microorganisms. Conventional dendritic cells (cDCs) in the gut are divided into two major subsets. CD103⁺CD11b⁻ (cDC1) cells are well equipped to drive immunity toward viruses through cross-presentation of antigen and IL-12 driven induction of T_H1 responses. They specifically express the pattern-recognition receptor TLR3, which recognizes dsRNA. In contrast, CD103⁺CD11b⁺ (cDC2) cells were shown to promote T_H2 and T_H17 responses and express TLR5, the receptor for bacterial flagellin.

We have previously shown that plasmacytoid dendritic cells (pDCs) play an important role in the mucosal RV-specific IgA response. Secretory IgA clears the virus and also mediates long-term protection in mice and in humans. We here analyzed the function of cDC1 cells in the IgA response as well as the potential interplay of cDC1s and pDCs during RV infection. We show that BATF3-deficient mice that lack cDC1 cells shed virus longer and exhibit markedly reduced RV-specific IgA levels. Optimal activation and migration of cDC1 cells depends on TLR3 expression and is blunted in the absence of pDCs. These data reveal a crucial role for the coordinated action of cDC1 cells and pDCs in the immune response to RV, and a previously unappreciated role for cDC1 cells in the induction of mucosal IgA.

2617

Apoptotic epithelial cells control the abundance of regulatory T cells at barrier surfaces

Nakahashi-Oda, C., Udayanga, K.G.S., Nakamura, Y., Nakazawa, Y., Totsuka, N., Miki, H., Iino, S., Tahara-Hanaoka, S., Honda, S.-I., Shibuya, K., Shibuya, A.
 University of Tsukuba, Tsukuba, Japan

Epithelial tissues continually undergo apoptosis. Commensal organisms inhabiting the epithelium influence tissue homeostasis, in which regulatory T (T_{reg}) cells play a central role. However, the physiological significance of epithelial cell apoptosis and how T_{reg} cell number is regulated are both incompletely understood. Here, we show that apoptotic epithelial cells negatively regulate commensal-stimulated T_{reg} cell proliferation. Gut commensals stimulated $CX_3CR_1^+CD103^+CD11b^+$ dendritic cells (DCs) to produce interferon- γ (IFN- γ), which augmented proliferation of T_{reg} cells in the intestine. Conversely, phosphatidylserine exposed on apoptotic epithelial cells suppressed IFN- γ production by the DCs via CD300a-mediated inhibitory signal, thus suppressing T_{reg} cell proliferation. Our findings reveal a regulatory role of apoptotic epithelial cells in maintaining T_{reg} cell number and tissue homeostasis.

Inhibition of Dectin-1 signaling ameliorates colitis by inducing Lactobacillus-mediated regulatory T cell expansion in the intestine

Tang, C.¹, Kamiya, T.^{1,2}, Iwakura, Y.¹

¹Center for Animal Disease Models, Research Institute for Biomedical Sciences, Tokyo University of Science, Noda, Japan,
²(Present address) Biomedical Research Institute, National Institute for Advanced Industrial Science and Technology-AIST, Tsukuba, Japan

Dectin-1, the receptor for beta-glucans, protects host from fungal infection. However, the role of Dectin-1 in intestinal immunity has not been elucidated completely. We found that Dectin-1-deficient (*Clec7a^{-/-}*) mice were refractory to both dextran sodium sulfate (DSS)- and CD45RB^{high}CD4⁺ T cell-induced colitis associated with an increase of regulatory T (Treg) cells. The proportion of lactobacilli, especially *Lactobacillus murinus* (*L. murinus*), in commensal microflora was increased in *Clec7a^{-/-}* mouse colon accompanied by a decrease of a group of antimicrobial peptides induced by Dectin-1 signaling. *L. murinus* colonization increased Treg cells in the colon. Oral administration of laminarin, a Dectin-1 antagonist, suppressed the development of DSS-colitis, associated with the increase of *L. murinus* and Treg cells. The proportion of closely related lactobacillus species was decreased in inflammatory bowel disease patients. These observations suggest that Dectin-1 regulates the homeostasis of intestinal immunity by controlling Treg cell differentiation through modification of microbiota.

Mendelian susceptibility to mycobacterial disease (MSMD) is a rare genetic condition predisposing otherwise healthy individuals to severe infection by weakly virulent mycobacteria. To date, 11 mutated genes, underlying 21 different genetic etiologies of MSMD, have been described. All of these mutations impair the production of, or response to, IL-12 or IFN- γ . Here we report 3 MSMD patients from two unrelated consanguineous families. All these patients carry essential splicing mutations in *SPPL2A* leading to a complete loss of SPPL2a enzyme expression, and causing the accumulation of SPPL2a's substrate, the N-terminal fragment of CD74, in B-cells and monocytes. Contrary to what is observed in *Spp12a^{-/-}* mice, these patients have normal B-cell frequency and function. *Spp12a^{-/-}* mice also have reduced numbers of CD11b⁺ myeloid dendritic cells (mDC) caused by the CD74 N-terminal fragment accumulation since the double knock out *Spp12a^{-/-} CD74^{-/-}* does not show this reduction. Resembling the mouse model and similarly to MSMD patients with autosomal dominant mutations in *IRF8*, SPPL2a deficient patients also have reduced CD1c⁺ IL-12 producing mDC (mDC₁). Furthermore, we demonstrated that the SPPL2a deficient humans' CD4 T-cells fail to produce IFN- γ in response to stimulation by mycobacterial antigens *in vitro*. In conclusion, our findings suggest autosomal recessive *SPPL2A* deficiency as a new genetic etiology of MSMD, show that human SPPL2a is essential for the homeostasis of IL-12 producing CD1c⁺ DCs and proposes a link between this DC population and T-cell IFN- γ mediated immunity against mycobacteria.

1940**Heterozygous mutations in IKAROS in patients with progressive loss of B cells and hypogammaglobulinemia***Boisson, B.*^{1,2}¹Rockefeller University, New York, United States, ²Institut Imagine UMR 1163, Paris, France

Common variable immunodeficiency disorders (CVID) are characterized by delayed onset of hypogammaglobulinemia in the absence of predisposing factors. The genetic etiology is unknown in the majority of cases and < 10% of patients have a family history of disease. Most patients have normal numbers of B cells but lack plasma cells. Whole exome sequencing and array comparative genomic hybridization were used to analyze a subset of CVID patients with low B cell numbers. Mutant proteins were analyzed for DNA binding using electrophoretic mobility shift assays (EMSA) and confocal microscopy. Flow cytometry was used to analyze peripheral blood lymphocytes and bone marrow aspirates. Six different heterozygous mutations in *IKZF1*, the gene encoding the transcription factor IKAROS, were identified in 29 individuals from 6 families. All of the mutations, 4 amino acid substitutions, an intragenic deletion and a 4.7 Mb multi-gene deletion, involved the DNA binding domain of IKAROS. The proteins bearing missense mutations did not bind target DNA sequences in EMSAs or by confocal microscopy but they did not inhibit the binding of wild type IKAROS. Family studies demonstrated progressive loss of B cells and serum immunoglobulins. Bone marrow aspirates revealed a marked decrease of early B cell precursors but the presence of plasma cells. Heterozygous mutations in the transcription factor IKAROS cause an autosomal dominant form of CVID associated with a striking decrease in B cell numbers.

2037**Human TYK2 deficiency: mycobacterial and viral infections without hyper-IgE syndrome***Boisson-Dupuis, S.**Rockefeller University, New York, United States*

Autosomal recessive, complete TYK2 deficiency was previously described in a patient (P1) with intracellular bacterial and viral infections and features of hyper-IgE syndrome (HIES), including atopic dermatitis, high serum IgE levels, and staphylococcal abscesses. We identified seven other TYK2-deficient patients from five families and four different ethnic groups. These patients were homozygous for one of five null mutations, different from that seen in P1. They displayed mycobacterial and/or viral infections, but no HIES. All eight TYK2-deficient patients displayed impaired but not abolished cellular responses to (a) IL-12 and IFN- α accounting for mycobacterial and viral infections, respectively; (b) IL-23, with normal proportions of circulating IL-17+ T cells, accounting for their apparent lack of mucocutaneous candidiasis; and (c) IL-10, with no overt clinical consequences, including a lack of inflammatory bowel disease. Cellular responses to IL-21, IL-27, IFN- γ , IL-28/29, and leukemia inhibitory factor (LIF) were normal. The leukocytes and fibroblasts of all seven newly identified TYK2-deficient patients, unlike those of P1, responded normally to IL-6, possibly

accounting for the lack of HIES in these patients. The expression of exogenous wild-type TYK2 or the silencing of endogenous TYK2 did not rescue IL-6 hyporesponsiveness, suggesting that this phenotype was not a consequence of the TYK2 genotype. The core clinical phenotype of TYK2 deficiency is mycobacterial and/or viral infections, caused by impaired responses to IL-12 and IFN- α . Moreover, impaired IL-6 responses and HIES do not appear to be intrinsic features of TYK2 deficiency in humans.

3889**Next generation TREC and KREC: quantification of human T- and B-cell replication from purified subsets and dried blood spots***Brooks, G.D.*¹, *Verstegen, R.H.J.*^{2,3}, *Bartol, S.J.W.*², *de Vries, E.*^{4,5}, *van Zelm, M.C.*^{1,2}¹Monash University, Alfred Hospital, Department of Immunology and Pathology, Melbourne, Australia, ²Erasmus Medical Center, Department of Immunology, Rotterdam, Netherlands, ³The Hospital for Sick Children, Department of Pediatric Rheumatology, Toronto, Canada, ⁴Jeroen Bosch Hospital, 4. Department of Pediatrics, 's-Hertogenbosch, Netherlands, ⁵Tilburg University, Scientific Center for Care and Welfare, Tilburg, Netherlands

Screening of newborns for primary immunodeficiencies is being implemented world-wide using quantitative PCR detection of signal joints on excision circles formed by T-cell receptor delta-deletion (TRECs) and immunoglobulin kappa-deletion rearrangements (KRECs). However technical limitations exist that prevent reproducible quantification of cells, and calculation of T-cell replication due to the lack of specific genomic markers, which impact on the sensitivity of these assays. Here, we have developed a new cell line control with TREC construct and a multiplex PCR to quantify T-cell receptor gamma (TRG) rearrangements to overcome these limitations.

A single copy of the TREC construct was retrovirally introduced into the DB01 cell line that was previously established with a KREC construct. We used DNA from this DB01-TREC cell line to correct for efficiencies between the control gene, KREC and TREC PCRs, and showed, from dried blood spots, that neonates with Down syndrome carried lower numbers of T- and B-cells. The multiplex TRG assay detected 90% of alleles in purified $\alpha\beta$ T-cells. Quantifications of TRG rearrangements and intronRSS-Kde coding joints were used to calculate T- and B-cell replication histories in combination with TRECs and KRECs. We showed that neonates with and without Down syndrome carried similar levels of proliferation for T-cells (2.5 divisions) and B-cells (0.6 divisions). Studies into replication histories of naive and memory T cells are ongoing.

These studies provide new insights into T- and B-cell replication in neonates, and our newly developed cell line and TRG assay will help to improve neonatal screening of primary immunodeficiencies world-wide.

1088

Life-threatening enterovirus 71 encephalitis in unrelated children with autosomal dominant TLR3 deficiency*KU, C.-L.¹, Kuo, C.-Y.², Lo, C.-C.¹, Lim, H.K.³, Zhang, S.-Y.³*¹*Chang Gung University, Graduate Institute of Clinical Medical Science, Taoyuan, Taiwan, Republic of China,* ²*Chang Gung Children's Hospital, Taoyuan, Taiwan, Republic of China,*³*Rockefeller University, New York, United States*

The spectrum of diseases of childhood caused by enterovirus 71 (EV71) is broad, ranging from asymptomatic infection or self-limited hand-foot-and-mouth diseases (HFMD) to life-threatening encephalitis. The molecular mechanisms underlying these different clinical presentations remain unknown. We hypothesized that EV71 encephalitis in children might reflect an intrinsic host single-gene defect of anti-viral immunity. We searched for mutations in Toll-like receptor 3 (TLR3), which have been previously found in children with herpes simplex encephalitis (HSE). We sequenced TLR3 and tested the impact of the mutation found. We tested dermal fibroblasts from TLR3-mutated patients and other patients with known genetic defects in TLR3 or related genes, for their response to both poly(I:C) stimulation and EV71 infection. We found that three children with EV71 encephalitis were heterozygous for the TLR3 W769X, E211K and R867Q rare mutations, which were all shown to have severe impact on TLR3 function. Moreover, fibroblasts from the W769X heterozygous patient displayed impaired but not abolished response to TLR3 agonist poly(I:C). We further showed that TLR3-deficient and TLR3 heterozygous W769X fibroblasts were highly vulnerable to EV71 infection. Autosomal dominant TLR3 deficiency may underlie severe EV71 infection with encephalitis. Human TLR3 immunity is non redundant against not only HSV, but also EV71. Children with severe EV71 infection, especially encephalitis, should be tested for inborn errors of TLR3 immunity.

1010

NFκB deficiency: new genes and new insights into CVID pathogenesis*Slade, C.^{1,2,3}, Tempny, J.^{1,2}, Fliegauf, M.⁴, Woon, S.-T.⁵, Scerri, T.^{1,2}, Leung, E.⁶, Bahlo, M.^{1,2}, van der Meer, J.⁷, Ameratunga, R.⁵, Grimbacher, B.⁴, Douglass, J.^{3,8}, Hodgkin, P.^{1,2}, Bryant, V.^{1,2}*¹*Walter & Eliza Hall Institute, Melbourne, Australia,* ²*University of Melbourne, Dept of Medical Biology, Melbourne, Australia,* ³*Royal Melbourne Hospital, Dept. Clinical Immunology & Allergy, Melbourne, Australia,* ⁴*University of Freiburg Medical Center, Center for Chronic Immunodeficiency, Freiburg, Germany,* ⁵*Auckland City Hospital, Dept. Virology & Immunology, Auckland, New Zealand,* ⁶*University of Auckland, School of Medical Sciences, Auckland, New Zealand,* ⁷*Radboud University Nijmegen Medical Center, Dept. Internal Medicine, Nijmegen, Netherlands,* ⁸*University of Melbourne, Dept. Medicine, Melbourne, Australia*

Common Variable Immunodeficiency (CVID), the most common Primary Immunodeficiency, both in Australia and worldwide, is characterised by hypogammaglobulinaemia (reduced serum IgG, IgA and/or IgM) and poor responses to antigens, and is largely a diagnosis of exclusion. As a result, CVID is a clinically heterogeneous disorder; many patients are diagnosed as adults,

despite 1 in 5 being symptomatic since childhood. Until recently the known genetic causes of CVID were mostly recessive, and exceedingly rare; the genetic basis of only 5-10% of CVID patients is known. Here, we identified, by whole-exome sequencing 5 families with CVID, 5 novel mutations in 3 genes within the NFκB pathway. In 3 families with heterozygous mutations in *NFKB1*, and a fourth family with a novel heterozygous *NFKB2* mutation truncated mutant proteins were expressed at reduced levels and were not processed to active mutant forms, but rapidly degraded. In a fifth family a novel homozygous mutation of *NFKBID* was identified. Amongst these individuals with defective NFκB signaling there exist overlapping clinical features, such as alopecia areata, and nodular regenerative hyperplasia of the liver. However there is variability of the severity of the immune defects observed, including the B cell phenotype, autoimmunity and the susceptibility to viral infection. This works suggests that defects in NFκB signalling could account for a significant proportion of CVID with autoimmune complications. Understanding the mechanisms of CVID pathogenesis and the polarising conditions that drive a given immunological phenotype will lead to novel therapeutic strategies for patients with this complex disorder.

1434

Cxcr4 desensitization is required for efficient humoral immune response and plasma cell trafficking*Natt, J.¹, Biajoux, V.¹, Freitas, C.¹, Alouche, N.¹, Sacquin, A.^{2,3,4}, Hemon, P.⁵, Gaudin, F.¹, Fazilleau, N.^{2,3,4}, Espéli, M.¹, Balabanian, K.¹*¹*UMR 996 - Inflammation, Chemokines and Immunopathology -, Inserm, Univ Paris-Sud, Université Paris-Saclay, Clamart, France,* ²*INSERM, U 1043, Toulouse, France,* ³*CNRS, U 5282, Toulouse, France,* ⁴*Centre de Physiopathologie de Toulouse Purpan, Université Toulouse III Paul-Sabatier, Toulouse, France,* ⁵*Plateforme d'Histologie (PHIC), Institut Paris-Saclay d'Innovation Thérapeutique (IPSIT), Clamart, France*

The Warts, Hypogammaglobulinemia, Infections and Myelokathexis Syndrome (WS) is a rare immuno-hematological disorder characterized by chronic pan-lymphopenia caused by heterozygous gain-of-function mutations in *CXCR4*. Patients mount an adaptive humoral immune response following vaccination, but fail to maintain it. The underlying mechanisms are unknown and often associated to the peripheral lymphopenia. We used the *Cxcr4^{+/1013}* knock-in mice that phenocopy WS-related pan-lymphopenia to assess how a gain-of-*Cxcr4*-function impacts on germinal center (GC) formation and vaccine responses. We showed that despite spleen follicular hypoplasia and absence of primary follicles in the lymph nodes (LNs), *Cxcr4^{+/1013}* mice mount a potent immune response against T-dependent antigen (Ag) as shown by increased numbers of Ag-specific GC B cells and plasma cells (PCs) in the spleen and LNs. Mechanistically, we unraveled that the gain-of-*Cxcr4*-function leads to enhanced signaling through Akt and exacerbated PC differentiation upon Cxcl12 exposure. Despite this and similarly to WS patients, the Ag-specific antibody titers were not maintained over time in *Cxcr4^{+/1013}* mice and Ag-specific PCs were almost completely absent from the BM. Surprisingly, we highlighted an accumulation of immature PCs in the BM,

potentially occupying the niches of long-lived Ag-specific PCs. So, failure to maintain the immune response in WS patients could be explained by the CXCR4-mediated deregulation of the adaptive immune response in secondary lymphoid organs, rather than the observed circulating lymphopenia. Therefore, a gain-of-function *Cxcr4* mutation intrinsically alters PC differentiation and homing, potentially accounting for the defective humoral immunity observed in WS patients.

1211

DOCK8-deficient CD4⁺ T cells are biased to a Th2 effector fate at the expense of Th1 and Th17 cells

Dedicator of cytokinesis 8 (DOCK8) deficiency is a combined immunodeficiency caused by autosomal recessive loss-of-function mutations in *DOCK8*. This disorder, often referred to as autosomal recessive hyper IgE, is characterised by elevated levels of serum IgE, severe recurrent cutaneous infections and atopic disease including anaphylaxis to certain foods. Here we investigated the peripheral CD4⁺ T cell compartment in DOCK8 deficient patients to determine whether there are defects present that can account for the disease phenotype in DOCK8 deficiency. We performed in depth analysis of the CD4⁺ T cell compartment of DOCK8-deficient patients with respect to naïve, central memory and effector memory CD4⁺ T cells, and Treg, Tfh, Th1, Th2 and Th17 subsets. Furthermore, cytokine production was determined after a 5-day culture with non-polarising stimulus. We found that DOCK8-deficient memory CD4⁺ T cells were biased towards a Th2 effector fate, characterised by high expression/secretion of IL-4, IL-5 and IL-13. This was at the expense of other Th cell subsets as evidenced by defects in IFN γ -expressing Th1 and IL-17A- and IL-17F-expressing Th17 cells. Thus, investigations into the CD4⁺ T cell compartment in DOCK8 deficient patients provided an explanation for some of the clinical signs of this disorder. On one hand, the Th2 bias is likely to contribute to atopic disease, such as eczema and food allergies, characteristic to DOCK8 deficiency. On the other hand, defects in Th1 and Th17 cells may compromise anti-viral and anti-fungal immunity, respectively in DOCK8-deficient patients.

An autosomal recessive *TCF3* mutation underlies association of agammaglobulinemia and B-cell acute lymphoblastic leukemia

Barbouche, M.R.^{1,2}, Ben-Ali, M.^{1,2}, Yang, J.³, Chan, K.W.³, Mekki, N.^{1,2}, Ben-Mustapha, I.^{1,2}, Mellouli, F.⁴, Bejaoui, M.⁴, Yang, W.-L.³, Aissaoui, L.⁵, Lau, Y.L.³

¹Pasteur Institute of Tunis, Immunology, Tunis, Tunisia, ²University Tunis El Manar, Tunis, Tunisia, ³University of Hong Kong, Hong Kong, China, ⁴Bone Marrow Transplantation Center, Tunis, Tunisia, ⁵Aziza Othmana Hospital, Tunis, Tunisia

TCF3 (*E2A*) gene encodes E12 and E47 transcription factors which are essential in differentiation process of common lymphoid progenitors into B-lineage cells and are key regulators of B-cell development. Herein, we report the first patient with a homozygous mutation in *TCF3* gene, who presented with agammaglobulinemia, absent peripheral blood B cells and developed B-cell acute lymphoblastic leukemia (B-ALL).

The patient was born to Tunisian first cousin parents. He had recurrent pneumonia and meningitis since early childhood and mild facial dysmorphism. At age 7 years he developed pancytopenia and splenomegaly, with a diagnosis of B-ALL made. Complete remission was obtained under chemotherapy but at age 10 years he relapsed and died despite treatment.

Whole exome sequencing revealed a novel homozygous mutation within exon 9 of *TCF3* (c.C807T) resulting in a premature stop codon (p.Q270X). The resulting proteins are predicted to be deleterious since they lack two functional domains, the activation domain 2 and the bHLH domain. The parents were heterozygous for the variant.

Considering the crucial role of *TCF3* in the regulation of normal B cell development, it is not surprising that disruption of this transcription factor causes a profound B cell defect. Since *TCF3* is also known to be affected (translocations and deletions) in B-ALL, this could explain the clinical phenotype herein observed.

Mechanisms of anaphylaxis in human low-affinity IgG receptor locus knock-in mice

Gillis, C.M.^{1,2,3}, Jönsson, F.^{1,2}, Mancardi, D.^{1,2}, Tu, N.⁴, Beutier, H.^{1,2,3}, Van Rooijen, N.⁵, Macdonald, L.E.⁴, Murphy, A.J.⁴, Bruhns, P.^{1,2}

¹Institut Pasteur, Department of Immunology, Unit of Antibodies in Therapy & Pathology, Paris, France, ²INSERM U 1222, Paris, France, ³Université Pierre et Marie Curie, Paris, France, ⁴Regeneron Pharmaceuticals, Inc., Tarrytown, United States, ⁵VU Medical Center, Department of Molecular Cell Biology, Amsterdam, Netherlands

Background: Anaphylaxis can proceed through distinct IgE- or IgG-dependant pathways, which have been investigated in various mouse models. We developed a novel mouse strain in which the human low-affinity IgG receptor locus, comprising both activating (hFc γ RIIA, hFc γ RIIIA, hFc γ RIIIB) and inhibitory (hFc γ RIIB) hFc γ R genes, has been inserted into the equivalent murine locus, corresponding to a locus 'swap'.

Objective: We sought to determine the capabilities of hFcγRs to induce systemic anaphylaxis, and identify the cell types and mediators involved.

Methods: hFcγR expression on mouse and human cells was compared to validate the model. Passive systemic anaphylaxis was induced by injection of heat-aggregated human IVIG, and active systemic anaphylaxis following immunisation and challenge. Anaphylaxis severity was evaluated by hypothermia and mortality. The contribution of receptors, mediators or cell types was assessed by receptor blockade or depletion.

Results: The human to mouse low-affinity FcγR locus swap engendered hFcγRIIA/IIIB/IIIA/IIIB expression in mice comparable to that in humans. Knock-in mice were susceptible to passive and active anaphylaxis that was accompanied by downregulation of both activating and inhibitory hFcγR expression on specific myeloid cells. The contribution of hFcγRIIA was predominant. Depletion of neutrophils, but not monocytes/macrophages or basophils, protected against hypothermia and mortality. Both passive and active anaphylaxis relied on PAF, rather than histamine.

Conclusion: Low-affinity FcγR locus-switched mice represent an unprecedented model of cognate hFcγR expression. Importantly, IgG-anaphylaxis proceeds within a native context of activating and inhibitory hFcγRs; indicating that, despite robust hFcγRIIB expression, activating signals can dominate to initiate a severe anaphylactic reaction.

FGD2 is a novel negative regulator of IgE-dependent mast cell activation

Mackay, G.A.¹, Kuek, L.E.¹, Heng, P.¹, Gavin, A.²

¹University of Melbourne, Dept of Pharmacology & Therapeutics and Lung Health Research Centre, Melbourne, Australia, ²Scripps Research Institute, Dept of Immunology and Microbial Science, La Jolla, United States

Introduction: The faciogenital dysplasia (FGD) family of proteins are guanine nucleotide exchange factors (GEFs) that selectively activate the small G-protein Cdc42. Little is known about the regulatory roles of family members such as FGD2. Given the well-established role of Cdc42 in regulating vesicular trafficking and cell signalling, this study aimed to examine the expression and function of FGD2 in mast cells.

Methods: Bone marrow-derived mast cells (BMMCs) were generated from FGD2^{-/-} mice and IgE-dependent degranulation (β-hexosaminidase release) and cytokine (IL-6) production compared with wild type BMMCs. A murine model of passive systemic anaphylaxis was used to examine the in vivo effects of FGD2 deletion. The expression of FGD2 was measured in BMMCs and the mast cell line RBL-2H3 by quantitative PCR (qPCR) and Western blotting.

Results: FGD2^{-/-} BMMCs showed enhanced IgE-dependent degranulation and IL-6 release. In keeping with this, FGD2^{-/-} mice exhibited a more profound systemic anaphylaxis response (as measured by a decline in core body temperature). FGD2 levels were dramatically down-regulated following FcεRI activation in both WT BMMCs and RBL-2H3 cells.

Discussion and conclusions: Our work identifies FGD2 as a

novel negative regulator of FcεRI signalling in mast cells. The marked down-regulation of FGD2 gene expression upon FcεRI activation would be predicted to reduce the impact of this negative regulating pathway enhancing the severity of allergic reactions. Ongoing work aims to more fully establish the effects of FGD2 at the mechanistic level with a view to harnessing its inhibitory actions as a novel anti-allergic strategy.

Production of a hypoallergenic variant of the major peanut allergen Ara h 2 in the baculovirus insect cell system

Tscheppe, A.¹, Palmberger, D.², Bublin, M.¹, Radauer, C.¹, Palladino, C.¹, Gepp, B.¹, Lengger, N.¹, Grabherr, R.², Breiteneder, H.¹

¹Medical University of Vienna, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria, ²University of Natural Resources and Life Sciences, Department of Biotechnology, Vienna, Austria

Introduction: Ara h 2 is the most important peanut allergen. Currently peanut allergen-specific immunotherapy is not available for clinical use. We produced a hypoallergenic mutant, mtAra h 2, lacking the IgE-binding loops.

Methods: Trichoplusia ni BTI-TN5B1-4 "HighFive" cells were used to produce mtAra h 2 and wtAra h 2. Proteins were purified from the supernatants and their physicochemical characteristics were determined. IgE-binding to purified natural nAra h 2, wtAra h 2 and mtAra h 2 was tested by direct ELISA and inhibition ELISA using sera of five peanut allergic patients.

Results: Mass spectrometry confirmed the absence of post-translational modifications for the main fraction of wtAra h 2. Folding and N-terminal sequence of the wild-type recombinant corresponded to the natural protein. For mtAra h 2, mass spectrometry and N-terminal sequencing yielded results corresponding to those predicted from the sequence. CD-spectrometry showed a high alpha-helix content. Immunoblots with Ara h 2-sensitized patients' sera indicated lower IgE-binding to the mutant than to the wild-type and the natural proteins. Direct ELISA revealed 20-50% reduction of IgE-binding to mtAra h 2 compared with the wild-type allergen. Preincubation of sera with nAra h 2 and wtAra h 2 resulted in 98% and 56% inhibition of IgE-binding to immobilized nAra h 2 while the mutant showed significantly reduced inhibition (34%).

Conclusions: Our mutant is a promising template for designing next-generation hypoallergens. Slightly reduced IgE-binding of wtAra h 2 might be caused by the presence of altered post-translational modifications.

Intensity of local skin memory response varying with the type of locally persisting T cell subsets

Murata, A., Yoshino, M., Hikosaka, M., Hayashi, S.-I.

Division of Immunology, Department of Molecular and Cellular Biology, School of Life Science, Faculty of Medicine, Tottori University, Tottori, Japan

In allergic contact dermatitis (ACD), previously ACD-experienced skin regions show an accelerated swelling upon re-exposure to the same hapten. This 'local skin memory (LSM)' is thought to involve locally persisting immune cells; however, it is unclear which cells determine the intensity of LSM. We found that ear skin of BALB/c but not C57BL/6 (B6) mice showed strong and prolonged LSM responses upon re-exposure to a hapten (1% TNCB).

To explain the difference, we compared immune cell subsets in ACD-experienced ear skin with the opposite vehicle-treated control ears, prior to TNCB re-exposure. In BALB/c mice, CD8⁺ T cells became localized in the epidermis, CD4⁺ and CD8⁺ T cells, and mast cells, increased in the dermis by the experience of ACD. There were few CD3⁺CD4⁺CD8⁻ cells in the skin of BALB/c mice. In B6 mice, by contrast, both ACD-experienced and control ears contained a substantial number of $\gamma\delta$ T cells (CD3⁺CD4⁺CD8⁻) in epidermis, few CD4⁺ or CD8⁺ cells, and increased dermal mast cells. The weak LSM response was impaired in B6-*Rag1*-KO but not mast cell-deficient B6-*Kit^{W-sh/W-sh}* mice, suggesting that LSM involved locally persisting T lineage cells.

These results suggest that,

- 1) strong LSM responses may be formed by locally persisting CD4⁺ and CD8⁺ T cells,
 - 2) locally persisting $\gamma\delta$ T cells generate only a weak LSM responses.
- We will discuss possibilities that the presence of skin $\gamma\delta$ T cells leads to suppression of $\alpha\beta$ T cell-based LSM formation and the strong human LSM responses involve the loss of skin $\gamma\delta$ T cells.

Regulatory role of an oligopeptide transporter SLC15A4 in the inflammatory responses in mast cells

Kobayashi, T., Ohshima, D., Toyama-Sorimachi, N.

National Center for Global Health and Medicine, Tokyo, Japan

SLC15A4 is a proton-coupled amino acid/oligopeptide transporter that resides in the late endosome/lysosome of immune cells. We have reported that SLC15A4 is necessary for endo/lysosome-dependent inflammatory responses of DCs and B cells including TLR7/9- or mTORC1-mediated signaling events by controlling amino acids/proton concentration in the vesicles. Mast cells have specialized lysosomes, in which histamine, proteases and other inflammatory mediators are included, and secretion of these granules is the pivotal in their functions. We here investigated the requirement of SLC15A4 in the lysosome-dependent mast cell functions using SLC15A4-deficient mice.

SLC15A4^{-/-} mast cells showed striking alteration of lysosomal morphology. This was caused by enhancement of lysosome biogenesis, since nuclear localization of TFEB, a master regulator of lysosome biogenesis, which is regulated by mTORC1, was augmented in SLC15A4-deficient mast cells. Upon Fc ϵ RI crosslinking, SLC15A4^{-/-} mast cells released higher amounts of histamine than wild type (WT). Consistent with this, serum histamine levels were increased in SLC15A4-deficient mice in IgE-mediated passive anaphylaxis. In contrast, Fc ϵ RI-mediated cytokine productions such as TNF α or IL-6 in SLC15A4^{-/-} mice were comparable with WT mice. When mast cells were stimulated with IL-33, SLC15A4^{-/-} mast cells produced higher amounts of inflammatory cytokines than WT. Furthermore,

SLC15A4-deficient mice showed enhanced response than WT in airway inflammation induced by IL-33. Our results indicated that SLC15A4-mediated regulation of endo/lysosomal condition have an enormous impact on mast cell's effector functions and subsequent allergic responses. In this presentation, we discuss the mechanism of how SLC15A4-mediated regulation of endo/lysosomal condition regulate mast cell's effector functions.

Posttranscriptional control of antigen-specific T cell proliferation and allergen induced airway inflammation by RNA binding protein HuR

Ellis, J.S.^{1,2}, Techasintana, P.^{1,2}, Glascock, J.^{1,2}, Ridenhour, S.², Atasoy, U.^{1,2}

¹University of Missouri, Molecular Microbiology & Immunology, Columbia, United States, ²University of Missouri, Surgery, Columbia, United States

RNA binding protein HuR (ELAVL1) governs transcript stability of IL-4, IL-13 and GATA-3 mRNAs, thereby controlling Th2 differentiation. We hypothesized that HuR plays a role in antigen induced T cell activation and initiation of allergic airway inflammation. We conditionally ablated HuR in T cells prior to activation (distal Ick-Cre.ROSA HuR^{fl/fl} mouse). Half of mature CD4⁺ T cells were HuR deficient in these mice. To determine the effects of HuR KO in T cells, mice were immunized with OVA, boosted 7 days later, and antigen specific proliferative responses were measured *in vitro*. Despite being capable of proliferation upon anti-CD3/CD28 stimulation, YFP⁺ (HuR KO) T cells did not proliferate in response to antigen while YFP⁻ control cells had no proliferative defects. We then used the OVA challenge model of airway inflammation to ascertain effects of HuR KO *in vivo*. HuR KO mice had significantly less total cellular inflammation and significantly reduced BAL IL-13. To determine the mechanism of suppression, we conducted *in vitro* activation experiments. HuR KO CD4⁺ T cells were sorted into YFP⁺ and YFP⁻ pools and activated. YFP⁺ T cells had significant decreases in IL-4, IL-5, IL-13 but not IFN γ protein. Gata-3, IL-4 and IL-2Ra (CD25) transcription were significantly reduced. KO T cells have reductions in pSTAT5 signaling which is required for robust Th2 differentiation. While only 50% of CD4⁺ T cells lack HuR, there was total suppression of Th2 differentiation in airway inflammation. These data elucidate a critical role for HuR in regulating Th2 differentiation and allergic airway inflammation.

Tolerogenic immune modifying nanoparticles are a highly efficacious antigen-specific therapy for the treatment of Th2-mediated allergic airway inflammation

Smarr, C.¹, Shea, L.², Podojil, J.R.³, Getts, D.^{1,4}, Miller, S.D.¹

¹Northwestern University Feinberg School of Medicine, Chicago, United States, ²University of Michigan Medical School, Ann Arbor, United States, ³Cour Pharmaceuticals Development Co, Northbrook, United States, ⁴Cour Pharmaceuticals Development Co, Chicago, United States

Specific immunotherapy (SIT) is the most widely used treatment for allergic diseases, however, clinical applications of SIT require

a long period of dose escalation with soluble antigen and carry a significant risk of adverse reactions. We hypothesized that Tolerogenic Immune Modifying Nanoparticles (TIMP), which are in clinical development for treating celiac disease, would also be effective for the induction of immune tolerance in murine models of Th2-mediated allergic airway inflammation. Initially, using the model antigen, Ovalbumin we demonstrate that antigen-conjugated to the surface of polystyrene nanoparticles, while effective for the prophylactic induction of tolerance, induce anaphylaxis in pre-sensitized mice. Similarly, antigen-conjugated Immune Modifying Nanoparticles, derived from PLGA, are effective prophylactically. In contrast to the polystyrene nanoparticles, the PLGA nanoparticles are well tolerated by sensitized animals, but were not as effective at inhibiting airway inflammation when administered therapeutically. This efficacy, however, was overcome using TIMP. TIMP encapsulating the allergen were well tolerated, and most importantly TIMP inhibited OVA/Alum Th2 responses and airway inflammation when given either prophylactically or therapeutically. We show that this tolerance strategy may also be applied to Japanese Cedar Pollen airway inflammation, with TIMP containing pollen antigens abrogating JCP airway inflammation. In both models, this abrogation was not the result of immune deviation, but was correlated with a specific inhibition of antigen specific T cell responses and expansion of regulatory T cells. Thus, we illustrate the TIMP platform to be a safe and effective strategy to treat allergic airway inflammation without the need for nonspecific immunosuppression.

Gut microbiota, bacterial metabolites and metabolite-sensing GPCRs determine mucosal tolerance and protection against food allergy

Macia, L.¹, Tan, J.², Mackay, C.²

¹University of Sydney, Charles Perkins Centre, Physiology, The University of Sydney, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia

Incidence of food allergy has increased dramatically in recent decades particularly in Western countries. The diet hypothesis states that western diet enriched in fat and sugars while deprived in fibre contributes to development of western diseases such as allergy. Dietary fibre is potent prebiotic, reshaping beneficially gut microbiota. It is also fermented in the colon by anaerobic bacteria into short chain fatty acids (SCFA) that bind specific G-protein coupled receptors widely expressed in the host.

The aim of this study was to determine the impact of diet enriched in dietary fibre and SCFA on the development of food allergy in mice.

Mice were fed on diets either enriched or deprived in fibre in models of oral tolerance to peanut and of peanut allergy. In both models, dietary fibre was beneficial as enhanced oral tolerance and protection from food allergy were observed under high fibre feeding conditions. SCFA were behind these benefits as both acetate and butyrate protected from development of peanut allergy while propionate had no effects. Accordingly, mice knockout for GPR43 or for GPR109A, respectively preferential receptor for acetate and butyrate, were not protected from

food allergy development under high fibre feeding conditions. To determine the role of gut microbiota, germ free mice were reconstituted with microbiota isolated from high fibre vs zero fibre fed mice and we found that the first was protective in food allergy.

In conclusion, high fibre feeding protects from food allergy development by reshaping of gut microbiota and through the SCFA acetate and butyrate.

Contact hypersensitivity is ameliorated by 17,18-epoxy-eicosatetraenoic acid, a metabolite from eicosapentaenoic acid, in the skin

Nagatake, T.¹, Shioyama, Y.², Honda, T.³, Isobe, Y.⁴, Arita, M.⁴, Matsumoto, N.¹, Shimojima, M.¹, Tiwari, P.¹, Suzuki, H.¹, Yasutomi, Y.², Kiyono, H.⁵, Kabashima, K.³, Kunisawa, J.^{1,5,6,7}

¹National Institutes of Biomedical Innovation, Health and Nutrition, Laboratory of Vaccine Materials, Ibaraki, Japan, ²Tsukuba Primate Research Center, National Institutes of Biomedical Innovation, Health and Nutrition, Laboratory of Immunoregulation and Vaccine Research, Tsukuba, Japan, ³Kyoto University Graduate School of Medicine, Department of Dermatology, Kyoto, Japan, ⁴RIKEN Center for Integrative Medical Sciences, Laboratory for Metabolomics, Yokohama, Japan, ⁵Institute of Medical Science, University of Tokyo, Division of Mucosal Immunology, Department of Microbiology and Immunology / International Research and Development Center for Mucosal Vaccines, Tokyo, Japan, ⁶Osaka University, Graduate School of Medicine / Pharmaceutical Sciences / Dentistry, Suita, Japan, ⁷Kobe University, Graduate School of Medicine, Kobe, Japan

Our group has previously reported that dietary intake of ω 3 polyunsaturated fatty acids-rich linseed oil led to the increase of 17,18-epoxy-eicosatetraenoic acid (17,18-EpETE), a metabolite of eicosapentaenoic acid, in the body, which could inhibit the development of allergic responses in the intestine. In this study, we extend our study to assess the effects of 17,18-EpETE on contact hypersensitivity in the skin. When mice were preventively or therapeutically treated with 17,18-EpETE, the development of dinitrofluorobenzene-induced contact hypersensitivity was inhibited, which was associated with the decrease of neutrophil accumulation in the skin without affecting the dendritic cell-cluster formation and cytokine productions (e.g., IL-17A and IFN γ) from T cells. 17,18-EpETE suppressed Rac activation in neutrophils and consequently inhibited their infiltration to the skin. Unlike 17,18-EpETE, its metabolite 17,18-diHETE did not show any effects on contact hypersensitivity. It was also shown that therapeutic treatment of 17,18-EpETE ameliorated contact hypersensitivity in cynomolgus monkey. These results indicate that 17,18-EpETE could be applied to be a therapeutic agent for the control of allergic inflammatory diseases.

IRF8-dependent DCs play a key role in the regulation of CD8 T cell responses to epithelial-derived antigen in the steady state but not in inflammation

Joeris, T.^{1,2}, Gomez Casado, C.², Holmkvist, P.², Luda, K.², Tavernier, S.³, Lambrecht, B.N.³, Agace, W.W.^{1,2}

¹Danish Technical University - DTU, National Veterinary Institute - Section of Immunology and Vaccinology, Fredrighsberg C, Denmark,

²Lund University, Experimental Medical Sciences- Section for Immunology, Lund, Sweden, ³Inflammation Research Center (IRC), VIB-UGent, Ghent, Belgium

Along the process of epithelial self-renewal, antigens derived from apoptotic intestinal epithelial cells (IECs) are taken up by antigen presenting cells (APCs), transported to the gut-draining lymph nodes and cross-presented to CD8 T cells. In steady state, rapid tolerization of CD8 T cells reactive towards epithelial-derived antigens is crucial to maintain tissue homeostasis. In contrast, infection of IECs by intracellular pathogens requires induction of cytotoxic CD8 T cells (CTLs) towards epithelial-associated, pathogen-derived antigens. Currently, little is known about the regulation of CD8 T cells by intestinal APCs in these two different contexts. Since IRF8-dependent dendritic cells (IRF8-DCs) have superior cross-presenting capabilities, we aimed to investigate their role in this process. IFABP-tOva mice, expressing the model-antigen Ovalbumin (Ova) in IECs, were used as recipients to set up chimeras using either CD11c-cre. Irf8^{fl/fl} bone marrow, which cannot generate IRF8-DCs, or cre-negative Irf8^{fl/fl} control bone marrow. Whereas transfer of Ova-specific CD8 T cells (OT-I cells) to steady state control chimeras resulted in their rapid tolerization, OT-I cells transferred to CD11c-cre.Irf8^{fl/fl} chimeras spontaneously developed into CTLs, causing epithelial destruction and intestinal inflammation. However, when the TLR7-ligand R848 was applied as an inflammatory trigger mimicking viral infection in addition to OT-I transfer, expansion of CTLs occurred at similar rates in both, CD11c-cre. Irf8^{fl/fl} and control chimeras. Taken together, this demonstrates that IRF8-DCs are crucial for the rapid tolerization of CD8 T cells reactive towards epithelial-derived antigen in steady state, but are not essential for the induction of CTLs in an inflammatory setting such as found in infection.

4051

tRNAs: new regularors of immunity?

Arguello, R.J.¹, Reverendo, M.¹, Terawaki, S.¹, Combes, A.¹, Vu-Manh, T.P.¹, Santos, M.², Gatti, E.¹, Pierre, P.^{1,2}

¹CIML, Marseille, France, ²University of Aveiro, Aveiro, Portugal

Dendritic cells (DCs) respond to microbial cues by activating several coordinated metabolic and gene expression programs that altogether maximize their capacity to orchestrate immune responses. Translation of costimulatory molecules, cytokines and other induced mRNAs is an essential part of the program and it is tightly regulated. Recently, a connection between ribosomal speed of elongation, mRNA stability and protein expression has been found tumors and model

organisms. Analysing microarray data, we found that genes involved in tRNAs metabolism were coordinately regulated during the first hours after DC activation, suggesting a role connecting transcriptional and translational programs during DCs maturation. To test this hypothesis, we performed tRNA microarrays, codon usage analysis in DC transcriptomic data, and studied the effect of modulating tRNA metabolic pathways in the capacity of DCs mature in response to different stimuli. We have found, an essential inducible regulatory program in DCs that involves qualitative and quantitative changes in the tRNA pool and the presence of an evolutionarily conserved bias of codon usage in genes annotated to immune function. As we could show by using reporter with different codon usage his program affects both translation mRNA stability and antigen presentation. A deeper understanding on how the translation machinery is modified upon immune activation and how it affects decoding of mRNAs is required in order to further characterize this previously unexplored feature of immune gene regulation, which is embedded in the genetic code.

Characterization of Sirpa+ dendritic cell paralysis following systemic inflammatory response syndrome

Valikhani, S., Mackay, L., Mueller, S., Roquilly, A., Villadangos, J. Doherty Institute, Microbiology & Immunology, University of Melbourne, Melbourne, Australia

Systemic/severe infections cause Systemic Inflammatory Response Syndrome (SIRS). The period of immunosuppression following SIRS (lasting several weeks) is associated with an increased risk of secondary infections. Impairment of dendritic cells (DCs) (primary initiators of T-cell immunity) clearly plays a prominent role in this inhibition. Our current studies have shown that SIRS triggers the lasting production of altered signals leading to sustained production of paralysed CD8+ DC; these have poor antigen presenting and T cell stimulating activity until the effect of SIRS decreases leading to return of normal signals. In this project, we aim to further characterise DC paralysis and extend the study to Sirpa+ (CD8-) DCs that are involved in classical antigen presentation. We used mouse models that utilized different SIRS triggers such as CpG (bacterial mimic), *E. coli* and Influenza A to initiate DC paralysis. Our results thus far show that newly formed Sirpa+ DCs (previously not exposed to SIRS trigger) were paralysed for up to 21 days following CpG-induced SIRS but not *E. coli*-induced SIRS probably due to the pneumonia model causing only local DC paralysis rather than systemic. Other functional defects that were found to be present in both DC subsets using the CpG model included decreased cytokine production and phagocytosis. Furthermore, transcriptomic analyses of paralysed Sirpa+ DC has identified several potential paralysis markers that could be used in future investigations. Our ultimate goal is to develop strategies to manage patients with SIRS-induced immunosuppression and to develop therapeutic treatments to prevent, shorten or overcome DC paralysis.

T cell help amplifies innate signals in CD8+ DC for optimal CD8+ T cell priming

Greger, M.¹, Whitney, P.G.¹, Stock, A.T.¹, Davey, G.M.¹, Tebartz, C.¹, Bachem, A.¹, Mintern, J.D.², Strugnelli, R.A.¹, Turner, S.J.¹, Gebhardt, T.¹, O'Keeffe, M.³, Heath, W.R.¹, Bedoui, S.¹

¹The University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ²The University of Melbourne, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ³Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia

DC often require stimulation from CD4+ T cells to propagate CD8+ T cell responses, but precisely how T cell help optimizes the priming capacity of DC and why this appears to differ between varying types of CD8+ T cell immunity remains unclear. We show that CD8+ T cell priming upon HSV-1 skin infection depended on DC receiving stimulation from both IFN- α/β and CD4+ T cells to provide IL-15. This was not an additive effect, but resulted from CD4+ T cells amplifying DC production of IL-15 in response to IFN- α/β . We also observed that increased innate stimulation reversed the helper-dependence of CD8+ T cell priming and that the innate stimulus, rather than the CD4+ T cells themselves, determined how 'help' was integrated into the priming response by DC. These findings identify T cell help as a flexible means to amplify varying suboptimal innate signals in DC.

3238

Involvement of XCR1-expressing dendritic cells through the XCR1-XCL1 chemokine axis in intestinal immune homeostasis

Ohta, T.^{1,2}, Hemmi, H.^{1,2}, Kaisho, T.^{1,2}

¹Wakayama Medical University, Institute of Advanced Medicine, Department of Immunology, Wakayama, Japan, ²Osaka University, WPI Immunology Frontier Research Center, Suita, Japan

Intestinal immune homeostasis depends on innate and adaptive immune cells. Dendritic cells (DCs), which are professional Ag presenting cells linking innate and adaptive immunity, consist of several functionally distinct subsets. A DC subset expressing XCR1, a chemokine receptor conserved across mammalian species, is involved in protective immunity against microbial infection or tumors. However, it remains unknown how XCR1-expressing DCs are involved in the intestinal immune homeostasis. Here, we have generated and analyzed the mutant mice, XCR1-DTA mice, in which XCR1-expressing DCs are specifically ablated due to the expression of diphtheria toxin A subunit (DTA). In XCR1-DTA mice, all lamina propria and intraepithelial T cell populations were decreased concomitantly with defective survival, although splenic and lymph node (LN) T cells were normal. The remaining intestinal T cells exhibited defective intestinal T cell phenotype, i.e. higher and lower expression of CD62L and CD103. XCR1-DTA mice showed exaggerated manifestations of chemically induced colitis, indicating regulatory roles of XCR1-expressing DCs or intestinal T cells in inflammation. Furthermore, XCR1- or its ligand XCL1-

deficient mice also showed intestinal T cell decrease, suggesting that XCR1 is not just a marker, but involved in the intestinal homeostasis. The XCR1-XCL1 axis is also involved in homeostatic migration of XCR1-expressing DCs, because lamina propria and mesenteric LN XCR1-expressing DCs are increased and decreased, respectively, in XCR1- or XCL1-deficient mice. This study thus clarified that XCR1-expressing DCs play critical roles in the intestinal immune homeostasis through the XCR1-XCL1 chemokine axis, which is a novel regulatory point for intestinal immune system.

2232

Molecular basis for the efficient processing of antigens taken up by Clec9A, a DAMP receptor on dendritic cells

Tan, P.S.¹, Tullett, K.¹, Park, H.-Y.¹, Gruber, E.¹, Radford, K.², Nicola, N.³, Zhang, J.-G.³, Shortman, K.³, Caminschi, I.¹, Lahoud, M.¹

¹Monash University, Clayton, Australia, ²Mater Research Institute-University of Queensland, Brisbane, Australia, ³Walter & Eliza Hall Institute of Medical Research, Parkville, Australia

Dendritic cells (DC) use a variety of cell surface receptors to monitor the environment for potential dangers, including cells that have died of non-homeostatic causes (eg. infected cells), to induce appropriate immune responses. Clec9A is a DC-specific Damage-Associated Molecular Pattern receptor, that is expressed by mouse and human cross-presenting DC subsets. Clec9A recognises dead cells and plays an important role in the recognition and processing of dead cell-derived Ag. Our research has focussed on identification of Clec9A ligands, and determining the molecular basis of Clec9A recognition of dead cells. We identified that Clec9A recognises filamentous actin revealed by dead cells, to facilitate trafficking of dead cell-derived Ag. We sought to determine the proteins within DC that regulate Clec9A function and intracellular trafficking. We identified Clec9A interacts with an E3 Ubiquitin ligase, which regulates ubiquitination of Clec9A complexes, thereby targeting Clec9A complexes for downstream processing and regulating Clec9A function. Our research is currently focussed on elucidating the control of Clec9A by ubiquitination, and on characterising the molecular interactions that underpin Clec9A function and the role of these interactions in mediating immune responses.

Transcription factor Ikaros regulates lineage choice in dendritic cell-committed progenitors

Roediger, B.^{1,2}, Mitchell, A.^{2,3}, Bailey, C.^{2,3}, Ashurst, T.⁴, Jain, R.^{2,3}, Shklovskaya, E.^{3,5}, Saunders, B.^{2,3,6}, Rasko, J.E.^{2,3,7}, King, N.J.C.⁴, Fazekas de St. Groth, B.^{2,3}, Holst, J.^{2,3}, Weninger, W.^{2,3,7}

¹Centenary Institute, University of Sydney, Sydney, Australia, ²Sydney Medical School, Sydney, Australia, ³Centenary Institute, Sydney, Australia, ⁴University of Sydney, Sydney, Australia, ⁵Sydney Children's Hospital, Sydney, Australia, ⁶University of Technology Sydney, Sydney, Australia, ⁷Royal Prince Alfred Hospital, Sydney, Australia

Dendritic cells (DCs) comprise a heterogeneous population of antigen presenting cells of which different subsets perform

specialized functions. How DC subset determination is regulated remains incompletely understood. Previous studies have shown that CD11b⁺ conventional (lymphoid) DCs require high levels of the transcription factor Ikaros for their development, but how and where Ikaros exerts its action within the DC lineage remains unknown. It also remains unclear what roles, if any, Ikaros plays in the other DC subsets. We have identified a cell-intrinsic requirement for Ikaros by both lymphoid-resident and migratory CD11b⁺ DCs, part of which is attributable to an upstream requirement in pre-DCs. We further demonstrate that DC progenitors with low levels of Ikaros are predisposed to differentiate into the CD8⁺/CD103⁺ DC pathway at the expense of CD11b⁺ DC development. This developmental bias offsets the pre-DC defect in the CD8⁺/CD103⁺ DC lineage but further compromises CD11b⁺ DC development. Collectively, our data identify a critical role for Ikaros in fate determination within the DC lineage, and lend support for a shared developmental pathway by lymphoid and non-lymphoid CD11b⁺ DCs.

1924

BCG skin infection triggers IL-1R-MyD88-dependent migration of EpCAM^{low} CD11b^{high} skin dendritic cells to draining lymph node during CD4⁺ T-cell priming

Bollampalli, V.P.¹, Yamashiro, L.H.¹, Feng, X.¹, Bierschenk, D.¹, Gao, Y.¹, Blom, H.², Henriques-Normark, B.¹, Nylén, S.¹, Rothfuchs, A.G.¹
¹Karolinska Institutet, MTC, Stockholm, Sweden, ²Royal Institute of Technology, Science for Life Laboratory, Stockholm, Sweden

The transport of antigen from the periphery to the draining lymph node (DLN) is critical for T-cell priming but remains poorly studied during infection with *Mycobacterium bovis* Bacille Calmette-Guérin (BCG). To address this we employed a mouse model to track the traffic of Dendritic cells (DCs) and mycobacteria from the BCG inoculation site in the skin to the DLN. Detection of BCG in the DLN was concomitant with the priming of antigen-specific CD4⁺

T cells at that site. We found EpCAM^{low} CD11b^{high} migratory skin DCs to be mobilized during the transport of BCG to the DLN. Migratory skin DCs distributed to the T-cell area of the LN, co-localized with BCG and were found in close apposition to antigen-specific CD4⁺ T cells. Consequently, blockade of skin DC traffic into DLN dramatically reduced mycobacterial entry into DLN and muted T-cell priming. Interestingly, DC and mycobacterial entry into the DLN was dependent on IL-1R-I, MyD88, TNFR-I and IL-12p40. In addition, we found using DC adoptive transfers that the requirement for MyD88 in BCG-triggered migration was not restricted to the migrating DC itself and that hematopoietic expression of MyD88 was needed in part for full-fledged migration. Our observations thus identify a population of DCs that contribute towards the priming of CD4⁺ T cells to BCG infection by transporting bacilli into the DLN in an IL-1R-MyD88-dependent manner and reveal both DC-intrinsic and -extrinsic requirements for MyD88 in DC migration.

Immunoregulation by O-GlcNAc glycosylation in dendritic cells

Gupta, N.¹, Meuter, S.², Infusini, G.³, Zhan, Y.³, Mintern, J.D.¹, Villadangos, J.A.^{1,2}

¹Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ²The Doherty Institute for Infection and Immunity, University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ³The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

O-GlcNAc glycosylation is a unique post-translational modification found on nucleo-cytoplasmic proteins. It involves addition of a monosaccharide (GlcNAc) on serine or threonine residues of proteins such as kinases, phosphatases, metabolic enzymes, cytoskeletal proteins and transcription factors, often inhibiting or promoting phosphorylation of the same proteins. The enzymes O-GlcNAc transferase (OGT) and O-GlcNAcase (OGA) catalyse the addition and removal of O-GlcNAc respectively. O-GlcNAc glycosylation acts as a nutrient and environmental sensor and by engaging in an extensive crosstalk with phosphorylation, regulates various cellular processes.

Considering the transcripts of O-GlcNAc cycling enzymes are highly expressed in immune cells, we have investigated the role of O-GlcNAc glycosylation in dendritic cells (DCs). Genetic alteration of OGT/OGA expression in DCs affected T cell priming and modulated pro-inflammatory cytokine and chemokine production. Using biochemical and proteomic/mass spectrometric methods, we identified differential O-GlcNAcylation of proteins in resting and activated DCs, of which several proteins played key roles in signalling and metabolic processes.

Overall, we demonstrate that O-GlcNAcylation is a critical protein modification that regulates DC physiology and function.

Activation of the myeloid-specific Src-family kinase Hematopoietic Cell Kinase (HCK) promotes proliferation and survival of immune cells, and triggers hematological malignancies as a tumor cell-intrinsic oncogene. However, the role of HCK in the tumor stroma of solid cancers remains unexplored.

We analyzed the expression level of HCK in matched biopsies from sporadic colorectal cancer patients and observed elevated HCK phosphorylation in more than half of tumors compared to unaffected colons. Analysis of corresponding RNAseq data revealed a striking correlation between tumors with high HCK

gene expression and a gene signature of tumor-promoting alternatively-activated macrophages (AAMs). To functionally assess this observation, we subjected Hck^{CA} mice that express a constitutively active form of the kinase (Hck^{CA}) to a chemically-induced model of sporadic colorectal cancer. Hck^{CA} mice developed more and larger tumors compared to wild-type (WT) animals, and this was associated with a significant increase in AAMs in tumors of Hck^{CA} mice. Likewise, adoptive bone-marrow transfer experiments enhanced tumor formation and AAM differentiation in WT mice reconstituted with Hck^{CA} bone-marrow, with a reciprocal decrease of these parameters in Hck^{CA} mice reconstituted with WT bone-marrow. Accordingly, pharmacological inhibition of Hck activity suppressed AAM polarization and the growth of grafted colorectal tumors.

Together, our findings suggest that increased Hck activity in the tumor stroma promotes the progression of solid cancers by modulating the phenotype of tumor-associated myeloid cells. Thus, Hck represents a rational therapeutic target for macrophage re-education in solid cancers by limiting polarization of tumor-promoting AAMs.

Oncolytic virus-mediated immunotherapy

Bourgeois-Daigneault, M.-C., Roy, D., Falls, T., Bell, J.
Ottawa Hospital Research Institute, Ottawa, Canada

The lack of treatment options for patients with chemotherapy-resistant cancers is pushing forward the rapid development of alternative therapies. One such option, especially for disseminated or recurrent diseases, is the use of oncolytic viruses, with the first candidate now approved for the use in patients. Oncolytic viruses are known to specifically destroy tumors by mediating direct killing and tumor vascular shutdown, but the induction of an efficient and persistent anti-tumor immune response is a facet that is underappreciated. Using the clinical trial candidate rhabdovirus Maraba MG1 in orthotopic murine breast tumor models, we demonstrate here the importance of this immune response. Our results show that the administration of MG1 is sufficient to control the growth of subsequent tumors and even cure some animals without the need for further treatments. The virus induces an efficient tumor-specific immune response and recruits immune cells to the tumor. Also, tumor-infiltrating lymphocytes are able to penetrate the tumor more profoundly. Importantly, treatment with MG1 causes the upregulation of PDL1 by tumor cells and active regulatory T cells were found in greater amounts. Given the recent success of immune checkpoint inhibitors, we investigated if this second treatment could further improve oncolytic virotherapy. Indeed, our data demonstrate the successful combination of MG1 with immune checkpoint inhibitors in tumor models that are usually resistant to the latter. We believe that our study is the first to reveal the extent of the potential of oncolytic viruses as immunotherapeutic agents.

CIS is a potent checkpoint in NK cell-mediated tumour immunity

Huntington, N.
WEHI, Parkville, Australia

Natural killer (NK) cells have evolved to detect and kill aberrant cells with this activity being governed by the cytokine interleukin (IL)-15 and foreign and self-ligands. We have identified CIS (Cytokine-inducible SH2-containing protein; *Cish* gene) as the critical negative regulator of IL-15 signalling in NK cells. *Cish* was rapidly induced in response to IL-15 and deletion of *Cish* rendered NK cells hypersensitive to IL-15, as evidenced by superior proliferation, survival, IFN- γ production and cytotoxicity towards tumours. This was associated with enhanced JAK/STAT signalling in *Cish*-deleted NK cells. Correspondingly, CIS interacted with the tyrosine kinase JAK1, inhibiting its enzymatic activity and targeting JAK for proteasomal degradation. *Cish*^{-/-} mice were resistant to melanoma, prostate and breast cancer metastasis *in vivo*, and this was intrinsic to NK cell activity. This study has uncovered a potent checkpoint in NK cell-mediated tumour immunity and holds promise for novel immunotherapies directed at blocking CIS function.

Mechanisms driving co-inhibitory receptor expression on T cells

Chihara, N.¹, Madi, A.¹, Kondo, T.¹, Singer, M.², Zhang, H.¹, Wang, C.¹, Kurtulus, S.¹, Burkett, P.¹, Regev, A.², Anderson, A.¹, Kuchroo, V.¹
¹Evergrande Center for Immunologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, United States, ²Broad Institute of MIT and Harvard, Cambridge, United States

The dysfunctional or exhausted CD8⁺T cells that arise in chronic disease settings such as cancer exhibit deficits in effector functions and express high levels of co-inhibitory receptors, such as PD-1 and CTLA-4. The expression of these receptors contributes to the maintenance of dysfunctional phenotype as blockade of these receptors has been associated with the recovery of effector T cell responses in multiple experimental tumor models. Indeed, the blockade of both CTLA-4 and PD-1 has now been successfully translated to the clinic for the treatment of several different cancers. In addition to CTLA-4 and PD-1, tumor-infiltrating lymphocytes (TILs) have been noted to co-express other co-inhibitory receptors (Tim-3, Lag-3, TIGIT), indicating shared regulatory mechanisms driving their expression. We have used cytometry by time of flight (CyTOF) to examine the degree of co-variance of co-inhibitory and co-stimulatory receptors on T cells at the single cell level both *in vitro* and *in vivo*. We have further identified an immunoregulatory cytokine that drives the expression of multiple known co-inhibitory receptors including Tim-3, Lag-3 and TIGIT. Our findings not only provide insight into the extracellular signals that drive the expression of co-inhibitory receptors in T cells but also provide a platform for the identification of novel molecules and the molecular mechanism underlying the co-expression of co-inhibitory receptors on T cells during T cell dysfunction.

T cell exhaustion was first described in mice during chronic lymphocytic choriomeningitis virus (LCMV) infection and later shown to occur in humans during persistent infections and cancer. Sustained expression of the inhibitory receptor programmed cell death-1 (PD-1) is a hallmark of T cell exhaustion, and therapeutic blockade of PD-1 reinvigorates exhausted T cells. PD-1 targeted therapies have shown efficacy for multiple cancer types, but the requirements for T cell rescue by blockade of the PD-1 pathway remain elusive. We analyzed T cells infiltrating human lung tumors, and found that PD-1^{hi} CD8 T cells were predominantly CD28 negative. To address the role of the CD28/B7 pathway on CD8 T cell rescue by PD-1 targeted therapies, we used the LCMV chronic infection model. When B7 signals were impeded by CTLA-4-Ig or B7 blocking antibodies, PD-1 pathway blockade failed to rescue virus-specific CD8 T cells. To investigate a cell intrinsic requirement of CD28 on exhausted CD8 T cells, we analyzed cells genetically deficient in CD28. We found that CD28-deficient LCMV-specific CD8 T cells do not expand after blockade of the PD-1 pathway. Furthermore, CD28-negative CD8 T cells were refractory to PD-1 targeted therapies; even when CD28-signaling was intact during priming, and eliminated by CD28-conditional gene deletion in exhausted CD8 T cells. These data demonstrate that CD28 signaling is required for CD8 T cell rescue following PD-1 blockade, and CD28 expression on tumor-specific CD8 T cells may constitute a predictive biomarker for PD-1 targeted therapies.

Gastric cancer (GC) is a leading cause of cancer-related deaths world-wide. The often late-stage diagnosis has hindered understanding of early events in GC pathophysiology, resulting in a paucity of early diagnostic markers but limited targeted therapy development. We describe mice lacking NFκB1, a member of the NFκB family of transcription factors, as the first animal model of human intestinal-type GC (IGC) that faithfully recapitulates all histopathological disease stages, from inflammation (gastritis) to invasive adenocarcinoma and uniquely secondary metastasis in a time frame akin to human GC. Pertinently, reduced *nfk1* promoter activity resulting from polymorphisms/mutations is associated with human IGC but how loss of NFκB1 causes gastric cancer development is unknown.

We show that IGC in the *nfk1*^{-/-} mouse develops both independently of *H.pylori* infection and even occurs in an abiotic environment. We have generated bone marrow chimaeric mice to demonstrate that loss of NFκB1 in both inflammatory and gastric epithelial cells is required for the development of IGC. Transcriptome, protein expression and gene network analysis in pre-disease *nfk1*^{-/-} mice reveals a deregulation of cytokine receptor signalling and aberrant activation of STAT transcription factors, implicating these pathways in IGC. Accordingly, a gain of function mutation in gp130, the common chain of the IL-6, LIF and OSM receptors accelerates IGC development. These compound mutant mice constitute an ideal model to test novel therapeutics.

We conclude that NFκB1 suppresses GC development by preventing leukocyte infiltration, their cytokine overproduction, driving chronic gastric inflammation and conspires with epithelial cell intrinsic defects in their neoplastic transformation.

Immunology in Cancer and Infection Laboratory, Adelaide,

Australia

Australia has the highest incidence of melanoma worldwide where it represents the most common cancer amongst young Australians. In particular, metastatic melanoma is associated with high rates of mortality, highlighting an urgent need for new therapies. Melanoma progression and metastasis is influenced

by the chemokine family which includes typical and atypical chemokine receptors and their cognate ligands. Atypical chemokine receptors are uncoupled from classical signal transduction cascades and do not mediate cell migration. One of these receptors, ACKR4, has been implicated in melanoma progression. We have knocked down expression of ACKR4 in B16 melanoma cells, which results in tumour regression and complete survival in haematogenous metastases experiments. This is accompanied by immune cell infiltration, ectopic lymphoid neogenesis, loss of pigmentation and resistance to anoikis. To explore the mechanistic basis for this phenotype we performed genome-wide transcriptional analysis of B16 melanoma cells expressing an off-target shRNA or shRNA specific for ACKR4. The gene arrays show dramatic transcriptional changes between these two cell lines with 1303 differentially expressed genes exhibiting at least a 2-fold change. Many of the genes identified are involved in pigmentation, melanocyte differentiation and solute transport. Gene ontology term enrichment and pathway analyses indicates cell adhesion molecule and lipid binding, regulatory region nucleic acid binding and the TGF β pathway as some of the pathways and processes significantly impacted by ACKR4 knockdown. Further investigation is currently focusing on the mechanisms by which the knockdown of ACKR4 results in these transcriptional and phenotypic changes observed in the B16 ACKR4 knockdown model.

3959

Intravital 2-photon imaging of the anti-leukemia immunity in living bone marrow

Mizuno, H., Yamashita, E., Ishii, M.

Osaka University, Immunology and Cell Biology, Suita, Japan

Within a living organism, the adaptive immune system, e.g. cytotoxic T lymphocytes (CTLs), induce apoptosis in tumor cells, and therefore limit tumor development. Bone marrow is a mysterious hidden place for different tumor cells and the anti-tumor immunity in the bone marrow is important because the specific microenvironment had been considered to contribute to escape of tumor cells from immune attack. However, the practical mechanism of anti-tumor immune elimination by CTLs in the bone marrow is still unclear. In this study, to elucidate how the CTLs response against tumor cells in bone marrow, we observed the interaction of leukemic cells and CTLs as well as CTL-induced apoptosis in the bone marrow using an intravital two-photon microscopy.

For visualizing the adaptive immune system, we used a fluorescent FRET-probe that allows us to monitor caspase-3 activity and also used the ovalbumin-OT-I CTL system for inducing antigen specific T cell immunity.

First we visualized anti-tumor immune responses facilitated by CTLs in vitro. In results, leukemic cell death was dependent on the total cell number of CTLs. The CTLs took 6 hours on average to induce apoptosis after capturing.

Secondly in mouse leukemia model, we observed that CTLs inducing apoptosis in leukemic cells upon directed cell-cell contact in the bone marrow by intravital 2-photon imaging.

Visualizing how tumor cells are killed by CTLs in vivo, especially in bone marrow, offers new perspectives for understanding

anti-tumor immune elimination and the mechanism of escape from immune attack.

Engaging deactivated tumor associated macrophages against cancer cells through TLR-3 ligand stimulation via IFN- $\alpha\beta$ signaling

Vidyarthi, A.¹, Khan, N.², Agnihotri, T.¹, Agrewala, J.¹

¹Institute of Microbial Technology, Immunology, Chandigarh,

India, ²McGill University, Dept Micro & Immunol, Montreal, Canada

Macrophages are known for their indispensable role in eliciting inflammation, pathogen clearance and anti-tumor immunity. However during tumor progression, macrophages shift their functional phenotype and acquire the properties of M2 subtype, which exhibit suppressive properties. M2 macrophages exert anti-inflammatory and pro-tumorigenic activities and therefore are attractive targets for therapeutic intervention. The role of TLR-3 has been extensively studied as a vaccine adjuvants for cancer immunotherapy. The current study demonstrates the crucial role of TLR-3 ligand in reversion of M2 macrophages to a protective subtype M1. TLR-3 signaling downregulated M2 specific marker CD206 and simultaneously upregulated CD86, CD80, CD40 and MHCII, which are highly expressed on M1 phenotype. Further, TLR-3 stimulated M2 macrophages shift their cytokine profile from anti-inflammatory to pro-inflammatory, as evidenced by significant increase in IL-6, IL-12 and TNF- α yield. Noteworthy, TLR-3 signaling altered the M2 profiling via IFN- $\alpha\beta$ signaling. TLR-3 triggered M2 macrophages incubated with anti-IFN- $\alpha\beta$ R Abs failed to acquire M1 property. Interestingly, we observed that triggering through TLR-3 suppressed the expression of TIM-3 on M2c macrophages. Administration of TLR-3 agonist in murine tumor model, reverted the M2 to M1 phenotype and regressed the tumor growth. Conversely, mice pre-treated with anti-IFN- $\alpha\beta$ R failed to respond to TLR-3 administration and thus no regression in tumor growth was noticed. Overall, the results indicate that the signaling through TLR-3 may be quite crucial in imparting protection against tumors by skewing macrophages to M1 subtype. Consequently, this strategy has enough potential to be explored for treatment of cancer.

The role of Endoplasmic Reticulum Aminopeptidase 1 in NK cell function

Fruci, D.¹, D'Alicandro, V.¹, Romania, P.¹, Cifaldi, L.¹, Melaiu, O.¹, Falco, M.², Pende, D.², Locatelli F.¹

¹Paediatric Haematology/Oncology Department, IRCCS, Ospedale Pediatrico Bambino Gesù, Rome, Italy, ²Istituto Giannina Gaslini, IRCCS, Genoa, Italy, ³IRCCS AOU San Martino-IST, Genoa, Italy

Endoplasmic reticulum aminopeptidase 1 (ERAP1) is an ER-resident aminopeptidase that generates optimal peptides for presentation by MHC class I molecules. Several functional genetic variations of this peptidase are known to be associated with a large number of immune-mediated diseases and resistance to infectious disease. In vitro and in vivo studies have demonstrated that an altered ERAP1 activity results in substantial change of the peptide repertoire presented by MHC class I molecules. Consistently, we have shown that in mice ERAP1 abrogation results in a conformational change of MHC class I molecules that stimulates both innate and adaptive immune responses leading to the concerted rejection of a murine t T-cell lymphoma, which is otherwise refractory to immune elimination. In human tumor cell lines, genetic or pharmacological inhibition of ERAP1 perturbs the engagement of inhibitory NK cell receptors by their specific ligands, in each case leading to NK cell killing. The protective effect of peptide-MHC class I complexes was restored in ERAP1-deficient settings by replacement of endogenous aberrant peptides with correctly trimmed high-affinity peptides, suggesting that ERAP1 was needed to positively modify the affinity of natural ligands. Notably, ERAP1 inhibition enhanced the ability of NK cells to kill freshly established human lymphoblastoid cell lines from autologous or allogeneic sources, thereby promoting NK cytotoxic activity against target cells that would not be expected due to KIR-KIR ligand matching. Therefore, these results identify ERAP1 as a modifier to leverage immune functions to improve the efficacy of NK cell-based approaches for cancer immunotherapy.

MAIT Cells

MAIT cells: Friend or Foe in recognising microbial vitamin metabolites presented by the MHC-I-related molecule MR1

McCluskey, J.¹, Corbett, A.J.¹, Eckle, S.B.G.¹, Chen, Z.¹, Wang, H.¹, Sun, S.¹, D'Souza, C.¹, Kostenko, L.¹, Reantragoon, R.¹, Meehan, B.¹, Birkinshaw, R.W.², Liu, L.³, Patel, O.², Mahony, J.⁴, Cao, H.¹, Jackson, D.¹, Williamson, N.A.⁵, Strugnelli, R.A.¹, Mak, J.Y.W.³, Van Sinderen, D.^{4,6}, Fairlie, D.P.^{3,7}, Kjer-Nielsen, L.¹, Godfrey, D.I.^{1,7}, Rossjohn, J.^{2,7,8}

T cells discriminate between foreign and host molecules by recognizing distinct microbial molecules, predominantly peptides and lipids. Riboflavin precursors found in many bacteria and yeast also selectively activate mucosal-associated invariant T (MAIT) cells an abundant population of innate-like T cells in humans. We have shown that MAIT-cell activation requires key genes encoding enzymes that form 5-amino-6-D-ribitylaminouracil (5-A-RU), an early intermediate in bacterial riboflavin synthesis. MAIT antigens formed as simple adducts by the reactions between 5-A-RU and glyoxal/methylglyoxal, 5-(2-oxoethylideneamino)-6-D-ribitylaminouracil (5-OE-RU) and 5-(2-oxopropylideneamino)-6-D-ribitylaminouracil (5-OP-RU), bound to MR1 as shown by crystal structures of MAIT TCR ternary complexes. Although 5-OP-RU and 5-OE-RU are unstable intermediates, they became trapped by MR1 as reversible covalent Schiff base complexes. Thus, MR1 is able to capture, stabilize and present chemically unstable pyrimidine intermediates, which otherwise convert to lumazines, as potent antigens to MAIT cells. These pyrimidine adducts are created by microbes such as bacteria and yeast but not by humans or other mammals who obtain vitamin B from the diet rather than endogenous synthesis. MR1-5-OP-RU tetramers specifically identified MAIT cells demonstrating that they were rapidly enriched in the lungs of C57BL/6 mice infected with *Salmonella enterica* var Typhimurium, comprising up to half of all $\alpha\beta$ T-cells after one week. MAIT cell accumulation in the lungs was MR1-dependent a

Innate Regulation

Orphan nuclear receptors and regulation of innate immunity

Jo, E., Yuk, J. M., Kim, S. Y., Lee, H. M.

Chungnam National University School of Medicine

Nuclear receptors (NRs) are critically involved in various physiological responses through the regulation of numerous target genes. Orphan NRs are a subset of NR superfamily which ligands and functions have not been fully characterized. Emerging evidence has accumulated that several orphan NRs play critical roles in regulation of innate immunity to prevent harmful inflammatory responses in the host. The orphan NR small heterodimer partner (SHP, NR0B2) is a well-known corepressor of numerous other NRs, and functions in lipid/glucose metabolic homeostasis and regulation of endocrine function. Our recent studies showed that SHP was an important negative regulator of NLRP3 inflammasome activation through interaction with NLRP3 and translocation into mitochondria. Estrogen-related receptor α (ERR α ; NR3B1) is the first identified orphan NR that plays an important

role in regulation of energy metabolism and mitochondrial biogenesis. We found that ERR α was a novel regulator of the toll-like receptor-induced inflammatory response, with the unique capacity to modulate Tnfrsf3 transcriptional induction and p65 acetylation through metabolic reprogramming via enhancement of mitochondrial function. Unveiling the new and existing functions of orphan NRs could accelerate develop and improve novel strategies against human inflammatory diseases.

Lymphocyte Development

Dissecting the transcriptional regulatory network for early T-cell commitment

Rothenberg, E.¹, Kueh, H.Y.¹, Hosokawa, H.¹, Ng, K.K.H.¹, Mehta, A.^{1,2}, Pease, S.S.¹, Romero-Wolf, M.¹, Ungerback, J.¹, Wang, X.¹, Yui, M.A.¹, Zeng, W.B.³, Elowitz, M.B.¹, Mortazavi, A.³

¹California Institute of Technology Division of Biology & Biological Engineering, ²David Geffen School of Medicine at UCLA, ³University of California, Irvine, Department of Developmental and Cell Biology

Multipotent precursors proliferating in the thymus become committed to a T-cell fate when their access to alternative cell fates is intrinsically and unconditionally closed. This process involves very dynamic changes in transcription factor expression and activity: PU.1 and other factors expressed in multipotent progenitors are downregulated and are usually permanently silenced, while T-cell transcription factors, especially Bcl11b, are sharply activated. The abrupt activation of Bcl11b from a silent state is not only a landmark in T-cell differentiation, marking commitment, but also a functional contributor to commitment. Key target genes affected by Bcl11b function at this particular stage will be described: many of them appear to be under the control of Bcl11b as a repressor. Recent proteomic characterization of Bcl11b-containing protein complexes indicates the corepressor and coactivator partners that it uses to mediate different types of regulatory activity at different genomic sites. Since Bcl11b is such a powerful factor, a central question is how the onset of expression of Bcl11b itself is controlled. The talk will describe the combination of trans-acting factors that are needed to open the Bcl11b locus and activate it, and show that these factors each play slightly different temporal and functional roles in the activation process. Interestingly, evidence will also be shown for an epigenetic component of Bcl11b regulation that further slows its activation but helps to make it irreversible.

Mucosal Immunology

Homing of Immune cells via afferent lymphatics

Förster, R.

Hannover Medical School

Homing of immune cells to lymph nodes via specialized high endothelial venules (HEV) has been intensively studied during the past two decades. In contrast, little is known about molecules and pathways that allow immune cells to home via the second port of entry to lymph nodes i.e. via afferent lymphatics. We have recently developed intra lymphatic transfer of immune cells to identify the route and molecules involved that guide the various immune cell subsets that arrive via afferent lymphatics into the lymph node parenchyma. In this presentation I will give new insights into cues that target dendritic cells and T cells from the afferent lymph into lymph nodes.

Evolution of innate versus adaptive lymphoid cells in vertebrates

Hirano, M., Li, J., Rosenberg, C.S., Cooper, M.D.

Emory University School of Medicine, Pathology and Laboratory Medicine, Atlanta, United States

Mammalian innate lymphoid cells (ILCs) are early responders to pathogen entry at barrier surfaces, modulate development and function of antigen-specific T and B lymphocytes and may facilitate wound healing by reaction to tissue injury. In order to determine when the ILCs evolved, we purified antigen receptor-positive and -negative lymphocytes in the sea lamprey, a jawless vertebrate representative, and examined their expression of genes shown to be important for ILC development and function in mammals. We first compared the gene expression profiles for four sorted lymphocyte populations: variable lymphocyte receptor (VLR) A⁺, VLRB⁺, VLRC⁺ and triple VLR⁻ cells by quantitative real-time PCR analysis. We next divided the VLR⁻ lymphocyte population into two subpopulations by using LysoTracker[®] to identify NK-like cells rich in acidic intracellular vesicles (i.e., lysosomes). The lysosome-positive (Lyso⁺) VLR⁻ lymphocytes preferentially expressed *CD56*, *interleukin 23 receptor*, *Runx2* and *granzyme K/A* orthologues, whereas the Lyso⁻ VLR⁻ lymphocytes preferentially expressed *PLZF*, *Id2*, *c-Kit*, *GATA3* and *RORalpha*. Furthermore, by staining with a lamprey TLR5-specific monoclonal antibody, we found that Lyso⁺ VLR⁻ lymphocytes expressed high levels of TLR5 on their cell surface. Electron microscopic analysis of the TLR5^{high}/Lyso⁺/VLR⁻ cells indicated a remarkable morphological resemblance to mammalian NK cells. Our composite findings suggest that the basic genetic programs for T-like cells, B-like cells, NK-like cells and ILC2-like cells were already present in a common vertebrate ancestor ~500 million years ago.

New insights from amphioxus: on the origins of the adaptive immune system of jawed vertebrates

Huang, S., Yuan, S., Xu, A.

Sun Yat-sen University, Guangzhou, China

Amphioxus (or lancelets) is an extant basal lineage of chordates, which is important for understanding the vertebrate evolution, including the origins of adaptive immunity. By comparing two amphioxus draft genomes, we reconstruct the protoMHC region in amphioxus, which shares high syntenic conservation with the human paraMHC regions, but shows a local rearrangement rate twice the average genome-wide rearrangement rate. This observation agrees with the MHC "big bang" hypothesis, which suggests that the MHC regions are the "arsenal" for creating many novel domains and domain combinations used by adaptive immunity. Furthermore, we discover a large number

of ancient transposon families in lancelets, many of which have been lost in vertebrates. We show that one of these ancient transposons is the long-sought RAG transposon, the co-option of which by jawed vertebrates was crucial to the origin of V(D)J rearrangement.

Divergence of bacteria sensing (TLR 4, 5) and virus sensing (TLR 3, 7) within the reptilian lineage

Priyam, M.¹, Rai, U.¹, Ghorai, S.M.²

¹University of Delhi, Department of Zoology, Delhi, India, ²Hindu College, University of Delhi, Delhi, India

Toll-like receptors (TLRs) are the best characterized pattern recognition receptors in all vertebrate classes, with the exception of reptiles. It was only earlier this year that the first reptilian TLR - TLR5, was functionally characterized to demonstrate the divergent nature of TLR ligand recognition. In the current study, the evolution of the bacteria sensing and virus sensing TLRs in the reptilian lineage was assessed with respect to selection pressure acting on extracellular ligand recognition domain (ECD) and intracellular Toll/interleukin-1 receptor (TIR) domain. Six TLRs (TLR2, 3, 4, 5, 7 and 13) from each TLR family were identified in the wall lizard, *Hemidactylus flaviviridis*. The expression of TLR2, 7 and 13 was omnipresent across the five selected tissues (lungs, liver, spleen, kidney and ovary). Screening of splenic transcriptome data of *H.flaviviridis* gave the potential full length coding sequences of four TLRs- bacteria sensing TLR 4, 5 and virus sensing TLR3, 7. Alignment wide selection studies showed positive selection for ECD of TLR3, 4 and 5 while high degree of conservation was noted for TIR domain. Episodic selection was distinctly noted in both virus and bacteria sensing TLRs of reptilian lineage. Most of the positively selected sites on the ECD of TLRs were mapped to the LRR regions pointing towards specie-specific divergence of ligand recognition in TLRs. Overall, our findings showed a higher degree of episodic diversifying selection for TLR3 and TLR4 as compared to TLR7 and TLR5.

Plasticity of MHC-driven responses in the California sea lion: an eco-immunological approach

Montano-Frias, J.E.¹, Alvarez-Martinez, R.¹, Soto-Garcia, L.A.¹, Flores-Moran, A.¹, Acevedo-Whitehouse, K.^{1,2}

¹Autonomous University of Queretaro, Basic and Applied Microbiology Unit, Queretaro, Mexico, ²The Marine Mammal Center, Sausalito CA, United States

Studies based on the Major Histocompatibility Complex (MHC) have reported associations with resistance and susceptibility to certain pathogens and diseases, but little is known about MHC transcription in an ecological context. The California sea lion (CSL) is a good model to understand the eco-evolutionary dynamics of a marine predator's immune responses. Taking into account that their 'pathogenic environment' and food availability may vary spatially and temporally, and that implementing immune responses is energetically costly, we hypothesize that transcription of MHC-II *ZacaDRB* genes in CSL pups

1) varies spatially due to ecological differences among rookeries, 2) is limited by MHC diversity, body condition and pathogen exposure, and 3) influences other immune responses, such as inflammation.

Constitutive and expressed diversities were calculated as the number of *ZacaDRB* genes present in the genomic DNA and buffy coat cDNA, respectively. Expressed diversity was partly explained by constitutive diversity (GLM, $F=18.96$, $df=154$, $p<0.001$, $adj-r^2=10.4\%$), regardless of body condition, age and sex. Expressed diversity was influenced by ecological variables among rookeries in the Gulf of California, such as presence of enteric viruses (GLM_{ADV} $F=5.27$, $df=43$, $p<0.05$; GLM_{RTV} $F=5.71$, $df=35$, $p<0.05$). Expression of particular loci was influenced by circulating eosinophils when enteric viruses were included in the models. Finally, transcription of certain loci was linked to PHA-induced inflammation, with patterns that varied markedly between ages. Life history constraints and physiological processes associated with development, in conjunction with a changing 'pathogenic environment' of the marine ecosystem appear to explain the observed plasticity of the MHC.

V_H and V_L from polyspecific IgM and monospecific IgG antibodies contribute differentially to antigen recognition and virus neutralization function

Pasman, Y., Kaushik, A.

University of Guelph, Molecular and Cellular Biology, Guelph, Canada

We analyzed role of individual variable heavy (FdVH) and variable light (FdVL) domains in comparison with VH+VL pair (scFv) originating from a polyspecific bovine IgM, with an exceptionally long CDR3H (61 amino acids), and a monospecific IgG1 antibody in antigen (Ag) recognition and virus neutralization functions. To this end, recombinant FdVH, FdVL and scFv were constructed and expressed in *Pichia pastoris* from bovine polyspecific IgM and IgG1 encoding cDNA. The scFv1H12 showed polyspecific antigen recognition similar to parent IgM antibody with minor differences. Unlike variable light domain FdVL1H12, variable heavy domain FdVH1H12 recognized multiple antigens that differed from scFv1H12 and the parent IgM antibody. Nevertheless, role of FdVL1H12 in providing structural support to FdVH in antigen recognition is noted. By contrast, the individual FdVH073 and FdVL074, originating from induced BoHV-1 neutralizing IgG1 antibody, recognized target epitope on BoHV-1 relatively weakly when compared to VH+VL pair as scFv3-18L. Both VH and VL domains of induced IgG antibody are required to achieve BoHV-1 neutralization function. To conclude, there exist subtle functional differences in relative contribution of VH and VL from polyspecific IgM and monospecific IgG antibodies in antigen recognition and virus neutralization functions.

Th1 paradigm: redirect the cell-mediated immune response in a typical Th2 disease such as Leishmaniasis

Scarpona, S.¹, Berardi, S.¹, Bordicchia, M.², Rossi, G.¹

¹University of Camerino, School of Biosciences and Veterinary Medicine, Matelica (MC), Italy, ²University of Sydney, University Veterinary Teaching Hospital, Sidney, Australia

Many diseases are the result of the Th2-phenotype immune response directed against an antigen, by triggering an immune-complex disease. In this situation, the manifestation of disease is not closely related to the pathogen, but to an inappropriate host immune response. Leishmaniasis is one of the most classic examples. We investigated the possibility of clinical recovery in dogs with Leishmaniasis following stimulation of the Th1-type immune response.

The immunomodulation was based on the exaltation of cell-mediated immune response, by extract of Mycobacteria, and the restraint of phlogosis that follows, by antiCOX-2 molecules. This combination gives a notable expansion of cell-mediated cytotoxic effect.

Naturally-infected dogs were enrolled and treated with the immunomodulatory therapy (group A) and a previous reported conventional therapy (group B). All animals were evaluated by clinical, parasitological and immunological criteria to monitor treatment efficacy.

Clinical and laboratory results demonstrated differences in both humoral and cell-mediated immune responses between the two groups. They highlighted a Th2/Th1-shift in group A, together with a significant improvement ($p<0.05$) in all parameters, whereas group B showed variable clinical improvement in absence of any immune shift.

The approach to diseases characterized by Th2 phenotype should not be limited to fight the pathogen, but also aim to restore an appropriate host immune response. The stimulation with antigens totally divorced from the biomolecular type of *Leishmania* antigens, and the subsequent control of the disease, indicate that modulation of the immunophenotypical attitude of the host response can be a cutting-edge approach both in veterinary and human medicine.

The role of T cells in highly pathogenic avian influenza in the chicken

Layton, D., Butler, J., Stewart, C., Bruce, M., Rootes, C., Gough, T., Rohringer, A., Wang, J., Wong, F., Williams, D., Bingham, J., Bean, A. CSIRO, Health and Biosecurity, Geelong, Australia

Highly pathogenic avian influenza (HPAI) viruses with a H5 subtype arise from poultry and can cause severe morbidity and mortality in humans. In May 2014, a new assortant of HPAI H5N6 (A/Duck/Laos/XBY004/2014 (H5N6)) emerged in Laos and in China, causing the death of several hundred poultry and one individual. We have assessed the infectivity, pathobiology and immunological response associated with HPAI H5N6 infection in chickens. Infection caused 100 % mortality in all birds within 30-48 hours of inoculation, with clinical signs including facial swelling, depression, hunching and fluffed feathers. High

virus titers were observed at necropsy in blood and all tissues, indicating systemic infection. Pro-inflammatory cytokines were greatly elevated in birds infected with H5N6 compared to non-infected control birds. Furthermore, we showed a significant decrease in proportion of CD8 T cell and an increase in IgM low and IgY positive B cells. Our study is the first to describe disease in chickens caused by HPAI H5N6 and demonstrates several pathological and immunological responses comparable to HPAI H5 subtypes.

Th2/Th17 cytokines are involved in the early stage of immune responses during PEDV infection

Chen, J., Liu, G.

Lanzhou Veterinary Research Institute, Chinese Academy of Agricultural Sciences, Animal Immunology Group, Lanzhou, China

Porcine epidemic diarrhea (PED) has resulted significant economic losses for pig industry in Asia, North America, and some European countries in recent years. Porcine epidemic diarrhea virus (PEDV), a member within the family *Coronaviridae* of the order *Nidovirales*, initiates the infection via small intestinal villous enterocytes and infected enterocytes rapidly undergo acute necrosis, leading to marked villous atrophy in the small but not in the large intestine. In order to elucidate the immune responses induced by PEDV infection within the small intestine, a PEDV LIX strain was employed to infect the IPEC-J2 cell lines, intestinal porcine enterocytes isolated from the jejunum of a neonatal unsuckled piglet. A whole set of cytokines were measured by Real-time RT-PCR with 12 hours interval between 12 hpi and 72 hpi. The results showed that ISGs and type I and type III IFNs were down-regulated upon PEDV infection. On the contrary, the expression of IL2, IL4, IL10, IL12, IL15, TGF β 1, IL17A, and GM-CSF were significantly elevated post PEDV infection with a time-dependent manner. These data indicated that PEDV infection activate Th2, Th17, and Treg, as well as inflammatory responses within the small intestines. In conclusion, Th2/Th17 cytokines are involved in the early stage of immune responses during PEDV infection.

Regulation role of metalloprotease ADAM17 on porcine reproductive and respiratory syndrome virus infection

Wang, Y., Feng, L.

Harbin Veterinary Research Institute, Chinese Academy of Agricultural Sciences, Harbin, China

Metalloprotease ADAM17 has been implicated in the control of cancer, inflammation, and other pathologies. In this study, we demonstrated for the first time that ADAM17 plays a critical role on controlling PRRSV infection. First, we found that porcine alveolar macrophages produced a great amount of soluble TNF α upon PRRSV infection, and this soluble TNF α in turn has great anti-PRRSV effect. By using inhibitor and genetic modification methods, we addressed that the production of porcine TNF α was mediated by ADAM17. Next, we found that inhibition of ADAM17 activity with specific inhibitor/siRNA facilitated PRRSV infection in different target cells. Furthermore, we revealed that

virus infection-activated ADAM17 can cleave the PRRSV receptor CD163, which thus hinders virus entry. Lastly, we discovered that PRRSV treatment also can stimulate porcine neutrophils to produce soluble form of CD16 (sCD16) *in vivo* and *in vitro*, which might serve as a biomarker for PRRSV infection. We then discovered that the production of sCD16 is also an ADAM17-dependent ectodomain shedding event. Taken together, PRRSV infection can stimulate ADAM17, which subsequently plays an anti-virus role through cleaving its substrates. Our findings suggest that activation of ADAM17 may be useful in enhancing the porcine anti-PRRSV response.

Long lasting immunity against *Pasteurella multocida* in mice and cattle vaccinated with inactivated *Pasteurella multocida* and herbal adjuvant 'DIP-HIP'

Bhushan, B.¹, Shweta, S.², Tanwar, H.¹, Yadav, A.P.¹, Singh, S.B.¹, Ganju, L.¹

¹Defence Institute of Physiology and Allied Sciences, DRDO, Immunomodulation, Delhi, India, ²Delhi University, Nanotechnology Lab Department of Zoology, Delhi, India

Pasteurella multocida (PM) which causes Hemorrhagic septicaemia (HS) disease in cattles is a gram-negative coccobacillus belonging to Pasteurellaceae family. *P. multocida* and transmitted by ingestion or inhalation, either during direct contact or via fomites such as contaminated feed and water. Currently, there are no broadly protective vaccines with long-lasting immunity are available against HS. Aluminium-based minerals salts (alum) continue to be the only immunologic adjuvant approved by the US Food and Drug Administration (FDA) other than surfactant based oil adjuvant. Herbal adjuvants are being evaluated extensively to replace the classical adjuvants. Hence, herbal immunomodulators can be ideal candidates to elicit effective and long lasting immune response with minimum side effects. In the present study, herbal adjuvant DIP-HIP was evaluated with inactivated PM (iPM) antigen as vaccine in mice and compared with classical alum adjuvant. The results suggest that after single booster DIP-HIP + iPM emulsion gave maximum neutralizing antibody titre in comparison to HS alone or Alum + iPM. The LD₅₀ dose of PM was found to be 1 X 10⁷ CFU/ml and mice were challenged with this dose to assess efficiency of DIP-HIP adjuvant with iPM antigen in providing protection against HS. Taking cue from these findings, finally, seronegative calves were also vaccinated with DIP-HIP + HS and Alum + HS to evaluate vaccine efficacy. DIP-HIP containing formulation turned out to be broadly protective against HS with long-lasting immunity in cattle. Hence, DIP-HIP is a potential adjuvant which can be used in HS vaccines to provide long lasting immunity.

Somatic hypermutation serves two independent functions: antibody maturation away from binding self and towards binding foreign

*Burnett, D., Schofield, P., Christ, D., Brink, R., Goodnow, C.
Garvan Institute of Medical Research, Darlinghurst, Australia*

Purging of all self-reactive B-lymphocytes from the naïve repertoire would create “holes” in the immune repertoire. A compromise may be to retain anergic self-reactive B-lymphocytes in the repertoire, able to be reawakened to undergo somatic hypermutation away from self-reactivity.

We generated transgenic mice that allowed *in vivo* tracking of B cells carrying a knock-in BCR with physiologically low starting affinity for a self-antigen referred to here as “S”. In transgenic mice with S on the surface of all haematopoietic cells, anti-S B cells emigrate to the spleen but show an anergy profile including surface IgM downregulation and reduced lifespan.

These mice were then challenged with an antigen of identical primary sequence but displayed on foreign sheep red blood cells (S*), where the xenogeneic cell carrier elicits strong T follicular help. Anergic anti-S B-cells were activated to form germinal centres, which accumulated recurring V-region mutations that decrease affinity to S and S*. Despite mutating away from self, autoantibodies that retained S-binding were secreted into serum. In contrast, when S* differed from S by six contact residue amino-acids, progeny of anti-S B cells acquired different mutations that decreased affinity for S but concurrently increased affinity for S*. The serum now contained IgG with high binding to foreign S* but low S-binding.

We have shown a novel mechanism for maintaining self-tolerance while maximising the repertoire of antibodies against foreign antigens. The results show that the germinal centre serves to mutate B-cells away from self-reactivity, independently to its role increasing foreign antigen affinity.

Antigen-specific suppression by TCR and scFv CAR-engineered CD4 Tregs and cytotoxic CD8's

*Kim, Y.C., Zhang, A., Parvatheni, K., Scott, D.W.
Uniformed Services University of the Health Sciences, Medicine,
Bethesda, United States*

Clinical application of expanded T regulatory cells (Tregs) offers great promise for the treatment of undesirable immune responses. However, treatment with polyclonal Tregs, which are not specific for a single epitope, could potentially lead to global immunosuppression. We have engineered human T cells to express chimeric antigen receptors (CARs) using either T-cell receptors from MS or hemophilia patients or specific single chain Fv's. Thus, we adapted the CAR approach utilized successfully for leukemia therapy (e.g. CD19 CAR CD8's) to create specific T regulatory cells recognizing myelin basic protein (for MS) or FVIII, in the case of hemophilia. Such cells can actively suppress effector T cell proliferation and cytokine formation, as well as antibody formation *in vitro*. These cells can mediate

“bystander” suppression of multiple epitopes expressed locally and function even on the presence of strong inflammatory signals. Mechanistic studies suggest both contact dependent and contact-independent pathways. Further development with B-cell targeting strategies have also been successful by expressing antigen domains in CD8 T cells that kill B cells specific for FVIII, for example. Application of these engineered T cells to modulate adverse antibody responses in hemophilia and pathogenic responses to CNS proteins will be presented, and the mechanisms further discussed.

Consequences of CD79B and MYD88 mutations for B cell tolerance and lymphomagenesis

Wang, J.Q.^{1,2}, Batchelor, E.², Kaya, S.^{1,2}, Goodnow, C.C.^{2,3}, Horikawa, K.^{1,2}

¹John Curtin School of Medical Research, Australian National University, Department of Cancer Biology and Therapeutics, Canberra, Australia, ²John Curtin School of Medical Research, Australian National University, Department of Immunology and Infectious Disease, Canberra, Australia, ³Garvan Institute of Medical Research, Immunology Division, Darlinghurst, Australia

Mechanisms of B cell tolerance include the selective elimination of self-reactive B cells with B cell receptors (BCRs) that constitutively bind to self-antigen and the inactivation of Toll-like receptors (TLRs) that bind to self-ligands. BCR and TLR signalling involve the adaptor proteins CD79A/B and MYD88 respectively. *CD79B* and *MYD88* are frequently and concomitantly mutated in activated B cell type diffuse large B cell lymphoma (ABC-DLBCL). Since the survival of some human ABC-DLBCL cells requires BCR engagement by self-antigen, we investigated the consequences of *CD79B* and *MYD88* mutations for self-antigen-binding B cells. We transduced mature hen egg lysozyme (HEL)-specific B cells with retroviral constructs encoding *CD79B* and *MYD88* mutations and tracked the transduced B cells when adoptively transferred into HEL-expressing *Rag1*^{-/-} recipient mice, where the B cells were constitutively stimulated by self-antigen. While B cells that carried a single *CD79B* or *MYD88* mutation were eliminated from the recipient mice, B cells that over expressed either wild type or mutant *CD79B* together with *MYD88* mutation escaped deletion and differentiated into antibody producing cells. Using retroviral constructs that regulated *CD79B* expression, we demonstrated the number of accumulating B cells correlated with *CD79B* mutation status and increasing surface expression of *CD79B* and IgM, suggesting that protection of self-antigen-binding B cells was conferred by elevated BCR expression. Conversely, *MYD88* mutation alone caused decrease surface *CD79B* and IgM expression. Overall, our results demonstrated the cooperative effects of the frequently overlapping *CD79B* and *MYD88* mutations for B cell tolerance and how self-antigen stimulation may contribute to ABC-DLBCL.

High-affinity disease-ameliorating autoantibodies in APECED patients reveal their origins

Kisand, K.¹, Meyer, S.², Hertel, C.², Vlaicu, P.², Macagno, A.², Kärner, J.¹, Trebusak Podkrajsek, K.³, Battelino, T.³, Krohn, K.⁴, Ranki, A.⁴, Wolff, A.S.B.⁵, Husebye, E.S.⁵, Peterson, P.¹, Hayday, A.C.⁶

¹University of Tartu, Tartu, Estonia, ²ImmunoQure AG, Düsseldorf, Germany, ³University of Ljubljana, Ljubljana, Slovenia, ⁴University of Helsinki, Helsinki, Finland, ⁵University of Bergen, Bergen, Norway, ⁶King's College London, London, United Kingdom

APECED (autoimmune polyendocrinopathy candidiasis ectodermal dystrophy) patients are characterized by multiorgan autoimmunity and chronic mucocutaneous candidiasis. Their autoimmunity is explained by impaired central T cell tolerance due to recessive *AIRE* gene mutations resulting in defective negative selection of tissue-specific thymocytes. However, one of the most striking features of APECED patients is the presence of multiple high-titer autoantibodies that target certain cytokines. So far studies describing the B cell compartment in relation to impaired central T cell tolerance are lacking. Flow cytometric study of circulating B cell subpopulations and T follicular helper cells revealed only slight alterations in adult but not pediatric patients compared to age-matched healthy individuals indicating to secondary changes caused by e.g. inflammatory process throughout the life. Monoclonal auto-antibodies isolated from patients' single B cells recognized native and conformational epitopes of studied cytokines, were mostly of extremely high (sub-picomolar) affinity, and broadly neutralizing. The sequences in the complementarity determining regions of both the heavy and light chain of all the isolated autoantibodies were heavily mutated and the reversion of these mutations completely abolished the binding of these „germline ancestor antibodies“ to their targets. This is consistent with normal central B cell tolerance in APECED patients, and with dysregulated germinal centre reaction that drives the affinity maturation of B cells initially primed to exogenous antigens. Moreover, we found that neutralizing capacity of serum autoantibodies reactive to type I interferons correlated inversely with the clinical presentation of type I diabetes in APECED patients indicating to disease-ameliorating properties of these autoantibodies.

Actively acquired self-tolerance by clonal redemption of autoantibodies during human immunization

Reed, J.¹, Jackson, J.¹, Christ, D.^{1,2}, Goodnow, C.^{1,2}

¹Garvan Institute of Medical Research, Immunology, Sydney, Australia, ²St Vincent's Clinical School, UNSW Faculty of Medicine, Sydney, Australia

B cell clonal anergy is an enigmatic mechanism for actively acquiring self-tolerance because no apparent purpose is served by retaining functionally suppressed B cells bearing autoantibodies. We propose a novel tolerance mechanism, clonal redemption, allowing reactivation of anergic B cells and somatic hypermutation of autoantibodies away from binding self. To test this hypothesis, we traced the somatic evolution of three IGHV4-34*01 IgG antibodies isolated from healthy

donors immunized against foreign RhD alloantigen or vaccinia virus. Human antibodies with IGHV4-34*01 heavy chains are of interest as autoantibodies because they bind to a well-defined self-antigen, poly-N-acetyllactosamine carbohydrates (I/i antigen) on erythrocytes and B lymphocytes, cause cold agglutinin disease, and are carried by 5% of naive B cells that are anergic. Each IGHV4-34*01 IgG was expressed and analysed either in hypermutated immune state or after reverting to its unmutated pre-immune ancestor. In each case the pre-immune ancestor was self-reactive, binding intensely to normal human B cells expressing I/i antigen. Self-reactivity was removed by a single somatic mutation that paradoxically decreased binding to the foreign immunogen, while additional mutations conferred increased foreign reactivity. These data show that potentially pathogenic autoantibodies on human B cells can evolve into foreign-specific antibodies by somatic hypermutation during the course of normal immunisation. Since 2.5% of switched memory B cells use IGHV4-34*01 and >43% of these have mutations that remove I/i binding, clonal redemption of anergic B cells is an efficient process for specificity maturation and mutation away from self-reactivity during physiological human antibody responses.

Myelin Oligodendrocyte Glycoprotein induces incomplete tolerance of CD4 T cells specific for both a myelin and a neuronal self antigen

Axisa, P.-P.^{1,2,3}, Lucca, L.E.^{1,2,3}, Aloulou, M.^{1,2,3}, Perals, C.^{1,2,3}, Ramadan, A.^{1,2,3}, Rufas, P.^{1,2,3}, Kyewski, B.⁴, Derbinski, J.⁴, Fazilleau, N.^{1,2,3}, Mars, L.T.^{1,2,3}, Liblau, R.S.^{1,2,3}

¹INSERM, U 1043, Toulouse, France, ²CNRS, U 5282, Toulouse, France, ³Université Toulouse 3, CPTP, Toulouse, France, ⁴Developmental Immunobiology, Tumor Immunology Program, German Cancer Research Center, Heidelberg, Germany

The paradigm that each T cell can recognize a continuum of related ligands, defined as T-cell polyspecificity, implies that multiple antigens can tolerize T cells specific for a given self-antigen. We previously showed in C57BL/6 mice that part of the CD4 T-cell repertoire specific for the encephalitogenic antigen myelin oligodendrocyte glycoprotein (MOG) 35-55 also recognizes the neuronal antigen neurofilament medium (NF-M) 15-35. Such bi-specific autoreactive CD4 T cells are frequent, produce inflammatory cytokines after stimulation and are essential to disease progression.

Since T cells recognizing two self-antigens would be expected to be more likely to be tolerized, we were prompted to study how tolerance to bi-specific T cells is imparted. We found that similar to MOG, NF-M is expressed in the thymus by medullary thymic epithelial cells, i.e. in a potentially tolerogenic setting. Nevertheless, we found that the frequency, pro-inflammatory phenotype, and capacity to transfer experimental encephalomyelitis (EAE) of MOG₃₅₋₅₅-reactive CD4 T cells were increased in MOG-deficient but not in NF-M-deficient mice. This observation led us to investigate the efficiency of NF-M₁₅₋₃₅ presentation by antigen presenting cells, which we found of short duration, suggesting unstable MHC class II binding. Consistent with this hypothesis, introducing an MHC-

anchoring residue into NF-M₁₅₋₃₅ (NF-M₁₅₋₃₅ T20Y) increased its immunogenicity, and activated a repertoire able to induce EAE. Our results show that in C57BL/6 mice the expression of MOG, but not of NF-M, restrains bi-specific autoreactive CD4 T cells, but not to a level sufficient as to prevent EAE induction.

PD-1 upholds the unresponsive phenotype of self-reactive TCR- $\alpha\beta$ CD4⁺ CD8⁻ (double negative) T cells

Rodriguez-Rodriguez, N.^{1,2}, Apostolidis, S.³, Martin Villa, J.M.², Tsokos, G.³, Crispin, J.C.¹

¹Instituto Nacional de Ciencias Médicas y Nutrición 'Salvador Zubirán', Immunology and Rheumatology, Mexico City, Mexico,

²Universidad Complutense de Madrid, Madrid, Spain, ³Beth Israel Deaconess Medical Center, Boston, United States

Self-reactive CD8 T cells that encounter cognate antigen in peripheral tissues become inactivated, downregulate CD8, and express high levels of PD-1 becoming PD-1⁺ DN T cells. Moreover, a similar subpopulation of PD-1⁺ DN T cells induced by self-antigens is found in healthy normal mice. Because PD-1 maintains immune tolerance, we investigated whether PD-1 plays a role in the generation of DN T cells induced by self-antigen, or in the maintenance of their phenotype. PD-1 deficiency or blockade did not affect the conversion of self-reactive CD8 cells into DN cells, although it was associated to expansion of both autoreactive populations (CD8 and DN). The expression of master regulator transcription factors (i.e. T-bet, ROR- γ t, Eomes) was likewise not affected by the absence of PD-1. On the contrary, steady state proliferation and cytokine production in DN T cells was released by the deficiency of PD-1 or its blockade. Interestingly, blocking PD-1 engagement abrogated the upregulation of several transcription factors (i.e. EGR2 and Helios) implicated in T cell inactivation. In addition, blocking PD-1 induced a partial recovery of CD8 expression in DN T cells in the presence of antigen. Overall, these results highlight the importance of PD-1 in controlling the expansion and pro-inflammatory potential of self-reactive DN T cells and suggest that dysregulation of this important immune checkpoint may underlie the increased numbers of DN T cells in certain autoimmune diseases such as Sjogren's syndrome and systemic lupus erythematosus.

T cells specific for posttranslational modifications escape negative selection in thymus

Raposo, B.¹, Merky, P.¹, Yamada, H.², Niaudet, C.³, Urbonaviciute, V.¹, Pinto, S.⁴, Kyewski, B.⁴, Holmdahl, R.¹, Backlund, J.¹

¹Karolinska Institute, Medical Biochemistry & Biophysics, Section for Medical Inflammation Research, Stockholm, Sweden, ²Kyushu University, Medical Institute of Bioregulation, Division of Host Defense, Fukuoka, Japan, ³Karolinska Institute, Department of Medical Biochemistry and Biophysics, Division of Vascular Biology, Stockholm, Sweden, ⁴German Cancer Research Center (DKFZ), Division of Developmental Immunology, Tumor Immunology Program, Heidelberg, Germany

In the thymus, tissue-restricted antigen (TRA) expression is to a large extent dependent on the expression of Aire in medullary thymic epithelial cells (mTECs). This promiscuous gene expression contributes to the deletion of auto-reactive T cells. In the current study, we addressed the possibility that this central tolerance mechanism may exclude tolerance to TRAs that are normally subjected to post-translational modifications (PTM). We report that Aire-dependent central tolerance to a model self-antigen indeed targets T cells specific to the native antigen in an efficient manner. However, T cells specific for the PTM epitope variant escape tolerance, despite the PTM variant of the auto-antigen being the physiological form in the periphery. As the majority of self-antigens is subjected to different forms of post-translational modifications, our findings highlight a potential general mechanism, whereby T cells can escape an otherwise efficient tolerance mechanism and contribute to the development of autoimmune diseases.

3010

A highly conserved NF- κ B-responsive enhancer is critical for thymic expression of Aire in mice

Peterson, P., Haljasorg, U., Bichele, R., Saare, M., Guha, M., Maslovskaja, J., Kond, K., Remm, A., Pihlap, M., Tomson, L., Kisand, K., Laan, M.

University of Tartu, Tartu, Estonia

Autoimmune regulator (Aire) has a unique expression pattern in thymic medullary epithelial cells (mTECs), in which it plays a critical role in the activation of tissue-specific antigens. The expression of Aire in mTECs is activated by receptor activator of nuclear factor κ B (RANK) signaling; however, the molecular mechanism behind this activation is unknown. Here, we characterize a conserved noncoding sequence 1 (CNS1) containing two NF- κ B binding sites upstream of the Aire coding region. We show that CNS1-deficient mice lack thymic expression of Aire and share several features of Aire-knockout mice, including downregulation of Aire-dependent genes, impaired terminal differentiation of the mTEC population, and reduced production of thymic Treg cells. In addition, we show that CNS1 is indispensable for RANK-induced Aire expression and that CNS1 is activated by NF- κ B pathway complexes containing RelA. Together, our results indicate that CNS1 is a critical link between RANK signaling, NF- κ B activation, and thymic expression of Aire.

Immunological tolerance mechanisms controlling human autoreactive CD8⁺ T cells in healthy and autoimmune conditions

Barnaba, V.¹, Martire, C.¹, Cammarata, I.¹, Citro, A.¹, Peruzzi, G.², Guerrieri, F.², Scrivo, R.¹, Valesini, G.¹

¹Sapienza, Internal Medicine e Specialità Mediche, Rome, Italy,

²Istituto Italiano di Tecnologia, CLNS@Sapienza, Rome, Italy

We report that apoptotic self-epitope (AE)-specific CD8⁺ T cells, derived from activated T cells undergoing apoptosis, maintain a naïve (N) phenotype in both healthy individuals (HIs) and

patients with autoimmune diseases (ADs) (rheumatoid arthritis or multiple sclerosis) showing a low disease activity (ADs^{lo} pts) or efficiently responding to anti-TNF- α therapy; whereas they show an effector memory or terminally-differentiated (EM or EMRA) phenotype, as well as a higher TCR avidity, in ADs^{hi} pts non-responding to the therapy. The combination of *in vitro* and *in vivo* evidences indicates that high peripheral levels of CD40L⁺ apoptotic T cells contribute to the selection of high avidity AE-specific CD8⁺ TEM/EMRA cells. In addition, at the light of the observation of a direct correlation between the percentage of activated (act)Tregs and AE-specific CD8⁺ TN cell frequency *in vivo*, and of a series of experiments on isolated Treg and AE-specific CD8⁺ TN or TEM/EMRA cell populations *in vitro*, we provide evidence that actTregs condition a naïve phenotype in AE-specific CD8⁺ T cells (that efficiently proliferate when made free from the Treg suppression), but they are unable to suppress the expansion of the differentiated ones. These data suggest that a high repertoire of autoreactive T cells is not deleted and is governed by various overlapping mechanisms to avoid intolerance by autoreactive T cells in HIs or ADs^{lo} pts. Gene expression profile analyses are in progress to define more in depth differences in this repertoire, and to identify the molecular pathway whereby Tregs control autoreactive CD8⁺ T cells.

Oral vaccines for transmissible prion diseases for multiple animal species at risk of infection

Goni, E.¹, Elisei, A.², Yim, L.³, Marta-Ariza, M.¹, Mathiason, C.⁴, Hoover, E.⁴, Chabalgoity, J.A.³, Wisniewski, T.⁵

¹New York University School of Medicine, Neurology, New York, United States, ²Instituto de Virologia INTA, Virologia, Hurlingham, Argentina, ³Facultad de Medicina Universidad de la Republica, Biotechnology-Laboratory for Vaccine Research, Montevideo, Uruguay, ⁴College of Veterinary Medicine and Biomedical Sciences, CSU, Microbiology, Immunology and Pathology, Fort Collins, United States, ⁵New York University Langone Medical Center, Neurology, Pathology, Psychiatry, New York, United States

We have developed an oral vaccination with PrP molecules delivered by an attenuated Salmonella carrier that was successful in preventing transmission and infection of prionoses in susceptible mice (Goni et al 2008, Neuroscience). The methodology was scaled up for testing in white tail deer, where we were able to elicit a distinct mucosal and systemic antibody response to prion proteins and achieve a partial protection to an oral challenge with a pathological CWD-prion (Goni et al 2015 Vaccine). We have now constructed six different PrP-like peptides that are able in the same Salmonella vaccine delivery system, or by controlled polymerization, to produce a sustained response against prion proteins from different species, using a reduced number of inoculations. The proof of concept study included a preparation of the Salmonella vaccines 10 days before inoculation, which we document to be viable (>90%) for at least a week at 4°C and subsequently for 36 hours at room temperature. Wild type CD-1 mice and transgenic mice

expressing sheep, elk or human PrP were inoculated weekly for three weeks with the oral preparations. A week after the last inoculation the animals were bled and fresh feces was collected. Each cohort of mice produced antibodies (both IgA and IgG) that cross-react with PrPs from different species. Production of these new vaccine formulations could be scaled up to be used in larger animals of any species and administered in enclosed facilities or potentially as bait in the wild.

A dual Chikungunya and smallpox vaccine derived from a novel, replication-incompetent poxvirus vaccine system provides mice with complete protection from Chikungunya virus and mousepox infection

Hayball, J.¹, Cooper, T.¹, Liu, L.¹, Eldi, P.¹, Tan, M.¹, Prow, N.², Suhrbier, A.², Howley, P.³

¹University of South Australia, Pharmacy and Medical Sciences, Adelaide, Australia, ²Queensland Institute of Medical Research, Berghofer Medical Research Institute, Brisbane, Australia, ³Sementis Ltd, Melbourne, Australia

Chikungunya virus (CHIKV) is a re-emerging pathogen responsible for febrile illness often accompanied by a rash, and arthralgia that may persist for years. Recent outbreaks in Asia, Europe and the Americas have highlighted the urgent need for a vaccine. The proprietary SCV vaccine delivery system consists of a live replication-defective Vaccinia virus vector (SCV) and a co-developed, CHO-derived, rescue cell line for virus production. The CHIKV structural polyprotein (C-E3-E2-Gp6K-E1) was inserted into SCV to produce SCV-CHIKV. Viral attenuation and an improved safety profile was demonstrated compared to the replication-competent counterpart (VACV-CHIKV) whereby immune deficient SCID mice remained healthy following infection with SCV-CHIKV while mice infected with the replication-competent counterpart (VACV-CHIKV) accumulated an increasing clinical score from 6 days post-infection. Vaccination of BALB/c mice with SCV-CHIKV (10⁶ pfu, i.p) was able to confer complete immunity against mousepox infection (3x10⁵ pfu, s.c), although a 10-fold higher dose was required compared to Vaccinia virus. Anti-CHIKV IgG1 and IgG2c antibodies (endpoint titres >2x10³) were detected three weeks after a single vaccination with 10⁶ pfu in C57BL/6 mice. Mice were then challenged with CHIKV (2x10⁴ CCID₅₀; s.c in both hind feet) and SCV-CHIKV vaccination completely protected mice from the viraemia and foot swelling produced in naive or Vaccinia vaccinated mice. The protective immune responses against CHIKV were equivalent to those generated by VACV-CHIKV at the dose used. In summary, SCV-CHIKV is a promising smallpox/CHIKV vaccine candidate that demonstrates the potential of the SCV delivery system in vaccine development for infectious diseases.

1308**Developing a non-human primate model for skin vaccination**Sandgren, K.¹, Kim, M.¹, Baharlou, H.¹, Bertram, K.¹, Pavelsky, T.², Botting, R.¹, Harman, A.¹, Cunningham, A.¹¹Westmead Institute for Medical Research, Centre for Virus Research, Westmead, Australia, ²University of North Carolina, Geological Sciences, Chapel Hill, United States

Dermal vaccination appears increasingly promising as the dense network of immune cells in the skin, especially dendritic cells (DC), allows for enhanced immune responses and the opportunity to tailor vaccine responses by targeting specific subsets for activation. A macaque model for skin vaccination will be valuable for dissecting the immune response to novel vaccines, incorporating both resident and migratory immune cells and may be critical for HIV challenge studies, where no small animal model of infection exists.

To inform accurate design and interpretation of such trials, we are comparing the anatomy and immune cell composition of pigtail macaque skin to human skin.

Macaque epidermis was significantly thinner than human which means devices aiming to deliver vaccines to the dermo-epidermal junction may not be accurate in macaques, although there were equivalent numbers of Langerhans cells. By fluorescence microscopy, similar populations of DCs (CD1a⁺, CD14⁺, XCR1⁺) and T cells were present in macaque and human dermis although some frequencies differed. We identified potential macaque equivalents of human BDCA-3⁺ cross-presenting DCs as XCR1⁺CADM1⁺ and further transcriptomic analysis will confirm this. These cells were the dominant dermal DC population in macaques, unlike humans, which could mean cross-presenting effects of vaccines tested in macaques are enhanced compared to humans. Langerin⁺ dermal DCs were rare in humans but present in marked numbers in macaques although the function of this subset is yet unknown.

These results will help inform design of delivery devices and vaccine formulations targeting specific DC subsets in skin, for testing in macaque models.

1324**Therapeutic vaccination enhances 4-1BB-mediated anti-tumor CD8 T cell immunity against poorly immunogenic haematological cancers**Doff, B., Soon, M., Kobayashi, T., McKee, S., Mattarollo, S.
The University of Queensland Diamantina Institute, Brisbane, Australia

Immunomodulators are effective in controlling haematological malignancy by initiating host anti-tumor immunity to otherwise poorly immunogenic and immune suppressive cancers. We questioned whether immune checkpoint modulation was sufficient to control poorly immunogenic pre-clinical models of non-Hodgkin's B cell lymphoma (B-NHL) and acute myeloid leukaemia (AML). Enhancing T cell co-stimulation with agonistic anti-4-1BB monoclonal antibody (mAb) was effective at suppressing the development of spontaneous Eμ-myc B-NHL in transgenic mice, and the growth of transplanted Eμ-myc

tumor clones that expressed ovalbumin. However, anti-4-1BB mAb treatment had limited efficacy against transplanted Eμ-myc tumors that had been 'immuno-selected'. In this setting, combination immunotherapy incorporating an alpha-Galactosylceramide (α-GalCer) based therapeutic vaccine with anti-4-1BB mAb was required to control these poorly immunogenic tumors. We observed potent synergy with vaccine + immune checkpoint treatment combination resulting in significantly enhanced survival, including durable complete responses in over 50% of mice. Elimination of lymphoma burden was associated with increased expansion and persistence of KLRG1⁺ CD8 T cell effector subsets upon combination treatment. Similar therapeutic efficacy was observed against AML-ETO9a tumors. In addition, anti-4-1BB mAb treatment led to significant increase in surface PD-1 expression on activated CD8 T cells and PD-L1 expression on myeloid cells, suggesting that sequential administration of anti-4-1BB mAb co-stimulation and anti-PD1 mAb blockage may provide further enhanced T cell-directed control of blood malignancies. Overall, our results demonstrate a powerful immune adjuvant effect of α-GalCer that acts in synergy with agonistic anti-4-1BB mAb therapy for control of poorly immunogenic lymphomas and leukaemias.

2684**Design of intracellular cleavable immune-conjugates**Kramer, K.^{1,2}, Young, S.L.², Walker, G.F.¹¹University of Otago, School of Pharmacy, Dunedin, New Zealand,²University of Otago, Department of Pathology, Dunedin, New Zealand

Antigen-adjuvant conjugates have shown to elevate immune-responses over mixtures, we hypothesised that antigen-adjuvant conjugates designed to be cleaved inside the cell may further enhance immunogenicity. Cytosine-phosphate-guanosine oligodeoxynucleotide (CpG) was conjugated onto the model antigen ovalbumin (OVA) using either stable or reversible disulphide linking chemistry. Two reversible conjugates were generated with different degrees of steric hindrance around the disulphide bond in order to vary the sensitivity to cleavage via disulphide exchange reactions. Stability towards intracellular as well as extracellular reducing conditions using glutathione (GSH) was characterised by size-exclusion chromatography. Stability studies showed that one disulphide linker was cleaved under extracellular reducing (extracellular triggered) conditions (10μM GSH) while the second disulphide linker was stable to the extracellular reducing environment however was cleaved by intracellular reducing (intracellular triggered) conditions (5mM GSH). Murine bone marrow derived dendritic cells (BMDC) were stimulated with either PBS, CpG/OVA mixture or a CpG-OVA conjugate. OTI and OTII cells were co-cultured with the stimulated BMDCs. Immunogenicity of the conjugates was measured by T-cell proliferation and interferon gamma (IFN-γ) production in the co-culture. The CpG/OVA mixture and the extracellular triggered conjugate induced a low percentage of proliferated T-cells as well as low IFN-γ production while the stable and intracellular triggered conjugates resulted in high immunogenicity as confirmed by high percentage of T-cell proliferation and high IFN-γ production. This work demonstrates

that the steric hindrance around disulphide linkers influences whether they are cleaved by extracellular or intracellular GSH concentrations and this stability correlates with activation of T-cells in cell culture studies.

Influenza vaccination with HA mini stem for broad antibody immunity

Valkenburg, S.¹, Mallajosyula, V.V.A.², Li, O.T.W.³, Chin, A.W.³, Varadarajan, R.², Poon, L.L.³

¹The University of Hong Kong, School of Public Health, HKU Pasteur Pole, Pokfulam, Hong Kong, ²Indian Institute of Science, Molecular Biophysics Unit, Bangalore, India, ³The University of Hong Kong, School of Public Health, Pokfulam, Hong Kong

A universal vaccine against influenza is needed to overcome antigenic drift and provide broad protection against outbreak and pandemic influenza viruses. We adopted the approach of protein minimization of the HA protein to focus the antibody response towards the functionally conserved epitopes of the HA stem. This HA-mini stem was then assessed in a mouse model to determine the protective efficacy of HA-stem specific antibodies. The H5 HA mini-stem protein refolds as a trimer, in a highly stable pre-fusion conformation representing the native conformation of the HA stem. Importantly, vaccination of mice with the H1 and H5 HA mini-stem resulted in significant protection from morbidity and mortality against challenge with homologous and heterologous influenza viruses, including group 2 influenza, H3N2 challenge. Our study is the first report of a Group 1 HA-stem vaccine showing Group 2 protection. Furthermore, passive immune sera transfer to naïve mice challenged with H5N1 demonstrated protection. However, virus micro-neutralization was observed by vaccine immune sera for H1N1, H7N7 and H3N2 viruses, but not H5N1 viruses, despite clear protection in vaccinated and passive transfer experiments for H5N1 viruses. This raises important issues for the role of stem-specific antibodies, and whether neutralization is a requisite for broad spectrum protection. We believe that this observation will provide critical research directions for developing novel universal influenza vaccines.

1947

Peptide-lipid nanovaccine for tumor imaging and immunotherapy

Zhang, Z.¹, Qian, Y.², Huang, C.², Shen, G.², Luo, Q.²

¹Huazhong University of Science and Technology, Wuhan National Laboratory for Optoelectronics, Wuhan, China, ²Huazhong University of Science and Technology, Department of Immunology, Tongji Medical College, Wuhan, China

By adopting a lipoprotein-mimicking peptide self-assembly principle, we created the high density lipoprotein (HDL)-like peptide-phospholipid scaffold (HPPS), a sub-30 nm core-shell lipid nanoparticle stabilized by apoA-1 mimetic peptides. The size of HPPS nanoparticle is tunable between 10-30nm depending on cargo payloads, which are shielded from leakage at physiological conditions until released intracellularly. The HPPS nanocarrier adds a new dimension to the core-shell

nanoparticle families particularly valuable for the intracellular delivery of imaging agents and therapeutic peptides to tumor. *In vivo* delivery of antigen peptide (Ap) to a specific type of immune cells especially dendritic cells (DCs), the most potent antigen-presenting cells, has gained increased interests in cancer immunotherapy field. Recently, we developed HPPS as a carrier to deliver antigen peptides to mature DCs in lymph node, which successfully elicited desiring anti-tumor immune response. The injection of Ap-HPPS allowed long-term tracking of its flow into lymph nodes using NIR imaging. More importantly, Ap-HPPS exhibited the ability to activate immature DCs and could be directly used as an effective targeting vaccine for *in vivo* cancer prevention without the need of immunologic adjuvants.

1197

Is the sustained release of vaccine antigens beneficial or detrimental to the development of immunity?

Bobbala, S., Gibson, B., Hook, S.

University of Otago, School of Pharmacy, Dunedin, New Zealand

Immunological dogma suggests that the sustained release of vaccine may be fraught with danger. If antigen is released at low levels in the absence of an adjuvant, tolerance may result. If antigen presenting cells (APCs) take up adjuvant in the absence of antigen, then autoimmunity may result. If antigen and adjuvant release is too high for too long then immune exhaustion may occur. However if a sustained release vaccine formulation could be developed which reduced the requirement for booster immunizations then the benefits would be enormous in terms of increased immunization completion and reduced costs.

We have been investigating if development of a sustained release vaccine is possible. In order to circumvent the issue of asynchronous release of antigen and adjuvant, vaccine is incorporated into a nanoparticle before being loaded into the sustained release formulation. The theory behind this is that intact nanoparticles will be released from the depot and taken up by APCs. The issue of the time required for optimal immune stimulation and the avoidance of immune exhaustion has been explored using systems with varied release kinetics. We have found that it is possible to develop systems that stimulate potent, long lasting, antigen specific CD4 and CD8 effector immune responses. With these systems the matching of the nanoparticle to the sustained release formulation is important as interactions between the systems will impact on release and the subsequent immune response. Finally, with the depot-forming systems we have investigated, vaccine incorporation in a nanoparticle is not always required.

to Fudan University, Key Laboratory of Medical Molecular Virology of MOE/MOH, Shanghai, China, ³Perelman School of Medicine, University of Pennsylvania, Department of Microbiology, Philadelphia, United States, ⁴Chinese National Human Genome Center at Shanghai, Shanghai-MOST Key Laboratory of Health and Disease Genomics, Shanghai, China

Due to less efficacy of Bacillus Calmette-Guérin (BCG), developing new vaccines against *M. tuberculosis* (*M.tb*) infection is still an urgent task. In the present study we have identified *M.tb* derived lipoprotein Z (LppZ) with high humoral and cellular responsiveness in pulmonary TB (PTB) patients when compared to healthy controls (HC), demonstrated by more LppZ-specific IFN- γ producing cells and higher titer of LppZ-specific antibody levels in PTB patients. The immunogenicity of LppZ in mice was determined furthermore. More LppZ-specific IFN- γ producing cells were generated in the mice immunized with LppZ emulsified in dimethyl dioctadecylammonium bromide (DDA) and monophosphoryl lipid A (MPL) mixture adjuvant when compared to adjuvant only group. Polyfunctional CD4⁺ T cells expressing two or triple cytokines, including IFN- γ , IL-2 and TNF- α , were apparently induced in the spleens of LppZ immunized mice. LppZ also exhibited strong capacity to recruit inflammatory cells and induce proinflammatory cytokine generation in a murine air pouch model. More importantly, LppZ provided more significant protection in mice challenged with the virulent H37Rv stain of *M.tb* after LppZ immunization than adjuvant alone or BCG vaccination. Apparent LppZ-specific Th1 immune responses were observed in the lungs of H37Rv challenged mice. Altogether, LppZ induces strong immune responsiveness upon *M.tb* infection both in human and mice. Its capacity to trigger inflammation reaction also implies its immune protection through innate immunity. LppZ is subjected to a novel candidate for subunit vaccine development against *M.tb* infection largely due to its capacity to induce strong innate and adaptive immunity.

A two-component synthetic peptide vaccine can protect against deep tissue infection with CovR/S mutant and wild type group A streptococci

Good, M.F.¹, Pandey, M.¹, Mortensen, R.^{2,3}, Calcutt, A.¹, Powell, J.¹, Dietrich, J.², Batzloff, M.R.¹

¹Griffith University, Institute for Glycomics, Gold Coast, Australia,

²Statens Serum Institut, Department of Infectious Disease Immunology, Copenhagen, Denmark, ³University of Copenhagen, Department of Immunology and Microbiology, Copenhagen, Denmark

Group A streptococci [GAS] are major human pathogens responsible for over 500,000 deaths annually mostly due to rheumatic heart disease or invasive (iGAS) disease. Two major virulence factors are the M protein and the IL8 protease, SpyCEP. Organisms that have a mutation within their 2-component negative regulatory system, CovR/S, are responsible for up to one half of all iGAS disease. The virulence of mutants is due in part to their ability to block neutrophil chemotaxis by upregulating SpyCEP. Although mice can be protected against WT organisms

by vaccination with a conserved M protein peptide (J8, linked to diphtheria toxoid [DT]), mutant organisms are vaccine-resistant. We show that vaccination with a large recombinant fragment of SpyCEP induces antibodies that protect IL8; furthermore we identify a 20-amino acid epitope from SpyCEP ('S2') and show that S2 linked to DT induces antibodies of equal potency. We combined S2-DT with J8-DT to create a combination vaccine. Vaccine resistance was completely overcome. Within 3 days of skin challenge the bio-burden in skin, blood and spleen of vaccinated mice was reduced by up to 99% with all organisms being cleared within 6 days. Histology demonstrated a significant increase of neutrophils at the infection site. Thus, the vaccine enables neutrophils to enter the site to destroy organisms that were opsonized by antibodies targeting the M protein. The data suggest that this vaccine that targets independent virulence factors would rectify the lack of immunity to hypervirulent GAS in humans. The vaccine is in clinical trials.

Deposition, protection and re-call of influenza virus specific memory CD8 T cells in the upper respiratory tract

Wakim, L.¹, Pizzolla, A.¹, Smith, J.¹, Brooks, A.¹, Reading, P.^{1,2}

¹Doherty Institute, The University of Melbourne, Microbiology and Immunology, Melbourne, Australia, ²World Health Organization Centre for Reference and Research on Influenza, Melbourne, Australia

Although the upper respiratory tract (URT) is the first site of contact for inhaled pathogens such as influenza virus, little is known regarding the site-specific immunity that can be evoked within this tissue following infection. Here we investigated the deposition, protection and re-call response of influenza virus-specific memory CD8 T cells in the upper respiratory tract. Our findings show that influenza virus-specific resident memory T cells (Trm) develop within the URT following intranasal influenza virus infection and persist long term with minimal decay. Using infection conditions that generate Trm only in the URT, we demonstrate that these cells are sufficient to prevent transmission of influenza virus from the URT to the lung. Given that effective generation of Trm in the URT is therefore likely to impact intranasal vaccine regimes, we investigated CD8 T cell priming and recall responses in the URT. Surprisingly, the mucosal associated lymphoid structures of the upper respiratory tract, termed nasal associated lymphoid tissue (NALTs), served as a site for the recall expansion of memory T cells following influenza virus infection, but failed to support activation of naive CD8 T cells. Together, these studies describe a unique Trm population in the URT which could be targeted for the development of novel strategies to limit the impact of influenza.

1590

Immune responses during acute allergic asthma promotes host protection against influenza a virus*Samarasinghe, A.^{1,2}, Melo, R.³, Duan, S.⁴, Lemessurier, K.¹, Liedmann, S.⁴, Lee, J.⁵, Thomas, P.⁴, Mccullers, J.^{1,6}**¹University of Tennessee Health Science Center, Pediatrics, Memphis, United States, ²St. Jude Children's Research Hospital, Infectious Diseases, Memphis, United States, ³Federal University of Juiz de Fora, Cellular Biology, Juiz de Fora, Brazil, ⁴St Jude Children's Research Hospital, Immunology, Memphis, United States, ⁵Mayo Clinic, Biochemistry, Scottsdale, United States, ⁶St Jude Children's Research Hospital, Infectious Diseases, Memphis, United States*

Allergic asthma caused by fungal sensitization is a prominent subtype affecting 70% of severe asthmatics. Asthmatics are generally considered to be more susceptible to respiratory viruses, and were identified as an 'at risk' group for hospitalization during the 2009 influenza pandemic. Retrospective studies showing that asthmatics were less likely to be admitted to the intensive care unit or die from influenza compared to non-asthmatics raised questions as to possible mechanisms for these seemingly counterintuitive findings. As a first step, we created and characterized a mouse model system that could be used to study influenza in severe fungal allergy. Herein we found that the timing of influenza virus infection determined the disease outcome. Mice infected during peak allergic inflammation were protected from influenza morbidity and had enhanced viral clearance compared to mice infected at the resolution of allergic inflammation. Since eosinophils were a prominent cell type in the airways of mice that were protected from influenza, we hypothesized that eosinophils promote host protection by enhancing cellular immunity. Eosinophils were susceptible to virus infection and underwent piecemeal degranulation in response, but were resistant to virus-induced cell death. Virus-exposed eosinophils upregulated antigen presenting machinery and were able to induce CD8⁺ T cell activation and proliferation *in vitro* and *ex vivo*. Adoptive transfer of eosinophils resulted in reduced lung viral burden, enhanced lung compliance, and higher virus-specific CD8⁺ T cells. Eosinophils were also able to prime naïve CD8⁺ T cells. These data suggest a possible mechanism for host protection against influenza virus in asthmatics.

Initial Interactions of herpes simplex virus with human skin dendritic cells*Kim, M.¹, Truong, N.R.¹, James, V.², Sandgren, K.J.¹, Bosnjak, L.², Harman, A.N.¹, Nasr, N.¹, Bertram, K.M.¹, Olbourne, N.³, Sawleshwarkar, S.⁴, McKinnon, K.⁵, Cohen, R.C.⁶, Cunningham, A.L.¹**¹The Westmead Institute for Medical Research and The University of Sydney, Westmead, Australia, ²The Westmead Institute for Medical Research, Westmead, Australia, ³Sydney Institute of Plastic and Reconstructive Surgery, Chatswood, Australia, ⁴Western Sydney Sexual Health Centre Health Centre, Westmead, Australia, ⁵Western Sydney Sexual Health Centre, Westmead, Australia, ⁶The Children's Hospital, Westmead, Australia*

HSV initially infects the stratified squamous epithelium of the

anogenital mucosa prior to entering nerve endings. We have previously reported that topical application of HSV-1 to human foreskin explants shows epidermal Langerhans cells (LCs) are initially infected, then emigrate into the dermis where they formed large cell clusters with BDCA3⁺ dermal dendritic cells (DCs) and DC-SIGN⁺ DCs/macrophages. HSV-expressing LC fragments were observed inside the dermal DCs/macrophages. No other infected epidermal cells interacted with dermal DCs (Kim et al., Plos Pathogens, 2015). Therefore, we isolated LCs and dermal DCs from large abdominal skin specimens by flow sorting. LCs were pulsed with GFP tagged HSV and co-cultured with BDCA3⁺ dermal DCs. All infected LCs showed markers of apoptosis at 18 hr p.i. Approximately 50% of BDCA3⁺ DCs co-localized with infected LCs and in some cases fragments of infected LCs were observed within the dermal DC cytoplasm. HSV infected LCs secreted CCL3, 4, 5, IL8, TNF α and IP10 and BDCA3⁺ DCs CCL2 and 5 [by cytometric bead assay] as potential 'find me' signals. Further changes in gene expression in HSV-LC-BDCA3⁺DC cultures during these processes are being examined by RNAseq. In genital herpes lesions the selective contact of CD8 T cells with BDCA3⁺ DCs rather than other dermal DCs was observed. Thus, we conclude that a viral antigen relay takes place where HSV infected LCs undergo apoptosis and are taken up by dermal DCs by phagocytosis for subsequent antigen presentation probably via different pathways for CD4 and CD8 T cells.

3761

An epithelial integrin regulates the amplitude of protective lung interferon responses through a TGF β -dependent mechanism*Meliopoulos, V.¹, Van de Velde, L.-A.¹, Thomas, P.², Sheppard, D.³, Murray, P.⁴, Schultz-Cherry, S.⁵**¹St Jude Children's Research Hospital, Infectious Diseases, Memphis, United States, ²St Jude Children's Research Hospital, Immunology, Memphis, United States, ³UCSF Medical Center, Medicine, San Francisco, United States, ⁴St Jude Children's Research Hospital, Infectious Diseases and Immunology, Memphis, United States, ⁵St Jude Children's Research Hospital, Memphis, Infectious Diseases, Memphis, United States*

Integrins facilitate intercellular movement and communication. Unlike the promiscuous activities of many integrins, $\beta 6$ integrin is restricted to damaged and developing epithelia and partners exclusively with integrin αV to modulate acute lung injury (ALI). Given that ALI is a complication of respiratory infection, we used mice lacking $\beta 6$ integrin ($\beta 6$ KO) to probe the role of the epithelial layer in controlling the lung microenvironment during infection. We found $\beta 6$ KO mice were resistant to a range of influenza virus strains, Sendai virus and displayed a remarkable resistance to *Streptococcus pneumoniae* infection after prior H1N1 infection; the main cause of death from influenza. Although there was no difference in overall viral load, the lungs of influenza virus infected $\beta 6$ KO mice had decreased inflammation, lower cytokine/chemokine levels, improved lung function and phenotypically distinct macrophages as compared to wild-type (WT) mice. Mechanistically, resistance in the absence of epithelial $\beta 6$ integrin was caused by intrinsic priming

of the lung microenvironment by type I interferons due to the absence of $\beta 6$ -activated latent TGF- β . Addition of exogenous TGF- β one day pre-influenza virus infection in $\beta 6$ KO mice resulted in morbidity, mortality and a lung microenvironment similar to WT mice. Our studies suggest that expression of $\beta 6$ on epithelia leads to activation of lung TGF- β that suppresses the production of interferons primarily from macrophages, leading to a dysregulated lung environment and increased lung injury. Timely modulation of $\beta 6$ integrin activity is therefore a means to improve outcomes in lung viral infections.

Human mucosal-associated invariant T cells contribute to anti-viral influenza immunity via IL-18-dependent activation

Loh, L.¹, Wang, Z.¹, Sant, S.¹, Nguyen, O.¹, Jegaskanda, S.¹, Corbett, A.¹, Rossjohn, J.², Xu, J.³, McCluskey, J.¹, Kedzierska, K.¹

¹The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia, ³Fudan University Shanghai Medical College, Shanghai, China

Mucosal-associated invariant T cells (MAIT) are innate-like T cells, which rapidly produce inflammatory mediators during microbial stimulation, thereby can contribute to the cytokine milieu and modulation of other immune populations. However, their role during viral infections remains unclear. We speculated that MAIT cells (CD161⁺Va7.2⁺) were activated in patients hospitalised with the novel avian H7N9 subtype influenza virus (N=16), as evidenced by dynamic changes in their frequencies during the course of a disease. To assess whether MAIT cells were activated and the mechanism underlying MAIT cell activation during an influenza virus infection, we utilized an *in vitro* co-culture system of influenza A virus (IAV)-infected human lung epithelial cells (A549) and human peripheral blood mononuclear cells (PBMC) with intracellular cytokine staining. We compared influenza-induced MAIT cell activation to the activation induced in NK cells. We showed robust upregulation of IFN- γ and GzmB after IAV co-culture with MAIT cells and NK cells, although responses varied across subjects (1-48% IFN- γ ⁺MAIT, N=22; 0.7-30% IFN- γ ⁺NK, N=22). The activation of MAIT cells was dependent on inflammatory mediators upregulated during IAV co-culture, whereas NK cells required cell-associated contact in addition to inflammatory milieu for their activation. Depletion of CD14⁺ monocytes and blocking of IL-18, but not IL-12, abrogated optimal MAIT cell activation. Overall, our data demonstrates the capacity for MAIT cells to be indirectly activated by IAV via an IL-18 dependent mechanism and highlight their potential to contribute to universal immunity and/or immunopathology in influenza virus-infected individuals.

Knockdown of p65 subunit of NF- κ B transcription factor downregulates the induction of pro-inflammatory cytokines in human lung epithelial cells infected with influenza H9N2 virus

Haghpour, A.¹, Farzin, H.², Toroghi, R.²

¹Ferdowsi University of Mashhad, Mashhad, Iran, Islamic Republic of, ²Razi Vaccine and Serum research Institute, Mashhad, Iran, Islamic Republic of

Inflammation is a hallmark feature of many influenza virus infections. To obtain insight into the inflammatory mechanisms involved in influenza H9N2 infection of human lung epithelial cells, A549 airway epithelial cells were infected with H9N2 virus and the expressions of pro-inflammatory cytokines (IL-1 β , IL-6) and chemokine (IL-8) in these cells were examined by qPCR and ELISA. Moreover, the effect of silencing of p65 component of NF- κ B in A549 cells infected with H9N2 virus on the expression and secretion of pro-inflammatory cytokines and chemokine and virus replication were evaluated by qPCR, ELISA, Immunocytochemistry and western blotting.

H9N2 virus was able to cultivate in the human lung epithelial cell line (A549) and stimulate production of IL-1 β , IL-6 and IL-8. Expressions of cytokine and chemokine genes were down-regulated to a significantly lower level (IL-1 β after 24hours (P < 0.1) and 48hours (P < 0.01), IL-6 after 24 hours (p < 0.01) and IL-8 after 24 hours (p < 0.05)) in p65 knocked down A549 cells as compared with scramble shRNA cultured cells infected with H9N2 influenza virus. The amount of IL-6 and IL-1 β proteins secreted into the culture medium was also decreased after silencing the p65 component of NF- κ B in A549 cells infected with H9N2 influenza virus in different multiplicity of infections (MOI).

The results presented in this study provide the mechanism by which H9N2 virus induce inflammation in human lung epithelial cells. These findings will broaden our understanding of host innate immune mechanisms and the pathogenesis of H9N2 influenza viruses in human respiratory epithelium.

Human TRIM5 is a functional restriction factor for tick-borne flaviviruses

Chiramel, A.¹, Meyerson, N.², McNally, K.¹, Mendes-Solis, O.¹, Montoya, V.¹, Robertson, S.¹, Sturdevant, G.¹, Sawyer, S.², Best, S.¹

¹Rocky Mountain Laboratories, NIAID, NIH, Hamilton, United States, ²University of Colorado Boulder, Molecular, Cellular, and Developmental Biology, Boulder, United States

Tripartite motif (TRIM) proteins function as interferon-inducible virus- and host-specific restriction factors that can bind to viral proteins and interrupt virus replication. The flaviviruses include globally significant human pathogens such as tick-borne encephalitis virus (TBEV), West Nile virus (WNV) and dengue virus. Previous studies demonstrated that TBEV replication is inhibited by TRIM30D, a rodent-specific protein that functions by binding to the viral RNA polymerase (called NS5) and targeting it for degradation. The closest human paralog of TRIM30D is TRIM5, a renowned restriction factor thought to

be retrovirus-specific. Our study reveals that both human (h) and rhesus (rh) TRIM5 restrict replication of viruses belonging to the TBEV serogroup but not WNV. The impact of ectopically expressed rhTRIM5 on TBEV was profound, reducing production of infectious virus by more than 99%. hTRIM5 overexpression imposed a 90% reduction whereas knock-down of hTRIM5 partially rescued the antiviral effects of interferon treatment. TRIM5 reduced production of both viral RNA and protein, suggesting that TRIM5 targets an early step in virus replication. However, unlike TRIM30D, TRIM5 did not interact with NS5 and instead interacts with and degrades NS3, an RNA helicase critical to virus replication. Moreover, TRIM5 colocalized with NS3 and dsRNA suggesting that TRIM5 disrupts the viral replication complex. This work demonstrates that TRIM5 can target two very different viral proteins, the HIV capsid and the TBEV helicase. Understanding the genetic trade-offs in TRIM5 that enable restriction of one virus versus another will illuminate how the evolution of host resistance is shaped by multiple pathogens.

Vaccine-elicited preferential induction of polyfunctional Th cells is associated with protection against acute retroviral infection

Motozono, C., Tsuji-Kawahara, S., Takamura, S., Miyazawa, M.
Kindai University Faculty of Medicine, Department of Immunology, Osaka, Japan

Understanding functional characteristics of antigen-specific CD4⁺ T-cell responses contributing rapid elimination of pathogenic retroviruses is crucial for the development of effective antiretroviral vaccines. We previously identified an MHC class II- restricted epitope derived from Friend mouse retrovirus envelope glycoprotein, peptide i_{18} , that completely protected a highly susceptible strain of mice against fatal Friend virus (FV) infection by a single immunization. Using this model, we investigated the characteristics of antigen-specific CD4⁺ T cell responses associated with immune protection against acute retroviral infection. We found that i_{18} -specific CD4⁺ T cells became detectable much earlier than those specific for peptide fn , another envelope epitope that elicited less effective protection. Associated with higher affinity of i_{18} -specific TCRs in comparison with fn -specific ones, clonotypically restricted i_{18} -specific CD4⁺ T cells with individually different variable regions were detected after FV challenge, and showed the ability to produce polyfunctional cytokines. Moreover, the priming with i_{18} resulted in more prominent induction of CXCR5⁺ PD-1⁺ Tfh cells upon FV challenge than fn -immunization. As a result, FV-neutralizing antibodies were produced earlier in mice immunized with i_{18} compared with those given fn . Taken together, these results indicate that the use of an appropriate epitope preferentially induces polyfunctional Th responses in the early phase of acute retroviral infection that contribute to the effective antiviral protection.

Orchestration of nucleic acid sensing pathways in HSV-specific CD8⁺ T cell priming

Bachem, A., Whitney, P.G., Greyer, M., Tebartz, C., Gebhardt, T., Bedoui, S.

The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia

Dendritic cells (DC) not only present antigens to T cells but also communicate pivotal information about the environmental context in which antigen uptake has occurred. Precisely how these signals are integrated by DC and then decoded by T cells remains unclear. We have addressed this question using an *in vivo* model of cutaneous Herpes Simplex virus (HSV) infection. Efficient HSV-1-specific CD8⁺ T cell priming relied heavily on the provision of type I interferon (IFN). However, it has been shown that a plethora of sensing pathways can induce the secretion of type I IFN. Unexpectedly, we demonstrate that the most prominent nucleic acid sensing pathways, such as those depending on STING, MAVS, MyD88 and Caspase-1/11 played redundant roles in HSV-specific CD8⁺ T cell priming. The TLR3-TRIF pathway, however, was essential for this process. Here, we untangle the type I IFN subtypes that were induced, the transcription factors that were required and the effects these factors have on IFN-stimulated genes, such as IL-15. These findings demonstrate that our immune system has evolved several independent mechanisms to translate the complex sensing of pathogens into effective adaptive immune responses.

Memory B cells recognising avian H5 and H7 influenza are widely prevalent - potential role as vaccine targets or as an immunotherapy

Wheatley, A.K., Kristensen, A.B., Ana-Sosa-Batiz, F.E., Vandervan, H.A., Kent, S.J.

University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia

Endemic H1N1 and H3N2 influenza viruses cause recurrent seasonal infections and significant global morbidity and mortality. Recently, zoonotic transmission has resulted in human infections with avian influenza strains such as H5N1, H10N8 and H7N9. Such infections are associated with high pathogenicity and lethality, and a lack of population level immunity raises significant concerns about pandemic potential. Low titres of serum antibodies binding H5 or H7 have been previously reported in unexposed individuals, however the protective potential of these responses remains unclear. Here, we used fluorescently-labelled, recombinant hemagglutinin (HA) proteins as flow cytometric probes to identify B cells specific for avian influenza in healthy unexposed subjects (N=18). Low frequencies of H5+ (0.02-0.12%) and H7+ (0.03-0.08%) B cells were found in all individuals studied to date, expressed surface IgA, IgM or IgG and displayed a classical resting memory phenotype (IgD- CD27+ CD21+). Rare B cells binding both H5 and H7 (0.002-0.046%) were also observed. Administration of the 2015 trivalent influenza vaccine drove a significant but

modest expansion of B cells recognising avian HAs. H5+, H7+ and H5+H7+ B cells were sorted and B-cell receptor transcripts sequenced. Representative antibodies were expressed and demonstrated in vitro neutralisation activity and/or non-neutralising effector functions such as antibody-dependent cellular cytotoxicity and antibody-dependent phagocytosis. Our results suggest seasonal influenza exposure primes, albeit inefficiently, pools of highly cross-reactive memory B cells that could

- (a) form a substrate targetable by improved vaccines and
- (b) provide a source of cross-reactive HA-specific antibodies with therapeutic potential against future pandemics.

XCR1+ dendritic cells promote memory CD8+ T cell recall upon secondary infections

Alexandre, Y.^{1,2,3}, Ghilas, S.^{1,2,3}, Sanchez, C.^{1,2,3}, Le Bon, A.^{4,5,6}, Crozat, K.^{1,2,3}, Dalod, M.^{1,2,3}

¹Aix Marseille Université UM 2, Centre d'Immunologie de Marseille-Luminy, Marseille, France, ²CNRS, UMR 7280, Marseille, France, ³INSERM, U 1104, Marseille, France, ⁴Université Paris Descartes, Institut Cochin, Paris, France, ⁵CNRS, UMR 8104, Paris, France, ⁶INSERM, U 1016, Paris, France

A subset of mouse dendritic cells (DCs) specifically express the chemokine receptor XCR1 and excels at priming CD8+ T cells including through cross-presentation. Naive CD8+ T cell priming during tumor development or first encounters with many intracellular pathogens requires cross-presentation by XCR1+ DCs. Memory CD8+ T lymphocytes (mCTLs) harbor a lower activation threshold as compared to naive cells. However, whether their recall responses depend on XCR1+ DCs is unknown. By using a new mouse model allowing fluorescent tracking and conditional depletion of XCR1+ DCs, we demonstrate a differential requirement of these cells for mCTL recall during secondary infections by different pathogens. XCR1+ DCs were instrumental to promote this function upon secondary challenges with *Listeria monocytogenes*, Vesicular Stomatitis Virus or Vaccinia virus, but dispensable in the case of mouse cytomegalovirus. We deciphered how XCR1+ DCs promote mCTL recall upon secondary infections with *Listeria*. By visualizing for the first time the in vivo choreography of XCR1+ DCs, NK cells and mCTLs during secondary immune responses, and by neutralizing in vivo candidate molecules, we demonstrate that, very early after infection, mCTLs are activated, and attracted in a CXCR3-dependent manner, by NK cell-boosted, IL-12- and CXCL9-producing, XCR1+ DCs. Hence, depending on the infectious agent, strong recall of mCTLs during secondary challenges can require cytokine- and chemokine-dependent cross-talk with XCR1+ DCs and NK cells. This work was funded by the European Research Council under the European Community's Seventh Framework Programme (FP7/2007-2013 Grant Agreement no. 281225 for the SystemsDendritic project).

RUNX2 mediates plasmacytoid dendritic cell egress from the bone marrow and controls viral immunity

Chopin, M.¹, Preston, S.², Lun, A.³, Tellier, J.¹, Pelligrini, M.², Visvader, J.¹, Corcoran, L.¹, Wu, L.¹, Nutt, S.¹

¹Walter & Eliza Hall Institute, Molecular Immunology, Parkville, Australia, ²Walter & Eliza Hall Institute, Infection and Immunity, Parkville, Australia, ³Walter & Eliza Hall Institute, Bioinformatics, Parkville, Australia

Dendritic cells (DCs) have evolved into a diverse family of cellular subsets, each with their own distinctive features. Plasmacytoid DCs (pDCs) represent a unique immune cell type that responds to viral nucleic acids through the rapid production of type I interferons. Within the hematopoietic system, the transcription factor RUNX2 is exclusively expressed in pDCs and is required for their peripheral homeostasis. Here we show that RUNX2 deficiency plays an essential role in promoting pDC localization and function. RUNX2 is required for the appropriate expression of the integrin-mediated adhesion machinery, enabling adherence to the extracellular matrix. We also show that bone marrow pDCs are highly responsive to the chemokine CXCL12, with the down-modulation of its receptor CXCR4 by RUNX2 being required for pDC egress into the circulation. RUNX2 also facilitates the robust response to acute viral infection through the direct control of IRF7, the major regulator of the type I interferon production. Mice lacking one copy of *Runx2* have reduced numbers of peripheral pDCs and IFN α expression, which might contribute to the reported difficulties of individuals with Cleidocranial Dysplasia, who are haploinsufficient for RUNX2, to clear viral infections.

Dendritic cell expressed ADAM10: a novel target for reducing Th2 immune responses

Damle, S.¹, Martin, R.¹, Lownik, J.^{1,2}, Conrad, D.¹

¹Virginia Commonwealth University, Department of Microbiology and Immunology, Richmond, United States, ²Virginia Commonwealth University, Center for Clinical and Translational Research, Richmond, United States

Allergy and allergic asthma are significant health burdens in developed countries and are increasing in prevalence. We previously demonstrated therapeutic potential of ADAM10 inhibitors in murine allergic airway inflammation. In this study, we examined the phenotype of a DC-specific ADAM10 knockout mouse model (A10DCKO) as DCs are critical in the development of Th2 responses. Using house dust mite (HDM) extract induced model of allergic airway disease, we found that the A10DCKOs had significantly less airway resistance and fewer eosinophils than wildtype (WT). Further, the A10DCKOs had less IL-4 and IL-13 cytokine expression in the lung, HDM-specific IgG1 in serum, and histological lung inflammation. Upon challenge with inhaled antigen, the A10DCKOs demonstrated less stimulation of antigen-specific T cell proliferation in the spleen, but not in the mediastinal lymph node. We recapitulated this *in vitro* with sorted splenic DCs and found less T cell proliferation with A10DCKO CD172⁺ DCs compared to WT. Whereas CD24⁺ DCs

from both mice stimulated T cells to similar extents. Intriguingly, CD172⁺ DCs are reduced in the A10DCKOs, similar to previous reports of the DC-specific Notch2KO. We demonstrated alterations in lung DCs subsets in the HDM model, which may also contribute to the effects on Th2 responses seen. In addition, splenic DCs from A10DCKO exhibited elevated levels of the co-stimulatory molecules, ICOSL and OX40L, but not CD86. Overall these results point to a mechanism involving both Notch and co-stimulatory molecules in the phenotype observed and point to a novel strategy for modulating Th2 immune responses.

Targeting CLEC9A can deliver antigen to human CD141⁺ DC for recognition by both CD4⁺ and CD8⁺ T cells

Tullett, K.M.^{1,2,3}, Leal Rojas, I.M.², Minoda, Y.², Tan, P.S.^{1,3}, Zhang, J.-G.^{4,5}, Smith, C.⁶, Khanna, R.⁶, Shortman, K.^{4,5}, Caminschi, I.^{1,3,5}, Lahoud, M.H.^{1,3}, Radford, K.J.²

¹Monash University, Melbourne, Australia, ²Mater Research Institute - University of Queensland, Brisbane, Australia, ³Burnet Institute, Melbourne, Australia, ⁴Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ⁵University of Melbourne, Melbourne, Australia, ⁶QIMR Berghofer Medical Research Institute, Brisbane, Australia

Targeting vaccine antigens (Ag) to the dendritic cells (DC) that initiate cytotoxic T lymphocyte (CTL) responses is an attractive strategy for tumor immunotherapy or viral clearance. The mouse CD8⁺DC-lineage and their human CD141⁺ DC equivalents cross-present Ag and initiate CTL responses. The C-type lectin-like receptor CLEC9A, that senses dead cells and facilitates Ag cross-presentation, is specifically expressed on CD141⁺DC, making it an ideal target for such immunotherapy. Indeed, when injected into mice the anti-Clec9A antibody (Ab) can deliver Ag to CD8⁺DC resulting in potent humoral and T cell responses. We therefore developed anti-human CLEC9A chimeric human IgG4 Ab and assessed its ability to deliver conjugated CMVpp65 Ag to CD141⁺DC for recognition by CD4 and CD8

T cells. For comparison we generated chimeric IgG4 Ab specific for DEC-205, a molecule expressed on CD141⁺DC and many human leukocytes; anti-DEC-205 has already been used to target human and mouse DC. The chimeric anti-CLEC9A and anti-DEC-205 Ab retained specificity for their target receptors and were accumulated equivalently by CD141⁺DC. Both chimeric Ab delivered Ag to CD141⁺DC for presentation to CD4⁺ T cells *in vitro*. However, anti-CLEC9A Ab were superior at delivering Ag for cross-presentation to CD8⁺ T cells *in vitro*. Anti-CLEC9A and anti-DEC-205 Ab were comparable at delivering Ag to splenic CD141⁺DC for cross-presentation *in vivo* in humanized mice comprising functional human DC. Therefore, anti-CLEC9A Ab are at least as effective as anti-DEC-205 at Ag delivery to CD141⁺ DC. The superior specificity of anti-CLEC9A Ab for this DC subset warrants further development for vaccines.

1352

Enhanced activation of human CD141⁺ DC and CD1c⁺ DC in vivo with combined TLR3/TLR8 ligation

Chang, K., Minoda, Y., Leal Rojas, I., Tullett, K., Radford, K. Mater Research Institute-University of Queensland, Brisbane, Australia

Mice reconstituted with human hematopoietic stem cells (humanised mice) are a practical model to study aspects of the human immune system. We developed a humanised mouse model in which fully functional human DC subsets, including CD141⁺ and CD1c⁺ DC and plasmacytoid (p)DC, develop from human CD34⁺ cord blood progenitor cells in immunodeficient mice. CD141⁺ DC are the human equivalents of the mouse CD8⁺ DC that are essential for the induction of cytotoxic T lymphocyte responses against cancers and many pathogens, making them attractive targets to exploit for the development of new vaccines. We used humanised mice to investigate activation of CD141⁺ DC by poly I:C and R848, agonists for TLR3 and TLR8 respectively, which are both expressed by CD141⁺ DC.

The transcriptome of CD141⁺ DC from humanised mice aligned with that of CD141⁺ DC found in human tissues, confirming this as a robust and practical model. Activation with either poly I:C or R848 upregulated costimulatory molecules CD40, CD80, CD83 and CD86 by CD141⁺ DC and CD1c⁺ DC to a similar extent *in vivo* and the combination of poly I:C and R848 further enhanced costimulatory molecule expression by both subsets. Poly I:C and R848 combined resulted in higher levels of IFN- λ and IL-12 in the serum compared to either agonist alone. Moreover, CD141⁺ DC activated with Poly I:C and R848 were more effective at priming naive antigen-specific CD8⁺ T cells compared to CD1c⁺ DC. These data suggest that poly I:C and R848 combined is an effective adjuvant for CD141⁺ DC.

3362

RelB-deficient dendritic cells have increased retinoic acid dehydrogenase activity and promote regulatory T cell differentiation in mice and humans

Nel, H.J., Ruscher, R., Boks, M., Thomas, R., O'Sullivan, B. UQDI, TRI, Brisbane, Australia

Peripherally-derived Foxp3⁺ regulatory T (pTreg) cell generation from naive T cells in the TGF- β -enriched intestinal environment depends on specialized dendritic cells (DCs). RelB-deficient mice have an increased proportion of Treg cells in the spleen despite their thymic atrophy and lack of lymph nodes and Peyer's patches. The mechanism by which RelB influences pTreg is incompletely understood. We demonstrate in RelB^{-/-} mice, that antigen-exposed RelB^{-/-} DCs induce significantly more Tregs from adoptively-transferred CD4⁺CD25⁻ precursors than RelB^{+/-} mice. This was recapitulated *in vitro*. Treg induction was TGF- β - and retinoic acid (RA)-dependent. RA-metabolizing *Raldh2* enzyme expression and ALDH activity were increased in RelB^{-/-} relative to RelB^{+/-} splenic DCs. In naive mice, these ALDH⁺ DCs developing in the absence of RelB generated pTreg cells in the spleen in the context of high TGF- β production. To determine the relevance to immunotherapy, we compared human monocyte-derived DCs generated in the absence or presence of calcitriol, a

selective suppressor of RelB. Similar to RelB^{-/-} DCs, ALDH activity, *ALDH1A2* and RA-responsive transcription factors *RARA* and *RXRA* expression were increased and LPS-induced costimulatory molecule expression was decreased in calcitriol-modified human DCs. In allogeneic mixed lymphocyte cultures, T cell proliferation decreased and IL-10⁺ regulatory T cells increased in response to calcitriol-modified, relative to untreated DCs. These data indicate that RelB deficiency or pharmacological inhibition promotes RA metabolism in DCs and RA- and TGF- β -dependent induction of regulatory T cells and support clinical application of DC targeting with RelB inhibitor and antigen.

Developmental heterogeneity of splenic CD11b⁺ dendritic cells

Schraml, B.¹, van Blijswijk, J.², Snelgrove, K.², Rogers, N.², Reis e Sousa, C.²

¹Klinikum der Universität München, Walter-Brendel-Centre for Experimental Medicine, Planegg-Martinsried, Germany, ²The Francis Crick Institute, Lincoln's Inn Fields Laboratory, London, United Kingdom

Early life immune balance is essential for survival and establishment of healthy immunity in later life. In neonates, dendritic cells (DCs), which are versatile controllers of immunity, are qualitatively distinct from adults. Newborns have an underdeveloped DC compartment when compared to adults, containing not only fewer DCs, but also an altered ratio of DC subsets. Why such age-dependent differences exist is unclear but newborn DCs are considered underdeveloped and functionally immature.

We have recently generated a model to fate map conventional DC precursors (CDP) with yellow fluorescent protein (YFP) and have revisited the development of DCs during mouse embryogenesis, as well as in perinatal and adult mice. We found that cells resembling adult CD11c⁺MHCII⁺ DCs were present in spleen as early as embryonic day 17. Surprisingly, CD11c⁺MHCII⁺CD11b⁺ splenocytes, which phenotypically resemble CDP-derived CD11b⁺ DCs that label strongly with YFP in adult mice, were poorly labeled in embryonic and neonatal mice. However, the labeling frequency increased gradually overtime, reaching adult levels by five weeks of age, when the splenic DC pool is fully established. Thus, splenic CD11c⁺MHCII⁺CD11b⁺ DCs are predominantly CDP-derived in adults, yet cells with similar phenotypic characteristics but distinct ontogeny populate the spleen in young mice. Preliminary data indicate that these ontogenetically distinct DCs exhibit functional differences. Thus, our studies reveal a previously unappreciated developmental heterogeneity of splenic CD11b⁺ DCs in young mice. Characterizing how developmentally regulated DC poiesis shapes the unique features of early life immunity will provide novel insights into immune development.

2078

Defining CD16⁺ dendritic cells as a unique myeloid antigen presenting cell

Fromm, P.¹, Papadimitriou, M.¹, Hsu, J.¹, Larson, S.², Gibson, J.², Bradstock, K.³, Kupresanin, F.¹, Clark, G.¹, Hart, D.¹

¹ANZAC Research Institute, Dendritic Cell Research, Sydney, Australia, ²Royal Prince Alfred Hospital, Department of Haematology, Sydney, Australia, ³Westmead Hospital, Blood and Bone Marrow Transplant Service, Sydney, Australia

Dendritic Cells (DC) are phenotypically identified in human blood as HLA-DR⁺ cells, which lack major cell surface lineage markers. As part of the Human Leucocyte Differentiation Antigen Workshop, we demonstrated that myeloid antigen presenting cells including monocytes and DC display a continuum of CD14 and CD16 expression. This limits the robustness of accurate DC and monocyte identification, particularly when identifying cell subsets with little or no surface CD14. Application of poisson counting statistics established that rare cell types such as CD16⁺ DC are often overlooked in analyses powered to detect much larger populations such as classical and non-classical monocytes.

We used fluorescent and mass cytometry approaches, in conjunction with high dimensional clustering, to demonstrate that the continuum of CD14 expression separates CD14^{lo} "non-classical monocytes" and CD14⁺ DC. We have defined the CD14⁺CD16⁺ DC as both phenotypically and transcriptionally different to other CD16⁺ monocyte populations. The CD16⁺ DC have different functional responses to antigen-uptake, processing and presentation of antigen by MHC compared to other primary blood monocytes and DC populations. They have a limited capacity for further differentiation. We monitored leucocyte recovery in hematopoietic cell transplant patients after myeloablative conditioning and showed that the recovery of CD16⁺ DC followed similar kinetics to other myeloid cell populations. Interestingly, our analysis of reconstituting myeloid populations in transplant patients identified the early differentiation and activation of circulating CD16⁺ DC as predicting for the onset of acute graft versus host disease. Thus, CD16⁺ DC represent an important clinically relevant human DC population.

932

Tolerogenic dendritic cells generated by activin-A-induced regulatory T cells protect against allergic asthma through the instruction of Foxp3⁺ regulatory T cells

Semitekolou, M.¹, Morianos, I.¹, Sparwasser, T.², Xanthou, G.¹

¹Biomedical Research Foundation of the Academy of Athens, Athens, Greece, ²Institute of Infection Immunology, TWINCORE, Centre for Experimental and Clinical Infection Research, Hannover, Germany

Our previous studies have uncovered the cytokine activin-A as a novel inducer of regulatory T cells (activin-A-iTregs) that protect against experimental asthma. Still, the cellular and molecular mechanisms underlying the suppressive functions of activin-A-iTregs remain elusive. In the present study, we hypothesized that activin-A-iTregs inhibit Th2 cell-driven responses through

induction of tolerogenic dendritic cells (DCs). For this, we adoptively transferred allergen-primed activin-A-iTregs into immunodeficient mice and examined their effects on CD11c⁺DC responses.

Our findings reveal that act-Treg-modified DCs exhibit an immature phenotype, reflected by low expression of MHC-II, CD80, CD86 and CCR7, impaired capacity to uptake antigen and traffic to the draining lymph nodes and attenuated IL-12, IL-6 and TNF- α release in response to LPS stimulation. Moreover, act-Treg-modified DCs display poor immunostimulatory potential, exemplified by decreased ability to prime the proliferation and cytokine release by allergen-specific Tg(DO11.10) T responders *in vitro* and upon adoptive co-transfer *in vivo*. Importantly, administration of act-Treg-modified DCs protects against experimental asthma both in preventive and therapeutic protocols mainly through the *de novo* generation and expansion of Foxp3⁺ Tregs. In fact, depletion of CD4⁺Foxp3⁺Tregs in DEREK mice before act-Treg-modified DC transfer hampers the suppressive capacities of act-Treg-modified DCs, demonstrated by exacerbated asthma manifestations and overactive Th2 cell responses. Disruption of PD-1 signaling, hinders the capacity of activin-A-iTreg cells to generate tolerogenic DCs, highlighting the involvement of the regulatory PD-1/PDL-1 pathway. Our findings unravel a novel immunoregulatory circuit encompassing activin-A-iTreg cells, tolerogenic DCs and Foxp3⁺ Tregs critical for the regulation of allergic asthma.

A long noncoding RNA attenuates dendritic cell function and decreases autoimmune disease susceptibility

Brodnicki, T.¹, Ashton, M.², Elso, C.¹, Mackin, L.¹, Chu, E.¹, Ford, S.³, Payne, N.³, Alsayb, M.¹, Thomas, H.¹, Mannering, S.¹, Kay, T.¹, Papenfuss, A.⁴, Kitching, A.R.³, Bernard, C.³, Acha-Orbea, H.⁵, Morahan, G.⁶, Shortman, K.⁴, O'Keeffe, M.³

¹St Vincent's Institute, Fitzroy North, Australia, ²Technische Universität Dresden, Dresden, Germany, ³Monash University, Clayton, Australia, ⁴The Walter and Eliza Hall Institute, Parkville, Australia, ⁵University of Lausanne, Epalinges, Switzerland, ⁶Harry Perkins Institute of Medical Research, Nedlands, Australia

A complex network of mechanisms allows appropriate immune responses to pathogens while preventing destruction of one's own tissues. Cell-based studies have demonstrated the potential for long noncoding RNAs (lncRNAs) to regulate innate immune responses, but their effect upon immune tolerance *in vivo* is poorly understood. lncRNAs are broadly defined as RNAs that are >200 nucleotides in length and perform molecular functions without encoding proteins. We have identified more than fifty putative murine lncRNAs that are differentially expressed in dendritic cells upon toll-like receptor (TLR) activation. We found that genetic disruption of one of these lncRNAs increases autoimmune disease susceptibility. This lncRNA is detected in the nucleus and cytoplasm of dendritic cells after induction by TLR activation, and binds SHIP1, an inositol phosphatase that regulates dendritic cell function. Upon TLR activation, dendritic cells deficient for this lncRNA exhibit enhanced cytokine production associated with decreased SHIP1. Our findings highlight a role for lncRNAs in promoting immune tolerance by

stabilizing regulatory proteins and attenuating specific innate immune responses that may otherwise precipitate pathological tissue destruction.

Where and how memory cells are reactivated in the secondary antibody response in the lymph node

Moran, L., Nguyen, A., Brink, R., Phan, T.G.

Garvan Institute of Medical Research, Immunology, Sydney, Australia

Despite the importance of immunological memory, the precise mechanism of memory B cell activation is still largely unknown. To address this our lab has undertaken *in situ* studies of unmanipulated memory T and B cells in their native environment in immune animals. Utilising two photon microscopy, we identified a novel population of memory CD4⁺ T cells, T follicular memory (T_{FM}) cells, that occupy a unique niche in the subcapsular region of the B cell follicle of the draining lymph node (dLN). Within the dLN, T_{FM} cells scan CD169⁺ subcapsular sinus (SCS) macrophages and may be reactivated by them to initiate the memory antibody response. We now describe an equivalent population of lymph node resident B follicular memory (B_{FM}) cells which can be re-activated by antigen captured and presented on SCS macrophages, mirroring the role of SCS macrophages in activating naive B cells to initiate the primary antibody response. These reactivated memory B cells expand and differentiate into short-lived plasmablasts in subcapsular proliferative foci (SPF), a novel structure that is distinct from CD35⁺ secondary germinal centres. Thus, these SPF facilitate the initial antigen reactivation of LN resident T_{FM} and B_{FM} cells by SCS macrophages. These studies highlight the importance of microanatomical location in the orchestration of a rapid and efficient secondary antibody response.

ICOSL-controlled regulation of germinal center formation and relative affinity-based plasma cell fate determination

Liu, D.¹, Xu, H.^{1,2}, Shih, C.¹, Wan, Z.¹, Ma, X.³, Ma, W.¹, Luo, D.^{1,4}, Qi, H.¹

¹Tsinghua University, School of Medicine, Beijing, China, ²Cincinnati Children's Hospital Medical Center, Cincinnati, United States,

³Tsinghua University, School of Life Sciences, Beijing, China,

⁴Jiaotong University, College of Life Sciences & Bioengineering, Beijing, China

The germinal center (GC) reaction supports affinity-based B cell competition and generates high-affinity bone-marrow plasma cells (BMPC). Follicular T-helper (TFH) cells are specialized in regulating the GC formation and the high quality of the GC output, but the mechanism is not clear. A genetic deficiency in the inducible co-stimulator ligand (ICOSL) causes profound germinal center defects, leading to the view that ICOS-ICOSL signal induces the T_{FH} differentiation program to affect GC formation. Unexpectedly, we find that only ICOSL on follicular bystander B cells is sufficient and necessary for the GC formation.

As for antigen-specific ICOSL signal, intravital imaging aided by a calcium reporter reveals that ICOSL promotes an 'entangled' mode of T_{FH} -B cell interactions, characterized by brief but extensive surface engagement, productive T-cell calcium spikes, and B-cell acquisition of CD40 signals. ICOSL on GC B cells is upregulated by CD40 signals. Such an intercellular positive feedback between contact-dependent help and ICOSL-controlled entanglement promotes positive selection and BMPC development, as evidenced by observations that higher-affinity B-cell receptor variants are enriched in the ICOSL^{high} fraction, and that when GC competition proceeds without ICOSL, selection of high-affinity variants in GC reactions is impaired. By identifying different role of ICOSL in GC responses, our study reveals a pathway by which TFH cells control the quality of long-lived humoral immunity.

2496

NFκB1 prevents the development of multi-organ autoimmunity by limiting IL-6 production in follicular B cells

de Valle, E.^{1,2}, Grigoriadis, G.³, O'Reilly, L.⁴, Willis, S.⁴, Maxwell, M.¹, Tsantakis, E.¹, Cornish, J.¹, Fairfax, K.⁴, Vasanthakumar, A.⁴, Gugasyan, R.²

¹Central Clinical School, Monash University, Immunology, Melbourne, Australia, ²Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ³Hudson Institute of Medical Research, Centre for Cancer Research, Melbourne, Australia, ⁴Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia

NFκB1 (p50/p105) is a member of the NFκB family of transcription factors, and signaling through this pathway regulates numerous target genes that control cell survival, proliferation and differentiation. Genetic inheritance and single nucleotide polymorphisms in the promoter region of *NFκB1* have been linked with Crohn's disease, ulcerative colitis and more recently common variable immunodeficiency syndrome. In this study we have shown that the absence of *NFκB1* in mice (*Nfkb1*^{-/-}) is associated with premature ageing and the development of multi-organ autoimmune disease. The pathogenesis of disease was primarily associated with the altered homeostasis and function of peripheral Follicular (Fo) B cells and enhanced B cell differentiation that contributes to the elevated production of immunoglobulins and autoantibodies. The study of mixed BM chimeric mice revealed that the Fo B cell intrinsic loss of NFκB1 led to the spontaneous generation of GC B cells. This was strongly linked to the excessive production of IL-6 by *Nfkb1*^{-/-} Fo B cells, which promotes the enhanced differentiation of *Nfkb1*^{-/-} germinal centre B cells and CD4⁺ follicular helper T cells (T_{FH}). The p50 component of NFκB1 was found to repress *Il-6* transcription in wild-type Fo B cells, with the absence of p50-NFκB1 in Fo B cells resulting in the uncontrolled expression of *Il-6* through RelA, the major dimer partner of p50. Collectively, these findings highlight a previously unrecognized role of p50-NFκB1 that serves to prevent multi-organ autoimmune disease in part through the negative regulation of the *Il-6* gene.

A glucocorticoid alternative that interferes with B cell activation

Jones, S.A.¹, Toh, A.E.J.¹, Odobasic, D.¹, Oudin, M.A.V.¹, Chen, Q.¹, Lee, J.P.W.¹, White, S.J.², Russ, B.E.³, Infantino, S.⁴, Light, A.⁴, Tarlinton, D.M.⁴, Harris, J.¹, Morand, E.F.¹

¹Monash University, Centre for Inflammatory Diseases, School of Clinical Sciences, Clayton, Australia, ²Leiden University Medical Center, Leiden Genome Technology Center, Department of Human Genetics, Leiden, Netherlands, ³The Doherty Institute at The University of Melbourne, Department of Microbiology and Immunology, Parkville, Australia, ⁴The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

Glucocorticoids are routinely used to achieve control over autoimmune diseases, but their side effects cause unacceptable health and financial costs. GILZ is a glucocorticoid-induced transcriptional regulator and signal transduction modulator that we have found to recapitulate anti-inflammatory effects of glucocorticoids without the associated adverse effects. GILZ acts in multiple inflammatory cell types of mice and humans to provide a natural barrier to the acquisition of an activated state. In B cells, GILZ mediated activation-induced cell death and limited the extent of proliferation, class switching and plasma cell differentiation in response to stimulation. Down-regulation of GILZ occurred in germinal centre B cells, and naïve B cells lacking GILZ resembled germinal centre B cells in their transcriptional profile. Absence of GILZ was associated with development of a phenotype resembling systemic lupus erythematosus (SLE) in mice and in SLE patients, low GILZ induction in response to glucocorticoid treatment correlated with highest disease severity. Treatment of human B cells with a cell-permeable GILZ fusion protein potently suppressed their responsiveness to T-dependent stimuli. Thus we have shown GILZ to be an essential regulator of B cells, adding to the growing evidence that targeting this pathway may be a plausible and valuable alternative to the use of glucocorticoids for treatment of autoimmunity.

IkBNS is an essential mediator of Toll-like receptor-induced B cell responses

Touma, M., Ishizuki, M.

Niigata University, Biology, Niigata, Japan

The activation of NF-κB is regulated by several IκB proteins, a family comprising classical (cytoplasmic) and atypical (nuclear) IκBs. A nuclear IκB protein, IκBNS, was originally identified in thymocytes undergoing negative selection and is now recognized as positive and negative regulator of cytokines in T cells, macrophages, and dendritic cells. In addition, we have shown that IκBNS deficiency results in a defective TI-antigen response and a developmental defect in peritoneal B1 B cells. Thus it appears an additional role for IκBNS in the B cell lineage. Further analysis revealed that the IκBNS deficiency leads to a significant reduction in IL-10-competent B10 cells and that IκBNS-deficient B cells failed to secrete TLR-induced IL-10. The impairment of IL-10 production by a lack of IκBNS was not

observed in macrophages or T cells. The *in vitro* suppressive function of LPS-stimulated B cells was impaired in the absence of IκBNS. We also found that two IL-10-producing B cell populations increase upon TLR-triggering: CD138⁺ and CD138⁻, and that IκBNS-deficient B cells are unable to generate IL-10-producing CD138⁺CD44^{hi} plasmablasts.

These results suggest that IκBNS is selectively required for IL-10 production in B cells responding to TLR signals. Overall, our findings indicate a significant role for IκBNS in the control of the TLR-mediated B cell responses. To address the *in vivo* impact of IκBNS-deficiency in B cells, investigations using IκBNS-deficient autoimmune-prone mice are ongoing.

The antibody gene repertoire of the mouse lacks diversity and is highly skewed towards core VDJ sequences

Collins, A.¹, Edwards, R.¹, Jackson, K.²

¹University of New South Wales, School of Biotechnology and Biomolecular Sciences, Sydney, Australia, ²Stanford University, Department of Pathology, Stanford, United States

The mammalian immune system can create literally hundreds of billions of different antibodies from a relative handful of rearranging gene segments, but the small B cell population of the mouse allows it to express just a tiny fraction of this theoretical potential. We have used high throughput sequencing of immunoglobulin VDJ genes, to better understand how the small arsenal of the mouse can meet its immunological needs. Against all expectations, analysis shows the heavy chain IGHV gene repertoire of the C57BL/6 mouse strain to be almost completely different to that of the BALB/c strain. On the other hand, it is remarkably common for rearranged VDJ genes from the two strains to share identical complementarity determining region 3 (CDR3) sequences. Data will be presented demonstrating that a core group of sequences with short CDR3 regions are present at high frequency in the repertoires of both strains, and are often found in multiple individuals of each strain. We hypothesise that the mouse has evolved to limit the diversity of its repertoire, and that its limited repertoire is directed against anticipated pathogens. This would explain reports that the mouse can mount rapid and effective primary antibody responses to some viral infections. We further hypothesise that the divergent sets of IGHV genes seen in BALB/c and C57BL/6 mice are derived from different subspecies of the house mouse, as a result of their early breeding histories, and that the divergent gene sets evolved in response to the different pathogens faced by geographically separated mouse subspecies.

The role of antigen and persistent germinal centers in recall memory responses

Hao, Y., Espinasse, M.-A., Weill, J.-C., Reynaud, C.-A.

Université Paris Descartes Faculté de Médecine, Institut Necker-Enfants Malades - INSERM U 1151/CNRS UMR 8253, Paris Cedex, France

The mouse B cell response against external challenges generates IgG and IgM memory B cells. We have proposed,

based on the AID-Cre-EYFP mouse reporter line (Dogan et al., 2009), that the IgG memory compartment was mainly involved in rapid plasma cell formation during recall responses, while the IgM compartment was mainly driven into new germinal center reactions. However, the behavior of IgM memory B cells upon successive challenges is still a debated issue. Based on the same mouse reporter line, we have tested three main parameters that likely impact the response: the presence of persistent germinal centers (which depends upon the nature of the antigen, soluble protein like NP-CGG or complex, particulate antigen, like sheep red blood cells (SRBC)); the level of circulating antibodies, specific for the relevant antigen (which will vary according to the elapsed time and the number of challenges), and the nature of the adjuvant (MPL vs. alum, i.e. TH1 vs. TH2 response bias). Our preliminary data, based on disruption of germinal centers by inhibition of the lymphotoxin-beta survival function, as well as prime-boost immunizations with NP-CGG and NP-SRBC in various combinations, allow us to delineate the relative impact of these different parameters on the outcome of the recall response, and to reconcile some divergent reports on memory B cell function.

3402

IL-10 secreting innate-like B cells migrate between the peritoneum and the inflamed skin

Geherin, S.¹, Gomez, D.¹, Glabman, R.¹, Ruthel, G.¹, Hamann, A.², Debes, G.¹

¹University of Pennsylvania, Philadelphia, United States,

²Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany

The skin is an important barrier organ and frequent target of autoimmunity and allergy. We found innate-like B cells that express the anti-inflammatory cytokine IL-10 in the skin of humans and mice. Unexpectedly, innate-like B-1 and conventional B-2 cells show differential homing capacities with peritoneal B-1 cells preferentially migrating into the inflamed skin of mice. Importantly, the skin-homing B-1 cells includes IL-10 secreting cells. B-1 cell homing into the skin is independent of typical skin-homing trafficking receptors and instead requires alpha4-beta1 integrin. Moreover, B-1 cells constitutively express activated beta1 integrin and relocate from the peritoneum to the inflamed skin and intestine upon innate stimulation, indicating an inherent propensity to extravasate into inflamed and barrier sites. We conclude that innate-like B cells migrate from central reservoirs into skin, adding an important cell type with regulatory and protective functions to the skin immune system.

3474

The 'Ins and Outs' of Myc - Molecular regulation of division progression in B and T cells

Heinzel, S.^{1,2}, Giang, T.B.^{1,2}, Kan, A.^{1,2}, Corcoran, L.^{1,2}, Hodgkin, P.^{1,2}

¹Walter and Eliza Hall Institute, Parkville, Australia, ²University of Melbourne, Department of Medical Biology, Parkville, Australia

T and B lymphocytes integrate activating signals to trigger a controlled proliferation burst. While much is known about the

initiation signals, little is known about how the maintenance of cell division progression or the sudden loss of cells is regulated. Recent studies (Turner M, *Jl* 2008, Marchingo J, *Science* 2014) have shown that the number of times B and T cells divide upon stimulation before returning to quiescence is imprinted into the first generation and is dependent on the type and the strength of the stimulus. These features led to the hypothesis of a 'mitosis promoting factor' induced through activation and consequently diluted progressively to drop below a threshold level, at which division stops.

Here we have identified the proto-oncogene Myc as the division driving factor. Myc accumulates after activation in T and B cells and is then gradually lost over time. Myc expression levels correlate with stimulation strength and are not affected by cell division, identifying the molecular machinery as a division-independent timer. Variable sensitivity to signals is achieved by manipulating the kinetics of Myc production, directly integrating stimulating signals to determine clonal burst size. Forced overexpression leads to increased division rounds before cells return to quiescence. In addition, another division-independent timer controlling cell survival is induced through activation. These two cell intrinsic timers operate independently and together shape the early T and B cell response. Modelling reveals that small changes in these timed processes, as might occur during oncogenic transformation, synergize to significantly enhance cell numbers over time.

The ion channel TRPM7 regulates actin organization and antigen internalization in B cells

Krishnamoorthy, M.¹, Buhari, H.², Wasim, L.², Ho, J.², Perraud, A.-L.³, Schmitz, C.³, Treanor, B.^{1,2,4}

¹University of Toronto, Department of Cell and Systems Biology, Toronto, Canada, ²University of Toronto Scarborough, Department of Biological Sciences, Toronto, Canada, ³University of Colorado, Department of Immunology and Microbiology, Denver, United States, ⁴University of Toronto, Department of Immunology, Toronto, Canada

The process of B cell spreading and contracting in response to membrane-bound antigen is important for collection of BCR-antigen microclusters for internalization and subsequent presentation to T cells. The spreading and contraction response is dependent on reorganization of actin, yet the molecular mechanism that leads to this reorganization is not well understood. Several studies have implicated the ion channel transient receptor potential member 7 (TRPM7) in regulating the cellular actomyosin network. TRPM7 is one of only two known channel proteins with a kinase domain. Interestingly, TRPM7 was recently found to phosphorylate PLC γ 2, a key regulator of B cell spreading and formation of antigen microclusters, and thus implicates TRPM7 in B cell signaling. Our studies have shown that TRPM7 plays an important role in early B cell activation through both channel and kinase activities. B cells that lack TRPM7 or express a phosphotransferase-deficient point mutant show enhanced antigen accumulation and prolonged signaling in addition to altered microcluster movement and contraction. Our findings suggest that this is due to alterations in the actin cytoskeleton. Importantly, antigen internalization is

defective in TRPM7-KO cells, and primary B cells treated with a pharmacological inhibitor of TRPM7 exhibit impaired antigen presentation and consequently T cell activation is compromised. Taken together, these results highlight TRPM7 as an important novel regulator of B cell activation.

Suppression of metastases using a new lymphocyte checkpoint target for cancer immunotherapy

Smyth, M., Blake, S., Teng, M., Miles, J.

QIMR Berghofer Medical Research Institute, Herston, Australia

CD96 has recently been shown as a negative regulator of mouse NK cell activity, with *Cd96*^{-/-} mice shown to have hyper-responsive NK cells upon immune challenge. In this study we have demonstrated that blocking CD96 with a monoclonal antibody inhibited experimental metastases in multiple tumor models. The anti-metastatic activity of anti-CD96 was dependent on NK cells, CD226 (DNAM-1) and IFN γ , but independent of activating Fc receptors. Anti-CD96 was more effective in combination with anti-CTLA4, anti-PD1 or doxorubicin chemotherapy. Blocking CD96 in *Tigit*^{-/-} mice significantly reduced experimental and spontaneous metastasis compared to its activity in WT mice. Co-blockade of CD96 and PD1 potently inhibited lung metastases, with the combination increasing local NK cell IFN γ production and infiltration. Overall these data demonstrate that blocking CD96 is a new and complementary immunotherapeutic strategy to reduce tumor metastases. Ongoing studies in primary mouse and human tumours will be discussed.

The emerging role of tissue-resident memory (T_{RM}) CD8 T cells in antitumor immunity and malignant disease

Mami-Chouaib, F., Cognac, S., Djenidi, F., Boutet, M.

INSERM, Gustave Roussy, Villejuif, France

Tissue-resident memory (T_{RM}) T cells play an essential role in protecting human epithelial tissues against infectious and inflammatory diseases. They are highly activated T lymphocytes that reside within a variety of peripheral tissues including intestine, brain, skin and lung, and provide rapid and effective responses to viral reinfections. However, the presence of T_{RM} in human epithelial tumors and their role in the antitumor immunity have thus far not been systematically addressed. Accumulating evidence indicates that TGF- β 1, abundant at the tumor site, plays an essential role in the formation and maintenance of T_{RM} at least in part via induction of CD103 integrin. In this context, our results indicated that human lung tumor-infiltrating lymphocytes (TIL) include a homogeneous CD8⁺ T-cell population that displays a unique phenotypic and molecular signature associated with T_{RM} cells, which results in optimal effector functions within the tumor microenvironment. We also demonstrated that an enhanced CD103⁺ TIL subset correlates with improved early-stage non-small cell lung

carcinoma (NSCLC) patient survival and increased intraepithelial lymphocyte infiltration. Indeed, we provide evidence that CD103 is directly involved in T-cell recruitment within epithelial tumor islets and in local early T-cell signaling. Moreover, TGF- β upregulates CD103-mediated T-cell activities by promoting phosphorylation of integrin-linked kinase (ILK) by TGFBR1 and its subsequent binding to CD103, thereby initiating integrin inside-out signaling. These data emphasize the role of CD8⁺/CD103⁺ T_{RM} in promoting intratumoral cytotoxic T lymphocyte (CTL) responses and suggest their use in adoptive T-cell therapy or as a biomarker to predict patient response to checkpoint blockade immunotherapy.

Dual-specific T cells and oncolytic virus eradicate large solid tumors

Slaney, C.Y.^{1,2}, Von Scheidt, B.^{1,2}, Beavis, P.A.^{1,2}, Davenport, A.J.^{1,2}, Westwood, J.A.^{1,2}, Mardiana, S.^{1,2}, Tschärke, D.C.³, Restifo, N.P.⁴, Darcy, P.K.^{1,2,5}, Kershaw, M.H.^{1,2,5}

¹Peter MacCallum Cancer Centre, Cancer Immunology Program, East Melbourne, Australia, ²University of Melbourne, Sir Peter MacCallum Department of Oncology, Parkville, Australia, ³Australian National University, Research School of Biology, Canberra, Australia, ⁴National Cancer Institute, National Institute of Health, Center for Cancer Research, Bethesda, United States, ⁵Monash University, Department of Immunology, Clayton, Australia

While immunotherapy can eliminate substantial burdens of leukemia, the ultimate challenge remains the consistent eradication of large solid tumors. Here we generate dual-specific CARaMEL T cells expressing a chimeric antigen receptor (CAR) reactive with Her2⁺ tumor and a TCR specific for the premelanocyte antigen (pMEL, gp100). Adoptive transfer of these T cells, together with systemic delivery of recombinant vaccinia virus expressing gp100, induced durable complete remission of a variety of Her2⁺ tumors, some in excess of 150 mm², in immunocompetent mice expressing Her2 as a self-antigen. Vaccinia virus effected changes to the tumor microenvironment and induced extensive proliferation of CARaMEL T cells. Tumor destruction mediated by dual-specific T cells and vaccinia occurred rapidly over a period of seven days and was associated with an extensive infiltrate of T cells. Mice that had rejected tumors were resistant to rechallenge with the same Her2⁺ tumor cells and partially resistant to rechallenge with Her2⁻ cells, indicating the formation of immune memory and epitope spreading. Transient toxicity against Her⁺ brain tissue was observed, which was associated with temporary accumulation of T cells in the cerebellum. This study supports a view that it is possible to design a highly effective combination immunotherapy for solid cancers, with acceptable transient toxicity, even when the target antigen is also expressed in vital tissues.

3699

SLAMF7 is a novel target for immunotherapy of multiple myeloma

Jenkins, M.¹, Rogers, A.¹, Canfield, R.¹, Robbins, M.², Bezman, N.², Darcy, P.¹, Kershaw, M.¹, Johnstone, R.¹, Ritchie, D.³, Prince, H.M.¹, Trapani, J.¹, Neeson, P.¹

¹Peter MacCallum Cancer Centre, Cancer Immunology Research, Melbourne, Australia, ²Bristol-Myers Squibb, Princeton, United States, ³Melbourne Health, Haematology, Melbourne, Australia

Elotuzumab (Elo) targets SLAMF7, a protein highly expressed on myeloma plasma cells and broadly on immune cell subsets. This project investigated the mechanisms whereby Elo activates NK cells and myeloma cell killing.

Elo and SLAMF7⁺ OPM-2 myeloma cells induce normal donor NK cell degranulation, IFN- γ production and myeloma cell ADCC. In the same conditions, MM patient NK cells are poor responders. Elo induced loss of the CD56^{lo}CD16⁺ NK subset in normal donors, but not in myeloma patients. This loss of the CD56^{lo}CD16⁺ NK subset was due to a combination of NK fratricide and ADAM-17 mediated cleavage of CD16a from the NK cell surface. Elo mediated dual activation of NK cells by binding directly to SLAMF7 and also via binding to CD16a. The CD16a binding was required for NK cell fratricide.

We then examined whether Elo altered the NK cell killing kinetics of myeloma target cells using time lapse live video microscopy (TLLVM). Normal donor NK cells used ADCC to kill OPM-2 cells in the presence of Elo, the killing kinetics was equivalent to the human IgG isotype control, delivery of the lethal hit occurring in under three minutes. Elo also mediated serial killing of OPM-2 cells. Interestingly, Elo delayed the NK cell detachment from dying myeloma plasma cell targets, this correlated with higher levels of secreted cytokines and pro-inflammatory chemokines. Taken together, this data indicates Elo-induced a profound change in the NK-mediated killing kinetics of myeloma cells which likely recruits other immune effectors to the myeloma killing site.

Jak-STAT3 pathway triggers DICER1 for proteasomal degradation by ubiquitin ligase complex of CUL4A^{DCAF1} to promote colorectal cancer cells growth

Ren, W.¹, Shen, S.¹, Li, G.², Ma, J.^{1,2}

¹Central South University, The Third Xiangya Hospital, Changsha, China, ²Central South University, Cancer Research Institute, Changsha, China

Chronic intestinal inflammation is closely associated with colorectal cancer (CRC) development and STAT3 seems to take center stage in bridging chronic inflammation to CRC progress. Here, we discovered that DICER1 was significantly downregulated in response to IL-6 or LPS stimulation and identified a novel mechanism for DICER1 downregulation via proteasomal degradation by ubiquitin ligase complex of CUL4A^{DCAF1} in CRC cells. Meanwhile, PI3K-AKT signaling pathway phosphorylated DICER1 and contributed to its proteasomal degradation. The regulation of DICER1 by CUL4A^{DCAF1} affected cell growth and apoptosis which controlled by IL-6 activated

Jak-STAT3 pathway. Intervention of CUL4A^{DCAF1} ubiquitin ligase complex led to fluctuation in expression levels of DICER1 and microRNAs, and thus affected tumor growth in a mouse xenograft model. Furthermore, clinical specimens' analysis revealed that decreased DICER1 expression was negatively correlated with STAT3 activation and cancer progression in human CRC. DICER1 and p-STAT3 expression levels correlated with 5-year overall survival of CRC patients. Consequently, this study proposes that inflammation-induced Jak-STAT3 signaling leads to CRC cells growth through proteasomal degradation of DICER1 by ubiquitin ligase complex of CUL4A^{DCAF1}, which suggests a novel therapeutic opportunity for CRC.

2215

Therapeutic DNA vaccination against colorectal cancer by targeting the MYB oncoprotein

Ramsay, R.

Peter MacCallum Cancer Centre, Research, Melbourne, Australia

Cancers are often addicted to continued and relatively high expression of nuclear oncoproteins. This is evident in colorectal cancer (CRC) where the oncoprotein and transcription factor MYB is over-expressed and essential to continued proliferation and tumour cell survival. In adenoid cystic carcinoma MYB-NFIB fusion proteins are considered the key driver of this cancer. Historically, targeting transcription factors in the context of cancer has been very challenging. Nevertheless, we formulated a DNA vaccine to generate a MYB-specific immune response in the belief MYB peptides might be aberrantly presented on the cell surface of CRC cells. MYB, like many tumour antigens, is weakly immunogenic as it is a "self" antigen and is subject to tolerance. To break self-tolerance, a fusion vaccine was generated comprising a full-length MYB cDNA flanked by two potent CD4-epitopes derived from tetanus toxoid. Vaccination was achieved against tumours initiated by two distinct highly aggressive, syngeneic CRC cell lines that express MYB. We introduced multiple inactivating mutations into the oncogene sequence for safety and sub-cloned the cDNA into a FDA-compliant vector. We used low-dose cyclophosphamide (CY) to overcome T-regulatory cell immune suppression, and anti-PD-1 antibodies to block T-cell exhaustion. Anti-PD-1 administered alone slightly delayed tumour growth, while CY did not. We found that therapeutic vaccination elicits protection when tumour burden is low, mounts tumour-specific cell killing and affords enhanced protection when tumour burden is higher but only in combination with anti-PD-1 antibody and/or low dose CY. These data have now set the stage for a funded first-in-man clinical trial.

Mismatch in epitope specificities between IFN inflamed and non-inflamed conditions may lead to escape from T lymphocyte killing in melanoma

Woods, K.^{1,2}, Knights, A.³, Anaka, M.³, Schittenhelm, R.B.⁴, Purcell, A.W.⁴, Behren, A.^{1,2}, Cebon, J.^{1,2}

¹Olivia Newton-John Cancer Research Institute, Cancer Immunobiology, Melbourne, Australia, ²La Trobe University, School

of Cancer Medicine, Melbourne, Australia, ³Ludwig Institute for Cancer Research, Cancer Immunobiology Laboratory, Melbourne, Australia, ⁴Monash University, Biochemistry and Molecular Biology, Melbourne, Australia

Degradation of cellular proteins by the proteasome is critical for generation of MHC-associated peptides. The constitutive proteasome and the IFN γ -induced immunoproteasome (IP) differ in the use of three catalytic β subunits, which alters production of MHC class I epitopes. The potential for a disparate repertoire of epitopes produced between inflammatory/non-inflammatory tumours therefore arises.

We have extensively investigated this phenomenon both broadly, in terms of the cancer cell as a whole, and specifically, by evaluating presentation of three NY-ESO-1 HLA-Cw3 restricted epitopes.

We profiled the immunopeptidome of a melanoma cell line under steady state or IFN γ -treated conditions; by mass spectrometry analysis of HLA Class I bound peptides. Profound changes in the overall epitope profile presented on HLA Class I molecules were observed.

We studied processing and presentation of three NY-ESO-1 HLA-Cw3 restricted epitopes by melanoma cell lines. We found changes in surface presentation of each of the three epitopes following processing through different proteasome subtypes. We further investigated processing of these epitopes by selective inhibition of the IP catalytic subunit LMP7 by siRNA knockdown, or direct inhibition.

In vivo, we manipulated melanoma cells to switch proteasome subtype following treatments which induced IFN γ at the tumour site.

Our data demonstrate broad changes in epitopes presented by melanoma cells under inflammatory versus non-inflammatory conditions. These results illustrate a little-studied mechanism of immune escape by tumour cells. Awareness of how individual cancer epitopes are processed by melanoma cells may be critical to inform development of therapies involving cancer vaccination, adoptive T-lymphocyte transfer, or combination treatments including these.

2545

Radiation dose and fractionation can influence the immune modulatory effects of radiotherapy and anti-cancer activity of checkpoint blockade therapy

Haynes, N.M.^{1,2}, Hagekyriakou, J.³, Halkerwal, S.¹, Darcy, P.K.^{2,4}, Chua, B.⁵, Johnstone, R.W.^{1,2}

¹Peter MacCallum Cancer Centre, Cancer Therapeutics Program, East Melbourne, Australia, ²The University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia, ³Peter MacCallum Cancer Centre, Department of Physical Sciences, East Melbourne, Australia, ⁴Peter MacCallum Cancer Centre, Cancer Immunology Research, East Melbourne, Australia, ⁵Peter MacCallum Cancer Centre, Division of Radiation Oncology and Cancer Imaging, East Melbourne, Australia

Activation of host anti-cancer immune defenses is one mechanism by which radiation therapy can eliminate cancer cells. To promote radiation-induced immune responses to

cancer, radiotherapy is now being trialed in combination with immunotherapy, with promising success. In an effort to ensure that the full therapeutic potential of radiotherapy can be harnessed with immunotherapy, we have examined the impact of radiation dose and fractionation regimen on the immunomodulatory activity of radiotherapy, and its ability to support the anti-cancer effects of antibody-based immunotherapy. Importantly, we demonstrate that different fractionated radiation regimens are not equivalent in their ability to support the therapeutic activity of antibody-based checkpoint blockade therapy. A 3x4Gy (consecutive day) or 2x10Gy (10Gy/week) treatment regimen was significantly more effective than a single 12Gy or 20Gy (or 2x10Gy given over consecutive days) dose, respectively, in promoting T-cell based immune responses and the anti-cancer activity of anti-PD-1 therapy in a C57BL/6 model of triple negative breast cancer. Conversely, a single 20Gy dose of radiotherapy was most effective in supporting the growth inhibitory effects of anti-CTLA-4 therapy. Given that low dose (2Gy) fractionated radiotherapy is routinely used for the treatment of breast cancer we have also demonstrated that such fractionation regimens can enhance the combined curative activity of anti-PD-1 and anti-CTLA-4 therapy. Collectively these findings will help optimize the selection and method of integration of immunotherapeutic agents with radiation therapy and ensure that the burgeoning paradigm of cancer immunotherapy can be best capitalized on for the treatment of cancer.

T cell mediated immune surveillance is essential for the control of spontaneous B cell lymphomas

Zotos, D.^{1,2}, Sterle, S.^{1,2}, Bernard, N.^{1,2}, Scherger, A.^{1,2}, Rodling, L.^{1,2}, Alsop, A.^{1,2}, Walker, J.^{1,2}, Masson, F.^{1,2}, Belz, G.^{1,2}, Corcoran, L.^{1,2}, O'Reilly, L.^{1,2}, Strasser, A.^{1,2}, Smyth, M.^{3,4}, Johnstone, R.^{5,6}, Tarlinton, D.^{1,2}, Nutt, S.^{1,2}, Kallies, A.^{1,2}

¹Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, ²University of Melbourne, Department of Medical Biology, Parkville, Australia, ³QIMR Berghofer Medical Research Institute, Herston, Australia, ⁴University of Queensland, School of Medicine, Herston, Australia, ⁵Peter MacCallum Cancer Centre, East Melbourne, Australia, ⁶University of Melbourne, Sir Peter MacCallum Department of Oncology, Parkville, Australia

Non-Hodgkin lymphoma is a heterogeneous group of malignancies of lymphoid origin, the most common type being diffuse large B cell lymphoma (DLBCL), which represents 30-40% of cases. Despite improved treatment, 40-50% of DLBCL patients still succumb to their disease. A better understanding of DLBCL pathogenesis is therefore needed to identify new therapeutic approaches. Loss of function of the tumour suppressor PRDM1/Blimp1 or deregulated expression of the oncogene BCL6 are thought to be causative for a large proportion of DLBCL cases; however, mutations in either of these genes leads to only slow and infrequent development of overt lymphoma, and despite frequent mutations of the Bcl6 gene in activated B cells of healthy individuals lymphoma development is rare. Because B lymphomas show a strong association with immune suppression and immune deficiencies, it has been postulated that mutations that result in a breakdown of immune surveillance are necessary

to allow progression of lymphomas or other tumours. In the present study we show that Blimp1 deficiency or overexpression of Bcl6 in the B cell lineage leads to a pronounced accumulation of pre-plasmablast B cells, but does not result in overt lymphoma in the presence of a functioning T cell compartment. Removal of T cell control results in the rapid development of DLBCL-like lymphoma, which can be eradicated by polyclonal CD8 T cells in a Fas and T cell receptor/CD28-dependent manner. Thus, malignant transformation of mature B cells requires mutations that impair intrinsic differentiation processes and the escape from constant T cell-mediated tumour surveillance.

4074

Invariant NKT lymphocytes increase the development of intestinal tumors by promoting Treg cells and suppressing TH1 immunity

Wang, Y.¹, Sedimbi, S.², Löfbom, L.¹, Cardell, S.¹

¹University of Gothenburg, Dept of Microbiology and Immunology, Gothenburg, Sweden, ²Karolinska Institute, Dept of Microbiology Tumor and Cell Biology, Stockholm, Sweden

CD1d-restricted natural killer T (NKT) cells are potent immunoregulatory cells. Activation of invariant NKT (iNKT) cells suppresses tumor formation in murine models, and iNKT cells can naturally protect against spontaneous tumors, and also enhance immune responses to infections. Intestinal tumors develop in an environment of constant microbial pressure and inflammatory signals that increase tumor formation, raising the question whether NKT cells would suppress or promote tumor formation in this tissue. Here we have investigated the role for iNKT cells in intestinal tumor immunity. *APC^{Min/+}* mice develop intestinal polyps due to a mutation in the adenomatous polyposis coli (APC) gene, recapitulating early events in human colorectal cancerogenesis. Absence of iNKT cells in *APC^{Min/+}* mice decreased the total number of intestinal polyps with 60%. iNKT cells were present in the polyps of *APC^{Min/+}* mice, and showed a distinct phenotype compared to other organs, being CD4⁺, NK1.1⁻ CD44⁺, CD69⁺ and PD-1^o. They had an intermediate expression level of T-bet but were negative for the NKT cell transcription factor PLZF. In *APC^{Min/+} Jα18^{-/-}* mice, absence of iNKT cells was associated with a reduced frequency of Treg cells and lower expression levels of FoxP3 protein and transcript uniquely in the polyps. Moreover, in iNKT cell deficient *APC^{Min/+}* mice, expression of TH1-associated genes, such as *IFN-γ* and *Nos2*, was increased in polyps, concomitant with elevated frequencies of conventional CD4⁺ and CD8⁺ T cells in this tissue. The results suggest that iNKT cells promote intestinal polyp formation by enhancing Treg cells and local immunosuppression of anti-tumor TH1-immunity.

Capacity of yolk sac macrophages, fetal liver and adult monocytes to colonize an empty niche and develop into functional tissue resident macrophages

van de Laar, L., Saelens, W., Scott, C.L., Saeys, Y., Lambrecht, B., Guillems, M.

Ghent University - VIB, Ghent, Belgium

Tissue-resident macrophages can derive from yolk sac macrophages (YS-MFs), fetal liver monocytes (FL-MOs) or adult bone marrow monocytes (BM-MOs). The relative capacity of these precursors to colonize a niche, self-maintain and perform tissue-specific functions is currently unknown. We simultaneously transferred traceable YS-MFs, FL-MOs and BM-MOs into the empty alveolar macrophage (AM) niche of neonatal *Csf2rb*^{-/-} mice. All subsets produced mature AMs, but in competition a preferential outgrowth of FL-MOs was observed, correlating with their superior GM-CSF reactivity and proliferation capacity. When transferred separately however, all precursors efficiently colonized the alveolar niche and generated AMs that were transcriptionally almost identical, self-maintained and durably prevented alveolar proteinosis. Mature liver, peritoneal or colon macrophages could not efficiently colonize the empty AM niche, whereas mature AMs could. Thus, precursor origin does not affect the development of functional self-maintaining tissue-resident macrophages and the plasticity of the mononuclear phagocyte system is largest at the precursor stage.

992

Histone deacetylase 7 (HDAC7) regulates a sub-set of TLR-mediated pro-inflammatory responses in macrophages by both deacetylase-dependent and -independent mechanisms

Das Gupta, K., Shakespear, M., Tunny, K., Hohenhaus, D., J. Bokil, N., Iyer, A., P. Fairlie, D., J. Sweet, M.

Institute for Molecular Bioscience, The University of Queensland, Cell Biology and Molecular Medicine, Brisbane, Australia

Histone Deacetylases (HDACs), which deacetylate lysine residues of both histone and non-histone proteins, regulate inflammation and many other cellular processes. Broad spectrum and class-selective HDAC inhibitors (HDACi) are efficacious in animal models of several inflammatory diseases, however undesirable effects have also been reported. A clear understanding of which HDACs drive inflammatory pathways is required to improve drug design. This study highlights the role of one particular isoform, HDAC7, in sustaining macrophage inflammatory responses. We previously showed that inflammatory macrophages express elevated levels of HDAC7, and thus transgenic mice that selectively over-express HDAC7 in the myeloid compartment (mac-HDAC7 mice) were generated. Serum from naive mac-HDAC7 mice showed elevated levels of specific inflammatory mediators (e.g. IL-6, Ccl2), confirming the pro-inflammatory nature of HDAC7. Macrophages from these mice also displayed enhanced LPS-induced expression

of a sub-set of inflammatory mediators including IL-12, IL-6, Ccl2, and Edn1. These effects were also apparent in wild type primary macrophages, in which HDAC7 was over-expressed by retroviral transduction. The hyper inflammatory phenotype of macrophages from mac-HDAC7 mice was restricted to TLR1/2/4 agonists, since TLR3/7 responses were unaffected. Mechanistically, HDAC7 over-expression did not affect proximal TLR4 signalling, but down-regulated basal phosphorylation of AKT and ERK. Retroviral transduction of primary macrophages with enzyme-dead HDAC7 resulted in heightened LPS-inducible responses for some inflammatory mediators (e.g. IL-12, TNF), whereas others (e.g. Ccl2) were dependent on deacetylase activity. Overall these studies reveal both enzyme-dependent and -independent pro-inflammatory functions of HDAC7, which has important implications for development of selective HDAC inhibitors as anti-inflammatory agents.

Identification and characterization of CD300H, a new member of the Human CD300 immunoreceptor family

Niizuma, K.^{1,2}, Tahara-Hanaoka, S.^{1,3}, Noguchi, E.⁴, Shibuya, A.^{1,3}

¹University of Tsukuba, Faculty of Medicine, Department of Immunology, Tsukuba, Japan, ²University of Tsukuba, School of Integrative and Global Majors, Ph.D. Program in Human Biology, Tsukuba, Japan, ³University of Tsukuba, Center for Tsukuba Advanced Research Alliance (TARA), Tsukuba, Japan, ⁴University of Tsukuba, Faculty of Medicine, Department of Medical Genetics, Tsukuba, Japan

Recruitment of circulating monocytes and neutrophils to infection sites is essential for host defense against infections. Here, we identified a previously unannotated gene that encodes an immunoglobulin-like receptor, designated CD300H, which is located in the CD300 gene cluster. CD300H has a short cytoplasmic tail and associates with the signaling adaptor proteins, DAP12 and DAP10. CD300H is expressed on CD16⁺ monocytes and myeloid dendritic cells. Ligation of CD300H on CD16⁺ monocytes and myeloid dendritic cells with anti-CD300H monoclonal antibody induced the production of neutrophil chemoattractants.

Interestingly, CD300H expression varied among healthy subjects, who could be classified into two groups according to "positive" and "negative" expression. Genomic sequence analysis revealed a single-nucleotide substitution (rs905709 (G→A)) at a splice donor site on intron 1 on either one or both alleles. The International HapMap Project database has demonstrated that homozygosity for the A allele of single nucleotide polymorphism (SNP) rs905709 ("negative" expression) is highly frequent in Han Chinese in Beijing, Japanese in Tokyo, and Europeans (A/A genotype frequencies 0.349, 0.167, and 0.138, respectively) but extremely rare in Sub-Saharan African populations.

Together, these results suggest that CD300H may play an important role in innate immunity, at least in populations that carry the G/G or G/A genotype of *CD300H*.

1072

Epigenetic and transcriptional regulation of macrophage polarization and endotoxin tolerance by Akt kinases and insulin signalling

Ieronymaki, E., Lyroni, K., Theodorakis, E., Patsalos, A., Daskalaki, M., Eliopoulos, A., Kampranis, S., Vaporidi, A., Tsatsanis, C.
University of Crete, School of Medicine, Heraklion, Greece

Macrophages possess different phenotypes in response to inflammatory stimuli described as M1 and M2 types, each of which includes an array of individual subtypes. Endotoxin tolerant macrophages is an M2 subtype characterised by hypo responsiveness to pro-inflammatory stimuli. Using mice lacking Akt1 or Akt2 kinase we demonstrated epigenetic and transcriptional events that regulate LPS responses, M1/M2 polarisation and endotoxin tolerance and are under the control of Akt kinases. Using siRNA library screening we showed that the methyl-transferase EZH2 and the demethylase UTX control endotoxin tolerance via methylation of Histone 3 on genes regulating endotoxin tolerance and macrophage polarisation. MiRNAs miR-155 and miR-146a, both contributing to endotoxin tolerance and macrophage polarization, were epigenetically controlled by H3 methylation/demethylation and transcriptionally regulated by C/EBP β , under the control of Akt kinases. Since Akt kinases mediate insulin signalling, we compared the RNAome of macrophages derived from diet-induced insulin resistant mice with those from Akt-deficient or wild type mice. We identified transcriptome networks that characterise a distinct subset of M2-like macrophages. Central role in these networks play metabolic processes that are under the control of Akt2 kinase. Exposure of diet-induced insulin resistant mice and Akt2 deficient mice in polymicrobial sepsis confirmed that changes in macrophage metabolism that occur upon development of insulin resistance mediate obesity-driven changes in the response to sepsis. Overall our work supports a central role of Akt kinases and insulin signaling in macrophages shaping their response phenotype via epigenetic, transcriptional and metabolic changes.

925

Notch signaling plays a role in regulating IL-10 production in immune complex-stimulated macrophages

Wongchana, W.^{1,2}, Palaga, T.^{2,3}

¹Chulalongkorn University Faculty of Science, Graduate Program in Biotechnology, Bangkok, Thailand, ²Chulalongkorn University, Center of Excellence in Immunology and Immune-Mediate Diseases, Bangkok, Thailand, ³Chulalongkorn University Faculty of Science, Microbiology, Bangkok, Thailand

Macrophages are highly plastic during the effector phase, depending mainly on the stimuli and microenvironment. Classically activated macrophages are stimulated with IFN γ with TLR ligands such as LPS and referred to as M(LPS+IFN γ). They produce inflammatory mediators together with inflammatory cytokines such as IL-12 and low level of anti-inflammatory cytokine, IL-10. In the presence of immune complex, classically activated macrophages reduce the amount of IL-12 while increase IL-10 production. This type of activated macrophages is

referred to as M(IC). Previously, a well conserved Notch signaling is shown to regulate effector functions, including cytokine production in M(LPS+IFN γ). In this study, we investigated the role of Notch signaling in regulating IL-10 production in M(IC). Upon stimulation, M(IC) readily increased the level of cleaved Notch1, indicating that Notch signaling is activated. Cleaved Notch1 was observed at a similar level in M(LPS+IFN γ) and M(IC), regardless of the presence of immune complex. M(IC) also increased the expression level of Notch ligands, Jagged1, Jagged2 and DLL1, similar to M(LPS+IFN γ). CSL/RBP-J κ is a DNA-binding protein central to transcriptional activity of Notch signaling pathway. Macrophages with CSL/RBP-J κ KO produced significantly less IL-10. Similar impact of inhibiting Notch signaling using gamma-secretase inhibitor (GSI) was observed. The effect of GSI treatment on early signaling pathways, including PI3K/AKT, p38, Erk and SAPK/JNK, was not observed in M(IC). In contrast, defects in NF- κ B p50 nuclear localization was observed. Taken together, these results suggest that the Notch signaling pathway plays a role in regulating IL-10 production in M(IC), possibly through NF- κ B pathway.

2383

miR-155 promotes inflammatory macrophage phenotype signature

Guerau-de-Arellano, M., Jablonski, K., Amici, S., Webb, L., Gaudet, A., Popovich, P.

Ohio State University, Columbus, United States

Classical M1 (LPS + IFN-g) macrophage responses drive inflammation and tissue damage. Therefore, harnessing the pathways that drive inflammatory macrophage phenotype may be beneficial in inflammatory diseases. miRNA are small RNAs that post-transcriptionally suppress gene expression. Among several miRNAs associated with inflammatory responses miR-155 was the most highly up-regulated, with a 100-fold increase in M1 macrophages. To determine to what extent miR-155 is required for full expression of the classical inflammatory macrophage phenotype, we performed microarray analyses of wild-type (WT) and miR-155 knockout (KO) macrophages. This analysis revealed that miR-155 controls over 600 genes, corresponding to half of the WT M1 signature. Real-Time PCR and flow cytometry analyses on independent datasets showed that classical inflammatory markers IL-6, iNOS, IL-1b, TNF-a and IL-12 as well as the novel M1 marker CD38 were suppressed in miR-155 KO macrophages. In contrast, miR-155 deficiency did not reduce expression of genes associated with beneficial M2 macrophages (e.g., Arginase-1). The pro-inflammatory effects of miR-155 may be mediated by reduction in miR-155 targets Inpp5d, Mafk, c-Maf, Tspan14 and Il6ra, which were recovered in miR-155 KO M1 macrophages. Treatment with a miR-155 oligonucleotide inhibitor suppressed iNOS and TNF-a gene expressions in wild-type M1 macrophages. Overall, these data indicate that miR-155 plays an essential role in M1 macrophages inflammatory phenotype that miR-155 targeting may be beneficial in inflammatory disease.

4376

Understanding the anti-tumour potential of bisphosphonate drugs: inhibitory effects on macrophage populations outside the skeleton

Munoz, M.A.¹, Junankar, S.², Jurczyk, J.¹, Preston, A.¹, Zlatev, H.³, Auriola, S.³, Rogers, M.¹

¹Garvan Institute of Medical Research, Bone Biology, Darlinghurst, Australia, ²Garvan Institute of Medical Research, Darlinghurst, Australia, ³University of Eastern Finland, Kuopio, Finland

Bisphosphonates (BPs) are a class of calcium-seeking drugs used to inhibit bone destruction in cancer patients. BPs such as zoledronic acid (ZOL) act by inhibiting FPP synthase in osteoclasts, causing accumulation of the upstream metabolite IPP and preventing prenylation of small GTPase proteins required for bone resorption.

Evidence suggests that BPs have pleiotropic effects outside the skeleton, including anti-tumour activity. Using 2-photon intravital imaging of a fluorescently-tagged BP, we demonstrated that BPs diffuse from leaky vasculature and accumulate in the tumour tissue by binding to microcalcifications. These drug-bound microcalcifications are then efficiently engulfed by tumour-associated macrophages (TAMs). However, despite rapid drug uptake, we could not detect any defects in protein prenylation in TAMs from ZOL-treated animals, while by contrast, ZOL administration inhibited the prenylation of Rab proteins in CD11b⁺ peritoneal macrophages. To determine whether the lack of effect of ZOL on prenylation in TAMs was due to reduced drug activity of microcalcification-bound ZOL, we treated mice weekly for 4 weeks with free ZOL or an equivalent dose of liposome-encapsulated ZOL that is efficiently internalised by macrophages. We found that while treatment with free ZOL resulted in IPP accumulation in TAMs, only liposomal ZOL had a clear inhibitory effect on Rab prenylation.

Together, our data suggest that, at least in 4T1 tumours, engulfment of ZOL-bound microcalcifications leads to cytosolic ZOL concentrations that are sufficient to inhibit FPP synthase and cause accumulation of IPP, but insufficient to inhibit protein prenylation. How this affects TAM function *in vivo* remains to be determined.

Swiprosin-1 (EFhd2) regulates the TLR4 signals for TNF- α production in macrophage

Wakabayashi, N.¹, Ogawa, M.¹, Ishikawa, S.¹, Hachiya, M.¹, Mielenz, D.², Katagiri, T.¹

¹University of Toyama, Dept. Biology (Faculty of Pharmaceutical Sciences), Toyama-shi, Japan, ²University of Erlangen-Nuremberg, Division of Molecular Immunology, Nikolaus-Fiebiger-Centre, Nuremberg, Germany

Swiprosin-1, also called as EFhd2, has a unique structure; single CC domain and tandem EF hand domains, which is reminiscent of the important role as a signal protein. In fact, it has been reported that Swip-1 involves antigen receptor signals in T cells and B cells. Nevertheless, there is no report about Swip-1 function in TLRs signals. In this study, we focused on TLR4 signals in macrophages. Swip-1 has also been reported as

cytoskeletal binding protein. However, Swip-1 knocked-down (KD) RAW264.7 was almost similar to the control cells that of the morphology and proliferation pattern. On the other hand, Swip-1 KD RAW264.7 showed a very low production of TNF- α even by LPS stimulation at high concentrations level. Under the same condition, RAW264.7, which was treated with control RNA, produced TNF- α to the same extent as normal signaling of TLR4. Then we tried to identify the target point of Swip-1 action in the signal that leads to TNF- α production. As a result of this analysis, at least partially, we could get the proof of suggesting a possibility to affect the breakdown of I κ B. In addition, we also have accumulated data that suggest Swip-1 is involved in the MAPK cascade. Furthermore, we found the results that Swip-1 KD RAW264.7 affected some of the phosphorylation pattern of tyrosine phosphorylated proteins, which are characteristic in TLR4 signal. As a conclusion, Swip-1 is important to regulate TNF- α production in macrophages, so our study allow develop new inflammation control.

Lysophosphatidylcholine acyltransferase (LPCAT) 2 regulates macrophage inflammatory responses through acylation of key metabolic proteins

Abate, W., Sharma, V., Jackson, S.

Plymouth University, Plymouth, United Kingdom

We have previously shown that acyl-CoA: lysophosphatidylcholine acyltransferases (LPCAT) 2, which is involved in phospholipid remodelling, plays a key regulatory role in the inflammatory response to bacterial ligands. The mechanism through which LPCAT2 exerts this regulatory function on the inflammatory response in macrophages is not well defined. It has been demonstrated that modification of signalling proteins by covalent attachment of fatty acids promotes specific targeting of these proteins to membrane domains to facilitate signalling. In this work, we investigated the LPCAT2-mediated acylation of proteins in LPS-stimulated macrophages. The expression of LPCAT2 in RAW264 cells was suppressed using RNAi technology and the effect of LPCAT2 silencing on protein acylation was investigated using LC-MS based proteomics after isolation of acylated proteins. This study shows, for the first time, that LPS induces modification of key proteins by acylation dependent on LPCAT2 and LPCAT2 silencing inhibits the acylation of 20 proteins involved in cell metabolism. Our data thus suggest a novel mechanism for the regulation of macrophage inflammatory responses by LPCAT2.

1996

Increased glycolytic capacity in CD16⁺ monocyte subset-derived M2 macrophages is linked to foam cell formation

Lee, M.¹, Woollard, K.², Henstridge, D.¹, Palmer, C.³, Hamilton, J.A.⁴, Sviridov, D.¹, Chin-Dusting, J.¹, Murphy, A.¹

¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Imperial College London, London, United Kingdom, ³Burnet Institute, Melbourne, Australia, ⁴University of Melbourne, Melbourne, Australia

Introduction: Macrophages scavenge lipids during atherogenesis. It remains unclear whether M1-inflammatory or M2-resolving macrophages have differing lipid-handling capacities. Intermediate (CD14+/16+) and non-classical (CD16+), but not classical (CD14+) monocytes, are inflammatory and significantly elevated in patients with cardiovascular disease. It is unknown if and how these specific subsets contribute to foam cell formation. We therefore aimed to determine the lipid-handling and metabolic phenotype of monocyte subset derived macrophages and to examine this in a mouse model of atherosclerosis.

Methods: The three human monocyte subsets were isolated from healthy donors by FACS and differentiated into macrophages with M-CSF and stimulated with LPS+IFN γ (M1) or IL-4 (M2) followed by incubation with oxLDL. Cell populations were analysed using flow cytometry, RT-PCR and XFe-96 Seahorse bioanalyzer. Ex vivo plaque macrophages were isolated from the atherosclerotic lesions of western-type diet fed Apoe^{-/-} mice.

Results: M2-macrophages from all human monocyte subsets express CD36, SR-A and LOX-1 receptors that take up oxLDL, whereas M1 macrophages do not. Interestingly, oxLDL-treated M2 macrophages derived from CD14+ and CD14+/16+ monocytes show upregulation of Abca1 mRNA levels which was not observed in macrophages derived from CD16+ monocytes, suggesting potential defects in cholesterol efflux capacity. Glycolytic activity was increased in CD16+ subset-derived M2-macrophages when stimulated with oxLDL. This glycolytic phenotype was also confirmed ex vivo in CD206+ (M2) macrophages in atherosclerotic plaques of Apoe^{-/-} mice.

Conclusions: We suggest that CD16+ subset-derived M2-macrophages are involved in foam cell formation through increased glycolytic metabolism. Studies exploring glycolytic pathways in atherosclerotic macrophage foam cells are warranted.

A helminth-derived suppressor of IL-33 in allergic asthma

McSorley, H.¹, Osbourn, M.¹, Toivakka, M.¹, Maizels, R.²

¹University of Edinburgh, MRC Centre for Inflammation Research, Edinburgh, United Kingdom, ²University of Glasgow, Wellcome Trust Centre for Molecular Parasitology, Glasgow, United Kingdom

The IL-33 pathway is strongly implicated in allergic asthma: IL-33 levels are increased in the asthmatic lung; genome-wide association studies implicate both IL-33 and the IL-33 receptor in development of disease; and administration of rIL-33 to mice results in an asthma-like phenotype. We previously showed that the excretory/secretory products (HES) of the helminth parasite *Heligmosomoides polygyrus* suppress both the release of IL-33 and expression of the IL-33 receptor in the *Alternaria* model of allergic asthma. More than 350 proteins can be identified in HES by proteomic analysis: to identify specific molecule in HES responsible for IL-33 suppression, we carried out size and charge fractionation, and identified candidate proteins in suppressive fractions by mass spectrometry. Expression of candidate

proteins in mammalian HEK293T cells, and testing in vitro, led to the identification of HpARI (*H. polygyrus* Alarmin Release Inhibitor), a protein which in recombinant form can replicate the IL-33 suppression shown by HES. In vivo, coadministration of HpARI with either *Alternaria* allergen or respiratory syncytial virus (RSV) (both of which are associated with the development of allergic asthma) results in reduced IL-33 release in the lung, in turn leading to reduced type 2 innate lymphoid cell cytokine production and ablation of BAL eosinophilia. The mechanism of action of HpARI and efficacy on human cells are presently being investigated, with an ultimate aim of developing HpARI for use as a novel treatment for human allergic disease.

2647

Role of interleukin-4 receptor alpha⁺ CD4⁺ T cells in chronic airway hyperresponsiveness

Kirstein, F., Nieuwenhuizen, N., Jayakumar, J., Horsnell, W., Brombacher, F.
University of Cape Town, Division of Immunology, Cape Town, South Africa

T-helper 2 (Th2) cells and their cytokines are associated with allergic asthma in humans and with mouse models of allergic airway disease. IL-4 signalling via interleukin-4 receptor alpha (IL-4Ra) on CD4⁺ T cells leads to Th2 cell differentiation *in vitro*, implying that IL-4Ra responsive CD4⁺ T cells are critical for the induction of allergic asthma.

This study defines the requirements for IL-4Ra responsive CD4⁺ T cells and the IL-4Ra ligands IL-4 and IL-13 during the onset and chronic phase of ovalbumin (OVA) induced allergic asthma in CD4⁺ T cell-specific IL-4Ra deficient BALB/c mice (Lck^{cre}IL4Ra^{-/lox}) mice, in the presence or absence of IL-4 or IL-13.

During acute allergic airway disease, IL-4 deficiency or absence of IL-4Ra responsive CD4⁺ T cells did not prevent the onset of Th2 immune responses, airway hyperresponsiveness (AHR) or goblet cell hyperplasia. In contrast, deficiency of IL-13 did prevent allergic asthma, irrespective of the presence or absence of IL-4Ra responsive CD4⁺ T cells. Importantly, IL-4Ra responsive CD4⁺ T cells were required to sustain chronic airway hyperresponsiveness and eosinophilic lung inflammation. Furthermore, deficiency in IL-4Ra responsive CD4⁺ T cells resulted in increased numbers of IL-17 producing T cells in Lck^{cre}IL4Ra^{-/lox} mice and consequently increased airway neutrophilia. However, airway hyperresponsiveness was not significantly altered by anti-IL-17 treatment.

In summary, IL-4-responsive T helper cells are dispensable for acute ovalbumin-induced airway disease but required to maintain chronic asthmatic pathology.

1223

B1 cells produce large amounts of IgE post-helminth infection and this IgE is protective against allergic disease

Martin, R.K., Damle, S.R., Conrad, D.H.

Virginia Commonwealth University, Microbiology and Immunology, Richmond, United States

Helminth infection is known for generating large amounts of non-specific IgE. This hinders parasite-specific IgE, thereby reducing

mast cell (MC) degranulation and anti-helminth immunity. Here we report that innate-like B1 cells are responsible for the non-specific IgE production during the helminth infection, *Nippostrongylus brasiliensis* (*Nb*). We utilize a mouse model that lacks B2 cells, but has equivalent IgE production to WT during *Nb* infection. Using this model with the NP-KLH system, B1 cells made no antigen-specific IgG1 nor exhibited memory. Notably, the B1 produced IgE is unable to induce MC degranulation in an active cutaneous anaphylaxis model and can block MC degranulation in a model of passive cutaneous anaphylaxis. Sorted B1 cells from *Nb*-infected WT mice make increased amounts of IgE in post-sort culture with IL-4, anti-CD40, and IL-5 over naïve B1-culture by ELISA, but equivalent secreted IgE message by RT-PCR. This is due to increased proliferative capacity of B1 cells in *Nb*-infected animals. Finally, we used RAG^{-/-} reconstitution to isolate the direct contribution of B1 cells alone, B2 cells alone, or B1 and B2 cells together. B1-only reconstituted RAG^{-/-} make large amounts of IgE in *Nb* infection and have higher fecal egg burdens than B2-only reconstituted RAG^{-/-}. Overall, these data represent a protective response that has evolved for the helminth. We hypothesize that human B1-IgE production could be harnessed as potential protection against allergic disease and may help explain the reduced atopy seen in parasite endemic populations.

2720

Serial mast cell tryptase measurements: sensitivity and specificity for a diagnosis of anaphylaxis in patients with shock and/or hypoxemia

Creamer, A.^{1,2}, *Fatovich, D.M.*^{1,2,3}, *Stone, S.F.*^{1,2}, *Macdonald, S.P.J.*^{1,2,3,4}, *Arendts, G.*^{1,2,3,5}, *Nagree, Y.*^{1,5}, *Mitenko, H.M.A.*^{1,6}, *Rajee, M.*^{1,7}, *Brown, S.G.A.*^{1,2,3,8,9}

¹Centre for Clinical Research in Emergency Medicine, Harry Perkins Institute of Medical Research, Perth, Australia, ²University of Western Australia, Crawley, Australia, ³Royal Perth Hospital, Perth, Australia, ⁴Armadale Kelmscott Memorial Hospital, Armadale, Australia, ⁵Fiona Stanley Hospital, Murdoch, Australia, ⁶South West Health Campus (formerly Bunbury Regional Hospital), Bunbury, Australia, ⁷Austin Hospital, Heidelberg, Australia, ⁸University of Tasmania, Hobart, Australia, ⁹Royal Hobart Hospital, Hobart, Australia

Background: Anaphylaxis is difficult to identify in cases presenting with atypical symptoms. Serial measurements of mast cell tryptase (MCT), looking for changes in MCT levels (delta-MCT) may increase the sensitivity of current diagnostic methods. The usefulness of this approach depends on the ability of delta-MCT to distinguish anaphylaxis from other critical illnesses, which is investigated in this study.

Methods: MCT was measured (ImmunoCAP®) in serum samples from patients with anaphylaxis (n=85) and non-anaphylactic critical illness (n=120) on at least three occasions: ED arrival, 1-2 hours, 3-4 hours, and 12-24 hours post-arrival where possible. Delta-MCT was calculated as the difference between the highest and lowest values regardless of time point, and analyzed using Receiver Operating Characteristic Curves. A positive delta-MCT was defined as >2.0 ng/mL.

Results: 48 (56%) of 85 anaphylaxis cases were positive,

compared to 31 (25%) of 120 cases of critical illness (including sepsis, cardiac arrest, trauma and toxicology). Non-anaphylaxis cases had delta-MCT values ranging from 0-22 ng/mL (2 cases had delta-MCT >10), whereas anaphylaxis cases had delta MCT values ranging from 0-114 ng/mL (22 cases had delta-MCT >10). The diagnostic specificity was 0.74 with a sensitivity of 0.56. Higher cutoff values provided higher specificity but lower sensitivity.

Conclusion: The specificity and sensitivity observed in this study indicate that delta-MCT measurements do not perform well in cases where anaphylactic shock has to be differentiated from other critical illnesses, which may also involve some mast cell degranulation. In this situation higher cut-offs are required, however this results in poor sensitivity.

517

Deficit of Treg cells and vitamin D are predisposing factors for the establishment of cow's milk protein allergy in infants

*López-Abente, J.*¹, *Perezabad, L.*², *Alonso-Lebrero, E.*³, *Seoane Reula, E.*⁴, *Pion, M.*¹, *Correa-Rocha, R.*¹

¹Gregorio Marañón Health Research Institute, Laboratory of Immune-Regulation, Madrid, Spain, ²CIAL-CSIC, Department of Bioactivity and Food Analysis, Madrid, Spain, ³Hospital General Universitario Gregorio Marañón, Immunopediatric Division, Madrid, Spain, ⁴Hospital General Universitario Gregorio Marañón, Pediatric-Allergy Division, Madrid, Spain

Background: Cow's milk protein allergy (CMPA) is the most common food allergy in infants. However, little is known about which specific immune mechanisms are responsible of the CMPA onset. The objective was to investigate which immune alterations constitute the differential factors between allergy and tolerance, and hence would be responsible for the CMPA onset in infants.

Methods: Blood samples from infants younger than 9 months were obtained 1-4 days after the first adverse reaction to milk. We performed an extensive analysis of immune subsets, including Treg and cytokine-secreting cells previous to the definitive diagnosis of CMPA.

Results: Less than 4 days after milk exposure, infants with a CMPA diagnosis had decreased counts of Treg cells and an increased frequency of IL4-secreting CD4 T cells compared to controls. The deficit of Treg cells was not due to their decreased production by the thymus, but it was significantly correlated with decreased values of vitamin D in plasma. Values of Treg, IL4-secreting cells and vitamin D were good predictors of CMPA diagnosis.

Conclusion: After a first reaction to milk proteins, Treg cells from CMPA infants would have an impaired survival related to a vitamin D deficit. Decreased Treg numbers might favor the expansion of IL4-secreting CD4 T cells, and consequently these infants acquire an allergic phenotype to milk proteins. These immune alterations would be the crucial factor behind the CMPA onset, they could constitute predictive markers and might be a target for the prevention and treatment of this allergy in infants.

Airway allergy can be controlled through dendritic cell subset manipulation in a mouse model

Takahashi, H.¹, Murakami, R.^{1,2}, Nakagawa, Y.¹, Shimizu, M.¹, Wakabayashi, A.¹, Negishi, Y.¹, Takachika, H.³, Shinya, E.¹, Ohkubo, K.²
¹Nippon Medical School, Department of Microbiology and Immunology, Tokyo, Japan, ²Nippon Medical School, Department of Otorhinolaryngology, Tokyo, Japan, ³Tokyo Metropolitan Institute of Medical Science, Department of Allergy and Immunology, Tokyo, Japan

Two major distinct subsets of dendritic cells (DCs) are arranged to regulate immune responses; DEC 205⁺ DCs drive Th1 polarization and 33D1⁺ DCs establish Th2 dominance. Th1 polarization can be achieved either by depletion of 33D1⁺ DCs with a 33D1-specific monoclonal antibody (mAb) or by activation of DEC-205⁺ DCs via intraperitoneal (i.p.) injection of α -galactosylceramide (α -GalCer). We studied the effect of 33D1⁺ DC depletion or DEC-205⁺ DC activation in vivo using an established mouse model of allergic rhinitis (AR). Mice were injected i.p. with OVA plus alum and challenged four times with daily intranasal (i.n.) administration of OVA. Immediately after the last challenge, allergic symptoms such as sneezing and nasal rubbing as well as the number of cells in the bronchoalveolar fluid (BALF) and nasal lavage fluid (NALF) were counted. The levels of serum OVA-specific IgG1, IgG2a and IgE were also determined by ELISA. The allergic symptom scores were significantly decreased in 33D1⁺ DC-depleted or DEC-205⁺ DC-activated AR mice. The levels of OVA-specific IgG1, IgG2a and IgE, and the number of NALF but not BALF cells were reduced in 33D1⁺ DC-depleted but not in DEC-205⁺ DC-activated AR mice. Moreover, the activated DEC-205⁺ DCs suppressed histamine release from IgE-sensitized mast cells, probably through IL-12 secretion. The manipulation of innate DC subsets may provide a new therapeutic strategy for controlling various allergic diseases by reducing histamine release from IgE-sensitized mast cells by driving the immune response towards Th1 dominance via activation of DEC-205⁺ DCs in vivo.

2766

Characterizing immune responses in severe T-cell mediated adverse drug reactions

Redwood, A.¹, Pavlos, R.¹, Strautins, K.¹, James, I.¹, Konvinse, K.², White, K.², Ergen, E.², Trubiano, J.³, Leary, S.¹, Koelle, D.⁴, Mallal, S.^{1,2}, Phillips, E.^{1,2}

¹Murdoch University, Institute for Immunology and Infectious Diseases, Murdoch, Australia, ²Vanderbilt University, Nashville, United States, ³Alfred Health, Department of Infectious Diseases, Melbourne, Australia, ⁴University of Washington School of Medicine, Seattle, United States

The severest of immune mediated adverse drug reactions (IM-ADR) are primarily class I HLA restricted, although only a small proportion of patients carrying an HLA risk allele develop an IM-ADR. To define the specific immunopathogenesis of these T-cell mediated ADRs we have drawn from a resource of HLA ABC DR DQ DP genotyped and cryopreserved paired PBMCs and blister fluid/skin biopsies developed from subjects with

severe IM-ADRs (Stevens-Johnson Syndrome/Toxic epidermal necrolysis (SJS/TEN), abacavir hypersensitivity, and drug reaction with eosinophilia and systemic symptoms (DRESS)). ELISpot and ICS were used to define drug specificity and T-cell involvement. Putative pathogenic TCRs were identified through single cell index sorting of drug reactive T cells and single cell T-cell receptor (TCR) sequencing. SNP analysis of genes involved in the antigen processing and presentation pathway was employed to refine genetic associations. A Jurkat T cell-based luciferase reporter assay was developed to further characterize the specificities of TCRs of interest. Immune responses differed with the drug, clinical phenotype/tissue specificity, longevity of immune response, CD4⁺, CD8⁺ and NK cell dependency, and the oligoclonality of drug specific T-cell populations. Two IM-ADR susceptibility genes were identified within the antigen presentation pathway, endoplasmic aminopeptidase 1 (ERAP1) and ERAP2. We hypothesize that an early immunodominant response to a chronic prevalent pathogen such as the human herpes viruses can later generate cross-reactive responses in the presence of drug-endogenous peptide and HLA risk allele and that this helps explain the short latency, long-lasting immunity and tissue specificity of many severe T-cell mediated ADRs.

Regional variation in allergic sensitivity to subtropical and temperate grass pollen allergens; outcomes of the multicentre cross-sectional Grass Pollen Allergy Survey (GPAS)

Davies, J.¹, Timbrell, V.¹, Reibelt, L.², Simmonds, C.², Solley, G.³, Smith, W.⁴, Mclean-Tooke, A.⁵, van Nunen, S.⁶, Smith, P.⁷, Upham, J.⁸, Langguth, D.²

¹Queensland University of Technology, Brisbane, Australia, ²Sullivan Nicolaides Pathology, Brisbane, Australia, ³Watkins Medical Centre, Brisbane, Australia, ⁴Royal Adelaide Hospital, Adelaide, Australia, ⁵Sir Charles Gairdner Hospital, Perth, Australia, ⁶Royal North Shore Hospital and University of Sydney, Sydney, Australia, ⁷Queensland Allergy Services, Gold Coast, Australia, ⁸The University of Queensland and The Princess Alexandra Hospital, Brisbane, Australia

Grass pollens (GP) are major outdoor aeroallergens globally. Whilst allergen immunotherapy focuses on temperate (Pooideae) GP, allergens of subtropical (Panicoidae, Chloridoideae) GP show species-specific immunity. We aimed to evaluate regional variations in allergic sensitivity to temperate and subtropical GP.

Subjects (patients; 321, non-atopic; n = 31, other allergies; n = 42) were recruited with informed consent. Clinical history of allergic rhinitis and asthma and skin prick test (SPT) to GP extracts were evaluated (prior GP immunotherapy excluded). Total and specific serum IgE to GP and seven purified allergen components were measured by ImmunoCAP.

GP-allergic patients from Queensland showed higher SPT and IgE to Bahia and Bermuda GP as well as Pas n 1 and Cyn d 1, than Ryegrass pollen and Lol p 1. Patients from Adelaide and Sydney however, showed higher SPT and IgE to Ryegrass than Bermuda and Johnson GP. In Perth, SPT to Ryegrass was higher than Johnson GP, and IgE with Ryegrass was higher than with

Bermuda GP. In Adelaide, Sydney or Perth sensitivity to Bahia GP was similar to Ryegrass, but IgE to Lol p 1 was higher than IgE to Cyn d 1 or Pas n 1. Patients from Adelaide showed higher IgE reactivity than patients from QLD with the allergen (Lol p 5) specific to temperate GP.

Patients show regional differences in levels and patterns of allergic sensitivity with subtropical or temperate GP consistent with grass distributions. The outcomes provide insights for design of more specific diagnosis and treatment of GP allergy.

Mucosal route of immunotherapy with transgenic rice seeds expressing hypoallergenic whole T cell epitopes of Cryj1 and Cryj2 - Investigation in murine model of cedar pollinosis

Kawauchi, H.¹, Aoi, N.¹, Yamada, T.², Takagi, H.³, Takaiwa, F.³

¹Shimane University, Faculty of Medicine, Otorhinolaryngology, Izumo, Japan, ²Shimane University, Center for Integrated Research in Science, Department of Experimental Animals, Izumo, Japan,

³National Institute of Agrobiological Sciences, Ministry of Agriculture, Tsukuba, Japan

For the last decade, we have been investigating the therapeutic effect of mucosal route of administration of transgenic rice (Tg-rice) seeds, which contain T-cell epitopes of Cryj1 and Cryj2, on murine allergic rhinitis models and reported its clinical efficacy to actually attenuate nasal symptoms. However, its mechanism remains to be further investigated and adverse events of this therapeutic approach should be very least with more sophisticated manners.

Results: Therefore, we have examined the effect of natural feeding with protein bodies (PB) of transgenic rice seeds expressing hypoallergenic whole T cell epitopes of Cryj1 and Cryj2 (PB-Tg rice), in comparison with whole Tg-rice, in a murine model of cedar pollinosis. The numbers of sneezing after final intranasal challenge in mice naturally fed with PB-Tg-rice powder were significantly decreased in a dose dependent manner, with less doses, in comparison with those of whole Tg-rice powder. Histopathological findings correspondingly demonstrated that the number of eosinophils infiltrating into nasal mucosa decreased and the damage of epithelial cells was less found in each group of mice. Sublingual route of administration is also effective to attenuate nasal symptoms.

Conclusion: Protein body fraction of Tg-rice more efficiently downregulated nasal symptom in murine model of cedar pollinosis with natural feeding or sublingual administration. These result implicates that intake of protein body form of Tg-rice can be more promising strategy and material to be utilized for mucosal route of immunotherapy to attenuate nasal symptoms of patients with cedar pollinosis.

Thermal processing enhances IgE but not T cell reactivity of shellfish allergens

Abramovitch, J.^{1,2}, Lopata, A.³, O'Hehir, R.^{1,2}, Rolland, J.^{1,2}

¹Monash University, Immunology and Pathology, Melbourne, Australia, ²Alfred Health, Central Clinical School, Monash University

Melbourne, Allergy, Immunology and Respiratory Medicine, Melbourne, Australia, ³James Cook University, School of Pharmacy and Molecular Science, Townsville, Australia

Background: Shellfish allergy is a major cause of food-induced anaphylaxis. We showed previously that heating increases IgE reactivity of crustacean allergens. Here we investigate the effects of heating of crustacean extracts on cellular immune reactivity.

Methods: IgE reactivity of raw and cooked black tiger prawn, banana prawn, mud crab and blue swimmer crab extracts was assessed by ELISA. PBMC from shellfish-allergic (n=8) and control, non-atopic (n=4) subjects were cultured with the extracts, proliferation assessed by CFSE labelling and effector responses by intracellular IL-4 and IFN- γ . Regulatory T (CD4⁺CD25⁺CD127^{lo}Foxp3⁺) cell proportions in cultures were also compared.

Results: For each crustacean species, the cooked extract had greater IgE reactivity than the raw (mud crab p< 0.05, others p< 0.01). In contrast, there was a trend for higher PBMC proliferation to raw extracts. In shellfish-stimulated PBMC cultures, dividing CD4⁺ and CD56⁺ lymphocytes showed higher IL-4/IFN- γ ratios for shellfish-allergic subjects than for non-atopics (p< 0.001), but there was no difference between raw and cooked extracts. The percentage IL-4⁺ of dividing CD4⁺ cells correlated with total and allergen-specific IgE levels. There was a trend for higher proportions of regulatory T cells in cultures stimulated with raw compared with cooked extracts (mud crab p< 0.001, banana prawn p< 0.05).

Conclusions: Our novel findings confirm that raw and cooked shellfish extracts should be included in reliable specific-IgE diagnostic assays, but suggest that raw extracts are suitable for analysis of cellular responses. This has important implications for development of a safe T cell-targeted allergen-specific treatment for shellfish allergy.

Treg reconstitution before allogeneic bone marrow transplantation reduces T cell proliferation, activation status, and inflammatory cytokine secretion

Pijning, A.E., Bolton, H.A., Terry, A.M., Shklovskaya, E.V., Fazekas de St Groth, B.

Centenary Institute, University of Sydney, NSW, Sydney, Australia

Transfer of regulatory T cells (Tregs) has been proposed as a therapy for graft-versus-host disease (GVHD) in bone marrow transplant (BMT) recipients. The exact mechanism by which Tregs control GVHD is not yet well established. Previously, we used a Treg reconstitution approach in Rag-KO mice to show that Tregs prevent rapid oligoclonal lymphopaenia-induced proliferation, while promoting slow homeostatic repopulation of the naïve T cell pool. This process was critically dependent upon Treg-mediated down regulation of the co-stimulatory molecules CD80 and CD86 on DCs. Using a mouse model in which the Treg compartment of allogeneic BMT recipients is selectively reconstituted prior to transfer of allogeneic donor T cells, we showed that early Treg reconstitution completely protected against GVHD up to 120 days post-transplant.

Here we characterized the effect of Tregs on the early GVH response. When adoptively transferred after Treg reconstitution, allogeneic donor T cells underwent slow homeostatic division and retained a naïve phenotype. In contrast, in BMT recipients that were not Treg reconstituted, donor T cells underwent rapid proliferation and acquired an effector memory phenotype. Rapid proliferation of donor T cells was associated with increased expression of inflammatory cytokines, which were not seen in Treg reconstituted BMT recipients. These results provide a mechanism for the clinically improved outcome of BMT after Treg transfer, and stress the importance of achieving full Treg reconstitution before transfer of allogeneic T cells. In ongoing research, the effects of Treg reconstitution on T cell homing, proliferation, and phenotype in GVHD target organs are being investigated.

Nedlands, Australia, ³Immunology and Virology Program, Centre for Ophthalmology and Visual Science, The University of Western Australia, Crawley, Australia

Cytomegalovirus (CMV) infection remains a significant complication after allogeneic bone marrow transplantation (BMT) and for reasons that are poorly understood, CMV seropositivity remains a major determinant of clinical transplant outcome.

Aim: To elucidate the mechanisms and immunological consequences of CMV reactivation in a newly established model.

Methods: Mice were infected with murine CMV (MCMV) and functional latency defined as the resolution of viremia in target organs and plasma. Latently infected mice were transplanted with Bone Marrow (BM) and T cells or Tcell-depleted (TCD) BM alone from MHC-disparate or MHC-matched uninfected donors to generate GVHD and non-GVHD conditions respectively. Reactivation was determined by qPCR on plasma and plaque assays in target organs after BMT.

Results: MCMV enters latency two months after primary infection with the resolution of viremia correlating with absence of replicating virus in organs by plaque assays. The reactivation of MCMV after BMT is GVHD-dependent: BALB/c→B6: 63% vs 17% (p< 0.05) and B6→BALB/c: 100% vs 15% (p< 0.0001) in GVHD vs non-GVHD recipients. This is corroborated by plaque assays, with virus replication detected in 54% vs 0% (p< 0.01) of livers and 46% vs 8% of lungs in the former model. GVHD is characterized in mice by an interferon-based cytokine storm early after BMT and recipients of IFN γ -/- grafts are more susceptible to CMV reactivation: wild type vs. IFN γ -/-: 20% vs 100% (p< 0.01) and 18% vs 100% (p< 0.001) in MHC-mismatched and MHC-matched systems, respectively.

Conclusion: CMV reactivation after BMT is GVHD-dependent and is inhibited by IFN γ signaling.

Identifying cellular subsets diagnostic for severity and organ specificity chronic GVHD

Stikvoort, A.¹, Chen, Y.², Rådestad, E.¹, Törlén, J.¹, Sundberg, B.¹, Sundin, M.³, Mattsson, J.⁴, Brodin, P.², Uhlin, M.¹

¹Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden, ²Karolinska Institutet, Department of Medicine, Stockholm, Sweden, ³Karolinska University Hospital, Division of Paediatrics, Huddinge, Sweden, ⁴Karolinska University Hospital, Centre for Allogeneic Stem Cell Transplantation, Huddinge, Sweden

Chronic graft-versus-host-disease (cGvHD) is a severe late complication after hematopoietic stem cell transplantation, with a pathophysiology similar to severe auto-immune disorders.

We performed an extensive immune-phenotypic analysis on peripheral blood from 42 patients diagnosed with varying grades of cGvHD by flow cytometry (FC) and mass cytometry (CyTOF). Patients were divided into 4 groups according to the NIH-criteria: no (n=11), mild (n=8), moderate (n=12) and severe cGvHD (n=11). Additionally, the moderate and severe cGvHD patients were sub-grouped dependent on organ involvement.

An increased expression of activation marker CD38 on CD8+ T cells was associated with an increased severity of cGvHD. This was also correlated to a decreased frequency of mucosal-associated-invariant T (MAIT) cells. Additionally, patients with GI-tract-associated cGvHD displayed reduced frequencies of

MAIT cells. Expression of KIR CD158b was reduced in several NK cell subsets in patients with skin-associated cGvHD. Interestingly, CXCL10 was found to be increased in patients with liver-associated cGvHD. CyTOF analysis demonstrated both the ability to identify similar cellular subsets as found by traditional FC, as well as the ability to identify novel subsets of interest. These novel subsets consist of mostly small populations that appear conserved among patients. The role of these subsets needs further investigation.

In conclusion, we identified several subsets that could be correlated to cGvHD severity and localization. CyTOF may aid in identifying new markers vital to increase our knowledge on cGvHD pathophysiology. Subsequently, these markers may then be used in smaller FC panels for diagnostic purposes.

⁵Karolinska University Hospital Huddinge, Clinical Immunology and Transfusion Medicine, Stockholm, Sweden

Severe acute graft-versus-host disease (GVHD) is a common complication after hematopoietic stem cell transplantation. In this study, we present immunological surveillance data from 25 interventions in patients who were treated with placenta-derived decidual stromal cells (DSCs) for severe acute GVHD. Depending on clinical response, the patients were retrospectively divided into responders (n=17) or non-responders (n=8). Blood samples were obtained before and 3h, 1 week, 2 weeks, and 4 weeks after the DSC infusion. OPLS-DA and subsequent univariate analyses were used to discriminate and detect potential differences between the two groups based on data from 27 cytokines and 56 flow cytometry parameters. Interestingly, non-responding patients had significantly higher levels of IL-6 ($P=0.035$), IL8 ($P=0.048$) and IP-10 ($P=0.001$) compared to responding patients before DSC treatment. The frequency of CD4⁺T-cells expressing HLA-DR was reduced over time in the responding ($P=0.037$), but not in the non-responding patients. The frequency of naive (CD45RA⁺CCR7⁺) CD4⁺T-cells was higher in the non-responders at 1 week ($P=0.033$). The expression of the gut homing marker CCR9 in CD4⁺T-cells was higher in the responders compared to the non-responders at 4 weeks ($P=0.022$), and the frequency of $\alpha 4\beta 7^+$ expression in CD4⁺CD25⁺T-cells was increased after DSC-therapy in the responders over the time of measurement ($P=0.005$). To conclude, DSCs may induce changes in parameters that are of interest in GVHD pathophysiology. The data also suggests that IL6, IL-8 and IP-10 can be used to predict response to DSC-therapy.

4173

Placenta-derived decidual stromal cells alter IL-2R expression and signaling in alloantigen-activated T cells

Erkers, T.¹, Solders, M.¹, Verlang, L.¹, Bergström, C.¹, Stikvoort, A.², Rane, L.¹, Nava, S.¹, Ringdén, O.¹, Kaipe, H.¹

¹Karolinska Institutet, Therapeutic Immunology, Stockholm, Sweden, ²Karolinska Institutet, Oncology and Pathology, Stockholm, Sweden

Stromal cells are important in immune homeostasis. Due to their immunoregulatory functions, stromal cells have received increased attention in translational medicine as a cellular therapy for inflammatory conditions. In the present study, we examined how decidual stromal cells (DSCs) from term placentas affect the IL-2 pathway in alloreactive T cells ($n \geq 11$). We found that DSCs promoted significantly higher production of IL-2 from alloantigen-activated T cells compared to control mixed lymphocyte reactions (median 1.9 ng/ml vs 0.02 ng/ml, $P < 0.001$). The intensity of expression of the IL2R α on T cells was increased by DSCs ($P < 0.001$), whereas the expression of the signaling subunits IL-2R β and IL-2R γ_c was reduced ($P < 0.001$). This was accompanied by a decreased uptake of exogenously added ¹²⁵I-labelled IL-2 ($P < 0.01$) and a reduced STAT5-phosphorylation ($P < 0.05$) in T cells co-cultured with DSCs. The anti-proliferative effect of sirolimus (SRL), which targets the IL2 signaling pathway via mTOR, was diminished by DSCs *in vitro* ($P < 0.05$). This was not observed when combining cyclosporine A (CsA) and DSCs. To investigate the clinical importance of our findings, IL-2 levels, proportion of regulatory T cells, and IL2R α expression on T-cells were determined in 21 patients treated with DSCs for acute graft-versus-host disease (GVHD). No differences were detected before or after treatment, or between patients who received SRL or CsA as GVHD prophylaxis. To conclude, DSCs affect IL-2 production and signaling *in vitro*, and may influence the efficacy of immunosuppressive drugs. However, there were no indications that DSCs have any systemic effect on the IL-2 pathway *in vivo*.

1925

Downregulating cyclin-dependent kinase 9 of alloreactive CD4⁺T cells prolonged allograft survival

Hou, G., Zhan, Y.

School of Medicine Shandong University, Institute of Experimental Nuclear Medicine, Jinan, China

Allograft acute rejection has been the main barrier in clinic and it is urgent to find new target molecules varied significantly during allojection for diagnosis and therapy. A variety of inflammatory cells and molecules contribute to the development of allograft rejection. CDK9 (Cyclin-Dependent Kinase 9), a Positive Transcription Elongation Factor b (P-TEFb) kinase component, was reported to regulate several inflammatory diseases, including arthritis and atherosclerosis. However, the roles played by of CDK9 during allojection have not been described. This study aim to investigate whether the CDK9/Cyclin T1/RNA polymerase II pathway impacts CD4⁺T cells mediated -allograft rejection in mice models. The results showed that CDK9/Cyclin T1 were apparently up-regulated in

the allogeneic group than in the syngeneic group at the all time point (days 4, 8, 12, and 16) and positively associated with the severity of graft damage. Allografted SCID mice with adoptive transfer of CD4+ T cells pretreated with PHA767491 (Inhibitors of CDK9) revealed CDK9 inhibition in CD4+ T cell-mediated allojection model, the PHA767491-pretreated group showed prolonged survival than the PBS-pretreated group. This effect was associated with increase of IL-10, IL-4 and decrease of IFN- γ . Thus, our results demonstrated that CDK9/Cyclin T1/Pol II signaling regulated allojection in a mouse skin allograft model, which provide a new approach for prolong allograft through targeting CDK9.

1981

Lymphocyte expression of CD31 and leukocyte-derived CD31, two new markers of antibody-mediated rejection in human heart transplantation

Sannier, A.^{1,2}, Dorent, R.^{1,3}, Le Borgne, M.¹, Stroumza, N.¹, Gaston, A.-T.¹, Khallou-Laschet, J.¹, Deschildre, C.¹, Nataf, P.^{1,4}, Couvelard, A.², Caligiuri, G.^{1,3}, Nicoletti, A.¹

¹INSERM U 1148, Paris, France, ²AP-HP, Department of Pathology, Bichat University Hospital, Paris, France, ³AP-HP, Department of Cardiology, Bichat University Hospital, Paris, France, ⁴AP-HP, Department of Cardiosurgery, Bichat University Hospital, Paris, France

Background: Antibody-mediated rejection (AMR) severely shortens survival of heart allografts for which accurate non-invasive diagnostic tools are lacking. CD31 is a protein exclusively expressed at the blood-vessel interface. Its extracellular portion is cleaved upon immune stimulation thereby constituting a promising biomarker in AMR diagnosis.

Materials: Heart-transplanted (HTx) patients received a 5-day induction therapy of rabbit anti-thymocyte globulin (rATG) followed by a classical maintenance immunosuppression. AMR diagnosis was based on detection of anti-donor antibodies associated with pathological criteria of AMR on endomyocardial biopsy (pAMR2 in ISHLT classification).

Results: HTx patients (n=25) had significantly increased plasma levels of leukocyte-derived CD31 but patients diagnosed with AMR (n=5) had lower CD31 plasma levels and a higher proportion of CD4 T cells with a CD31+ recent thymic emigrant (RTE) phenotype. The initial lymphodepletion under rATG treatment was less efficient in patients that later developed an AMR (5-day post-transplantation lymphocyte count: 0.26 versus 0.17 G/l, P < 0.05). However, rATG binding assays on T cells and complement-mediated cytotoxicity did not differ between AMR and other HTx patients.

Conclusion: Among HTx patients, those with AMR patients have a higher proportion of RTE T cells. These patients are less depleted during the induction therapy but this is not due to a lower sensitivity to the rATG treatment. A better lymphocyte replenishment may be an additional factor explaining their larger RTE compartment. Their thymopoiesis and/or antigen-independent cytokine-induced peripheral homeostatic proliferation must now be addressed since both processes can promote the expansion of T cells with a RTE naïve phenotype.

Tfh-derived dopamine: motivation, learning and reward in the germinal centre

Papa, I.¹, Ponzoni, M.², Bustamante, S.³, Sweet, R.A.¹, Vohra, H.⁴, Canete, P.F.¹, Gonzalez Figueroa, P.¹, Hawley, N.¹, Doglioni, C.², Vinuesa, C.G.¹

¹John Curtin School of Medical Research - the Australian National University, Immunology and Infectious Disease, Canberra, Australia, ²San Raffaele Scientific Institute, Pathology, Milan, Italy, ³The University of New South Wales, Bioanalytical Mass Spectrometry Facility Mark Wainwright Analytical Centre, Sydney, Australia, ⁴John Curtin School of Medical Research - the Australian National University, Imaging and Cytometry Facility, Canberra, Australia

The germinal centre (GC) is a unique structure that develops in secondary lymphoid organs during immune responses to protein antigens, where high affinity antibodies and memory B cells are generated. In order to ensure fast selection of rapidly evolving clones in GC, follicular dendritic cells (FDCs), GC B cells and T cells engage in multiple short-lived interactions. So far, only co-stimulatory or inhibitory membrane immune receptor/ligand pairs and cytokines have been investigated and are known to be involved in this process. The speed and complexity of cellular interactions in this microenvironment is reminiscent of cellular connections and synaptic communication within the nervous system. Furthermore, molecules involved in axon growth and guidance have been found to be differentially expressed within GC B cells, suggesting that a neural-like transmission pathways may also be involved in GC B cell selection. Here we show that a subset of germinal centre T cells contains chromogranin B⁺ electron-dense granules typically found in neurons, and catecholamines, such as dopamine and noradrenaline. Furthermore RNA analysis and *in vitro* stimulation with dopamine shows this neurotransmitter is involved in a cross-talk among Tfh, GC B cells and FDCs. Our findings suggest a new co-stimulatory role of Tfh cell-derived dopamine during B cell maturation in germinal centres.

736

Interferon-g receptor and STAT1 signaling in B cells are central to spontaneous germinal center formation and autoimmunity

Domeier, P.P.¹, Chodisetti, S.B.¹, Soni, C.¹, Schell, S.L.¹, Elias, M.J.¹, Kitamura, D.², Rahman, Z.S.M.¹

¹Penn State University College of Medicine, Microbiology and Immunology, Hershey, United States, ²Tokyo University of Science, Research Institute for Biomedical Sciences, Tokyo, Japan

In Systemic Lupus Erythematosus (SLE), spontaneously developed germinal centers (Spt-GCs) harbor autoAb-producing B cells that promote disease, but the mechanisms that control Spt-GC development are not clear. Here we report that B cell-intrinsic IFN γ R and STAT1 signaling are essential for Spt-GC formation. The IFN γ R deficiency, however, does not significantly affect foreign Ag-induced GC and Tfh responses,

suggesting that two distinct mechanisms regulate foreign-Ag vs Spt-GC responses. We also demonstrate that IFN γ R-mediated STAT1 signaling drives T-bet expression, pro-GC gene expression and IFN γ production by B cells, which are critical for Spt-GC and Tfh development. To understand how IFN γ signaling regulates the Spt-GC response and associated autoAb production in SLE, we utilized B6.*Sle1b* mice that harbor the lupus-prone NZM2410 strain-derived SLAM locus. B6.*Sle1b* mice exhibit elevated Spt-GC and follicular helper T cell (Tfh) responses that associate with impaired B cell selection in GCs. B6.*Sle1b* mice with B cell intrinsic IFN γ R deficiency also have significantly reduced Spt-GC and Tfh responses resulting in a markedly lower number of IgG-producing antibody forming cells and diminished IgG_{2c} and IgG_{2b} autoantibody titers than B6.*Sle1b* mice. Additionally, the proliferation and differentiation of DNA-reactive B cells into a GC B cell phenotype require B cell-intrinsic IFN γ R signaling. Together, our data define a novel B cell-intrinsic IFN γ R signaling pathway in Spt-GC development and autoimmunity.

Leucine-rich repeat kinase 1 (LRRK1), the homolog of famous Parkinson's disease-related gene LRRK2, has distinct functions including the regulation of intracellular trafficking of epidermal growth factor receptor, microtubule nucleation, autophagy, and osteoclast differentiation. In addition, LRRK1 has been shown to be expressed predominantly in B cells and monocytes in human peripheral blood, its contribution to the immune system remains to be elucidated. Here, we found that LRRK1 was expressed over the course of B cell development and *Lrrk1*^{-/-} mice showed altered B1a-cell development and impaired basal immunoglobulin production. Moreover, production of IgG3 antibody in response to

T cell-independent type 2 antigen was affected in *Lrrk1*^{-/-} mice due to defects in IgG3 class-switch recombination. In vitro analysis revealed that ablation of LRRK1 in B cells resulted in defective proliferation and survival in response to BCR stimulation, but not to LPS or anti-CD40 antibody. Further analysis revealed impaired BCR-mediated NF- κ B activation and reduced expression of NF- κ B target genes. Our results provide clues about how LRRK1 regulates B-cell mediated humoral immune response.

1997

Characterising CARD11 mutations in B cell malignancies

Horikawa, K., Hanioka, A., Kaya, S., Wang, J.

The John Curtin School of Medical Research, The Australian National University, Cancer Biology and Therapeutics, Acton, Australia

CARD11 is a multidomain adaptor protein essential for transmitting signal from B cell antigen receptor (BCR) to NF- κ B pathway. Numerous somatic mutations in *CARD11* are found in various types of lymphomas, which are addicted to NF- κ B enhanced by oncogenic mutant CARD11 proteins. However, it is not known if these mutations are oncogenic driver mutations or passenger mutations without significant function. We generated a library of vectors expressing CARD11 mutations derived from human malignancies and investigated the consequences of each CARD11 mutation with NF- κ B activity by reporter assay and B cell proliferation by retrovirus gene delivery. The 95 CARD11 mutations were classified as 5 very strong (> 20 fold compared to wild type), 19 strong (5~20 fold), 30 moderate (2~5 fold), and 41 weak (< 2 fold) based on NF- κ B activity. All (7/7) of the insertion or deletion mutations induced high NF- κ B activity (\geq 2 fold) compared to missense mutations (48/88). Potent mutations were enriched in a region between CARD and coiled-coil domains and several positions within the coiled-coil domains. B cell growth induced CARD11 mutations was not directly correlated with NF- κ B activity measured by reporter assay. The antigen stimulation generally turned CARD11 mutations into more potent mutations. This cooperation was cancelled by a BTK inhibitor. By investigating the effects of CARD11 mutations, we have shown that heterogeneity in lymphomas could be rooted deeply into mutated genes, mutation types, positions, and substitution residues. Characterising gene variants is essential to understand molecular mechanisms underlying lymphoma development, more importantly to provide rational therapies.

A role for CD40 signalling in the formation of unswitched CD73+ memory B cell subsets

D'Souza, L.L., Bal, V., Rath, S., George, A.

National Institute of Immunology, New Delhi, India

Memory B cells are formed by germinal centre dependent or independent mechanisms and can be classified into unswitched or isotype-switched cells. The former retain the IgM BCR while the latter have switched to an IgG, IgA or IgE BCR. Unswitched memory is characterised by reduced mutations in germline sequences and can form germinal centres in recall responses as well as undergo both isotype switching and somatic hypermutation therein. The markers CD73, CD80 and CD273 are used to characterise multiple phenotypically and functionally distinct populations within this compartment. The factors, however, involved in the formation of these subsets remain unclear. Our analysis of multiple gene deficient strains points to reductions in unswitched CD73⁺ subsets in mice deficient in TCR β and Ii but not in TCR δ , ICAM-1, TAP-1, IL-4, and IL-10. This suggests that this subset may be generated in a T cell dependent manner. This finding was consolidated in TCR δ ^{-/-} mice, which also exhibited reduced frequencies of unswitched

CD73+ subsets and provision of T cells by adoptive transfer or in mixed bone marrow chimeras rescued this deficiency. We also report a role for CD40-CD40L signalling in this phenomenon, as CD73+ subsets were also reduced in CD40^{-/-} mice and in the CD40^{-/-} compartment of mixed bone marrow chimeras. The expression of CD73 on other lymphocyte populations remains unaffected in CD40-CD40L deficient environments, suggesting a restriction to the memory compartment. Put together, our findings suggest a role for T cells and germinal centres in the generation of subsets of unswitched memory B cells.

3523

STAT3 is a critical B-cell intrinsic regulator of functional antibody responses and IgE production

Kane, A.^{1,2}, Lau, A.^{1,3}, Brink, R.^{1,2}, Tangye, S.^{1,2}, Deenick, E.^{1,2}

¹Garvan Institute, Immunology, Darlinghurst, Australia, ²University of New South Wales, St Vincent's Clinical School, NSW, Australia,

³Bath University, Bath, United Kingdom

Autosomal dominant hyper IgE syndrome (AD-HIES) is a rare human primary immunodeficiency caused by heterozygous mutations in the gene encoding the transcription factor STAT3. Patients with AD-HIES suffer recurrent bacterial pneumonia and have decreased memory B cells, impaired antigen-specific antibody responses and aberrantly elevated IgE levels, suggesting a critical role for STAT3 in regulating antibody-mediated immunity. The mechanism underlying these defects are poorly defined. In particular it is not clear whether these defects arise from a B cell intrinsic requirement for STAT3 or are secondary to defects in other cell types. To resolve this, antigens specific B cell responses were determined in mice with conditional deletion of *Stat3* in B cells. Strikingly, STAT3 deficiency in B cells alone replicated the key humoral defects seen in AD-HIES including excessive IgE production demonstrating that B cell intrinsic STAT3 signaling is a critical regulator of optimal B cell clonal expansion, differentiation, affinity maturation, class-switching. Together these results reveal the pathophysiology of the humoral defects observed in AD-HIES.

The mechanistic target of rapamycin (mTOR) is a conserved protein kinase with central roles in regulating cell growth, metabolic and stress responses. It functions via at least two distinct mTOR protein complexes called mTOR complex (mTORC)1 and mTORC2. The mTORCs control many members of the protein kinase (PK)A/PKG/PKC (AGC) family. The AGC kinases are key regulators of multiple cellular functions and deregulation of many members of this family underlies numerous pathological conditions. One unique feature in the regulation of this family kinases is the phosphorylation of the

conserved motifs by mTORCs to allosterically augment their kinase activity, influence their substrate specificity, and promote protein maturation and stability. Activated AGC kinases in turn trigger the phosphorylation of diverse targets that ultimately control cellular response to a wide spectrum of stimuli. We found that Sin1, an essential component of mTORC2, plays specific role in B cell development and differentiation. We show specifically how Sin1 regulates Akt, a best-known member of AGC kinase, thus mediating specific mTOR signals for B cell mediated immune responses.

Toll-like Receptors (TLRs) detect pathogen molecules to mount immune responses required for microbial resistance. However, inappropriate TLR activation by host-derived danger molecules may also contribute to inflammatory diseases, such as atherosclerosis. Here we document that TLRs utilise the adaptor protein Myd88 to induce the degradation of the IAP protein cIAP1, and its binding partner TRAF2. This can result in two distinct cellular outcomes. Firstly, TLR-induced loss of cIAP1/TRAF2 triggers non-canonical NF- κ B activity to induce a subset of pro-inflammatory cytokines and chemokines. Secondly, in the absence of the related IAP protein, XIAP, TLR-induced cIAP1 degradation triggers activation of the NLRP3-caspase-1 inflammasome, which cleaves and activates IL-1 β and IL-18. Despite the fact genetic deletion of XIAP and cIAP1 in myeloid cells causes no overt phenotype in mice, co-deletion sensitises macrophages *in vitro*, or mice *in vivo*, to endotoxin induced IL-1 β production, compared to *Xiap*-deficient mice. This may explain why in response to pathogen infection, many XIAP mutant patients develop severe autoinflammatory disease characterised by enhanced inflammasome activity. Finally, we describe a novel type I Interferon (IFN) signalling mechanism that is able to protect against TLR-induced cIAP1 degradation, raising the prospect of treating pathological TLR signalling with anti-IFN therapies.

Sterile signals generate weaker and delayed macrophage NLRP3 inflammasome responses relative to microbial signals

Coll, R.C., Bezbradica, J.S., Schroder, K.

Institute for Molecular Bioscience, The University of Queensland, Brisbane, St Lucia, Australia

Inflammation is the host response to microbial infection or sterile injury that aims to eliminate the insult, repair the tissue and restore homeostasis. Macrophages and the NLRP3

inflammasome are key sentinels for both types of insult. Although it is well established that the NLRP3 inflammasome is activated by microbial products and molecules released during sterile injury, it is unclear whether the responses elicited by these different types of signals are distinct. In this study, we used LPS and TNF as prototypical microbial and sterile signal 1 stimuli, respectively, to prime the NLRP3 inflammasome. We then used the bacterial toxin nigericin and a common product released from necrotic cells, ATP, as prototypical microbial and sterile signal 2 stimuli, respectively, to trigger the assembly of the NLRP3 inflammasome complex in mouse and human macrophages. We found that NLRP3 inflammasome responses were weakest when both signal 1 and signal 2 were sterile, but responses were faster and stronger when at least one of the two signals was microbial. Ultimately, the most rapid and potent responses were elicited when both signals were microbial. Together, these data suggest that microbial versus sterile signals are distinct, both kinetically and in magnitude, in their ability to generate inflammasome-dependent responses. This hierarchy of NLRP3 responses to sterile versus microbial stimuli likely reflects the urgent need for the immune system to respond rapidly to the presence of infection to halt pathogen dissemination.

Nucleic acid recognition via MAVS is critical for robust adaptive immunity

Loetsch, C.^{1,2}, Warren, J.¹, Jandl, C.^{1,2}, King, C.^{1,2}

¹Garvan Institute of Medical Research, Darlinghurst, Australia, ²St. Vincent's Clinical School, University of New South Wales, Sydney, Australia

Innate immunity to RNA depends on recognition by RIG-I-like receptors within the cytosol. The subsequent interaction of these receptors with the mitochondrial adaptor protein (MAVS) is essential for the induction of type I IFN and pro-inflammatory cytokines. However, the impact of MAVS-mediated signalling on adaptive immunity remains incompletely understood.

The role of cytosolic detection of RNA in the T-dependent humoral immune response was investigated by utilising a novel mutant mouse strain (MAVS^{SNP}), which carries a point mutation within the MAVS transmembrane domain. Sheep red blood cells (SRBC) are a model polyvalent antigen for the analyses of T-dependent immune responses. To our surprise, MAVS^{SNP} mice exhibited reduced GC formation and antibody forming GC B cells, as well as cell-intrinsic defects in Tfh differentiation following immunisation with SRBC. This was associated with diminished production of type I (T1) IFN, type III IFN and IL-6. SRBC were found to contain microRNAs and were detected inside both macrophages and dendritic cells 30 min after immunisation, suggesting that phagocytosed material can enter the cytosolic MAVS pathway to influence the immune response. T1 IFN was found to be critical for optimal Tfh cell expansion and for upregulation of TLRs. Notably, blockade of TLR signalling induced a similar phenotype in MAVS^{WT} mice, suggesting an important role for early induction of T1 IFN by MAVS signaling in amplifying TLR pathways. These findings demonstrate that recognition of foreign RNA is central to the immune response

to SRBC and that cell intrinsic sensing of nucleic acids promotes adaptive immune responses.

Caspase-11 modulates inflammation and attenuates *Toxoplasma gondii* pathogenesis

Allen, L., Coutermarsh-Ott, S., Doran, J., Campbell, C., Williams, T., Lindsay, D.

Virginia Tech, Department of Biomedical Sciences and Pathobiology, Blacksburg, United States

Toxoplasma gondii is an obligate intracellular parasite that is the etiologic agent responsible for toxoplasmosis. Recent studies have identified inflammasome forming members of the NLR family of cytosolic sensors that are essential for modulating host resistance to *T. gondii*. Parasite infection results in canonical NLR inflammasome activation of caspase-1 and the subsequent cleavage of IL-1 β and IL-18. Recently, a non-canonical inflammasome has been characterized that functions through caspase-11 and appears to augment many biological functions previously considered to be dependent on caspase-1 and the canonical inflammasome. To better elucidate the function of this non-canonical inflammasome in toxoplasmosis, we utilized *Asc*^{-/-} and *Casp11*^{-/-} mice and infected these animals with Me49 strain *T. gondii*. Our data indicates that caspase-11 plays a critical role in modulating the innate immune response following *T. gondii* infection through a mechanism that is distinct from that currently described for the canonical inflammasome. *Asc*^{-/-} mice demonstrated increased disease pathogenesis during the acute phase of *T. gondii* infection, whereas *Casp11*^{-/-} mice demonstrated significantly attenuated disease pathogenesis and reduced inflammation. The attenuated host response was associated with reduced local and systemic cytokine production, including diminished IL-1 β . During the chronic phase of infection, caspase-11 deficiency resulted in increased neuroinflammation and tissue cyst burden in the brain. Together, our data suggests that caspase-11 functions to protect the host by enhancing inflammation during the acute phase of infection in an effort to minimize disease pathogenesis during chronic toxoplasmosis.

Potential role of Toll-like receptors in calcific aortic valve disease: elevation of osteogenic activity of valvular cells by DAMPs

Meng, X., Ao, L., Fullerton, D.

University of Colorado Denver, Surgery, Aurora, United States

Calcific aortic valve disease (CAVD) affects elderly people and is becoming an increasingly important healthcare issue with the emerging longevity. Progressive aortic valve calcification causes heart failure. Currently, pharmacological intervention of the progression of this disease is unavailable. While CAVD is recognized as a chronic inflammatory disease, the pro-inflammatory mechanism of aortic valve calcification is poorly understood. Aortic valve interstitial cells (AVICs) are actively involved in valvular calcification. Our studies found that human AVICs express osteogenic proteins (including BMP-2 and

TGF- β 1) in response to stimulation of Toll-like receptor (TLR) 2, 3 or 4. Further, the TLR-mediated osteogenic response in human AVICs leads to pro-osteogenic reprogramming characterized by the expression of Runx2 and alkaline phosphatase, and formation of calcium deposits. These studies uncovered novel mechanistic roles of the innate immune receptors in aortic valve calcification. Our recent work identified several endogenous factors that can elicit the osteogenic response in human AVICs through TLRs, including oxidized low-density lipoprotein, biglycan and matrilin 2. While these factors utilize distinct TLRs, they induce the osteogenic response through common signaling pathways, mainly the NF- κ B and ERK1/2 pathways. Our findings demonstrate that DAMPs are capable of inducing the osteogenic response in human AVICs and that the innate immune receptors have novel functions in modulating the osteogenic response in human aortic valve cells. These findings suggest that TLRs may play a role in the pathogenesis of CAVD and that modulation of the common signaling pathways utilized by TLRs may have therapeutic potential for suppression of CAVD progression.

2214

Functional analysis of a novel E3 ubiquitin ligase in TLR4-mediated innate immune responses

Hsu, L.-C., Lai, T.-Y., Lee, C.-Y., Chou, C.-C., Chang, Y.-C., Ho, Y.-H.
National Taiwan University, Institute of Molecular Medicine, Taipei, Taiwan, Republic of China

The mammalian immune system is comprised of two branches: innate and adaptive immunity. During microbial infections, innate immune cells use pattern-recognition receptors, including Toll-like receptors (TLRs), to detect conserved microbial molecules termed pathogen-associated molecular patterns, and then mount a defense response to clear bacteria and control the initiation and determination of the adaptive immune response. Excess activation of pro-inflammatory responses has been associated with many inflammatory diseases including sepsis and infectious diseases. However, the precise mechanisms underlying the regulation of mammalian immune system remain fragmentary. Here, we identified a RING finger E3 ubiquitin ligase, which regulated TLR4-activated immune responses in bone marrow macrophages by modulating caveolin-1 (CAV1) expression. We demonstrated that this E3 ubiquitin ligase physically interacts with CAV1 in response to lipopolysaccharide and mediates ubiquitination and degradation of CAV1. Depletion of this E3 ubiquitin ligase in macrophages caused an increase in the expression of CAV1, which led to decreased GSK3 β activation resulting in enhanced production of pro-inflammatory cytokines and inhibition of anti-inflammatory cytokine IL-10. Likewise, overexpressing CAV1 in macrophages significantly suppressed GSK3 β activity in response to LPS. Importantly, mice with myeloid-specific the novel E3 ubiquitin ligase deficiency were significantly resistant to both LPS- and cecal ligation and puncture-induced septic death. Our data has identified this E3 ubiquitin ligase as a new regulator of TLR4-induced inflammatory responses and revealed a novel mechanism for the regulation of TLR4 signaling through CAV1.

Roles of MD-1 in inflammatory disorders

Tanimura, N., Miyake, K.

Institute of Medical Science, University of Tokyo, Tokyo, Japan

MD-1 is identified as an accessory molecule, which binds to the ectodomain on Radioprotective 105 (RP105), also known as CD180. The molecular structure of RP105/MD-1 is similar to that of Toll-like receptor 4 (TLR4)/MD-2, the endotoxin receptor, but is lacking its cytosolic Toll-and-interleukin-1 responding (TIR) domain. As MD-2 has a hydrophobic pocket to recognize lipopolysaccharide (LPS), MD-1 also has the pocket, which is supposed to bind self-derived bioactive lipids as well as pathogen-derived lipid agonists. Because the previous study of MD-1's crystal structure analysis was revealed that self-derived phosphatidylcholine is able to be enclosed in the pocket. Many bioactive lipids are released in inflammatory disorders *in vivo*. We have focused on the physiological role of RP105/MD-1 related to sterile inflammations.

To address the role of RP105 and MD-1 in inflammatory responses *in vivo*, we performed the 2,6,10,14-tetramethylpentadecan (TMPD)-induced peritonitis model by using RP105 or MD-1 deficient mice and dissect the peritonitis-bearing mice. In the peritonitis-bearing wild-type mouse, they showed elevations of serum MD-1 concentration. And we found that MD-1 or RP105 deficient mouse showed severe phenotype with large volumes of ascites fluid. This ascites was considered by the consequence of the abnormal elevation of vascular permeability with increased VEGF. These indicated that RP105 and/or MD-1 enrolled to regulate the responsiveness after tissue damages. It is suggesting that MD-1 and RP105 contribute to suppress exacerbation of inflammatory disorders by the consequence of modifying the bioactive lipid activities.

High salt modulates cellular metabolic processes essential for macrophage activation

Binger, K.¹, Gebhardt, M.², Heinig, M.³, Rintisch, C.³, Schroeder, A.⁴, Kleinewietfeld, M.⁵, Schatz, V.⁶, Hubner, N.³, Jantsch, J.⁶, Titze, J.⁷, Muller, D.²

High intake of dietary salt (NaCl) is an established environmental risk factor for hypertension, and more recently has been linked to chronic inflammation and autoimmune diseases. We have characterised the effects of high salt on immune cells: our first study showed that high salt promotes hyperactive responses in pro-inflammatory T cells (Th17). More recently, we reported that pro-inflammatory ("M1") macrophages have an augmented activation with high salt, while anti-inflammatory ("M2") macrophages are inhibited. Here, we have investigated the

molecular mechanism for the differential effect of high salt on macrophage activation. Briefly, mouse bone-marrow derived macrophages were generated from male C57Bl/6 mice and activated to M1 by stimulation with LPS, or to M2 by stimulation with IL-4 and IL-13 in isotonic ([Na⁺]=137mM) or high salt ([Na⁺]=177mM) media. Genome-wide gene expression, with subsequent gene ontology analyses, revealed alterations in genes important for cellular metabolism in both M1 and M2 macrophages activated in high salt. Several of these genes were confirmed by real-time qPCR, such as glucose transporter 1 (*Slc2a1*), which, in high salt, had augmented expression in M1, and reduced expression in M2 macrophages. Extracellular flux analysis indicated that both oxidative phosphorylation and glycolysis was blunted in M2 macrophages activated in high salt. Conversely, lactate production was boosted in M1 macrophages activated in high salt, indicating an increased glycolytic rate. We thus propose that changes in sodium concentrations within tissue microenvironments *in vivo* may directly affect the cellular metabolism of residing and recruited macrophages, subsequently affecting their response upon immune challenge.

CX3CR1 reduces choline-deficient, ethionine-supplemented diet-induced liver injury and liver progenitor cell proliferation

Elsegood, C.^{1,2}, Domenichini, A.¹, Jackaman, C.¹, Ganss, R.³, Plant, G.⁴, Yeoh, G.^{2,3}, Olynyk, J.^{1,5}

¹Curtin University, School of Biomedical Sciences, Curtin Health Innovation Research Institute, Bentley, Australia, ²University of Western Australia, School of Chemistry and Biochemistry, Crawley, Australia, ³Harry Perkins Institute of Medical Research, Nedlands, Australia, ⁴Stanford University School of Medicine, Department of Neurosurgery, Stanford Partnership for Spinal Cord Injury and Repair, Stanford, United States, ⁵Fiona Stanley and Fremantle Hospitals, Department of Gastroenterology, Bull Creek, Australia

CX3CR1 and its cognate ligand, CX3CL1, is elevated in choline-deficient, ethionine-supplemented (CDE) diet-induced liver injury. ¹We assessed the role of CX3CR1 in liver injury and liver progenitor cell (LPC) proliferation by comparing the response of heterozygous CX3CR1^{gfp/+} (control) and homozygous CX3CR1^{gfp/gfp} (CX3CR1 knockout) mice to the CDE diet after 3 days. Heterozygous CX3CR1^{gfp/+} mice exhibited markedly reduced CDE diet-induced LPC proliferation when compared to homozygous CX3CR1^{gfp/gfp} mice. Furthermore, liver mRNA expression of the LPC mitogens, TNF α and lymphotoxin beta, were also significantly reduced in the heterozygous mice. In contrast, levels of IL-6, interferon γ , HGF, and TWEAK were not affected. Heterozygous CX3CR1^{gfp/+} mice developed less liver injury, steatosis, and inflammation compared to the homozygous CX3CR1^{gfp/gfp}, as serum alanine transaminase levels, oil red o staining, and the number of inflammatory cells such as neutrophils and B cells, respectively were reduced. However, the numbers of Kupffer cells and monocyte-derived macrophages were similar in the heterozygous and homozygous mice. In conclusion, CX3CR1 attenuates CDE diet-induced LPC proliferation. This may be a consequence of the reduction in liver injury and accompanying reduced

production of the LPC mitogens, TNF and lymphotoxin beta. Reference: 1. Viebahn CS, Benseler V, Holz LE, Elsegood CL, Vo M, Bertolino P, Ganss R, Yeoh GCT: Invading macrophages play a major role in the liver progenitor cell response to chronic liver injury. *Journal of Hepatology* 2010; 53: 500-507.

Pdcd4 deficiency confers resistance to the assembly of stress granules in macrophages during high fat-diet challenge

Bai, Y., Dong, Z., Guo, C., Zhang, L., Wang, Q.
Shandong University School of Medicine, Department of Immunology, Jinan, China

Pdcd4, a translation repressor, has been reported to be implicated in obesity and associated stress responses. In response to various stresses such as oxidative and/or endoplasmic reticulum stresses, the cells assemble stress granules (SGs) that are translationally silent cytoplasmic ribonucleoprotein complexes. However, the possible link of Pdcd4 with SGs remains lacking. In this study we showed the critical roles of Pdcd4 in regulating SG assembly during high-fat diet (HFD) challenge. In HFD-fed mouse model, obvious TIA-1-positive SGs were detected in macrophages from wild type (WT) obese mice, whereas little were seen in those from Pdcd4-deficient lean mice, indicating Pdcd4 deficiency causes the resistance to SG formation in response to HFD challenge. Using oxidized low-density lipoprotein (ox-LDL) as a stress stimulus, we found the translocation of Pdcd4 from nuclei to cytoplasm that displayed granule-like expression and colocalized with SG markers TIA-1, FXR1 and eIF4A in WT macrophages. Accordingly, Pdcd4 deficiency also led to reduced SG assembly in ox-LDL-treated macrophages. Mechanistically, a marked elevation in eIF2 α phosphorylation, which is required for cap-dependent translation repression and SG assembly, was observed in ox-LDL-stimulated WT macrophages compared with non-treated ones, but abolished in Pdcd4-deficient macrophages in response to ox-LDL or HFD, suggesting that Pdcd4 is a key regulator during HFD factors-induced SGs, which is dependent on eIF2 α phosphorylation. These data link Pdcd4 with SG-associated stress responses, thereby proposing Pdcd4 as a potential target for obesity and associated diseases.

Macrophages affected with exosome-carried miRNA-150 release secondary vesicles to inhibit the proliferation of effector T lymphocytes of mouse contact and delayed-type hypersensitivity

Nazimek, K.¹, Ptak, M.¹, Ptak, W.¹, Askenase, P.W.², Bryniarski, K.¹
¹Jagiellonian University Medical College, Department of Immunology, Krakow, Poland, ²Yale University School of Medicine, Department of Internal Medicine, New Haven, United States

Introduction: Mouse contact and delayed-type hypersensitivity reactions could be suppressed by

T CD8⁺ cell-derived miRNA-150 carried by exosomes

[Bryniarski et al. J Allergy Clin Immunol 2013;132:170-181.e9] acting through the antigen-presenting macrophages (Mf) [Nazimek et al. Immunology 2015;146:23-32]. Our research aimed to investigate the mechanism of Mf-dependent suppression of effector T lymphocytes.

Methodology: Peritoneal Mf from CBA/J, C57BL/6 wild-type or miRNA-150KO mice pulsed with T cell exosomes carrying miRNA-150 were cultured with effector T lymphocytes in direct or transmembrane contact, and incorporation of tritiated thymidine by proliferating T cells was measured. Supernatant from 48-hour culture of miRNA-150-pulsed Mf was ultracentrifuged, and resulting fractions were either tested for suppressive activity, in some instances after pre-incubation with monoclonal antibodies against MHC class II and antigen, or analyzed cytometrically.

Results: Regardless of the culturing conditions, miRNA-150-pulsed Mf suppressed proliferation of effector T cells. Pellet of ultracentrifuged culture supernatant of miRNA-150-pulsed Mf contained the CD9, MHC positive vesicles, which suppressive activity was blocked by pre-incubation with anti-MHC and anti-antigen antibodies. miRNA-150KO mouse Mf failed to generate inhibitory vesicles, unless they were pre-treated with miRNA-150-containing T cell exosomes from wild-type mice.

Conclusion: T suppressor cell-derived, exosome-carried miRNA-150 stimulate Mf to release secondary vesicles acting in a MHC and antigen-dependent manner to suppress contact and delayed-type hypersensitivity response through the inhibition of effector T cell proliferation. According to our preliminary data, reduced proliferation of effector T lymphocytes results from induction of their apoptosis and from impaired secretion of IL-2.

Activation of L-type voltage gated calcium channel in macrophages during *Mycobacterium tuberculosis* infection leads to suppression of protective responses by the host

Sharma, D., Mehto, S., Tiwari, B., Antony, C., Natarajan, K.
University of Delhi, Dr. B.R Ambedkar Center for Biomedical Research, Delhi, India

With the emergence of drug resistant strains of *Mycobacterium tuberculosis* (*M. tb*) there is a need for understanding the intricacies of host pathogen interactions. In the recent times, Voltage Gated Calcium Channels have gained importance in the regulation of calcium homeostasis during *M.tb* infection. Our group, working on these lines have shown a suppressor role for VGCC during *M. tb* infections and recently reported the mechanisms of its regulation by *M. tb*. In this report, we characterized the role of VGCC in mediating defense responses by macrophages during mycobacterial infection. We report that activation of VGCC synergistically down modulates the generation of oxidative burst by macrophages. The route of calcium influx, protein kinase C (PKC) and mitogen activated protein kinase (MAPK) pathways regulates this attenuation. Activation of VGCC increases cell survival and down modulates autophagy. Concomitantly, the secretion of pro-inflammatory

cytokines (IFN- γ and IL-12) and the levels of their receptors on cell surface are inhibited. Finally, the ability of phagosomes to fuse with lysosomes in *M. bovis* BCG and *M. tb* H37Rv infected macrophages is also compromised by VGCC. The results point towards a well-orchestrated strategy adopted by mycobacteria to suppress protective responses mounted by the host. This begins with an increase in the surface levels of VGCC by mycobacteria and their antigens in well-controlled and regulated mechanisms. Activation of the up-regulated VGCC following tweaking of calcium levels by molecular sensors in turn mediates suppressor responses and prepares the macrophage for long-term persistent infection.

Epigenetic regulation of the overexpressed STAT-1/Myd88 in macrophages from type 1 diabetic mice

Ribeiro Filgueiras, L.¹, L Brandt, S.², Raquel Oliveira Ramalho, T.¹, Jancar, S.¹, Henrique Serezani, C.²

¹University of São Paulo, Department of Immunology, Institute of Biomedical Science, São Paulo, Brazil, ²Indiana University School of Medicine, Department of Microbiology and Immunology, Indianapolis, United States

There is evidence that the sterile inflammation present in diabetic patients is involved in the development of several diabetes comorbidities. We have previously shown that in type 1 diabetic (T1D) mice, enhanced expression of the STAT-1/MyD88 axis in macrophages promotes the sterile inflammation. Because some long-term diabetes complications still develop in insulin treated diabetic patients, we hypothesized that epigenetic mechanisms are triggered during diabetes that promote macrophages MyD88 and STAT-1 expression. We found that the increased Myd88 and Stat1 gene expression in resident peritoneal macrophages from T1D mice persisted up to 6 days after incubation in low glucose medium. When macrophages were differentiated from bone marrow of T1D mice in both high and low glucose, the expression of Myd88 and Stat1 was enhanced compared to cells differentiated from bone marrow of non-diabetic animals in low glucose medium. The total histone acetyltransferase activity was found increased in resident peritoneal macrophages from T1D mice while the histone deacetylases activity was decreased. Macrophages from non-diabetic mice treated *in vivo* with histone deacetylase inhibitor presented increased Myd88 and Stat1 expression. ChIP analysis demonstrated that macrophages from T1D mice presented increased acetylation of MyD88 and STAT1 promoter region in histone H3 lysine 9 residue. Moreover, treating macrophages from T1D mice with histone acetylase inhibitor restored Myd88 and Stat1 expression to the same levels found in macrophages from non-diabetic mice. Together these results indicate an essential role of histone acetylation in the macrophages increased Myd88 and Stat1 gene expression in T1D mice.

The role of mTORC1 on regulating tissue resident macrophage homeostasisDeng, W.^{1,2}, Yang, J.², Lin, X.¹, Shin, J.², Gao, J.¹, Zhong, X.-P.²¹Wenzhou Medical University, School of Laboratory Medicine, Wenzhou, China, ²Duke University Medical Center, Pediatrics, Division of Allergy and Immunology, Durham, United States

Alveolar macrophages (AM Φ) have the capacity of local self-renewal through adult life; however, mechanisms that regulate AM Φ self-renewal remain poorly understood. We found that myeloid specific deletion of Raptor, an essential component of the mammalian/mechanistic target of rapamycin complex 1 (mTORC1), resulted in a marked decrease of this population of cells accompanying altered phenotypic features and impaired phagocytosis activity. We demonstrated further that Raptor/mTORC1 deficiency did not affect AM Φ development, but compromised its proliferative activity at cell cycle entry in the steady state as well as in the context of repopulation in irradiation chimeras. Mechanically, mTORC1 confers AM Φ optimal responsiveness to GM-CSF induced proliferation. Thus, our results demonstrate an essential role of mTORC1 for AM Φ homeostasis by regulating proliferative renewal.

Immunity to Parasites 1

***Mycobacterium indicus pranii* (Mw) in combination with heat induced promastigotes persuade host protection against *Leishmania donovani* infection: activation of IL-6+CD11c+ cDC and induction of CXCL10**

Dey, S., Mukherjee, D., Sultana, S., Mallick, S., Mandal, S., Dutta, A., Ghosh, J., Hussain, A., Pal, C.

West Bengal State University, Zoology, Kolkata, India

The protozoan parasite *Leishmania* causes leishmaniasis which threatens 350 million people worldwide. Chemotherapy is the only treatment currently available, however, clinical efficacies are found not so precise by severe side effects and emergences of resistant parasites.

The aim of this work is to design a successful adjuvant in combination with *Mycobacterium indicus pranii* (Mw) and heat induced *L. donovani* promastigotes (HIP) against experimental visceral leishmaniasis. Subcutaneous administration of Mw+HIP effectively reduced the hepatic and splenic parasite burden of *L. donovani*-infected BALB/c mice. Mw+HIP induced CD4+IFN γ + splenic T cells correspondingly reducing the CD4+IL-10+ T cells along with the upregulation of the Th1 killing cytokines (IL-12, TNF- α), chemokines (CXCL10, CCL4) and TLR2. The production of CXCL10 and CCL4, *in vitro*, depends on the cooperation and involvement of TLR2 and we speculated that the Mw + HIP combination therapy requires the cooperation of an integrated TLR~Cytokine~Chemokine loop. Dendritic cells (DCs) play a crucial role in determining the balance of CMI and humoral immunity by steering the T cell population towards a Th1 or Th2 response. We used this approach to identify IL-6 and IL-12p40 as critical cytokines that mediate anti-*Ld* host protection. Mw+HIP induced the expansions of CD11c+CD11b+ and CD11c+CD8a+

conventional splenic DCs, *in vivo*, along with the upregulated expressions of IL-6 & IL-12p40 in treated animals. Interestingly, Mw+HIP were also found effective against Miltefosine resistant-*L. donovani* (HePC-R) *in vitro* and *in vivo* as evidenced by the concomitant surge in the level of iNOS and limited expression of amastigote specific Ld-kDNA in macrophages.

T cell memory allows for the rapid generation of effective immune responses to previously encountered pathogens. Although most memory T cells recirculate through the body, a recently discovered subset, the tissue resident memory T cells (T_{RM}), remains in the affected tissue after infection is cleared. By staying in the area most likely targeted by the pathogen in subsequent reinfections, T_{RM} have the potential to elicit faster, more focused, responses than recirculating memory T cell subsets. We have found that following vaccination with irradiated *Plasmodium berghei* ANKA sporozoites, a population of tissue-resident memory T cells forms in the liver. These memory cells patrol liver sinusoids and could be found in significant numbers more than 100 days after infection. A vaccination strategy involving dendritic cell priming and antigen recognition on hepatocytes was found to boost numbers of T_{RM} in the liver, resulting in high levels of sterile protection against live sporozoite challenge. Protection in vaccinated mice was lost when T_{RM} cells were depleted. Vaccination aimed at the generation of T_{RM} in the liver may be a more effective way to control liver-stage malaria than traditional strategies focused on generating circulating memory T cells.

Identification of malaria vaccine targets using the online tool PlasmoSIP (*Plasmodium* Structure, Immunology and Polymorphisms)

Richards, J.S.^{1,2,3}, *Guy, A.J.*^{1,4}, *Irani, V.*^{1,2}, *Ramsland, P.A.*^{1,4,5}

¹Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ²University of Melbourne, Department of Medicine, Parkville, Australia, ³Royal Melbourne Hospital, Victorian Infectious Diseases Service, Parkville, Australia, ⁴Monash University, Department of Immunology, Melbourne, Australia, ⁵RMIT University, School of Science, Melbourne, Australia

Identification of appropriate vaccine targets for *Plasmodium falciparum* malaria is a major priority in the development of an effective malaria vaccine. We have recently developed a novel online tool called PlasmoSIP (*Plasmodium* Structure, Immunology and Polymorphisms), which integrates a number of experimental data and computational predictions into an interactive online tool to assess the suitability of potential vaccine candidates from the malaria proteome. We present here an analysis of a number of existing and potential vaccine candidates using this tool, and illustrate the applicability to novel vaccine targets. We have previously examined a number of vaccine candidates in a prospective cohort study in Papua New Guinea, and identified a number of proteins with a strong association with protective immune responses. These were examined using PlasmoSIP, and key features such as protein disorder, MHC binding and location and clustering of polymorphisms were collated. Furthermore, we examined known and predicted structural models in conjunction with genomic sequence data to identify particular protein regions which appear to be under immune selection pressure. This case study illustrates the applicability of this new tool to the field of vaccine development and design.

Surfactant protein A (SP-A) is a critical lung defence factor against microbial pathogens but its role during pulmonary helminth infection is unknown. We found that SP-A protein levels increased following migration of *Nippostrongylus brasiliensis* through the lung and SP-A-deficient mice exhibited increased parasite burden and decreased resolution of tissue damage. The protective effect of SP-A during helminth infection

was explained by the ability of SP-A to enhance the effects of IL-4 receptor signalling in the lung. This was evidenced by reduced proliferation and alternative activation of alveolar macrophages in SP-A deficient mice following *N. brasiliensis* infection or IL-4 treatment. SP-A's effects on IL-4 signalling were also observed in vitro in alveolar macrophages isolated from mice, rats and humans, and occurred via Myo18A receptor. Critically, the in vitro effect of SP-A was restricted to alveolar and not peritoneal macrophages. Our studies indicated that SP-A is a tissue-specific factor that controls functional T_H2-type responses in the lung and that Myo18A receptor signalling functions to enhance IL-4 mediated proliferation and alternative activation.

289

The contribution of IL-17RB in protective immunity to *Trichinella spiralis* infection

*Angkasekwinai, P.*¹, *Sodthawon, W.*¹, *Pattanapanyasat, K.*²

¹Thammasat University, Department of Medical Technology, Faculty of Allied Health Sciences, Pathumthani, Thailand, ²Mahidol University, Center of Excellence for Flow Cytometry, Office for Research and Development, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand

IL-25, an IL-17 family cytokine, derived from epithelial cells was shown to regulate Th2-type immune responses. We previously reported that IL-25 was critical in promoting immunity to *T. spiralis* infection; however the cellular target and function of IL-25 receptor (IL-17RB) during infection have not yet been addressed. Here, we investigated the role of IL-17RB during *T. spiralis* infection. The expression of IL-17RB was shown to be highly up-regulated in type-2 innate lymphoid (ILC2) and Th2 cells after infection. Mice deficiency of IL-17RB displayed delayed *T. spiralis* worm expulsion with markedly reduced ILC2 cell numbers and Th2 cytokine production. Thus, our data indicate that IL-17RB is required for promoting *T. spiralis* worm expulsion through the expansion and function of ILC2 and Th2 cells. This study should help to extend our knowledge of cytokine-cytokine receptor interaction in regulating parasite infection and may provide information for the design of future therapies for intestinal parasitic infection.

2807

Route of infection affects pathogenicity and visceral growth of *Leishmania major* in BALB/c mice

*Niknam, H.M.*¹, *Sarreshteh, E.*¹, *Rostamian, M.*¹, *Abolghazi, M.*², *Tat Asadi, M.*¹, *Abrishami, F.*¹

¹Pasteur Institute of Iran, Immunology Department, Tehran, Iran, Islamic Republic of, ²Qom Branch of Islamic Azad University, Department of Microbiology, Qom, Iran, Islamic Republic of

Leishmaniasis is a group of diseases caused by *Leishmania* parasite. Experimental models can be used for development of new methods of prevention and treatment for these diseases. Route of infection is one of the variables that have been reported to influence the immune responses as well as the disease outcome in experimental models of leishmaniasis. Aim of this research is to study the effect of infection route on the

virulence of *Leishmania (L.)* parasite. Low (10^3 parasites / mouse) or high (10^6 parasites / mouse) doses of *L. major* was injected subcutaneously into foot pad or intradermally into ear dermis of BALB/c mice. Results showed that subcutaneous infection route has substantial differences with intradermal infection route which results in higher pathogenicity of *L. major* in BALB/c mice as assessed by lesion diameter, parasite load in the draining lymph node, and dissemination of the parasite to spleen. The different pathogenicity of *L. major* in subcutaneous in comparison to intradermal may be due to presence of different immunoregulatory mechanisms such as IL-10 and CD4+CD25+ T_{REG} cells in these two infection routes.

Oral formulations of *Brugia malayi* recombinant proteins elicited profound immune responses in mice against experimental lymphatic filariasis

Gangwar, M.¹, Banala, V.T.², Mishra, P.R.², Bajpai, P.³, Misra-Bhattacharya, S.¹

¹CSIR-Central Drug Research Institute, Division of Parasitology, Lucknow, India, ²CSIR-Central Drug Research Institute, Division of Pharmaceutics, Lucknow, India, ³Integral University, Department of Biotechnology, Lucknow, India

Human lymphatic filariasis (LF), world's most disabling and disfiguring disease is caused by mosquito-borne nematodes, *Wuchereria bancrofti*, *Brugia malayi* or *Brugia timori*. LF threatens 1.2 billion people in 81 countries with an estimated 120 million cases. The efficacy of protein vaccines may vary depending on the route or type of adjuvant. The oral route has numerous advantages in terms of improved safety and user compliance. Stabilization of proteins in delivery devices and design of appropriate protein carriers are major concern. We attempted to resolve these issues through biodegradable nanoparticles and liposome encapsulation that can continuously release the protein to enhance the oral absorption. In this study, male BALB/c mice were immunized with nano- and liposomal-formulations of *B. malayi* immunogenic recombinant proteins, trehalose-6-phosphate phosphatase (Bm-TPP) and heavy chain myosin (BmAF-Myo). Bm-TPP & BmAF-Myo loaded nanoparticles (SNEDDS) and liposomes in two doses (25 µg protein /dose) generated mixed Th1/Th2 immune responses as observed by ELISA, RT-PCR and flow cytometry. Nano-encapsulated and liposomal Bm-TPP led to the significantly increased accumulation of CD4+, CD8+ T-cells and CD19 B-cells in the spleen of immunized mice and also enhanced the production of both Th1 (IFN-γ, IL-12 and TNF-α) and Th2 (IL-13, IL-10 and IL-4) cytokines and IgG isotypes. On contrary, encapsulated preparation of BmAF-Myo did not show significant increase. The efficacy of nano-encapsulated Bm-TPP (65.5% protection) was superior to liposomal Bm-TPP (55.17%) with respect to control group. In conclusion, nano-formulation of Bm-TPP (25 µg, oral dose) in two doses showed improved protection against lymphatic filariasis.

CD8⁺T cells that co-express RORγt and T-bet are functionally impaired and expand in patients with distal bile duct cancer

Chelappa, S.^{1,2}, Hugenschmidt, H.³, Hagness, M.⁴, Line, P.D.⁴, Labori, K.-J.⁵, Wiedswang, G.⁶, Tasken, K.^{1,2}, Aandahl, E.M.^{1,2,4}

¹University of Oslo and Oslo University Hospital, Centre for Molecular Medicine Norway, Nordic EMBL Partnership, Oslo, Norway, ²University of Oslo, Biotechnology Centre, KG Jebsen Centre for Inflammation Research and KG Jebsen Centre for Cancer Immunotherapy, Oslo, Norway, ³Oslo University Hospital, Section for Transplantation Surgery and Department of Hepato-Pancreato-Biliary Surgery, Oslo, Norway, ⁴Oslo University Hospital-Rikshospitalet, Section for Transplantation Surgery, Oslo, Norway, ⁵Oslo University Hospital, Department of Hepato-Pancreato-Biliary Surgery, Oslo, Norway, ⁶Oslo University Hospital, Department of Gastrointestinal Surgery, Oslo, Norway

CD8⁺ T cells that express RORγt (Tc17 cells) have recently been shown to promote pro-carcinogenic inflammation and contribute to a tolerogenic microenvironment in tumors. We investigated their phenotype and functional properties in relation to the pathogenesis of human distal bile duct cancer (DBDC). DBDC patients have an elevated level of type 17 immune responses and the frequency of CD8⁺RORγt⁺ T cells (Tc17 cells) was increased in peripheral blood. The CD8⁺RORγt⁺ T cells represented a highly activated subset and produced IL-17A in equal amount compared to CD4⁺RORγt⁺ T cells (Th17 cells). The majority of CD8⁺RORγt⁺ T cells also expressed T-bet, a lineage transcription factor for Th1 and Tc1 development, which suggested that CD8⁺RORγt⁺ T cells undergo plasticity towards a Tc17/1-like phenotype that led to co-production of the pro-inflammatory cytokines IL-17A and INFγ. In comparison to CD8⁺RORγt⁺ T cells, the CD8⁺RORγt⁺ T cells had significantly higher level of TCR signaling and were both phenotypically and functionally terminally differentiated and exhausted. The CD8⁺RORγt⁺ T cells also had impaired ability to re-express perforin after initial degranulation, which may affect their ability to sustain a cytotoxic immune response. These data reveal that CD8⁺RORγt⁺ T cells are pro-inflammatory and functionally impaired and may contribute to the pathogenesis of DBDC.

982

IL-15 activated NK cells overcame DC maturation defects induced by head and neck cancer microenvironment

Upreti, D., Zhang, M., Kung, S.K.P.

University of Manitoba, Winnipeg, Canada

Head and neck squamous cell carcinoma (HNSCC) patients have the lowest 5-year disease-free survival rate. There is need to develop novel therapeutics of HNSCC. Natural Killer (NK) cells play key roles in innate immunity against infections and transformed cells. Through interactions with dendritic cell (DC), NK cells can shape also subsequently induced adaptive T-cell immunity.

Here we used an immunocompetent mouse model (AT-84) to evaluate anti-tumor potential of IL-15 activated NK cells. A

direct injection of NK cells at tumor site significantly suppressed AT-84 tumor growth in vivo. It induced also protective memory responses against a secondary AT-84 challenge. AT-84 tumor cell was relatively resistant to IL-15 activated NK cells killing in vitro, suggesting that direct killing of AT-84 is unlikely the major underlying mechanism. We therefore hypothesized that IL-15 activated NK cells promoted anti-tumor activities via NK-DC crosstalk. Using bone marrow derived DC cultures; we observed that conditioned medium of AT-84 impaired DC maturation induced by TLR ligands in vitro. These DC were impaired in inducing T cell activations in vitro. Addition of IL-15 NK cells to the AT-84-exposed DC overcame the DC maturation and functional defects in vitro. These in vitro data was further corroborated by in vivo data obtained from the tumor infiltrating dendritic cells. Collectively, our data demonstrated that IL-15 activated NK cells were able to reverse the immunosuppressed DCs to an immunostimulatory state that correlated well with tumor regressions. It supported future development of IL-15 NK-based immunotherapy of HNSCC.

An immune monitoring model that allows association between anti tumor immune surveillance and clinical response elicited by neoadjuvant chemotherapy in patients with breast cancer

Bernal-Estevez, D.^{1,2}, García, O.³, Sánchez, R.^{4,5}, Parra-López, C.¹

¹Universidad Nacional de Colombia, Microbiology, Bogota, Colombia, ²Fundación Salud de los Andes, Grupo de Investigación en Inmunología y Oncología Clínica, Bogota, Colombia,

³Instituto Nacional de Cancerología, Unidad de Seno y Tejidos Blandos, Bogota, Colombia, ⁴Clínica del Seno, Bogota, Colombia,

⁵Universidad Nacional de Colombia, Internal Medicine, Bogota, Colombia

In cancer animal models chemotherapy with anthracyclines (A/C) induce immunogenic cell death in tumors eliciting T cell responses that limits tumor growth in treated animals. Although neoadjuvant A/C is widely used in breast cancer patients, the relevance of its immune stimulating effect on clinical response has been difficult to prove. To evaluate this, we compared in blood samples before and after chemotherapy the behavior of APC and T cell compartments responsible of tumor immune-surveillance. We monitored by flow cytometry both ex vivo and after in vitro stimulation of PBMCs multiple parameters related to

- (i) levels of Tregs; MDSCs; myeloid and plasmacytoid dendritic cells;
- (ii) the responsiveness of T cells to anti-CD3 and APCs to pro-inflammatory stimuli and
- (iii) the immune-phenotype of naïve and tumor specific memory T cells.

The results show in samples from patients after three cycles of A/C, a T cell responsiveness and maturation of DCs not observed in pre-chemotherapy samples. Interestingly, the T cell responsiveness highly correlate with IL-12 secretion by CD83+ DCs. Using principal component analysis (PCA), our immune-monitoring model shows a significant difference among pre- and post-chemotherapy patients compared with healthy

donors that correlates with tumor regression.

The PCA lead us to propose an immune stimulating role attributed to A/C characterized by immune responsiveness of T and APC compartments to different stimuli in post-chemotherapy samples with levels close to those exhibited by healthy donors not observed in the pre-chemotherapy samples.

Evaluating prediction strategies for identification of T cell responsive mutation-derived neo-epitopes in cancer

Andersen, S.R.¹, Bjerregaard, A.-M.², Fugmann, T.³, Donia, M.⁴, Bentzen, A.K.¹, Andersen, R.⁴, Szallasi, Z.², Neri, D.³, Svane, I.M.⁴, Eklund, A.C.², Hadrup, S.R.¹

¹Technical University of Denmark, Section for Immunology and Vaccinology, Frederiksberg C, Denmark, ²Technical University of Denmark, Center for Biological Sequence Analyses, Lyngby, Denmark, ³Philochem AG, Zürich, Switzerland, ⁴University Hospital Herlev, Center for Cancer Immune Therapy, Herlev, Denmark

Increasing evidences point to an important role of mutation-derived antigens in immune recognition of cancer. Current strategies for prediction of immunogenic neoepitopes results in large personalized peptide libraries, but only a minority (< 1%) elicit T cell responses at detectable levels. Neoepitopes are of potential valuable as predictors of response to therapy and targets for personalized immunotherapeutic approached. Consequently, there is an unmet need to understand the rules identifying immunogenic neoepitopes.

Both tumor mutation mapping via exome sequencing and mass-spectrometry-based elution for MHC class I presented peptides has been applied in different studies, combined with RNA sequencing to determine the expression level of relevant transcripts. Additionally, neoepitopes may be defined based on either autologous tumor cell lines or snapfrozen tumor material. We present here a study in which all the above mentioned strategies are assessed in three melanoma patients. Predicted large peptide libraries matching the HLA expression of the patients was identified and selected based on any of the strategies given above. This resulted in a total of ~3000 peptides for the three patients. We investigated the T cell recognition of these personalized peptide libraries using a new technology based on DNA-barcode labeled MHC multimers to detect multiple, potentially > 1000, different neoepitope specific T cell populations in a single sample. Through this unbiased comparison, we evaluate selection strategies for prediction of immunogenic cancer-associated neoepitopes, and identify rules for precise prediction. Precise prediction is essential for future application of neoepitopes both as predictors of responses to therapy and immunotherapeutic targets.

2537**Features of cancer associated fibroblasts that resemble circulating fibrocytes which constitute a unique subset of MDSCs***Gunaydin, G., Guc, D.**Hacettepe University Cancer Institute, Department of Basic Oncology, Ankara, Turkey*

The role of tumor stroma in the functional insufficiency of tumor-infiltrating T-cells has not yet been well determined. Circulating-fibrocytes represent a novel MDSC subset and they take part in the tumor immune escape. Fibroblasts turn into cancer-associated-fibroblasts(CAFs) in the tumor microenvironment. Our aim is to evaluate if CAFs demonstrate similar molecular/gene expression patterns and functional characteristics to the circulating-fibrocytes. N-Nitroso-N-Methylurea (NMU) induced breast cancer model was utilized. DNA damages due to NMU injections were evaluated by Comet-Assays. Fibroblasts were isolated using collagenase/hyaluronidase. Isolated CAFs and NFs were immunostained to investigate differential expressions of surface markers such as α -Smooth-Muscle-Actin (α SMA) and vimentin, in order to distinguish CAFs from NFs. CAFs/NFs were evaluated for their surface marker expressions by flow cytometry and for gene expression profiles by gene-set-enrichment-analysis. Cocultures of CAFs/NFs with PBMCs were performed and CFSE proliferation assays were used for functional analyses. Levels of DNA damage of tumor-bearing animals were similar to control levels about 2 months after injections. CAFs were spindle shaped cells unlike their circulating counterparts and had significantly higher levels of α SMA than NFs. CAFs did not express CD80, granulocytic or neutrophilic markers. Their MHC-II expression was lower than NFs. CAFs expressed the myeloid marker CD11b/c; however, its expression was lower than that on their circulating counterparts. They appeared to have developed in a milieu containing T_{HELPER}²-like cytokines. CFSE proliferation assays showed the immunosuppressive effects of CAFs similar to their blood-borne counterparts. In summary, CAFs resemble the circulating-fibrocytes that were reported to represent a novel MDSC subset.

3329**Regulation of IL-15 in the tumor microenvironment by the STING pathway***Rivas, S.¹, Anthony, S.¹, Pham, G.², Schluns, K.S.¹**¹University of Texas MD Anderson Cancer Center, Immunology, Houston, United States, ²University of Cincinnati College of Medicine, Cincinnati, United States*

Previous studies have shown that IL-15 expression within tumors correlates with increased tumor infiltrating T cells, decreased metastasis, and increased patient survival. Unfortunately, the regulation of IL-15 within the tumor microenvironment is not clear. Since we have recently shown IFN- α induces sIL-15 complexes and activation of the Stimulator of Interferon Genes (STING) pathway is important for regulating type I Interferons (IFN) in tumors, we set out to determine if sIL-15 complexes are produced in tumor microenvironment and are regulated by STING signaling. To examine this, B16-F10 tumors of various sizes

were isolated from mice and sIL-15 complexes were measured in homogenates from tumors and spleen. Interestingly, levels of sIL-15 complexes were high in homogenates from small tumors and low in larger tumors but were absent in IL-15Ra^{-/-} mice indicating sIL-15 complexes were derived from the tumor stroma. During the steady state, STING agonists were potent inducers of sIL-15 complexes in vivo and could directly stimulate production by BM-derived DCs. In addition, optimal induction of sIL-15 complexes in response to Ab-mediated T cell depletion or total body irradiation was dependent on the STING pathway suggesting products of cell death are a mediator of sIL-15 complexes in response to lymphodepletion. Furthermore, intratumoral delivery of STING agonists enhanced production of sIL-15 complexes in B16 tumors, which correlated increased T cells in the draining LN and decreased tumor growth. Altogether, these findings suggest soluble IL-15 complexes are a component of the inflammatory milieu of the tumor microenvironment that are regulated by the STING pathway.

3800**Interactions between CD4 T cells, regulatory T cells and B cells shape the immune response to tumours***Shklovskaya, E.¹, Terry, A.¹, Guy, T.¹, Bolton, H.¹, Brink, R.², Fazekas de St Groth, B.¹**¹Centenary Institute, University of Sydney, Sydney, Australia,**²Garvan Institute of Medical Research, Sydney, Australia*

Recent clinical studies have demonstrated that *de novo* immune responses to tumour-specific neo-antigens occur in melanoma patients treated with immune checkpoint inhibitors. We have developed a novel preclinical model in which the effects of current and future inhibitors and their combinations on anti-tumour responses can be tested and their effects on individual tumour-specific lymphocytes defined.

Our animal model is designed to measure the independent and collective contributions of CD4 T cells, regulatory T cells (Tregs) and B cells to anti-tumour immunity. The model uses B16 melanoma cells expressing a model antigen Hen Egg Lysozyme-Moth Cytochrome C (HELMCC), in combination with 5C.C7 CD4 T cells and Tregs (MCC-specific TCR-transgenic) and/or HEL-specific B cells capable of isotype switching. Our use of I-E-deficient tumours and I-E-restricted T cells mimics a common situation in which tumour antigen-specific CD4 T cells are unable to directly recognise an MHC class II-negative tumour. Adoptively transferred naive 5C.C7 T cells efficiently controlled growth of subcutaneous tumours in I-E⁺ RAG^{-/-} mice, or wild-type mice acutely depleted of Tregs, in an IFN γ -dependent manner. Co-transfer of 5C.C7 Tregs with naive 5C.C7 T cells inhibited Th1 effector differentiation and prevented efficient tumour rejection in RAG^{-/-} mice. Co-transfer of HEL-specific B cells with naive 5C.C7 T cells had a negative effect on CD4 T cell numbers and long-term survival of RAG^{-/-} tumour-bearing mice, although tumour-specific isotype-switched antibodies were protective in a lung metastasis model.

We are currently investigating the cellular mechanisms responsible for activation of anti-tumour immunity after treatment with immune checkpoint inhibitors.

A therapeutic neutralizing anti-G-CSFR antibody blocks G-CSF-induced neutrophilia but does not induce neutropenia in non-human primates

Scalzo-Inguanti, K.¹, Monaghan, K.¹, Edwards, K.¹, Nash, A.¹, Busfeild, S.², Andrews, A.¹

¹CSL Ltd, Melbourne, Australia, ²Nexvet, Melbourne, Australia

Neutrophils are the most abundant white blood cells and play an essential role in the clearance of pathogens. Tight regulation of neutrophil number and their recruitment to sites of inflammation is critical in maintaining a balanced immune response. In various inflammatory conditions, such as rheumatoid arthritis, vasculitis, cystic fibrosis and inflammatory bowel disease, there is an increase in serum G-CSF that correlates with neutrophilia and an enhanced neutrophil infiltration into the inflamed tissues, which contributes to disease pathogenesis. In this study, we describe a fully human therapeutic anti-G-CSFR antibody (CSL324) that is safe and well tolerated when administered to cynomolgus macaques. This antibody is effective in controlling G-CSF-mediated neutrophilia in a therapeutic and prophylactic manner. Surprisingly, CSL324 does not alter steady-state neutrophil numbers when administered in single or multiple doses. In addition, CSL324 completely neutralizes G-CSF-mediated pSTAT3 phosphorylation but does not impact on basic neutrophil functions such as phagocytosis and oxidative burst. This work suggests that targeting G-CSFR may provide a safe and effective way to control aberrant neutrophil-mediated inflammation in various inflammatory conditions.

3153

Loss of autophagy enhances macrophage migration inhibitory factor (MIF) release by macrophages

Lee, J.P.W.¹, Foote, A.¹, Huapeng, F.¹, Peral de Castro, C.², Lang, T.¹, Jones, S.A.¹, Mills, K.H.G.², Leech, M.¹, Morand, E.F.¹, Harris, J.¹

¹Monash University, Centre for Inflammatory Diseases, Clayton, Australia, ²Trinity Biomedical Sciences Institute, Trinity College, Dublin, Ireland

Macrophage migration inhibitory factor (MIF) is a pro-inflammatory cytokine expressed in multiple cells types, including macrophages. MIF plays a pathogenic role in a number of inflammatory diseases, including rheumatoid arthritis and systemic lupus erythematosus. MIF has also been linked to tumour progression in some cancers. Previous work has demonstrated that loss of autophagy in macrophages enhances secretion of the IL1 family cytokines IL-1 α , IL-1 β and IL-18. Here, we demonstrate that disruption of autophagy, either by pharmacological inhibition or siRNA silencing of *Atg5*, enhances MIF secretion by monocytes and macrophages. We further demonstrate that this is dependent on reactive oxygen species (ROS) released by mitochondria. Induction of autophagy with MTOR inhibitors had no effect on MIF secretion, suggesting that, unlike IL-1, MIF secretion is not directly regulated by autophagy. However, amino acid starvation did increase secretion. This was unaffected by *Atg5* siRNA but was

again dependent on mitochondrial ROS. Our data demonstrate that autophagic regulation of mitochondrial ROS plays a pivotal role in the regulation of inflammatory cytokine secretion in macrophages, with potential implications for the pathogenesis of inflammatory diseases and cancers.

Cellular and molecular mechanism of resveratrol-mediated amelioration of experimental colitis and associated colon cancer

Singh, U.P.¹, Marpe, B.¹, Singh, N.¹, Murphy, E.A.¹, Price, R.¹, Mishra, M.K.², Nagarkatti, M.¹, Nagarkatti, P.¹

¹University of South Carolina School of Medicine, Pathology, Microbiology and Immunology, Columbia, United States,

²Alabama State University, Biological Sciences, Montgomery, United States

Ulcerative colitis (UC) and Crohn's disease (CD) are two forms of inflammatory bowel disease (IBD) result from chronic intestinal inflammation caused by activated effector immune cells. Resveratrol (3,4,5-Trihydroxy-trans-stilbene) is a naturally occurring polyphenol that has beneficial anti-inflammatory properties. We have investigated resveratrol-mediated cellular and molecular mechanisms in both acute and chronic experimental colitis and associated colon cancer. Resveratrol improve inflammation scores and various pathological markers of experimental colitis. It also reversed colitis-associated decreases in body weight, increased serum amyloid A (SAA) levels, while attenuating systemic and mucosal pro-inflammatory cytokine levels, as well as markers of inflammation, including cyclooxygenase-2 (Cox-2) and inflammatory stress (p53 and p53-Phospho-Serine 15). Resveratrol decreased the number of activated T cells in the colon lamina propria (LPL), restoring them to normal levels in spleens and mesenteric lymph nodes (MLNs). Frequency of macrophages and CXCR3⁺ T cells were decreased in spleens, MLNs, and colon LPL. However, as compared with controls, the percentages of MDSCs in LP lymphocytes and spleens were increased after resveratrol treatment. Resveratrol treatment also induced the silent-mating type of information regulation-1 (SIRT1) gene expression and decreased p-IkBa expression and nuclear transcription factor kappaB (NF-kB) activation. Tumor incidence also reduced to 80% in mice treated with resveratrol. This study demonstrates the chemopreventive properties of resveratrol, including inverse regulation of NF-kB, upregulation of SIRT1 and decreased numbers of CXCR3⁺ effector T cells in the colon. Our results suggest that resveratrol is a nontoxic complementary and alternative strategy to abate colitis and, potentially, colon cancer associated with colitis.

Two hit induced acute lung injury impairs cognitive function in mice

Naura, A., Sahu, B., Sandhir, R.

Panjab University, Biochemistry, Chandigarh, India

Acute lung injury (ALI) is a life threatening disorder characterized by accumulation of large numbers of neutrophils in the lungs. ALI survivors frequently present some cognitive deterioration at

discharge; such as impaired memory, attention, concentration and/or mental processing speed. The aim of present work was to investigate potential impact of ALI on cognitive impairment in mice for its potential application as a model system to study cross talk between lung and brain at molecular level. ALI in male Balb/c mice was induced by intra-tracheal administration of either 0.1 N HCl or LPS as single hits or both agents were administered to mimic 'two hit' model of ALI. Administration of LPS or HCl alone increased the neutrophils in bronchoalveolar lavage fluid (BALF) significantly but did not cause any impairment in the memory of mice as assessed by Morris water maze test 1 week after induction of injury. Interestingly 'two hit' mediated injury resulted in more pronounced increase in neutrophils in BALF and such injury leads to persistent decline in memory. It appears that exaggerated lung injury through two hits disrupts the threshold barrier to cause cognitive dysfunction. Indeed further analysis revealed that two hit mediated injury leads to disruption of blood brain barrier. Overall, our preliminary findings show that two hit mediated ALI leads to cognitive impairment in mice and hence the model can be used to examine lung-brain cross talk at molecular level.

Hairy and enhancer of split 1 attenuates inflammation via regulating transcriptional elongation

Shang, Y.¹, Coppo, M.², Ning, F.¹, Yu, L.¹, He, T.³, Rogatsky, I.^{2,4}, Hu, X.¹

¹Tsinghua University, Institute for Immunology, Beijing, China,

²Hospital for Special Surgery, New York, United States, ³Peking University, Academy for Advanced Interdisciplinary Studies and Center for Quantitative Biology, Beijing, China, ⁴Weill Cornell Medical College, New York, United States

Most of the known regulatory mechanisms that curb inflammatory gene expression target pre-transcription initiation steps and evidence for regulation of inflammatory gene expression post initiation remains scarce. Here we show that transcription repressor hairy and enhancer of split 1 (Hes1) suppresses production of Cxcl1, a chemokine crucial for recruiting neutrophils. Hes1 negatively regulates neutrophil recruitment *in vivo* and attenuates severity of inflammatory arthritis. Mechanistically, inhibition of Cxcl1 expression by Hes1 does not involve modification of transcription initiation. Instead, Hes1 inhibits signal-induced recruitment of positive-transcription elongation complex P-TEFb, thereby preventing phosphorylation of RNA polymerase II on serine-2 and productive elongation. Thus, our results identify Hes1 as a homeostatic suppressor of inflammatory responses which exerts its suppressive function via regulating transcriptional elongation.

Inhalation of granulocyte/macrophage-colony stimulating factor (GM-CSF) and GM-CSF antibody

Tazawa, R., Nakagaki, K., Ito, Y., Hashimoto, A., Tanaka, T., Akasaka, K., Nakata, K.

Niigata University Medical and Dental Hospital, Bioscience Medical Research Center, Niigata, Japan

Backgrounds: Autoimmune pulmonary alveolar proteinosis (aPAP) has been thought to be caused by long-lasting autoantibodies against endogenous granulocyte/macrophage-colony stimulating factor (GM-CSF). In contrast, subcutaneous administration of recombinant human GM-CSF (rhGM-CSF) has been reported to cause transient induction of GM-CSF antibody (GM-Ab) in patients with metastatic colon cancer. We hypothesized that repeated inhalation of exogenous GM-CSF induces neutralizing antibodies against GM-CSF.

Methods: NHPs (*Macaca fascicularis*) were administered intra-tracheally with 0.015 mg/body of non-glycosylated rhGM-CSF produced in *E. coli* (molgramostim group, n=2), or glycosylated rhGM-CSF produced in Chinese hamster ovary cells (CHO-GMCSF group, n=2) using catheter sprayer twice a week for 12 weeks. After the first 12-week GM-CSF treatment followed by 12-week cessation, the animals underwent the second 12-week treatment. GM-Ab levels were measured in serum (ELISA), and the neutralizing capacity was evaluated using TF-1, a GM-CSF-dependent cell line. Bronchoalveolar lavage fluids (BALF) were obtained and evaluated microscopically.

Results: In week 4, GM-Ab was first observed in the animals. GM-Ab increased to a higher level (< 60mcg/mL) in molgramostim group, while GM-Ab remained at a moderate level (20-30 mcg/mL) in CHO-GMCSF group. GM-Ab was decreased to the undetectable level after the 12-week cessation, and observed again in week 2 of the second treatment in both groups. At the end of the second GM-CSF treatment, neutralizing capacity was observed in one animal of both groups, and foamy macrophages and GM-Ab were observed in BALF.

Conclusions: Repeated inhalation of rhGM-CSF in NHPs induced GM-Ab which could react to both rhGM-CSF and primate GM-CSF.

IL-37 requires the receptors IL-18Ra and IL-1R8 (SIGIRR) to carry out its multi-faceted anti-inflammatory program on innate signal transduction

Nold, C.¹, Lo, C.², Rudloff, I.¹, Elgass, K.³, Li, S.⁴, Gantier, M.¹, Lotz-Hayla, A.⁵, Gersting, S.⁵, Cho, S.¹, Lao, J.¹, Ellisdon, A.⁶, Rotter, B.⁷, Azam, T.⁴, Mangan, N.¹, Rosello, F.⁸, Whisstock, J.⁸, Bufler, P.⁵, Garlanda, C.⁹, Mantovani, A.¹⁰, Dinarello, C.¹¹, Nold, M.¹

IL37 and IL-1 receptor 8 (IL-1R8, also called SIGIRR or TIR8) are orphan anti-inflammatory IL1-family ligand and receptor family members. Here, we demonstrate formation and function of the endogenous ligand-receptor complex IL37:IL-1R8:IL-18 receptor a (IL18Ra). Cell-surface interaction between IL37, IL-1R8 and IL18Ra on untransfected human PBMC was maximal 30 min after stimulation with LPS. The relative affinity of IL-37:IL-

18Ra was higher than that of IL-37:IL-1R8. Silencing of IL-1R8 or IL18Ra impaired the anti-inflammatory activity of IL37 in PBMC, macrophages and epithelial cells. Whereas IL37-transgenic mice (IL37tg) with intact IL-1R8 are protected from endotoxemia, IL-1R8-deficient IL37tg are not. Proteomic and transcriptomic investigations revealed that IL37 requires IL-1R8 to harness the anti-inflammatory properties of the signaling molecules Mer, PTEN, STAT3 and DOK1, to inhibit Fyn, Tak1, NF- κ B and MAPKs, as well as to exert a pseudo-starvational effect on the mTOR pathway. IL37 thus binds to IL-18Ra and exploits IL-1R8 to activate a multi-faceted intracellular anti-inflammatory program.

Micro-fluidics is the powerful tool for revealing a mechanism of autoreactive B cell-inducing inflammation in vasculitis

Yoshizaki, A., Nakamura, K., Ebata, S., Fukasawa, T., Saigusa, R., Takahashi, T., Taniguchi, T., Asano, Y., Sato, S.
University of Tokyo Graduate School of Medicine, Dermatology, Tokyo, Japan

Vasculitis is an inflammatory disease, characterized by necrosis of blood vessels. Cutaneous leukocytoclastic vasculitis (CLV) is one of the vasculitides of unknown etiology. Although oral corticosteroid and anticoagulation agents were commonly used, some resistant and recurrent cases require strong immunosuppressive therapy, which we named severe inflammatory CLV (SICLV).

Previous studies have shown that B lymphocytes play important roles in the pathogenesis of anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis. Especially, regulatory B cells are known to be diminished in these vasculitides, suggesting that it is involved in the B cell abnormalities in ANCA associated vasculitis. However, the population of pathogenic B cells is so small that its function is not fully elucidated.

In present study, we developed original assay system utilizing micro flow channels that simulates the environment of blood vessels, by which the interaction of B cells with endothelial cells could be analyzed. Additionally, we utilized micro-enzyme-linked immunosorbent assay system that integrated immunoassay into a microchip in order to detect extremely small amounts of analytes. We found that the endothelium-specific B lymphocyte binds to endothelium in SICLV. This resulted in the increased expression of intercellular adhesion molecule 1 and programmed death-ligand 1 on endothelium, which can induce T cell recruitment and activation.

These findings show that B lymphocyte is the key player in SICLV whose pathophysiology is not fully understood to date. In addition, our original micro-fluidics methods can reveal new etiology of the inflammatory disease, which may lead the novel therapeutic strategies.

Identifying autoimmune beta-cell epitopes in type 1 diabetes by HLA-peptidomics

Gonzalez Duque, S.^{1,2}, Verdier, Y.², Vinh, J.², Mallone, R.¹

¹INSERM U 1016, Intitut Cochin, CNRS UMR 8104-Université Paris Descartes, Paris, France, ²ESPCI ParisTech - CNRS-USR 3149, Paris, France

Type 1 diabetes (T1D) is an autoimmune disease in which autoreactive CD8+ T-cells destroy pancreatic insulin-secreting beta-cells. This destruction is triggered by the recognition of peptide epitopes presented at the beta-cell surface in the pocket of HLA Class I molecules. We aimed at identifying these epitopes by HLA peptidomics. This strategy consists in purifying the peptide-HLA complexes from immortalized human beta-cell lines and to analyze the eluted peptides by mass spectrometry. This workflow was validated based on: 1) the 9-11-aminoacid length of most (93%) peptides identified, which fits the HLA pocket constraints; 2) the peptide signature, which reflects the HLA haplotype expressed by the beta-cells; and 3) the identification of several preproinsulin peptides already described as major CD8+ T-cell epitopes.

We thus obtained a catalogue of 65 unique peptides derived from 49 beta-cell proteins. Twenty-three peptides were derived from known beta-cell protein antigens (preproinsulin, GAD, IA-2, ZnT8, IAPP and chromogranin-A), and novel candidate epitopes were identified within their sequences. The remaining 43 proteins represent novel candidate antigens. One recurrent feature shared by several known and putative antigens is their expression in insulin granules and their processing by proconvertases, which cleave protein precursors to obtain bioactive products. Intriguingly, several of the peptides identified map next to these proconvertase cleavage sites. The processing of protein precursors within the β -cell may thus represent a major source of autoimmune epitopes. The candidate epitopes identified may lead to the development of novel T-cell biomarkers.

Anti-inflammatory effects of vitamin D are reduced in T-cells from the inflamed joints of rheumatoid arthritis patients

Jeffery, L.¹, Henley, P.¹, Filer, A.¹, Hewison, M.¹, Sansom, D.², Raza, K.^{1,3}

¹University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom, ²University College London, Institute of Immunity and Transplantation, London, United Kingdom, ³Sandwell and West Birmingham Hospitals NHS Trust, Department of Rheumatology, Birmingham, United Kingdom

Vitamin-D has potent anti-inflammatory effects and low serum vitamin-D associates with inflammatory diseases such as rheumatoid arthritis (RA), thus vitamin-D supplementation is suggested for their treatment. However, whether immune responses to vitamin-D are efficient in patients is unclear. This study aimed to characterize the effect of active vitamin-D (1,25(OH)₂D₃) upon CD4+T-cells from the blood and synovial fluid(SF) of RA patients.

1,25(OH)₂D₃ significantly reduced IL-17 and IFN γ in antiCD3-stimulated CD4+Tcells from patient blood at levels similar to

healthy controls but SF CD4+T-cells showed reduced suppression of IL-17 and no inhibition of IFN γ . Since 98(\pm 1.8)% of SF CD4+T-cells were memory versus 49(\pm 14)% in blood, 1,25(OH) $_2$ D $_3$ responses in naïve and memory CD4+T-cells from blood were compared. Unlike SF CD4+T-cells, 1,25(OH) $_2$ D $_3$ suppressed IFN γ production by memory and naïve blood CD4+T-cells. However across 1,25(OH) $_2$ D $_3$ targets (IL-17, IFN γ , IL-21, CTLA-4, FoxP3), 1,25(OH) $_2$ D $_3$ had greatest effect upon naïve CD4+T-cells, despite equivalent vitamin-D receptor (VDR) expression in both populations. qPCR for regulators of 1,25(OH) $_2$ D $_3$ signaling (VDR, RXR, co-enhancers(DRIP205, NcoA1), co-repressors(NcoR1, NcoR2) and 1,25(OH) $_2$ D $_3$ -inactivating CYP24A1) in memory CD4+T-cells from RA blood and SF revealed raised 1,25(OH) $_2$ D $_3$ responsiveness in SF CD4+T-cells ex-vivo but no difference between SF and blood after stimulation, which increased responsiveness in both populations.

Collectively these data confirm a 1,25(OH) $_2$ D $_3$ -response system in CD4+T-cells from blood and SF of RA patients. However, whilst blood CD4+T-cells responded normally to 1,25(OH) $_2$ D $_3$, SF CD4+T-cells were less sensitive, partly through greater memory bias. Such insensitivity of SF CD4+T-cells to 1,25(OH) $_2$ D $_3$ has important implications for use of vitamin-D to treat RA.

Convergent antibody repertoire in acquired thrombotic thrombocytopenic purpura patients

Skowronska, M., Schaller, M., Kremer Hovinga Strelbel, J.A. University of Bern, Department of Clinical Research, University Clinic of Hematology and Central Hematology Laboratory, Bern, Switzerland

Introduction: Autoantibodies neutralizing and/or accelerating the clearance of ADAMTS13 are hallmark of acquired thrombotic thrombocytopenic purpura (aTTP) and associated with risk of relapse in survivors of a first acute disease episode. To elucidate the pathophysiology and evolution of the anti-ADAMTS13 antibodies in aTTP, their genetic diversity, clonality and mutation status were studied.

Methods: Splenic mononuclear cells from eight patients splenectomized for frequently relapsing aTTP were sorted into naïve, switched as well as unswitched memory B-cell and plasma cell populations. Antibody cDNA libraries were deep sequenced on MiSeq Illumina. V(D)J gene alignments and junction were identified using IMGT/high V-QUEST. V(D)J pairings were visualized using Circos. From four patients anti-ADAMTS13 specific B-cells were individually sorted and IgG heavy/light chain genes were amplified. Additionally repertoire overlap analysis and diversity estimation were performed using VDJ tools.

Results: Deep sequencing of the total splenic B-cell repertoire revealed ~4 million functional antibody sequences divided into ~230 thousand different clones. Among the eight patients, 179 convergent and expanded clones were observed. Antibodies were encoded by V-genes from IGHV3 and IGHV4 families, J-genes from IGHJ4 and D-genes from IGHD3. Anti-ADAMTS13 specific B-cells revealed 80 unique clones with 15% antibodies encoded by IGHV1-69, compared to only 1% IGHV1-69

antibodies in the total repertoire.

Conclusion: The observed expanded convergent antibody sequences among 8 unrelated aTTP patients, as well as the enrichment of IGHV1-69 encoded anti-ADAMTS13 antibodies are highly unlikely to be coincidental and point at antigen-driven selection of autoantibodies in aTTP. Pathological relevance of the selected antibodies is under investigation.

Identification and quantitation of autoantigen peptides targeted by CD8+ T cells on human islet beta cells

*Giam, K.^{1,2}, Dudek, N.L.¹, Croft, N.P.¹, Ayala, R.¹, Peakman, M.³, Purcell, A.W.¹
¹Monash Biomedicine Discovery Institute, Department of Biochemistry and Molecular Biology, Clayton, Australia, ²Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Parkville, Australia, ³King's College London, Peter Gorer Department of Immunology, London, United Kingdom*

Type 1 diabetes (T1D) results from a targeted destruction of the insulin-secreting beta cells due to an islet-specific autoimmune response. Insulinitis, characterised by the infiltration of T cells into the islets, is predominantly driven by CD8+ T cells. Human leukocyte antigen (HLA) genes, specifically the class II HLA and to a lesser extent class I HLA genes, are strongly implicated in T1D. Class I HLA molecules constitutively present endogenous antigenic peptide fragments to incoming CD8+ T cells. Indeed, studies have documented the presence of circulating autoreactive CD8+ T cells reactive towards key islet epitopes in T1D patients. However, the presence of these epitopes on human islet beta cells have not been definitively shown.

We have used a reverse immunology strategy in combination with highly sensitive mass spectrometry to confirm and quantify the presentation of key HLA-A2 restricted preproinsulin epitopes, alongside the discovery of novel and posttranslationally modified autoantigenic HLA-bound peptides on human islets derived from a number of other candidate autoantigens including chromogranin A. This study represents the first characterisation of the class I restricted peptide repertoire that is naturally processed and presented by human islet beta cells. More importantly, we have identified a significant number of non-canonical HLA-bound peptides, posttranslationally modified and hybrid peptide species. Our current analysis of this complex peptidome data set and correlation with the proteome of the islets will allow us to start to understand the nature of the autoreactive immune response towards beta cells and provide a better understanding of T1D pathogenesis.

CD4+ T cell-intrinsic TRAF5 negatively regulates Th17 cell-dependent experimental autoimmune encephalomyelitis

Nagashima, H.¹, Okuyama, Y.¹, Hayashi, T.¹, Asao, A.¹, Kawabe, T.¹, Yamaki, S.¹, Nakano, H.², Croft, M.³, Ishii, N.¹, So, T.¹

¹Tohoku University Graduate School of Medicine, Department of Microbiology and Immunology, Sendai, Japan, ²Toho University School of Medicine, Department of Biochemistry, Tokyo, Japan, ³La Jolla Institute for Allergy and Immunology, Division of Immune Regulation, La Jolla, United States

TNF receptor-associated factor 5 (TRAF5) is an adaptor protein that is highly expressed in lymphocytes. We have found that TRAF5 antagonizes IL-6 receptor signaling that is required for the differentiation of IL-17-producing inflammatory helper T (Th17) cells. However, it is not clear how TRAF5 controls Th17-driven autoimmunity such as experimental autoimmune encephalomyelitis (EAE). To test this, *Traf5*^{-/-} mice were immunized subcutaneously with a peptide of myelin oligodendrocyte glycoprotein (MOG) emulsified in complete Freund's adjuvant on day 0, and injected intraperitoneally with pertussis toxin on day 0 and day 2. Clinical signs of diseases were evident on day 11 and peaked between days 14 and 18. Compared with wild-type mice, *Traf5*^{-/-} mice developed EAE with a strongly enhanced clinical score and marked body weight loss in line with the favored Th17 differentiation. Consistent with this, significantly higher numbers of Th17 cells were accumulated in the central nervous system of *Traf5*^{-/-} mice. To investigate if the enhanced EAE was caused by TRAF5-deficiency in CD4⁺ T cells, we adoptively transferred wild-type or *Traf5*^{-/-} CD45.2⁺ CD4⁺ T cells into congenic CD45.1⁺ B6 mice that had been sublethally irradiated, then immunized the recipient mice with MOG peptide as described above. Recipient mice developed EAE in a CD4⁺ T cell-intrinsic manner, and recipients with *Traf5*^{-/-} CD4⁺ T cells had significantly higher EAE scores than those with wild-type CD4⁺ T cells. Thus, TRAF5 limits EAE pathogenesis through negative regulation of the IL-6-dependent Th17 program in T cells.

GM-CSF induces multi-organ autoimmunity upon loss of regulatory T cell mediated suppression

Lanzinger, M., Croxford, A.L., Greter, M., Becher, B.

University of Zurich, Institute of Experimental Immunology, Zurich, Switzerland

The prevention of autoimmunity is largely mediated by regulatory T (T_{reg}) cells. Deletion of Foxp3⁺ cells in adult mice leads to severe multiple organ autoimmunity, which is driven by activated auto-aggressive helper T (T_H) cells. The nature and polarization pattern of these deregulated T_H cells is a matter of debate. We found that *in vivo* depletion of T_{reg} cells in Foxp3^{DTR} mice caused excessive GM-CSF and IFN- γ release by T_H cells. In order to assess the impact of individual T cell-derived proinflammatory cytokines, we generated Foxp3^{DTR} mice lacking either GM-CSF, IL-17A or IFN- γ . After T_{reg} cell depletion, GM-CSF emerged as a potent pathogenic mediator causing tissue damage in the absence of T_{reg} cells. The systematic application of the Foxp3^{DTR} mouse model to mice lacking either GM-CSF responsive cell types or the receptor for GM-CSF in a cell specific manner revealed that GM-CSF producing autoreactive T_H cells drive tissue inflammation through the licensing of pathogenic neutrophils.

Robust innate immunity underlies protection from acute endotoxemia in a long-lived mouse model of successful aging

Griffin, P.¹, Conover, C.², Bale, L.², Snyder, A.¹, Michel, J.¹, Vallejo, A.^{1,3,4}

¹University of Pittsburgh School of Medicine, Department of Pediatrics, Pittsburgh, United States, ²Mayo Clinic, Department of Medicine, Rochester, United States, ³UPMC Children's Hospital of Pittsburgh, Division of Rheumatology, Pittsburgh, United States, ⁴University of Pittsburgh School of Medicine, Department of Immunology, Pittsburgh, United States

We have shown that unlike healthy young adults and elderly persons with measurable disabilities, community-dwelling elders with high physical/cognitive function have a distinctive repertoire of oligoclonal T cells expressing highly diverse innate receptors. We propose therefore that innate immunity is a determinant of successful aging and long-term survivorship. To model successful aging, we examined mice deficient in pregnancy-associated plasma protein A (PAPPA) that we reported to have 40% lifespan extension and overall significant reduction in mid-life/end-of-life pathology. PAPPA is the enzyme that degrades inhibitory proteins bound to insulin-like growth factor (IGF) and thereby control the availability of bioactive IGF. Adopting the classic experimental platform of acute endotoxemia, we found that intraperitoneal doses of LPS that were lethal to 18 mos old wildtype (WT) mice, were survived by old *PAPPA*^{-/-} mice. Whereas moribund old WT mice showed classic LPS-induced cytokine storm, humoral profiles of LPS-treated old *PAPPA*^{-/-} mice showed significant global attenuation of cytokine levels. LPS induced high levels of Bcl-xL in all innate cell types of old *PAPPA*^{-/-} mice. Such *PAPPA*^{-/-} innate cells had nil evidence of apoptosis, and had significantly lower levels of intracellular TNF α , IL-6, and phospho-NF κ B, molecules linked to destructive inflammation. Significantly, old *PAPPA*^{-/-} mice have a distinctive transcriptomic signature of highly upregulated innate genes including antimicrobial peptides and inhibitors of TLR4 signaling. Collectively, our data underscore the relevance of immunologic factors in refining clinical definition(s) of successful longevity. Upmodulation of innate function could be an avenue for alternative innovations on immune intervention specifically for the elderly.

813

Thymic epithelial progenitor cell activation following sex steroid blockade

Lepletier, A.¹, Hammett, M.², Wong, K.², Hedger, M.³, Boyd, R.², Loveland, K.², P Chidgey, A.²

¹Queensland Institute of Medical Research, Brisbane, Australia, ²Monash University, Melbourne, Australia, ³Hudson Institute of Medical Research and Monash University, Melbourne, Australia

The decrease of naive T cell export and intrinsic defects in T cell activation characterized during aging has been broadly correlated with thymus atrophy. We have previously demonstrated that sex steroid blockade reverts thymic epithelial cells (TEC) numerical and compositional defects that accompany thymic involution and re-establishes thymocyte numbers in aged mice. The deleterious effects of androgens on thymus have been proposed to be associated with direct action on TEC, however, the mechanisms that underlie this phenomena remains unclear. Here we demonstrate that Activin A signalling in TEC progenitor cells (TEPC) plays an important role in thymus recovery of 9 month aged mice following castration (Cx). During thymus aging, follistatin (FST), a highly potent antagonist of Activin A, is increased in the thymic microenvironment. Castration re-establishes Activin A:FST ratio toward young thymus levels and at the same time influences upregulation of Activin receptors *Acvr1b*, *Acvr2a* and *Acvr2b* in progenitor cells of aged mice. Consistent with this, the addition of Activin A to aged TEPCs in our 3D in vitro culture system, increased differentiation into mTEC, whilst Activin A signalling blockade in young TEPC cultures decreased mTEC conversion. Young adult Activin A HET young mice have compromised mTEC development. Furthermore, thymi from E14.5 Activin A HET or KO mice grafted into athymic nude mice, generated reduced numbers of mTECs, total thymocytes and CD4+ T cells. In conclusion, sex steroid blockade unleashes an age-related block in TEPC differentiation, promoting mTEC recovery through an Activin A dependent mechanism.

Dendritic cells from aged subjects display impaired capacity to induce mucosal tolerance

Agrawal, A., Agrawal, S., Ganguly, S., Tran, A., Sundaram, P.
University of California, Medicine/Immunology, Irvine, United States

Aged subjects display increased susceptibility to mucosal diseases. Infections and diseases of the respiratory, gastrointestinal and urinary tract are prevalent in this population. Sterile inflammation of the mucosa is considered a major culprit. Retinoic Acid (RA) secreted by mucosal epithelial cells plays a major role in inducing tolerance in the mucosa. RA acts on Dendritic cells (DCs) to induce mucosal tolerance. Here we compared the response of DCs from aged and young individuals to RA with a view to understand the mechanisms underlying chronic sterile inflammation in aged mucosa. Our investigations revealed that compared to young DCs, RA stimulated DCs from aged subjects are defective in inducing T regulatory cells. Examinations of the underlying mechanisms indicated that impaired upregulation of CD141 expression on aged DCs by RA was a major factor in reduced induction of T regulatory cells. In summary, reduced response of aged DCs to RA enhances mucosal inflammation in the elderly, increasing their susceptibility to mucosal diseases. In addition, our data also suggests a novel mechanism of immunosuppression by RA in tumor microenvironment.

815

IGHV and IGHD encoding antibodies with exceptionally long CDR3H are most expressed at birth in the bovine neonate

Pasman, Y.¹, Merico, D.M.², Kaushik, A.¹

¹University of Guelph, Molecular and Cellular Biology, Guelph, Canada, ²Hospital for Sick Children, Centre for Applied Genomics, Toronto, Canada

We sequentially analyzed 18 RNA-seq libraries from three bovine calves at day 0, 7, 14 and 28, together with their dams (day 0 and 7) to delineate the development of neonatal immunity. A significant shift in neonatal transcriptome occurs within first week post-birth where a set of 717 genes is up-regulated. Global pathway analysis of the transcriptome showed 110 differentially expressed (DE) immune-related genes at birth as compared to day 7. These include immune related genes, such as, complement, *MHCII*, chemokine receptors, defensins and cytokines. As compared to adults, *IGKC* is expressed at higher levels in the neonates, despite predominant *IGLC* expression at birth. Two members of *IGKV2* family, *IGKV10* and *IGKV12*, are preferentially expressed in neonatal B cells. As for *IGLV1* family, *IGLV1b.1* and *IGLV1x.1* are most expressed in neonatal B cells. Another member, *IGLV3.4*, of rarely expressed *IGLV3* family is preferentially used in neonatal B cells. The *IGHM* and *IGHD* transcripts are expressed at birth and *IGHM* achieves adult levels by day 7. This is followed by *IGHA* and *IGHG* transcripts 14-28 days post birth. Interestingly, most 3' *IGHV1S1(BF4E9)* gene, known to encode antibodies with exceptionally long CDR3H, is preferentially expressed in neonatal B cells. In parallel, single longest *IGHD2(D_H2)* gene that encodes such an atypical CDR3H is expressed at high levels at birth. It seems that *IGHV1S1(BF4E9)* gene has an important functional role in the development and expansion of bovine neonatal B-cell repertoire. To conclude, the bovine neonate acquires IgM levels similar to adult by day 7.

816

Immune response and early transcriptional changes after primary and booster vaccination against hepatitis B in young and old adults

Weinberger, B.¹, Haks, M.C.², Katzgraber, F.³, Ottenhoff, T.H.M.², Grubeck-Loebenstien, B.¹

¹University Innsbruck, Institute for Biomedical Aging Research, Innsbruck, Austria, ²Leiden University Medical Center, Leiden, Netherlands, ³Public Health Department, Federal State of Tyrol, Innsbruck, Austria

Many currently used vaccines are less immunogenic and effective in the elderly compared to younger adults due to age-related changes of the immune system. Most vaccines utilized in the elderly contain antigens, with which the target population had previous contact. Therefore, most studies investigating vaccine-induced immune responses in the elderly do not analyze responses to neo-antigen but rather booster responses. It can be hypothesized that age-related differences in the immune response are distinct for primary and recall responses. We therefore aimed to investigate primary and recall responses using the same antigen in young and older adults

and chose Hepatitis B vaccine as a model antigen. Young (20-40 years) and elderly (>60 years) healthy volunteers received either a primary series (no prior vaccination) or a single booster shot (documented primary vaccination more than 10 years ago) of the registered vaccine Twinrix. Expression of immunity-related genes was measured before and 1 day after vaccination and antibody titers were determined at several time points with a long-term follow-up 6 months after the last vaccination. Antibody responses were lower and seemed to be delayed in the elderly compared to young adults. Non-responders after the 3-dose primary series were more frequent in the elderly group. Antibody titers after booster vaccination increased in all participants. Associations between early expression-profiles on day 1 and antibody responses were found.

817

Effects of Interleukin-1 receptor antagonist on airway remodeling and hyperreactivity in murine bronchopulmonary dysplasia induced by perinatal inflammation and hyperoxia

Royce, S.¹, Nold, M.², Bui, C.², Donovan, C.¹, Lam, M.¹, Lamanna, E.¹, Rudloff, I.², Bourke, J.¹, Nold, C.²

¹Monash University, Pharmacology, Clayton, Australia, ²Hudson Institute of Medical Research, Clayton, Australia

Bronchopulmonary dysplasia (BPD) is a chronic disease of extreme prematurity that has serious long-term consequences including increased asthma risk. We earlier identified Interleukin-1 receptor antagonist (IL-1Ra) as a potent inhibitor of murine BPD induced by combining perinatal inflammation (intra-peritoneal injection of lipopolysaccharide to pregnant dams) and exposure of pups to hyperoxia (FiO₂ 0.65).

The aim of this study was to determine whether airway remodeling and hyperresponsiveness similar to asthma are evident in this model, and whether IL-1Ra is protective. Pups received daily subcutaneous injections of vehicle or 10mg/kg IL-1Ra. At 28d, lungs were prepared for histology and morphometry of alveoli and airways, or inflated with agarose to prepare lung slices to visualise *ex vivo* airway contraction and relaxation by phase-contrast microscopy.

Pups reared in hyperoxia developed a severe BPD-like lung disease, with fewer, larger alveoli, and increased subepithelial collagen and airway α -smooth muscle actin. Following hyperoxia, methacholine elicited contraction with similar potency but increased maximum reduction in lumen area (air 44%; hyperoxia 89%), and the dilator potency of salbutamol was reduced. IL-1Ra treatment prevented hyperoxia-induced alveolar disruption and airway fibrosis, but surprisingly not the increase in methacholine-induced airway contraction.

The current study is the first to demonstrate *ex vivo* airway hyperreactivity and impaired dilator responsiveness caused by perinatal inflammation and hyperoxia and reveals further preclinical mechanistic insights of IL-1Ra as a treatment for BPD.

Targeting macrophages rescues age and tumor-induced T cell dysfunction in elderly mice

Jackaman, C.^{1,2}, Dye, D.E.^{1,2}, Crabb, H.G.^{1,2}, Gardner, J.K.^{1,2}, Grounds, M.D.³, Nelson, D.J.^{1,2}

¹Curtin University, Biomedical Sciences, Perth, Australia, ²Curtin University, Curtin Health Innovation Research Institute, Perth, Australia, ³University of Western Australia, School of Anatomy and Human Biology, Perth, Australia

Most cancers emerge in aging populations when immune function is declining. Macrophages make up a large percentage of the tumor microenvironment, a key site for effector tumour-specific T cells. Macrophage function may change with aging in multiple tissues and impact on T cell function, yet the consequences of macrophage interactions with T cells during aging is not understood. Flow cytometry showed that lymphoid tissues of healthy elderly mice (24 months, cf 70 human years) contained more anti-inflammatory IL-10⁺ macrophages than their younger counterparts (2 months, cf 16-18 human years). Interestingly, tumor-exposed elderly macrophages produced more suppressive TGF β and IL-4 than young macrophages; prevented young T cells from producing IFN γ ; and induced IL-10⁺ CD4⁺ T cells. These data imply that elderly macrophages are hypersensitive to suppressive signals and are more likely support tumour growth than younger counterparts. This was supported by data showing that mesothelioma tumours grew faster in elderly mice and that macrophage depletion inhibited tumour growth. We attempted to rescue tumor-exposed macrophages with LPS/IFN γ or IL-2/agonist anti-CD40 antibody immunotherapy. LPS/IFN γ upregulated CD40, but did not restore the ability of young or elderly tumour-exposed macrophages to secrete pro-inflammatory cytokines to the same levels as non-tumor-exposed, LPS/IFN γ controls. These macrophages induced young and elderly T cells to proliferate, however T cells did not secrete IFN γ . In contrast, tumor-exposed, IL-2/CD40-stimulated macrophages not only induced young and elderly T cells to proliferate, they also induced elderly T cells to produce IFN γ . These results support further studies examining macrophages in anti-cancer treatment the elderly.

819

Despite generating a weak tumour-specific CTL response during tumour progression chemotherapy is only effective in elderly mice if T cells are present

Nelson, D.¹, Spowart, J.¹, Crabb, H.¹, Dye, D.¹, Fox, S.², Metharom, P.³, Proksch, S.¹, Jackaman, C.¹

¹Curtin University, Biomedical Sciences, Perth, Australia, ²Curtin University, Pharmacy, Perth, Australia, ³Curtin University, Health Sciences, Perth, Australia

There is convincing evidence that the immune system protects from cancer. However, immune function declines with age and most cancers, including mesothelioma, emerge 30-40 years after exposure to the relevant carcinogen with most patients being greater than 60 years old. Studies in young mice (6-8 week old, cf 14-16 human years) have shown that several chemotherapeutic agents require a functional T cell

response to elicit an effective anti-cancer outcome, but T cells become increasingly dysfunctional with aging. We asked if chemotherapy in the elderly also requires T cells. We found that tumours grew faster in elderly mice (24-27 month old, cf 70-80 human years). This was associated with decreased muscle weight in the gastrocnemius and extensor digitorum longus, body weight loss, lower percentages of blood lymphocytes, higher percentages of blood granulocytes and increased liver damage, implying that elderly mice are more susceptible to cancer cachexia. Chemotherapy induced even more weight loss and liver damage in elderly but not young mice, and was not as effective in elderly mice as it was in young mice. We also found, using an in-vivo CFSE-based CTL assay, that, unlike their younger counterparts which generated a significant endogenous tumour-specific CD8+ CTL response, elderly mice generated only a weak tumour-specific CTL response during tumour progression. Nonetheless, T cell depletion studies showed that chemotherapy in elderly mice also required T cells to induce tumour regression. Future studies will determine if rescuing T cell function in the elderly improves their anti-cancer response to chemotherapy.

Refining anti-inflammatory therapy strategies in a murine model of bronchopulmonary dysplasia induced by perinatal inflammation and hyperoxia

Ngo, D.^{1,2}, Rudloff, I.^{1,2}, Nold, M.^{1,2}, Cho, S.^{1,2}, Bui, C.^{1,2}, McLean, C.³, Berger, P.^{1,2}, Nold, C.^{1,2}

¹Ritchie Centre, Hudson Institute of Medical Research, Clayton, Australia, ²Monash University, Department of Paediatrics, Clayton, Australia, ³The Alfred Hospital, Department of Anatomical Pathology, Melbourne, Australia

Bronchopulmonary dysplasia (BPD) is a common lung disease of premature infants, with devastating consequences. As no therapy for BPD exists, we investigated whether the anti-inflammatory protein C (PC) and interleukin 1 receptor antagonist (IL-1Ra) prevent murine BPD. BPD was precipitated by perinatal inflammation (intraperitoneal injection of lipopolysaccharide to pregnant dams) followed by postnatal exposure of pups to hyperoxia (65% or 85% O₂). Pups were treated daily with PC, IL-1Ra (10mg/kg or 100mg/kg), or vehicle (up to 28d). Vehicle animals in hyperoxia developed severe BPD (alveolar number and gas exchange-area decreased \leq 60%, alveolar size increased 4-fold). PC and IL-1Ra prevented structural lung damage in 65%, but not 85% O₂. Significant lung improvement was observed in mice treated with 10mg/kg of IL-1Ra immediately after birth compared to vehicle-treated hyperoxia group ($p < 0.001$) and in comparison to IL-1Ra (100mg/kg) and the delayed treatment with IL-1Ra ($p < 0.05$).

Perinatal inflammation and hyperoxia each triggered distinct pulmonary immune responses (20-fold increase), some reduced (\leq 94%) by PC or IL-1Ra or both. Pulmonary inflammatory mediators IL-1 β , MIP-1 α , and TREM-1, was found to play a critical role in murine BPD. Although the effectiveness of administering IL-1Ra to prevent alveolar lung damage is dose and timing dependent, our findings show that IL-1Ra and PC protect the

lungs of newborn mice from detrimental effects of hyperoxia and perinatal inflammation by attenuating the pulmonary immune response. Therefore, these two anti-inflammatory drugs could fundamentally change the prognosis of premature infants by treating or preventing the currently irremediable BPD.

Plasma vitamin D levels and the inflammatory status of preterm infants

Sava, F.¹, Treszl, A.¹, Hajdú, J.¹, Toldi, G.¹, Rigó Jrs, J.¹, Tulassay, T.², Vászrhelyi, B.³

¹Semmelweis University, First Department of Obstetrics and Gynecology, Budapest, Hungary, ²Semmelweis University, First Department of Pediatrics, Budapest, Hungary, ³Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary

Background: Vitamin D has an important immunomodulatory role. We investigated whether vitamin D levels at birth may associate with immune status in preterm infants.

Methods: Cord blood samples were collected from 28 preterm infants born \leq 30 weeks of gestation. Infants were divided into groups below and above median vitamin D level. We measured plasma cortisol and cytokine levels and also assessed the peripheral prevalence of distinct immune cell subsets using flow cytometry. The mixed effect model was used to analyse the effects of vitamin D, plasma cortisol levels and gestational age on cytokine levels and immune phenotype.

Results: Vitamin D level in our cohort was 23.3 [18.7-26.6] ng/ml (median [IQR]). In infants with vitamin D level below the median the prevalence of CD4+ CXCR3+ (Th1) and CD8+ CXCR3+ cell subsets was higher, while the prevalence of CD4+ CCR4+ (Th2), CD8+ CCR4+ and plasmacytoid dendritic cell (pDC) subsets was lower than in those with vitamin D level above median. pDCs and Th2 lymphocytes were the only cell subsets which were only influenced by vitamin D levels, but not by plasma cortisol and gestational age. No association between vitamin D level and any of the tested plasma cytokine levels was detected.

Conclusions: Vitamin D levels may together with cortisol levels and gestational age have an effect on Th1/Th2 balance and the prevalence of plasmacytoid dendritic cells in the preterm newborn.

822

Impact of aging on calcium influx and potassium channel characteristics of T lymphocytes

Toldi, G.¹, Kollár, S.², Berta, L.¹, Rigó Jr, J.¹

¹Semmelweis University, First Dept of Obstetrics, Budapest, Hungary, ²Semmelweis University, Second Dept of Obstetrics, Budapest, Hungary

Adaptive immunity and T cell function are affected by aging. Calcium influx patterns, regulated by Kv1.3 and IKCa1 potassium channels, influence T cell activation. We aimed to compare calcium influx kinetics in CD8, Th1 and Th2 cells in human peripheral blood samples obtained from five different age groups (cord blood, 10-15 ys, 25-40 ys, 45-55 ys, 60-75 ys).

We evaluated calcium influx kinetics in peripheral lymphocytes by flow cytometry following activation with phytohemagglutinin in the above T cell subsets. We also assessed their sensitivity to specific inhibition of the Kv1.3 and IKCa1 potassium channels by margatoxin (MGTX) and triarylmethane (TRAM), respectively. Data were evaluated using an algorithm based on the calculation of a double-logistic functions for each recording (the FacsKin method).

Calcium influx was greater in Th1 cells of adults, however, its extent decreased again with aging. Importantly, these changes were not detected in Th2 cells. MGTX had a more pronounced inhibitory effect on calcium influx in Th2 cells in adults, while in Th1 cells the same was true for TRAM. Calcium influx of CD8 cells were inhibited to a similar extent by both applied inhibitors, and had no effect in the elderly.

Altered lymphocyte potassium channel inhibitory patterns, regulators of calcium influx kinetics, might contribute to the development of age-related changes of T cell function. The lower level of activation of Th1 cells in the elderly upon the same stimuli may play an important role in the increased susceptibility to infections in this age group.

823

Shedding light on preterm immunity

Lao, J.C.^{1,2}, Beker, F.³, Konig, K.³, Noble, E.³, Walsh, G.³, Malhotra, A.^{2,4}, Tan, K.^{2,4}, Yeoman, E.⁴, Mockler, J.^{1,5}, Woodhead, G.³, Nold-Petry, C.A.^{1,2}, Nold, M.F.^{1,2}

¹Ritchie Centre, Hudson Institute of Medical Research, Clayton, Australia, ²Monash University, Department of Paediatrics, Clayton, Australia, ³Mercy Hospital for Women, Mercy Health, Department of Paediatrics, Melbourne, Australia, ⁴Monash Newborn, Monash Health, Melbourne, Australia, ⁵Monash University, Department of Obstetrics and Gynaecology, Clayton, Australia

There is little knowledge on the immune system of extremely premature infants (born 24-29 weeks of gestation). This paucity of evidence impedes advances in combating bronchopulmonary dysplasia (BPD), a common, severe chronic lung disease that entails significant morbidity and mortality. No safe and effective treatment exists.

In order to improve our understanding on preterm immunity and to characterize the immunological hallmarks of BPD to enable early intervention, an observational study was set up to recruit a cohort of 75 extremely premature infants. Blood was collected from 20 extremely preterm infants at 5 timepoints [birth, days 1, 7 and 14 and 36 weeks corrected gestational age (WCGA)] to date. Following overnight in vitro stimulation with PMA/ionomycin, LPS or vehicle, flow cytometry was used to explore various immune cell subsets.

From the analysis of seven preterm babies, the ability of neonatal CD4+ T cells to produce IFN-gamma in response to cell stimulation increases over time, leading to a clearly positive but still attenuated response at 36 WCGA. Comparing the three infants that developed BPD with the four that did not at 36 WCGA, we observed a marked increase in monocytes (6-fold), dendritic cells (2-fold) and neutrophil activation (9-fold), but fewer circulating endothelial progenitor cells (0.3% vs 1.4% of viable cells).

These early data from preterm infants reveal that this first-of-its-kind study will revolutionise the understanding of preterm immunity. BPD appears associated with markedly increased cellular activation - a promising finding that may provide a basis for therapeutic innovations.

824

Aging induces increased expression of checkpoint inhibitory molecules on dendritic cells

Gardner, J.^{1,2}, Jackaman, C.^{1,2}, Mamotte, C.^{1,2}, Nelson, D.^{1,2}

¹Immunology and Cancer Group, Curtin University, Perth, Australia, ²CHIRI Biosciences Research Precinct, Curtin University, Perth, Australia

The incidence of most cancers increases with age. Recent studies have shown that immune function declines with age and this may contribute to tumour development and progression in the elderly. However, the effects of aging on dendritic cells (DCs) in healthy and tumour-bearing hosts are not yet well-characterised. The aim of this study was to compare changes in DC phenotype and function in young (6-8 weeks old, equivalent to 14-16 human years) and elderly (24-27 months old, equivalent to 70-80 human years) healthy and tumour-bearing mice. The proportions and phenotype of DCs in lymph nodes (LN) and tumours of young and elderly mice were assessed using flow cytometry. DC proportions of total cells increased in LN of healthy and tumour-bearing elderly mice, but decreased in elderly tumours, relative to young mice. Expression of MHC-II was reduced on elderly tumour-associated DCs, suggesting that tumour antigen presentation to CD4+ T-cells may be impaired in the elderly. Healthy and tumour-bearing young and elderly LN DCs showed similar expression of co-stimulatory molecules (CD40, CD80 and CD86) and cytokines (interferon- γ) involved in T-cell activation. However, elderly LN DCs expressed increased levels of the checkpoint inhibitory molecules PD-L1 and CD73 (an ecto-enzyme involved in adenosine production) and the immunosuppressive cytokine TGF- β , relative to young counterparts. These data suggest that elderly LN DCs are more likely to inhibit T-cell function and impair generation of anti-tumour immunity in the elderly.

825

Comparison of intestinal innate lymphoid cell in neonatal mice with necrotizing enterocolitis to healthy controls and young adult mice

Cho, S.¹, Lao, J.¹, Rudloff, I.¹, Cheng, W.², Nold, M.¹, Nold, C.¹

¹Monash University, Hudson Institute of Medical Research, Clayton, Australia, ²Beijing United Family Hospital, Beijing, China

Background: The cytokine profile of innate lymphoid cells (ILC) resembles that canonically associated with adaptive immune responses, but their activation is not antigen-specific. ILC play important roles in intestinal immune homeostasis. Inflammatory bowel disease is linked to changes in intestinal ILC composition; e.g. increased IL-17 producing ILC3 are associated with Crohn's disease. However, little is known about developmental changes in ILC in neonatal intestinal disease. We aimed to explore

ILC regulation and function in a murine model of necrotizing enterocolitis (NEC).

Methods: 72h NEC model: formula feeding of newborn C57BL/6J pups combined with hypoxia and cold stress. Controls: dam-fed littermates. Both groups were compared to 10 weeks old mice and intestinal ILCs, analysed by flow cytometry.

Results: The intestinal NKp46⁻ ILC3 were markedly more abundant in neonatal than adult mice (43% vs 24%). In contrast, the NKp46⁺ ILC3 increased with age from 2.4% on d3 of life to 12% in young adults. The overall percentage of ILC2 was similar in pups and adults, but the fraction of KLRG1⁺ ILC2 was smaller in neonatal mice (2% vs 15% in adults). There was little change in intestinal ILC1 with age.

We observed an increase in NKp46⁻ ILC3 to 56%, and IL-17 and IL-22 in NEC on d3 of life when compared to dam-fed pups. The GATA3⁺ ILC2 and IL-33, were also markedly increased in NEC.

Conclusions: Murine NEC is associated with an increase in intestinal ILC2 and ILC3. The ILC repertoire changes markedly as the immune system matures.

826

The depletion of regulatory T cells in the third trimester increases the susceptibility for LPS-induced preterm birth and causes adverse neonatal outcomes

Arenas-Hernandez, M.^{1,2,3}, Romero, R.², Balancio, A.¹, Mial, T.¹, Hassan, S.¹, Sanchez-Torres, C.³, Gomez-Lopez, N.^{1,2}

¹Wayne State University, OB/GYN, Detroit, United States, ²National Institute of Health, Perinatology Research Branch, Detroit, United States, ³Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional, Departamento de Biomedicina Molecular, Mexico City, Mexico

Introduction: The role of regulatory T cells (Tregs) in the third trimester of pregnancy is poorly understood. The aims of this study were to investigate whether the depletion of Tregs:

- 1) induces preterm birth (PTB);
- 2) increases the susceptibility for LPS-induced PTB, and
- 3) has adverse effects on pup survival and weight during the first and second pregnancy.

Methods: B6-Foxp3DTR females were impregnated by B6 (DTRs=syngeneic) or BALB/c males (DTRa=allogeneic). Tregs were depleted by injecting Diphtheria toxin (DT; n=16-19 each) daily from 14.5 days postcoitum (dpc) until delivery. Control mice were injected with [Glu52]-Diphtheria toxin (GluDT; n=11-14 each). DTRa females were impregnated again (DTRall) and injected with DT (n=10). A second group of DTRa dams was injected with DT or GluDT (n=10 each), and LPS was injected at 16.5 dpc. Following injection(s), dams were video recorded to calculate the rate of PTB, gestational age, pup survival and weight at 1-3 weeks postpartum.

Results:

- 1) The depletion of Tregs in the third trimester did not induce PTB neither in DTRs nor in DTRa dams; yet, DTRa dams delivered earlier than DTRs dams;
- 2) The depletion of Tregs increased the susceptibility for LPS-induced PTB in DTRa dams;
- 3) DTRa dams delivered leaner pups than controls;

- 4) DTRall dams delivered leaner pups than DTRa dams; and
- 5) DTRall dams delivered leaner and less viable pups than controls.

Conclusion: The depletion of Tregs in the third trimester increases the susceptibility for LPS-induced PTB and causes adverse neonatal outcomes in the first and second pregnancy.

827

Aging with MCMV maintains TCR repertoire diversity in late life

Smithey, M.^{1,2}, Venturi, V.³, Davenport, M.³, Nikolich-Zugich, J.^{1,2}

¹University of Arizona College of Medicine, Immunobiology, Tucson, United States, ²University of Arizona, Arizona Center on Aging, Tucson, United States, ³University of New South Wales, Centre for Vascular Research, Kensington, Australia

Cytomegalovirus (CMV) is a ubiquitous persistent herpesvirus (worldwide infection rate 45-100%). CMV has coevolved with mammalian hosts for millennia. It has been postulated that lifelong persistent immune interactions between host and CMV may contribute to age-related immune senescence. We previously reported that mice aged with persistent murine CMV (MCMV) show impaired CD8 T cell function upon challenge with several microorganisms, including *Listeria monocytogenes* expressing the model OVA antigen (Lm-OVA) in late life. To further explore how lifelong persistent MCMV infection may influence aged immune responses, we challenged control adult and old mice, as well as lifelong MCMV-infected old mice (hereafter referred to as MCMV+) with Lm-OVA, and assessed the OVA-specific TCRb repertoire by single-cell sorting and TCRb CDR3 sequence analysis. We found that compared to old MCMV-negative animals, OVA-specific CD8 effector T cells generated in old MCMV+ mice contained diverse clonotypes exhibiting

- (i) non-canonical TCR genes;
- (ii) a loss of a conserved amino acid motif;
- (iii) reduced avidity for cognate antigen; and
- (iv) broader recognition of altered peptide ligands.

Thus, lifelong MCMV infection appeared to maintain/broaden diversity within the CD8 T cell response to a new infection in late life, by recruitment of clonotypes with broad cross-reactive antigen recognition capacity. These results have profound implications for our understanding of naive T cell maintenance over a lifespan, and suggest that our coevolution with CMV may include surprising, potentially positive impacts on adaptive immunity in late life.

828

The roles of Krüppel-like factors (KLF) 9 and 10 in the regulation of the fetal naive T cell epigenome

Ng, M.¹, Burt, T.^{2,3}

¹University of California, San Francisco, Biomedical Science Ph.D., San Francisco, United States, ²University of California, San Francisco (UCSF), Division of Neonatology, San Francisco, United States, ³University of California, San Francisco (UCSF), Eli and Edythe Blythe Broad Center of Regeneration Medicine and Stem Cell Research, San Francisco, United States

The developing human fetal immune system achieves active immune tolerance, in part, through a dominant population of CD25⁺FoxP3⁺ regulatory T (Treg) cells present in secondary lymphoid organs. Crucially, fetal naïve T cells preferentially differentiate into Treg cells upon T cell receptor (TCR) stimulation. Krüppel-like factors (KLF) 9 and 10 have been identified as genes differentially expressed between adult and fetal naïve T cells respectively, and are likely candidates that control the fetal naïve T cell phenotypes. Overexpression of KLF9 in fetal naïve T cells thus inhibits their innate ability to differentiate into Treg cells and enhances their ability to produce IFN γ under Th0 conditions. Members of the KLF family operate to influence cell differentiation by directing epigenetic modifications. In addition to epigenetic modifications at the FOXP3 gene, modifications at other genes are thought to be required for the full maintenance and stability of the Treg cell suppressive phenotype. Sequencing downstream of the Assay for Transposase-Accessible Chromatin (ATAC-seq) has revealed that fetal naïve T cells share areas of chromatin accessibility with adult Treg cells that are distinct from adult naïve T cells, especially in genes such as IKZF2 (Helios) that are a part of the proposed Treg cell epigenome. A pre-existing epigenomic landscape within fetal naïve T cells similar to Treg cells might thus underlie the predisposition for naïve fetal T cells to differentiate into Tregs. Further work in this project will then characterize the roles of KLF9 and KLF10 on the acquisition, maintenance, and acquiescence of the fetal naïve T cell epigenome.

829

Characterization of human TCR repertoire of CD4⁺ and CD8⁺ T cells and its implications in evaluation of T cell immunity and aging

Weng, N.-P.

National Institute on Aging, NIH, Baltimore, United States

A diverse TCR repertoire is considered as an essential property of T cell immunity to efficiently contain and eliminate any potential viral invasion. CD4⁺ and CD8⁺ T cells use the same genetic elements and process to generate a functional TCR but differ in their recognition of peptide bound to MHC class II and I, respectively. However, it is currently unclear to what extent the TCR repertoire of CD4⁺ and CD8⁺ T cells is different. Here, we report a comparative analysis of the TCR β repertoires of CD4⁺ and CD8⁺ T cells using a 5'-RACE/PCR/sequencing method. We found that TCR β diversity of CD4⁺ T cells ranges from 1.2-9.8 x10⁵ and is greater than that of CD8⁺ T cells in each study subject. TCR β sequences appeared to be distinct as there was little overlap in TCR β sequences between CD4⁺ and CD8⁺ T cells. Further analysis of CDR3 showed that CD4⁺ and CD8⁺ T cells exhibited distinct preferences for certain amino acids, and this was further confirmed by a supervised machine learning analysis, suggesting there are distinct and discernible differences between TCR β CDR3 in CD4⁺ and CD8⁺ T cells. Comparative sequence analysis also revealed 5-12% of the unique TCR β s that share an identical CDR3 with different V genes with an average of 3 V genes. Together, our findings reveal the distinct features of the TCR β repertoire between CD4⁺ and CD8⁺ T cells. Currently,

we are analyzing when and how the TCR repertoire change with age and the results will be presented at the congress.

830

Age-related decline in natural IgM function: diversification and selection of the B-1a cell pool with age

Holodick, N., Vizconde, T., Hopkins, T., Rothstein, T.

Feinstein Institute for Medical Research, Oncology and Cell Biology, Manhasset, United States

Streptococcus pneumoniae is the most common cause of pneumonia, which claims the lives of people over the age of 65 seven times more frequently than those aged 5-49. B-1a cells provide immediate and essential protection from *S. pneumoniae* through production of natural immunoglobulin, which is germline-like due to minimal insertion of N-region additions. The germline-like Ig B-1a cells produce has been attributed to their unique development occurring mainly during fetal life while their persistence throughout adult life is maintained through self-renewal. Yet, B-1a derived IgM moves away from the germline with age. We demonstrate the fetal B-1a cell repertoire is diversified by addition of bone marrow-derived B-1a cells and more importantly, altered by selection-induced skewing of both peritoneal and bone marrow-derived B-1a cells with increasing age. As a result of this selection, the protective capacity of natural serum IgM against *S. pneumoniae* infection is significantly decreased in aged mice.

831

Age-related profiling of DNA methylation in CD8⁺ T cells reveals changes in immune response and transcriptional regulator genes

Peterson, P., Tserel, L., Kolde, R., Limbach, M., Tretyakov, K., Kasela, S., Kisand, K., Saare, M., Vilo, J., Metspalu, A., Milani, L.

University of Tartu, Tartu, Estonia

Human ageing affects the immune system resulting in an overall decline in immunocompetence. Although all immune cells are affected during aging, the functional capacity of T cells is most influenced and is linked to decreased responsiveness to infections and impaired differentiation. We studied age-related changes in DNA methylation and gene expression in CD4⁺ and CD8⁺ T cells from younger and older individuals. We observed marked difference between T cell subsets, with increased number of methylation changes and higher methylome variation in CD8⁺ T cells with age. The majority of age-related hypermethylated sites were located at CpG islands of silent genes and enriched for repressive histone marks. Specifically, in CD8⁺ T cell subset we identified strong inverse correlation between methylation and expression levels in genes associated with T cell mediated immune response (LGALS1, IFNG, CCL5, GZMH, CCR7, CD27 and CD248) and differentiation (SATB1, TCF7, BCL11B and RUNX3). Our results thus suggest the link between age-related epigenetic changes and impaired T cell function.

832**Recombinant probiotic bacteria expressing allergen-chimers for the neonatal prevention of poly-sensitization**

Sarate, P.¹, Heini, S.², Daniel, C.³, Kozákova, H.⁴, Grabherr, R.², Schabussova, I.¹, Wiedermann, U.¹

¹Medical University of Vienna, Institute of Specific Prophylaxis and Tropical Medicine, Vienna, Austria, ²(c/o) CD Laboratory for Genetically Engineered Lactic Acid Bacteria, Department of Biotechnology University of Natural Resources and Life Sciences VIBT, Vienna, Austria, ³Institut Pasteur de Lille, Center for Infection and Immunity of Lille, Université Lille Nord de France, CNRS, UMR 8204, Institut National de la Santé et de la Recherche Médicale, Lille, France, ⁴Institute of Microbiology of Academy of Sciences of Czech Republic, V.V.I., Laboratory of Gnotobiology, Nový Hradek, Czech Republic

Poly-sensitization is becoming an increasing health issue in western countries, since poly-sensitized individuals are difficult to treat by conventional therapeutic measures. We recently developed a novel multi-allergen chimer of birch and grass pollen (Phl p 5-bet v 1-Phl p 1) and showed that allergic poly-sensitization was prevented by mucosal treatment with this novel allergen chimer in adult mice. An increasing number of studies report that immune responses induced in early life to environmental and dietary antigens including probiotic bacteria are decisive for future immune response to these antigens. With respect to neonatal interventions, we previously showed that neonatal colonization with recombinant lactic acid bacteria expressing the allergen Bet v 1 successfully prevented allergic responses.

With this background now we want to investigate whether the concept of neonatal colonization with recombinant probiotic bacteria expressing novel allergen constructs can be also used for prevention of allergic multi-sensitivities. Our first aim was to construct recombinant bacteria, constitutively expressing a birch (Bet v 1) and grass pollen (Phl p 1 and Phl p 5) chimer in order to test if this recombinant probiotic strains can be used to prevent poly-sensitization. The strains will be used for the neonatal colonization in

(a) conventional mice and in

(b) germ-free mice prior to poly-sensitization with allergens and test their immunosuppressive properties. Along with this we plan to investigate the gut-lung axis of the microbiota by testing the migration, colonization and interaction of orally or nasally applied bacteria with mucosal surfaces using an in vivo imaging system.

833**Immune mediators in the development of osteoarthritis**

Apinun, J.¹, Sengprasert, P.², Tanavalee, A.¹, Yuktanandan, P.¹, Ngarmukos, S.¹, Reantragoon, R.^{2,3}

¹King Chulalongkorn Memorial Hospital, Orthopedics, Bangkok, Thailand, ²Faculty of Medicine, Chulalongkorn University, Microbiology, Bangkok, Thailand, ³Faculty of Medicine, Chulalongkorn University, Center of Excellence in Immunology and Immune-Mediated Diseases, Bangkok, Thailand

Osteoarthritis is an age-related multifactorial disease

characterized by "joint failure" as pathologic changes of the disease can be detected in all joint components. A multitude of factors contribute to the pathogenesis and disease progression of osteoarthritis including immune mediators such as T cells. T cells have been shown to effect the progression of osteoarthritis in animal studies. However, their role in the development of osteoarthritis is yet unclear. Tissues of the joint that may partake in the development of osteoarthritis include the synovial tissue lining and more recently shown, the infrapatellar pad (Hoffa's pad), of which immune cells reside. Our aim was to investigate the role of T cells present in these joint tissues in the development of osteoarthritis. We therefore, isolated T cells from synovial tissue linings and the infrapatellar fat pad of patients undergoing total knee arthroplasty. Different composition of T cell subsets were observed at the local site of joint inflammation when compared to T cell subsets in the peripheral blood (of patient-matched). We also investigated expression of T cell receptors and other immune mediators that were present in the synovial tissue linings and infrapatellar fat pad and compared to those present in the systemic peripheral blood.

834**Long-term dynamics of individual T-cell receptor beta repertoires**

The T-cell receptor repertoire diversity largely determine our ability to effectively withstand infections. Both thymic involution and skewed peripheral clonal selection events during aging lead to decrease of TCR diversity and limited T-cell immunity performance in the elderly. Here we implemented deep TCR beta repertoire sequencing with molecular barcoding to explore the long-term dynamics of T-cell immunity in healthy volunteers of all age groups (0-103 years old). The TCR diversity and publicity decreased in age groups from umbilical cord blood to aged individuals, whether private clonotypes expanded. We demonstrated unexpected repertoire stability: more than half of clonotypes detected in first timepoint persist and preserve observed high frequencies at timepoint 3 years later. Specifically, 880-960 of top 1000 most expanded clonotypes remained and underwent 1.8-2-fold expansion. We tracked behaviour of CMV- and EBV-specific TCR clonotypes in various age groups. While diversity of viral-specific clonotypes decreased with aging, average size of clones increased. Interestingly, we observed gender difference in aging-related repertoire skewing. Aging in 25-75 years range was related to more rapid shrinkage in naïve T cell pool in men than in women although the gender difference vanished in the oldest group (76-103 y.o.).

This work was supported by the Russian Science Foundation project №16-15-00149 and RFBR grant №14-04-01247.

Neonatal sepsis affects one-third of infants born very prematurely, and kills 320,000 infants worldwide annually. Lower human breast milk (BM) consumption is associated with sepsis but it is unclear whether preterm BM contains the same protective levels of immune factors as term BM. Supplementation of preterm BM with specific deficient immune factor/s may be a useful preventative strategy. We developed assays to measure and compare the levels of antimicrobial proteins and peptides (AMPs), leukocyte subsets, cytokines and soluble bacterial receptors in preterm and term BM. In BM from mothers of gestational age-matched pairs of preterm infants with and without sepsis, we investigated

(i) composition of BM at days 7 and 21 postpartum,
(ii) inhibitory effects of physiological levels of AMPs on bacterial growth, and

(iii) BM consumption in the first 28 days postpartum.

Contrary to our hypothesis, preterm birth was associated with higher concentrations of beta-defensin 1, lysozyme and soluble CD14 in BM. Infants with sepsis consumed less BM than their healthy counterparts from day two of life onwards. Lactoferrin (but no other tested AMPs) inhibited bacterial growth (>50%) at levels found in preterm BM. There was no effect of preterm birth on BM leukocyte concentrations, and only minor effects on frequencies of leukocyte subsets. These findings suggest that the prevalence of sepsis in preterm infants is not due to low concentrations of immune factors in BM, but may be related to low total consumption of BM. Increasing BM consumption and supplemental lactoferrin are potential therapeutic targets for future research.

Aging is accompanied by many physiological changes and the immune system is not escaping this. This effect of time is affecting most cells of the immune system. Numerous changes have been described but most of them are phenomenological, a typical example is the change of phenotypes in T cells. We are interested since years to uncover the intracellular signaling associated with phenotypic and functional changes of various immune cells. We identified several signaling alterations starting from the early to the most downstream events in several cells like neutrophils, monocytes and T lymphocytes. We not only were interested in the forward signaling driven by kinases but also by the feedback or regulatory signaling mediated by phosphatases. We found profound alterations of regulatory phosphatases activity and phosphorylation (eg. SHP-1). The question was always whether these changes are occurring also uniformly in T cell or there are differences between the various subpopulations (naive to the continuum of memory T cells). Our studies indicate that there are changes according to the subpopulations and that basal hyper-phosphorylation status we observe may be explained by signaling crosstalks. We also observed that there is a resemblance between naive and TEMRA T cells, which differ much from CM and RM cells. In conclusion the different T cell subpopulations may have very specific changes distinguishing them from each other. This needs further investigations in relation to their functions.

Aging is the strongest predictor of cardiovascular diseases such as atherosclerosis, which are leading causes of morbidity and mortality in older men. Monocytes migrate into artery walls at sites of inflammation and play an important role in atherosclerosis by forming foam cells (lipid-laden macrophages) and producing pro-atherogenic inflammatory cytokines (IL-6, TNF), which promote formation of atherosclerotic plaques. We have shown that inflammatory CD14⁺⁺CD16⁺ monocytes are expanded in older men and produce elevated levels of pro-atherogenic IL-6 and TNF; however, whether monocytes from older men are more atherogenic than those from younger individuals is unknown.

Using an *in vitro* model of monocyte transendothelial migration and foam cell formation, isolated monocytes from older men (median age [range]: 75 [58-85] yrs., n=20) formed foam cells more readily than those of younger individuals (32 [23-46] yrs., n=20) ($P < 0.001$) following migration across activated endothelial cells into a collagen matrix. Of the three subsets, inflammatory CD14⁺⁺CD16⁺ monocytes most readily formed foam cells ($P < 0.05$). Cholesterol efflux was impaired in monocytes from the elderly, associated with lower expression of the cholesterol transporter ABCA1 ($P=0.01$). Serum factors enhanced foam cell formation in older men; however, foam cell formation was not associated with altered serum lipid levels. We show that monocytes from older men have a higher propensity to form foam cells *in vitro* and conclude that they display higher atherogenic potential than those from younger individuals, which may contribute to increased risk of atherosclerosis in this population.

Characteristics of age-related alteration of T cell repertoire, thymic recent output function and miRNAs

Xu, Y.¹, Xu, L.¹, Zeng, C.^{1,2}, Jin, Z.¹, Lu, S.², Yang, L.¹, Chen, S.¹, Li, B.¹, Li, Y.^{1,2,3}

¹Jinan University, Institute of Hematology, Guangzhou, China,

²Jinan University, Key Laboratory for Regenerative Medicine of Ministry of Education, Guangzhou, China, ³Jinan University, Department of Hematology, First Affiliated Hospital, Guangzhou, China

The expression of miR-17, miR-92a and miR-181a, the distribution pattern of the TCR repertoires, and the level of thymic recent output function (sjTRECs) were detected in PBMCs from 160 healthy individuals (HI) with different age (0 to 70 years old) and 20 case of cord blood mononuclear cells (CBMCs). The results showed that the expression levels of miR-17, miR-92a and miR-181a in PBMCs were down-regulated with aging. Compared with 0 ~ 9 ys HI group, miR-92a and miR-181a upregulated in the CBMCs, while miR-17 downregulated. The sjTRECs level in the PBMCs was inversely correlated with age, there was a largest decline of sjTRECs between 0~9 and 10~19 ys group. TCR V β 1, V β 2, V β 4~V β 11, V β 14~V β 16, V β 18, V β 20, V β 21 and V β 23 were expressed in 100%, while the remained V β families were absent in different frequency, the lowest expression frequency detected in V β 13 and V β 24 subfamily (both were 91.25%); polyclonality of TCR was the most common pattern in all the V β subfamilies, while oligoclonality was relatively high expressed in V β 6 and V β 23 (23.75%); the expression frequency of V β subfamilies were descend but the oligoclonal tendency were increased with aging. Similarly, the frequencies of TCR V γ and V δ were decreased by the increase of age, while oligoclonal proliferation tendency had no significant correlations with the ages, the distribution pattern of V δ was different from V β subfamilies, lower frequencies were found in V δ 5 and V δ 7 (30% and 18.75%). In conclusions, the study gives a more comprehensive description of the characteristics of the T cell immunosenescence.

Antigen Processing & Presentation

Homozygosity for the HLA-DRB1*15 allele is associated with a responder profile in RhD-immunised blood donors

Tan, J.C.G.¹, Yuan, F.F.², Daley, J.³, Marks, K.⁴, Flower, R.L.⁵, Dyer, W.B.¹

¹Australian Red Cross Blood Service, Research and Development, Alexandria, Australia, ²University of Sydney, Faculty of Medicine, Camperdown, Australia, ³Australian Red Cross Blood Service, Manufacturing, Alexandria, Australia, ⁴University of New South Wales / Kirby Institute, Kensington, Australia, ⁵Australian Red Cross Blood Service, Research and Development, Kelvin Grove, Australia

Cases of haemolytic disease of the newborn have dropped significantly since the successful administration of prophylactic anti-D immunoglobulin (Ig) to susceptible RhD-negative pregnant women. Our Blood Service conducts an Anti-D Program to actively immunise selected RhD-negative blood donors with small volumes of RhD-positive red blood cells to stimulate anti-D Ig production. Donors (n=431) were considered Responders if serum anti-D Ig concentrations >1 IU/mL were recorded. However, 39.2% were Non-Responders and did not produce any anti-D Ig despite multiple exposures. We sought to examine donor genetic factors associated with antigen presentation and to identify genetic characteristics that could be utilised to identify Responders prior to immunisation. We found that female donors were more likely to be Responders ($p < 0.0001$). DNA was extracted from a subset of donors (n=272) and genotyped by restriction fragment length polymorphism-polymerase chain reaction for polymorphisms in genes that play an important role in antigen presentation and pathogen recognition (TLR2, TLR4, CD14 and Fc γ RIIA), although no statistically significant association was identified. Further work examined the association between Responders and the HLA-DRB1 allele, and revealed that donors with DRB1*15 allele were significantly associated with a Responder profile ($p=0.049$). High-resolution typing of donors with DRB1*15 alleles (n=78) demonstrated that 90% possessing two DRB1*15 alleles and 73.5% possessing one DRB1*15 allele had a Responder profile. This study has identified a potentially useful genetic characteristic (HLA-DRB1*15 allele) that could be used to screen new donors prior to entry into the Blood Service Anti-D Program.

840

Biased T cell receptor usage by HLA-A*02-restricted CD8 T-cells specific for the yellow fever viral peptide NS4b₂₁₂₋₂₂₂

Bovay, A.^{1,2}, Fuertes Marraco, S.A.¹, Bulek, A.M.², Dolton, G.², Sewell, A.K.², Speiser, D.E.¹

¹Ludwig Cancer Research Center, Department of Oncology, University of Lausanne, Epalinges, Switzerland, ²Cardiff University School of Medicine, Cardiff, United Kingdom

The Yellow Fever vaccine YF-17D induces a dominant memory CD8 T-cell response against the HLA-A*02-restricted NS4b212-222 peptide LLWNGPMAV (hereafter, A2/LLW) that persists for at least 25 years. Curiously, naïve A2/LLW-specific CD8 T-cells are also extraordinarily frequent in unvaccinated donors. The only other system that enables direct visualisation of sizeable

populations of antigen-specific human naïve CD8 T-cells is the HLA-A*02-restricted melanoma derived epitope Melan-A/MART1. The high frequency of naïve Melan-A-specific CD8 T-cells arises in part as recognition of the cognate peptide EAAGIGILTV (A2/EAA) that occurs via contacts with amino acids in the germline encoded CDR1 loop of the TRAV12-2 gene utilised by most A2/EAA-specific T-cells. Major V α biases have also been observed for recognition of metabolites in the context of MR1 and in CD1d- α -galactocerimide. We examined the TCR chain usage of A2/LLW-specific CD8 T-cells in YF-17D-vaccinated individuals and naïve cells from unvaccinated donors and found that a single V α gene dominates both of these populations. Our work extends observations on V α -biased recognition of unconventional T-cell epitopes and melanoma-related A2/EAA to the recognition of viral-derived peptide epitopes. Ongoing structural and biophysical analyses of TCR-A2/LLW interactions are expected to reveal the underlying molecular reasons for this α -chain bias in A2/LLW-specific T-cell populations and to provide a potential mechanistic basis for the extraordinary frequency and immunodominance of T-cells with this specificity.

841

Study of viral antigen processing and presentation by MHC class II using recombinant antibodies that mimic T-cell receptor specificity

Fridman, A., Reiter, Y.

Technion, Biology, Haifa, Israel

Influenza hemagglutinin (HA) is an antigenic glycoprotein found on the surface of the Influenza virus. By binding to the sialic acid on the cell surface, HA protein allows the Influenza virus to attach host cells. After vaccination with inactivated Influenza A virus (A/Aichi/2/1968-H3N2 strain), one can find elevated frequency of T cells directed towards Influenza HA antigen, residues 306-318, in immunized HLA-DR4 positive subjects. Based on these observations, we hypothesize that T Cell Receptor-Like (TCRL) recombinant Abs (rAbs) against the HLA-DR4/HA-306-318 viral epitope can be of high significance for the study of antigen processing and presentation on APCs during Influenza infection.

TCRL rAb against recombinant HLA-DR4/HA-306-318 complexes was isolated using a phage display approach. This TCRL, termed H1, was characterized in detail to demonstrate its fine TCR-like specificity. H1 exhibited specific staining of DR4+ APCs loaded with HA-306-318 peptide, compared to cells loaded with controlled peptides, and successfully compete with the cognate interaction of HA-306-318 specific DR4 restricted T cell hybridoma with HLA-DR4/HA-306-318 epitopes presented by APCs. Moreover, H1 demonstrated a positive binding towards F4/80+ cells derived from splenocytes of HA-immunized DR4 transgenic mice.

These results are a major step in the study of HLA-DR4/HA-306-318 epitope presentation during Influenza infection using H1 TCRL. This study will enable us for the first time to use direct visualization and quantitation tools to study the process of antigen processing and presentation of a native T cell epitope during the natural course of viral infection in the context of an animal model.

842

Functional analysis of Immunodominant CD8+ T cell responses against unpredicted epitopes from Influenza virus

Di Carluccio, A., Chen, W.

La Trobe Institute for Molecular Science, Melbourne, Australia

CD8+ T cells recognise antigenic peptides of 8-12 amino acids which are presented by MHC-I molecules on the surface of infected cells. We are investigating the antigen processing and presentation characteristics of recently discovered Immunodominant CD8+ T cell epitopes derived from Influenza virus Nucleoprotein (NP). Interestingly, the selected epitopes are of varying lengths; including an 8mer (NP 219-226), 10mer (NP 172-181) and 12mer (NP 145-156). None of these selected epitopes were predicted by the online prediction programs IEDB (www.iedb.org/), NetMHC 4.0 (www.cbs.dtu.dk/services/NetMHC/) and SYFPEITHI (www.syfpeithi.de/), but were in fact Immunodominant in their respective donors. Each of these sites generated a different ranking order or 'score' of NP peptides most likely to bind to the HLA-ABC molecules from each individual donor. The ranking is based on the amino acids within the HLA binding groove, and the positions of potential binding residues within the NP protein, they also use published epitope anchors. To understand why these epitopes are not predicted, we characterised their antigen processing and presentation characteristics by performing functional kinetics of the CD8+ T cell response to infection, and confirmed the minimum epitope length by HPLC co-elution. HPLC fractions of the naturally presented NP 219-226 have also uncovered potential post translational modification of the epitope, which requires further investigation. It is still unclear which amino acids contribute to MHC-I binding in the ER during infection. Peptide-HLA binding assays will allow us to characterise any common rules associated with these Immunodominant epitopes, which could lead to improvement of the prediction programs.

QS-21 enhances cross-presentation of NY-ESO-1 by monocyte-derived dendritic cells *in vitro*

Pasam, A.^{1,2,3}, Woods, K.^{1,2,3}, Knights, A.², Gerard, C.⁴, Puaux, A.-L.⁴, Morel, S.⁴, Louahed, J.⁴, Cebon, J.^{1,2,3}

¹Olivia Newton-John Cancer Research Institute, Heidelberg, Australia, ²Ludwig Institute for Cancer Research, Olivia Newton-John Cancer and Wellness Centre, Austin Hospital, Heidelberg, Australia, ³La Trobe University, School of Cancer Medicine, Bundoora, Australia, ⁴GlaxoSmithKline Biologicals S.A., Rixensart, Belgium

Cancer-testis antigens serve as an attractive target for therapeutic cancer vaccines; based on their highly-restricted expression profile and also their frequent immunogenicity in cancer patients. NY-ESO-1 is an immunogenic cancer-testis antigen that has been extensively studied as a target for immunotherapeutic cancer vaccination. Dendritic cells (DC) take up and cross-present antigen to T cells, leading to their activation and stimulation of an immune response *in vivo*. Cross-presentation by antigen presenting cells, such as DC,

is therefore an essential element of any immunotherapeutic treatment. Several studies have described strategies to enhance antigen cross-presentation by DC. QS-21* is a naturally occurring saponin molecule which enhances T cell responses and is in current use as an immunostimulant in several clinical trials. We assessed the impact of QS-21 on the cross-presentation of three NY-ESO-1 epitopes by monocyte derived DC *in vitro*. In all cases, presence of QS-21 at the time of antigen delivery resulted in significantly enhanced cross-presentation. Strikingly, NY-ESO-1 epitopes could be cross-presented when delivered as a soluble protein only in the presence of QS-21, which suggests a novel role for QS-21 as a component of an immunotherapeutic vaccine.

Understanding these effects will be critical for evaluating the role of QS-21 as an immunostimulant, in addition to optimizing future immunotherapeutic cancer vaccine formulations.

Immunoproteasome subunit LMP2 is crucial for lymphocyte survival and is a pro-survival factor for human multiple myeloma

Zanker, D.¹, Pang, K.², Oveissi, S.¹, Lu, C.¹, Neeson, P.³, Puthalakath, H.¹, Chen, W.¹

¹La Trobe Institute for Molecular Science, Bundoora, Australia,

²Walter & Eliza Hall Institute, Parkville, Australia, ³Peter MacCallum Cancer Centre, East Melbourne, Australia

Immunoproteasomes are specialized protein degradation machinery that are proposed to enhance immune responses due to altered cleavage motifs and increased processing rates compared to housekeeping proteasomes. Immunoproteasomes are constitutively expressed by antigen presenting cells such as dendritic cells and cytokines including IFN-gamma induce expression of LMP2 ($\beta 1_i$), LMP7 ($\beta 5_i$) and LMP10 ($\beta 2_i$) catalytic β -subunits that differentiate these two proteasome forms. Interestingly, investigation into immunoproteasome single-subunit deficient strains found LMP2^{-/-} mice exhibit dramatic decreases in all lymphocyte subsets. Using bone marrow chimeric mice, we have shown this not from thymic selection, but an intrinsic defect. We identified that lymphocytes die at various stages of development and in the periphery associated with antigen receptor stimulation or stress. Surprisingly, we identified immunoproteasomes in lymphocytes and this expression is upregulated following antigen-receptor stimulus. We postulated that LMP2 has a housekeeping role and is crucial for cleavage of particular proteins for either degradation or activation of function. Using mass spectrometry and RNAseq approaches, we identified cell-wide protein dysregulation with ~15% of proteins significantly changed. Changes in metabolic pathways, the NF κ B pathway and apoptosis pathways lead to a pro-apoptotic phenotype in LMP2^{-/-} lymphocytes. In vitro analysis found decreased or no degradation of specific pro-apoptotic proteins in LMP2^{-/-} MEFs. It is reported that various cancers over-express LMP2. To investigate whether LMP2 enhances cancer survival, using shRNA knock-down of LMP2 in various human multiple myeloma cell lines we found increased

apoptosis, decreased proliferation and increased sensitivity to chemotherapeutic drugs. We believe LMP2 is a viable anti-cancer therapeutic target.

MHCII with full peptide occupancy is a substrate for HLA-DM catalyzed peptide exchange

Reyes-Vargas, E.¹, Barker, A.P.^{1,2}, Zhou, Z.¹, He, X.¹, Jensen, P.E.^{1,2}

¹University of Utah, Pathology, Salt Lake City, United States, ²ARUP Laboratories, Pathology, Salt Lake City, United States

The major histocompatibility complex class II (MHCII) antigen-processing pathway is critical for adaptive immunity as the mechanism through which ligands are generated for recognition by CD4 T-cells. HLA-DM edits the repertoire of peptides that are presented to T-cells by catalyzing multiple rounds of peptide exchange on MHCII molecules. The catalytic potency of DM varies such that peptide exchange is markedly enhanced on some peptide-MHCII complexes and not others. This capacity to differentially edit complexes influences specificity and immunodominance in T-cell responses. The catalytic mechanism and rules that govern DM susceptibility are not fully understood. Evidence suggests that partial occupancy at the N-terminus of bound peptides is critical for peptide-MHCII complex sensitivity to HLA-DM. We employed a fluorescence polarization assay to independently assess the effective affinity and catalytic turnover, components in the catalytic mechanism of DM for peptide-MHCII complexes, in real-time kinetic measurements of DM activity. We found that complexes with an N-terminal truncated form of the immunodominant HA peptide, resulting in the loss of three H-bonds, showed an expected decrease in complex stability and increase in affinity for DM binding, but an unexpected increase in catalytic turnover when compared to the unmodified HA-MHCII complex. This result was even more pronounced when a conserved bidentate H-bonding residue near the P1 anchor of the HA-MHCII complex was disrupted by site-directed mutagenesis. Together, this implies that peptide-MHCII interactions near the N-terminal segment of a peptide are intact during the functionally active DM-peptide-MHCII catalytic complex. These results provide insight into the DM catalytic mechanism.

EBV infection affects the processing of myelin oligodendrocyte glycoprotein in B cells - Implications for multiple sclerosis

Morandi, E.¹, Jagessar, A.², Gijon, M.³, 't Hart, B.², Gran, B.¹

¹University of Nottingham, Clinical Neurology Research Group, Division of Clinical Neuroscience, School of Medicine, QMC,

Nottingham, United Kingdom, ²Biomedical Primate Research Centre (BPRC), Immunobiology Department, Rijswijk, Netherlands,

³University of Nottingham, Academic Division of Clinical Oncology, School of Medicine, Nottingham, United Kingdom

Multiple Sclerosis (MS) is a neurodegenerative disease with an immune-mediated pathogenesis in which Epstein Barr Virus (EBV) is a risk factor. Our hypothesis is that EBV infection renders B cells potent antigen presenting cells (APC) for autoreactive T cells, through influences on intracellular proteolysis and post-translational modifications of self antigens. The aim of this study is to assess the effect of EBV infection in B cells on processing of myelin oligodendrocyte glycoprotein (MOG). We investigated the processing of MOG through SDS PAGE gel analysis in the presence or absence of cathepsin inhibitors and we determined the proteolytic activity of Cathepsin G by activity assay. We also studied the effect of citrullination of the immunodominant MOG₃₅₋₅₅ peptide in position 41 and 46. In addition, we measured the expression of peptidylarginine deiminase 2 by RT-PCR and LC3ii, an autophagy marker, by Western Blotting, in EBV infected and uninfected cells.

We found that EBV infection increases the activity of Cathepsin G, leading to increased degradation of the peptide MOG₃₅₋₅₅ by B cells. However, infection also rescues the whole extracellular rhMOG from total degradation. By contrast, inhibition of Cathepsin G or citrullination of Arg 46 abrogated the degradation of MOG₃₅₋₅₅.

We propose a model in which EBV infection induces autophagocytosis in B cells and activation of PAD which mediates citrullination of Arg. Citrullinated MOG₃₅₋₅₅ is protected from degradation and can be presented to T cells. This mechanism could facilitate presentation of a disease-relevant myelin autoantigen that may be involved in MS induction and progression.

848

VCG modulate innate and adaptive immune responses to vaccine antigens

Eko, F.O.¹, Russell, R.¹, He, Q.¹, Black, C.M.², Igiertseme, J.U.^{1,2}

¹Morehouse School of Medicine, Atlanta, United States, ²Centers for Disease Control and Prevention, Atlanta, United States

Vaccination strategies utilizing subunit antigens often rely on the incorporation of effective adjuvants to modulate immune responses. *Vibrio cholerae* ghosts (VCGs; genetically derived empty *V. cholerae* cell envelopes) constitute an effective delivery system that promotes the induction of protective immunity in the absence of external adjuvants. However, the mechanism by which VCGs enhance immunity has not been elucidated. We hypothesized that the immunostimulatory ability of VCGs involves dendritic cell (DC) activation and function. Thus, we investigated the ability of DCs to internalize VCGs and the immunomodulatory effect of internalized VCGs on the induction of innate immune responses, T cell proliferation, antigen presentation and enhancement of protective immunity. The results showed that VCGs were efficiently internalized by DCs without affecting their viability and modulated DC-mediated immune responses. VCG-pulsed DCs showed increased secretion of proinflammatory cytokines and expression of co-stimulatory molecules associated with DC maturation in response to stimulation with UV-irradiated *Chlamydia muridarum* elementary bodies (UV-EBs). This interaction resulted in effective chlamydial antigen presentation and enhancement

of protective immunity. The study demonstrated that VCGs activate the maturation of DCs leading to enhancement of innate and adaptive immunity to a co-delivered antigen. Thus, VCGs could be utilized as vaccine adjuvants for enhancement of protective immunity against microbial infections.

849

March8 regulates thymic epithelial cell MHC II trafficking and CD4+ T cell development

Liu, H.¹, Gray, D.², Johnston, A.³, Villadangos, J.^{1,4}, Mintern, J.¹

¹University of Melbourne, Biochemistry and Molecular Biology, Melbourne, Australia, ²The Walter and Eliza Hall Institute of Medical Research, Molecular Genetics of Cancer Division and Immunology Division, Melbourne, Australia, ³Monash University, Drug Delivery, Disposition and Dynamics, Monash Institute of Pharmaceutical Sciences, Melbourne, Australia, ⁴University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia

The development and activation of T cells depends on recognition of peptide:MHC II complexes displayed on the surface of antigen presenting cells, whose expression levels are tightly controlled. In dendritic cells and B cells, the E3 ligase Membrane Associated RING-CH 1 (MARCH1) downregulates MHC II via ubiquitination. MHC II is stabilized, on the other hand, by the immunoglobulin CD83, which is proposed to sequester MARCH1. CD83-deficient mice exhibit lower surface MHC II on DCs, B cells and thymic epithelial cells (TECs), and strongly reduced CD4+ T cell numbers. Interestingly, TECs do not express MARCH1, and TECs from MARCH1^{-/-} mice have normal MHC II levels, suggesting MARCH1 is not involved in MHC II regulation in TECs.

We now have identified MARCH8 as the E3 ligase controlling MHC II surface expression in TECs, particular in cortical TEC and AIRE- medullary TEC. TECs from MARCH8^{-/-} mice exhibit ~4-fold increased MHC II surface levels compared to wild type, while MHC II levels on DCs and B cells remain unchanged. Importantly, by deleting MARCH8 in CD83-deficient mice we restored CD4+ T cell numbers to wild type levels, implying that MARCH8, and not MARCH1, ubiquitinates MHC II in TECs.

Our results reveal a novel role for MARCH8 controlling surface MHC II in TECs in a physiological setting, and suggest that limiting MARCH8 activity is critical for the development of CD4+ T cells. Furthermore, our findings suggest that hematopoietic and non-hematopoietic antigen presenting cells employ different MARCH family ligases to regulate MHC II trafficking.

850

Immuno-proteomic interrogation of antigen presentation during dengue infection reveals novel and HLA haplotype-specific MHC-I antigens

Swaminathan, K.¹, Lund, P.², Olsson, N.¹, Marceau, C.², Carette, J.², Davis, M.², Elias, J.¹

¹Stanford University, Chemical & Systems Biology, Stanford, United States, ²Stanford University, Microbiology & Immunology, Stanford, United States

Dengue (DEN) virus infection is a leading cause of hospitalization and death in the developing world and broadly effective vaccines or therapies remain elusive. Identifying infection-specific peptide antigens would open new avenues for developing T cell based interventions. Past efforts towards mapping viral antigens used computational predictions that only partially reflect actual antigens presented by the major histocompatibility complex (MHC). To identify DEN-specific antigens without relying on error prone predictions, we developed an immuno-proteomics approach for interrogating antigen presentation in DEN infected B-lymphocytes. This approach enabled three fundamental findings; First, we identified 86 viral MHC-I antigens (including 59 novel ones), and mapped them to presentation hotspots in the DEN genome. Second, we discovered post-translationally modified viral and host antigens and antigens derived from alternate reading frames. Predicting these antigens using computational methods alone would be infeasible. Third, we found antigens responsible for HLA-haplotype dependent immune responses against DEN infection: we genetically engineered B-lymphocytes to express HLA alleles associated with either strong or weak DEN-immune responses and identified corresponding allele specific antigens. Together these discoveries let us assay the immunogenic potentials of an unprecedented range of DEN-specific antigens. *Ex vivo* assays including ELISPOT and HLA tetramer staining supported our identification of immunogenic antigens in DEN-specific CD8⁺ T cells. These antigens have potential as both diagnostic tools to characterize DEN-specific T cell immunity, and serve as candidates for designing effective DEN vaccines.

851

Studies on the binding affinities of *Yersinia pseudotuberculosis*-derived mitogen to MHC class II and TCR V β molecules

Kato, H.¹, Nunomura, W.², Takakuwa, Y.³, Uchiyama, T.¹, Imanishi, K.⁴

¹Tokyo Women's Medical University School of Medicine,

Department of Microbiology and Immunology, Tokyo, Japan,

²Akita University, Graduate School of Engineering and Resource Science Research Center for Engineering Science, Akita, Japan,

³Tokyo Women's Medical University School of Medicine, Department of Biochemistry, Tokyo, Japan, ⁴Japan University of Health Sciences, School of Health Sciences, Saitama, Japan

Yersinia pseudotuberculosis-derived mitogen (YPM) is a virulence factor of *Y. pseudotuberculosis* and a unique superantigen (SAG), which is identified from Gram-negative bacteria and has a smaller MW than other SAGs such as staphylococcal enterotoxins (SEs). The molecular basis of action of SAGs involves the binding of SAG to MHC class II and TCR V β molecules. It is known that YPM activates murine V β 7⁺ and V β 8⁺ T cells and that the tertiary structure of YPM is available. But little is known about the binding affinities of YPM to MHC class II and TCR V β molecules. In this paper, we compared two SAGs - YPM and SEA - with respect to their superantigenic activities and their binding affinities to MHC class II and TCR V β molecules. Their superantigenic activities in mice revealed a remarkable difference between them. Superantigenic activity of YPM is significantly lower than that of SEA *in vitro* and *in vivo*.

The binding affinity between SEA and TCR V β 3 molecules is nearly equal to that between YPM and TCR V β 7, while the affinity between SEA and I-A^b is 15 times stronger than that between YPM and I-A^b. These data suggest that the superantigenic activity seems to be highly associated with the binding affinity between SAG and MHC class II molecules. The difference in superantigenic activities between SEA and YPM is from 100 to 1000 times, while the difference of affinity between SEA or YPM and I-A^b is only around ten times. We will discuss this difference.

852

NLRC5/CITA is a target for immune evasion of cancer

Kobayashi, K.

Texas A&M Health Science Center, Department of Microbial Pathogenesis and Immunology, College Station, United States

Cancer develops under immune surveillance, thus necessitating immune escape for successful growth. Loss of MHC class I provides a key immune evasion strategy in many cancers, although the mechanisms remain elusive. MHC-I transactivator (CITA)/NLRC5 has recently been identified as a master transcriptional co-activator of MHC-I genes. Here we show that the MHC-I transactivation pathway mediated by CITA/NLRC5 constitutes a major target for cancer immune evasion. *NLRC5* expression was highly correlated with the expression of MHC-I, cytotoxic T cell markers, and genes in the MHC-I pathway including *LMP2/LMP7*, *TAP1* and β 2-microglobulin in all 21 tumor types we examined. Epigenetic/genetic changes including promoter methylation and copy number loss were highly prevalent in the *NLRC5* gene, resulting in the impaired MHC-I pathway and evasion from CD8⁺ cytotoxic T cells. Strikingly, *NLRC5* expression was significantly associated with cancer patient survival. Thus, *NLRC5* constitutes a novel prognostic biomarker and potential therapeutic target of cancers.

853

Immune modulation of Langerhans cells by microparticles from human papillomavirus type 16 E7 expressing keratinocytes

Zhang, T.¹, Burn, C.², Ly, K.¹, Young, K.¹, Wilson, M.^{1,2}, Braithwaite, A.¹, Baird, M.¹, Hibma, M.¹

¹University of Otago, Pathology, Dunedin, New Zealand, ²University of Otago, Microbiology and Immunology, Dunedin, New Zealand

Persistent infection with human papillomavirus type 16 (HPV-16) is a major risk factor for cervical cancer in females. The HPV-16 E7 oncoprotein is expressed in infected host keratinocytes and may contribute to viral persistence by suppressing the host immune response. Microparticles (MP) are small membrane fragments released by cells, that have been implicated in modulation of local immunity. The aim of this study is to determine the immunomodulatory effects of MP from HPV16 E7 expressing cells on Langerhans cells (LC).

MP were purified from control and an HPV16 E7 oncoprotein-expressing mouse keratinocyte cell line. Langerhans cell-like cells (LCLC) were differentiated from murine bone marrow derived cells and co-cultured with HPV16 E7 or control MPs

for 48h. Co-stimulatory molecule expression and cytokine production of LCLC was evaluated by flow cytometry analysis, and LCLC priming of CD8 T cells for antigen-specific cytotoxicity was investigated using an in vitro cytotoxic T lymphocyte (CTL) killing assay. Compared to cells incubated with control MP, HPV16 E7 MP-treated LCLC expressed significantly less CD40 and IL-12 following LPS-stimulation. Moreover, there was significantly reduced CTL killing in HPV-16E7 MP treated group compared with control MP treated cells.

MP from HPV16 E7-expressing cells therefore impair activation, cytokine secretion and the ability of LCLCs to prime an effective CTL response. This supports viral regulation of the local immune environment by E7 and MP in favor of tolerance, potentially contributing to viral persistence.

854

Role of melanoma apoptotic vesicles in tumour immunity and coagulation

Muhsin-Sharafaldine, M.-R., Saunderson, S.C., Dunn, A.C., McLellan, A.D.

University of Otago, Microbiology & Immunology, Dunedin, New Zealand

During chemotherapy, tumour cells release apoptotic vesicles (ApoV) as part of programmed cell death pathways. Subcutaneous immunisation with 25 µg of ApoV prior to challenge (at day seven) protected mice from B16 tumour for up to 60 days. Furthermore, ApoV protection was significantly higher than that induced by extracellular vesicles released from living tumour cells (exosomes and microvesicles). We detected only trace amounts of the OVA antigen (< 1 µg/ dose) in OVA-pulsed ApoV and the immunisation of molar equivalents amounts of soluble OVA or latex bead bound did not induce a detectable cytotoxic immune response, demonstrating a role for ApoV as natural adjuvants for tumour antigens. Finally, in addition to their intrinsic immunogenicity, ApoV were found to be significantly more procoagulant than parental tumour cells, or other extracellular vesicles (exosomes and microvesicles). The procoagulant activity was dependent on tissue factor expression and phosphatidylserine exposure at the vesicle surface. Given that thrombotic events are the second highest cause of death in cancer patients, these results also highlight a potential role for ApoV in coagulopathies. Together, these results emphasise the complexities of interaction between the host and tumour vesicles, and suggest an important role for ApoV released during chemotherapy in immunity, as well as in cancer / chemotherapy-related thrombosis.

Non-canonical MHC-I peptide binding enables a novel mechanism of HIV-1 escape

Pymm, P.¹, Illing, P.¹, Ramarathinam, S.¹, Hughes, V.¹, McLaren, J.², Sullivan, L.³, Price, D.², Brooks, A.³, Purcell, A.¹, Rossjohn, J.^{1,2}, Vivian, J.¹

¹Monash University, Biochemistry, Melbourne, Australia,

²Cardiff University School of Medicine, Cardiff, United Kingdom,

³Melbourne University, Melbourne, Australia

MHC-I molecules play a crucial role in adaptive and innate immunity by binding endogenous peptides from the cell and presenting them to CD8+ T-cells and natural killer (NK) cells for immune surveillance. In MHC-I the peptide-binding groove is closed at both ends, with the presented peptides being tethered in the groove at their N and C- termini. MHC-1 presented peptides extending C-terminally beyond the binding groove have occasionally been reported, although the extent to which other modes of peptide presentation occur is unknown. Analysis of the peptides eluted from HLA-B*57:01 revealed that 20% of the peptide repertoire formed N-terminally extended sets, in which multiple peptides are eluted that contain an identical "minimal motif" of at least nine amino acid residues. These nested sets shared a common motif at P2-P1. Crystal structures of HLA-B*57:01 presenting N-terminally extended peptides, including the well-characterised immunodominant HIV-1 epitope TSTLQEQIGW (TW10), showed that the N-terminus protruded out from the peptide-binding groove in a conserved manner. Notably, the common escape mutant TSNLQEQIGW bound HLA-B*57:01 in the canonical fashion without extension from the binding groove, therefore giving dramatically different peptide presentation compared with the wild-type epitope. Accordingly, this HIV-1 escape mutant causes a register shift of the TW10 epitope to enable immune evasion from T-cells. However, this shifted register also impacted on recognition by the inhibitory KIR3DL1 receptors expressed on NK cells. Collectively we define a previously uncharacterised feature of the HLA-I immunopeptidome with important implications for viral escape.

The flanking region of cedar pollen peptide in complex with HLA-DP5 facilitates T-cell activation

Kusano, S.¹, Ueda, S.², Hamana, H.³, Kishi, H.³, Ohsawa, N.⁴, Wakiyama, M.⁴, Muraguchi, A.³, Yoshikai, Y.², Yamada, H.², Yamamoto, K.², Kukimoto-Niino, M.⁴, Nishimura, Y.⁵, Shirouzu, M.⁴, Sasazuki, T.², Yokoyama, S.¹

¹RIKEN Structural Biology Laboratory, Yokohama, Japan, ²Kyushu University, Fukuoka, Japan, ³University of Toyama, Toyama, Japan,

⁴RIKEN Center for Life Science Technologies, Yokohama, Japan,

⁵Kumamoto University, Kumamoto, Japan

Cryptomeria japonica (Cry j, Japanese cedar) 1, one of the major cedar pollen allergens, causes cedar pollinosis as a type I allergy. Our previous analysis of the association between cedar pollinosis and HLA class II alleles revealed that the frequency of HLA-DP5 is significantly higher in the pollinosis patients, and we identified an immunodominant peptide derived from Cry j 1 that induces Th2 restricted by HLA-DP5. Subsequently, we reported the crystal structure of HLA-DP5 (DPA1*02:02 and DPB1*05:01) in complex with a nine-residue antigenic peptide from Cry j 1 [1]. The 9 amino acid residues were accommodated by the peptide-binding groove, and thus the mechanism of the specific receptor antigen binding was established.

In this study, we identified the unique sequence located on the flanking region (FR) of the antigenic peptide associated with HLA-DP5. Based on this information, mutational analyses (point mutants and deletion mutants) for the FR of the Cry j 1

peptide (pCry j 1) were performed, using B cell-lines derived from the peripheral blood of pollinosis patients and TG40 cells expressing T-cell receptor restricted by the HLA-DP5-pCry j 1(FR) complex. Intriguingly, strong T-cell activation involving IL-2 production was observed when the 'distal' FR was included in the peptide. Therefore, the distal FR is responsible for the immune response. To elucidate the molecular mechanisms underlying this unconventional mode of the immune response, we solved the crystal structure of HLA-DP5 in complex with a pCry j 1 including the 'distal' FR.

The spatial arrangement and mobility of molecules in the immunological synapse participate in regulation of the early immune response

Lin, W.^{1,2}, Suo, Y.³, Deng, Y.², Fan, Z.³, Qin, L.¹, Jiang, G.¹, Wei, X.³, Chu, Y.²

¹Shandong Academy of Medical Sciences, Jinan, China, ²Fudan University, Shanghai Medical College, Biotherapy Research Center of Fudan University, Shanghai, China, ³Shanghai Jiao Tong University, Med-X Research Institute and School of Biomedical Engineering, Shanghai, China

Immune regulation is the ability of the immune system to control and regulate its own responses. It plays an important role in properly balanced immune responses and this role is thought to be performed mostly by regulatory cells, inhibitory cytokines or inhibitory molecules. Are there any other factors involved in the regulation of the immune response? By using live-cell imaging, we found the localization and mobility of molecules in the immunological synapse (IS) between CD4⁺ T cells and Dendritic cells (DCs) participated in the regulation of early immune response:

(1) Cytotoxic T-lymphocyte antigen-4 (CTLA-4) in the IS promoted a suppressive synapse formation, which correlated with the low level of calcium releasing in T cell and the loss of the localization of TCR signaling molecules in the IS.

(2) The accumulation of the filamentous actin (F-actin) cytoskeleton in the IS regulated the calcium releasing in T cells by controlling the localization of the TCR signaling molecules and the calcium microdomains, such as ORAI1, PMCA and mitochondrion. Lack of adequate F-actin in the IS resulted in ineffective T-cell activation.

(3) The mobility of ICAM-1 in the IS formation participated in regulation of the calcium releasing in T cell. Loss of exclusion of ICAM-1 from the central of IS, could not induce the calcium releasing in T cell. Overall, the mobility and the localization of the molecules in the synapse formation participate in the regulation of early immune response. IS may play a regulatory role in balance of the early T-cell activation.

858

TCR-HLA interactions implicate vimentin as a candidate autoantigen in pulmonary sarcoidosis

Kaiser, Y.¹, Dubnovitsky, A.², Sandalova, T.², Eklund, A.¹, Achour, A.², Grunewald, J.¹

¹Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden, ²Science for Life Laboratory, Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden

Sarcoidosis is a granulomatous disorder of unknown aetiology, characterised by accumulations of activated CD4⁺ T cells in the lungs. HLA variant DRB1*03 is closely associated with acute onset, distinct clinical features, rapid disease resolution and a good prognosis. In bronchoalveolar lavage fluid (BALF), but not blood, of HLA-DRB1*03⁺ patients, we identified increased frequencies of differentiated CD4⁺ T cells expressing T cell receptor (TCR) V genes Va2.3 and Vβ22. Sequencing of the TCR chain CDR3 region revealed a high degree of clonality, indicating expansion following antigen recognition. Molecular modelling of this particular HLA-TCR complex showed an ideal fit of a peptide derived from cytoskeletal protein vimentin into the peptide-binding cleft, implicating vimentin as a candidate autoantigen. Consequently, the aim of this project was to functionally characterise the antigen specificity of Va2.3⁺Vβ22⁺ T cells and the immunogenic potential of vimentin. We here show that anti-vimentin IgG and IgA antibodies can be detected in serum and BALF of sarcoidosis patients. Competition assays showed capability of vimentin-derived peptides to replace high-affinity HLA-DRB1*03 binder myoglobin from the peptide-binding cleft. Moreover, peptide N- and C-terminal ends had significant influence on competition efficiency, providing a potential target amino acid sequence. BLAST analysis found no similarity between vimentin candidate peptides and known microbial proteins. Ongoing stimulation tests strive to characterise the Va2.3⁺Vβ22⁺ T cell response to candidate vimentin peptides in terms of proliferation and cytokine production, with the long-term objective of identifying the causative agent in sarcoidosis and improving diagnostic, prognostic and therapeutic strategies in a clinical setting.

Pathogenic Role of Anti-Voltage Gate Calcium Channel Antibodies in Mediating Beta Cells Stress in Type 1 Diabetes

Alshehri, A., Jackson, M.

Flinders University, Autoimmunity Research Laboratory, Department of Immunology, Adelaide, Australia

Type 1 diabetes (T1D) is an autoimmune disease caused by the loss of pancreatic beta cells, resulting in poor blood glucose regulation. Autonomic neuropathy is a common but poorly understood complication of T1D resulting in significant morbidity. We have previously described a functional autoantibody (Abs) in T1D directed against L type Voltage gated calcium channels (VGCC), which contributes to autonomic dysfunction of the gastrointestinal tract and bladder by increasing channel activity during target cell activation. The

presence in patients of these anti-VGCC Abs has recently been linked to immune responses against the Coxsackievirus B4, and anti-VGCC Abs have been shown to disrupt adherence, and promote apoptosis in cultured beta cells. In the current study, we have used an assay of reactive oxygen species production (ROS), as measured by DCFDA labeled, to demonstrate that anti-VGCC antibodies induce oxidative stress in beta cells, providing a potential pathogenic mechanism for Ab-mediated beta cell loss in T1D. The current assay of ROS generation confirmed the presence of pathogenic antibodies in patient samples which had previously been demonstrated to contain anti-VGCC Abs, suggesting that this assay may be a useful diagnostic tool for determining the presence of functional anti-VGCC Abs. We propose that increased VGCC activity resulting from the presence of pathogenic anti-VGCC Abs is a contributing factor in the beta cell dysfunction and loss associated with progression to insulin dependence in type 1 diabetes.

S1P₁ deletion differentially affects TH17 and regulatory T cells

Eken, A.¹, Duhon, R.², Singh, A.K.³, Fry, M.³, Buckner, J.H.², Kita, M.², Bettelli, E.², Oukka, M.³

¹Erciyes University, Medical Biology Department, Kayseri, Turkey,

²Benaroya Research Institute, Seattle, United States, ³Seattle Children's Research Institute, Seattle, United States

Sphingosine-1 phosphate receptor 1 (S1P₁) is a G-protein coupled receptor critical for the egress of T and B cells out of lymphoid organs. Although S1P₁ agonists (such as fingolimod) are currently used for the treatment of multiple sclerosis (MS) little is known how S1P₁ signaling regulates Th17 and T_{reg} cell homeostasis. To study the impact of S1P₁ signaling on Th17 and T_{reg} biology, we specifically deleted S1P₁ in Th17 and T_{reg} cells using *IL-17A^{Cre}* and *Foxp3^{Cre}* mice, respectively. Deletion of S1P₁ in Th17 cells conferred resistance to experimental autoimmune encephalomyelitis (EAE) characterized by reduced Th17 cell distribution across peripheral organs and diminished Th17 cell generation. On the other hand, permanent deletion of S1P₁ in T_{reg} cells resulted in autoimmunity and acute deletion rendered mice more susceptible to EAE. Importantly, our study revealed that S1P₁ not only regulated the egress of T_{reg} cells out of lymphoid organs and subsequent non-lymphoid tissue distribution but also their phenotypic diversity. Most of the T_{reg} cells found in S1P₁-deficient mice had an activated phenotype and were more prone to apoptosis, thus converted to effector T_{reg}. The comparison of T_{reg} cells obtained from MS patients treated with fingolimod to those treated with other oral drugs confirmed the switch of T_{reg} cells into effector memory phenotype. Our results provide novel insight into the functions of S1P₁ and potential impact of long term fingolimod use on Th17 and T_{reg} cell biology and general health in MS patients.

Apoptotic antigen-coupled splenocytes suppress autoimmune anti-myeloperoxidase glomerulonephritis in a tolerogenic manner

Godfrey, A.S.¹, Gan, P.-Y.¹, Kitching, A.R.^{1,2}, Holdsworth, S.R.^{1,2}

¹Centre for Inflammatory Diseases, Monash University, Department of Medicine, Clayton, Australia, ²Monash Health, Department of Nephrology, Clayton, Australia

Background: Glomerulonephritis, a major cause of end-stage renal failure, results from autoreactivity to the neutrophil derived enzyme myeloperoxidase (MPO). In most autoimmune conditions, treatment with apoptotic antigen-coupled splenocytes can induce peripheral T cell tolerance by facilitating host APCs to reprocess and present the Ag in a non-immunogenic manner. Recent discovery of immunodominant MPO peptides makes this approach relevant to anti-MPO glomerulonephritis.

Aim: To assess whether antigen-coupled ethylenecarbodiimide (ECDI)-fixed splenocytes (Ag-Sp) can induce tolerance to MPO and suppress anti-MPO glomerulonephritis.

Method: We compared disease between C57BL/6 (WT) mice receiving either MPO409-428-Sp or OVA323-339-Sp. A standard model of anti-MPO glomerulonephritis was used. Anti-MPO autoimmunity induced by MPO409-428 immunisations and glomerulonephritis triggered using low dose anti-glomerular basement membrane globulin.

Results: Glomerulonephritis and autoimmunity was less severe in mice treated with MPO409-428-Sp, prior to the induction of autoimmunity than in control mice (segmental necrosis 43±5 vs 19±1%), glomerular leukocytes (macrophages; 0.53 ± 0.08 vs 0.25 ± 0.02 cells per glomerular cross section [c/gcs]; CD4+ cells 0.47 ± 0.05 vs 0.24 ± 0.02c/gcs) Autoimmunity, assessed by MPO induced DTH was reduced in MPO409-428-Sp treated mice versus control (0.11 ± 0.02 vs 0.02 ± 0.01Δmm). Furthermore transfer of CD4+ cells from mice treated with MPO409-428-Sp to mice with established anti MPO autoimmunity significantly decreased induced glomerulonephritis (segmental necrosis 45.25 ± 4% vs 23.13 ± 3%) compared to controls receiving CD4+ cells from OVA323-339-Sp treated mice.

Conclusion: MPO409-428-Sp suppress anti-MPO glomerulonephritis by the induction of antigen specific tolerance mediated by Tregs and is relevant to human disease.

Isolating small extracellular vesicles from synovial fluid

Foers, A.^{1,2}, Cheng, L.³, Chatfield, S.^{1,2,4}, Scicluna, B.^{3,5}, Hill, A.³, Pang, K.^{1,6}, Wicks, J.^{1,2,4}

¹The Walter and Eliza Hall Institute of Medical Research, Inflammation Division, Parkville, Australia, ²Melbourne University, Department of Medical Biology, Parkville, Australia, ³La Trobe University, Department of Biochemistry and Genetics, Bundoora, Australia, ⁴Royal Melbourne Hospital, Department of Rheumatology, Melbourne, Australia, ⁵University of Melbourne, Department of Biochemistry & Molecular Biology, Parkville, Australia, ⁶Murdoch Childrens Research Institute, The Royal Children's Hospital, Parkville, Australia

Extracellular vesicles (EVs) are lipid bilayer enclosed vesicles that

are found in all body fluids. EVs contain a cargo consisting of proteins, RNAs and lipids; this cargo can have functional effects when EVs come into contact with recipient cells. In rheumatoid arthritis, the profile, number and functional effects of EVs in synovial fluid have been reported to change with disease. These changes are believed to not only contribute to disease, but may also serve as clinical biomarkers. However, the complexity of biological fluids presents challenges in the isolation of pure EV populations. This is especially true of synovial fluid, where standard ultracentrifugation-based methods co-isolate large amounts of particulate material including non-EV proteins and cause artifactual vesicle aggregation. These limitations are confounders in studying the content and function of EVs in synovial fluid, bringing into question the accuracy of published work where EVs have been purified using standard isolation procedures.

We have applied a size exclusion chromatography method to purify small EVs, including exosomes and small microvesicles from synovial fluid of arthritis patients. The EVs have been characterised by immunoblotting for standard exosomal markers (flotillin 1, transferrin receptor and heat shock protein 70) and dynamic light scattering. Our method separates small EVs from the bulk of non-EV proteins that are also pelleted by ultracentrifugation. The ability to isolate EVs from synovial fluid will be useful for future investigations to define the precise contents and role of synovial fluid EVs in rheumatoid arthritis.

863

The immunological effects of sitagliptin treatment in patients with psoriasis

Malara, A.^{1,2}, Lynch, M.³, Sweeney, C.^{1,2}, Awdeh, F.³, Kirby, B.³

¹University College Dublin, School of Medicine and Medical Science, Dublin, Ireland, ²St. Vincent's Hospital, Education and Research Centre, Dublin, Ireland, ³St. Vincent's Hospital, Department of Dermatology, Dublin, Ireland

Psoriasis is a chronic, immune-mediated skin disorder affecting approximately 2% of the population. The pathogenesis of psoriasis includes hyperproliferation and abnormal differentiation of keratinocytes and cutaneous inflammation. Pro-inflammatory cytokines such as TNF- α and IL-17 are central in the pathogenesis of psoriasis. Dipeptidyl peptidase-4 (DPP-4) is expressed on many cell types including keratinocytes and its activity is upregulated in psoriasis. DPP-4 is also expressed on T cells as CD26 and has been demonstrated to be crucial in the pathogenesis of autoimmune diseases. In this clinical study, we aimed to determine whether DPP-4 inhibition improves severity of psoriasis after 24 and 36 weeks of treatment in patients undergoing a course of narrowband ultraviolet-B phototherapy (NB-UVB). Patients were randomly allocated to be treated with both DPP-4 inhibitor sitagliptin and NB-UVB light therapy or with NB-UVB light therapy alone. Blood samples were collected at the baseline visit and after 24 and 36 weeks of treatment for analysis of cytokines in the serum. In addition, skin biopsies were taken to analyse expression pro-inflammatory cytokines. The preliminary results have shown that the serum level of pro-inflammatory cytokine IL-17A measured by ELISA decreased in patients treated with sitagliptin after 36 weeks (n=39). The

analysis of skin biopsies by quantitative PCR have demonstrated that the expression of IL-17 and TNF- α decreased after 24 weeks in patients treated with sitagliptin compared to patients undergoing NB-UVB therapy alone (n=11). These data show that DPP-4 inhibition has the capacity to modulate the expression of IL-17 and TNF- α in psoriasis.

864

Immunological studies on an Australian cohort of patients diagnosed with systemic lupus erythematosus

Margery-Muir, A.¹, Nelson, D.¹, Wetherall, J.¹, Bundell, C.², Groth, D.¹

¹Curtin University, Biomedical Sciences, Bentley, Australia, ²Sir Charles Gardner Hospital, QEII Medical Centre, Nedlands, Australia

Systemic lupus erythematosus (SLE) is an important autoimmune disease affecting mainly females and is associated with anti dsDNA autoantibodies, and is potentially associated with defective clearance of apoptotic cells. Blood samples were collected from 56 patients with confirmed diagnoses of SLE for whom cellular and serological parameters are being investigated and compared with age/sex matched controls.

We observed that the inflammatory cytokine IL17, which has been implicated in tissue damage associated with SLE, was synthesized by regulatory T cells (Tregs), Th17 cells and gamma delta ($\gamma\delta$) T cells. The synthesis of IL17 by $\gamma\delta$ T cells was significantly higher in patients than healthy controls (p< 0.005). However, the percentage of Th17 cells was higher in controls relative to patients (p< 0.05). Interestingly, in contrast to the controls, myeloid DC2 cells were more frequent than myeloid DC1 cells in SLE patients (p< 0.05). In this study the $\gamma\delta$ T cells produced more IL17, IL23 and TGF β than Tregs and Th17 cells from patients.

In summary, an expected increased frequency of Th17 cells was not observed in SLE patients relative to controls. Intracellular IL17 in patients was produced mostly by $\gamma\delta$ T cells. The clinical management and drug therapies of the SLE patients are currently under review and may explain the results obtained.

865

Rotavirus acceleration of type 1 diabetes depends on type I interferon signalling

Pane, J.^{1,2}, Fleming, F.¹, Graham, K.^{3,4}, Thomas, H.^{3,4}, Kay, T.^{3,4}, Coulson, B.¹

¹The University of Melbourne, Department of Microbiology at Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Skirball Institute of Biomolecular Medicine, NYU School of Medicine, Kimmel Center for Biology and Medicine, New York, United States, ³St Vincent's Institute, Fitzroy, Australia, ⁴The University of Melbourne, Department of Medicine at St Vincent's Hospital, Fitzroy, Australia

Background and aim: Rotavirus infection is associated with childhood progression to type 1 diabetes. Monkey rotavirus RRV acceleration of diabetes in NOD mice with pre-existing autoimmunity relates to regional lymph node (not pancreatic) infection and a Th1-specific immune response. RRV stimulation of plasmacytoid dendritic cells (pDCs) from NOD mice ex

vivo induces type I interferon (IFN) secretion and bystander lymphocyte activation, including islet-autoreactive T cells. We aimed to directly establish the dependence of RRV-induced diabetes acceleration on type I IFN signalling.

Methods: The requirement for type I IFN signalling was analysed in NOD.IFNAR1^{-/-} mice, which lack a functional type I IFN receptor. Rotavirus-infected adult female NOD, NOD.IFNAR1^{-/-} and C57BL/6 mice were studied. Rotavirus in lymph nodes and development of a Th1-specific antibody response were measured by ELISA, activation of DC and lymphocytes by flow cytometry, type I IFN-induced gene expression by quantitative PCR, and diabetes development by urinary and blood glucose monitoring.

Results: RRV infection of NOD mice induced pDC activation and strongly upregulated IFN-dependent gene expression, particularly within lymph nodes. Such pDC activation was absent following NOD mouse infection with porcine rotavirus, which does not modulate diabetes onset. RRV lymph node titres were slightly increased in NOD.IFNAR1^{-/-} mice over NOD mice. However, RRV-infected NOD.IFNAR1^{-/-} mice exhibited delayed pDC and lymphocyte activation, an absence of Th1 bias in RRV-specific antibody responses and unaltered diabetes onset.

Conclusion: Type I IFN signalling is required for the acceleration of type 1 diabetes onset by rotavirus infection in genetically-susceptible mice.

866

ΔdblGATA mice are resistant to experimental autoimmune encephalomyelitis

Ciric, B., Hwang, D.

Thomas Jefferson University, Neurology, Philadelphia, United States

GATA-binding factor 1 (GATA-1) is a transcription factor expressed in certain hematopoietic cells, governing their development and function. GATA-1 is expressed in myeloid cells but not in lymphoid cells, such as T cells. Since knockout of GATA-1 is embryonic lethal, mouse lines lacking individual enhancers to the GATA-1 gene have been generated. Lack of a particular enhancer selectively reduces, or precludes GATA-1 expression in some cell types, while in others its expression remains normal. We use mice lacking dblGATA enhancer (ΔdblGATA mice), which are devoid of eosinophils and have reduced numbers and function of basophils. No other defects in these mice have been described to date.

We found that ΔdblGATA mice are resistant to both direct and adoptive experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis. ΔdblGATA mice develop weaker myelin-specific Th responses upon immunization for EAE induction, indicating a defect in priming immune responses. The resistance of ΔdblGATA mice to adoptive EAE indicates a deficiency in effector mechanisms of CNS inflammation. We have ruled out lack of eosinophils as the reason for EAE resistance of ΔdblGATA mice by demonstrating that another mouse strain (PHIL), which also lacks eosinophils, develops normal EAE. These findings show that ΔdblGATA mice have defects in both the priming and effector phases of disease. Additionally, immunized ΔdblGATA mice had fewer inflammatory monocytes and myeloid dendritic cells in blood, draining lymph nodes

and the CNS. Our findings thus far suggest that an unknown defect in monocytes/dendritic cells causes resistance to EAE in ΔdblGATA mice.

867

NF-M is not critical to the development of MOG induced EAE

Lawrence, L., Blanchfield, L., Evavold, B.

Emory University, Microbiology and Immunology, Atlanta, United States

The 2D2 T cell receptor was reported to be cross-reactive to two neuropeptides, myelin oligodendrocyte glycoprotein epitope 35-55 (MOG35-55) and neurofilament medium polypeptide epitope 15-35 (NFM15-35). This information led us to consider cross-reactivity as a cause of demyelinating autoimmune disease. To tease out the functional relevance of NF-M for demyelinating disease, we investigated experimental autoimmune encephalomyelitis (EAE) in C57BL/6 mice. EAE could not be induced by the conventional induction protocol of NF-M emulsified in CFA and pertussis toxin. In addition, we made use of NF-M knockout (NFM-KO) mice to explore the functional contribution of the protein to disease. Before we began our experiments, we backcrossed the NF-M knockout onto a C57BL/6 background using a speed congenic process to identify individual mice from each litter with the highest amount of C57BL/6 genetic information. NFM-KO mice developed a severe EAE that was comparable to wildtype C57BL/6 mice after being challenged with MOG35-55. In conclusion, the presence of NF-M has a minimal contribution to the severity of MOG induced EAE.

868

Exhaled methylacetate levels differ according to dysimmune diseases and existence of severe liver steatosis

Donatini, B., Le Blaye, I.

Medicine Information Formation, Research, Cormontreuil, France

Methylacetate (MA) is a volatile organic compound synthesized by the gut microbiota. It can be measured in breath and is decreased in Crohn's disease (CD).¹ We measured MA levels in other dysimmune diseases.

Methods: All patients with CD, hemorrhagic recto-colitis (HRC), multiple sclerosis (MS), Hashimoto thyroiditis (HT), rheumatoid arthritis (RA) or ankylosing spondylitis or psoriatic polyarthritis (AS/PP) were prospectively enrolled into a 24-months cohort study. Non Alcoholic SteatoHepatitis (NASH) was identified to avoid a bias because of the liver metabolism of MA. Breath test was performed with MX6 (Gazdetect® France). Comparisons of percentages were performed with a Student's t-test.

Results: 247 patients with dysimmune diseases were enrolled. All patients with NASH (38 cases) exhaled low levels of MA (< 2.6 ppm).

Patients with CD or HRC never presented with NASH. Patients with MA < 2.6 ppm and MS, RA, AS/PP or HT have a high incidence of NASH: 70.6%, 37.5%, 44.4% and 42.3% respectively.

The percentage of patients with MA levels ≥ 2.6 ppm differs according to diseases: CD (29.1% out of 86 cases), HRC (93% out of 28), MS (50% out of 34), RA (55.6% out of 18), AS/PP (34.1% out of 41), HT (35% out of 40). The difference was significant between CD and MS or RA or HRC ($p < 0.01$).

Conclusions: MA measure is interesting in the diagnosis of CD or NASH. Differences of MA levels between CD and MS or RA or HRC suggest differences in gut microbiota.

1. Donatini B, Le Blaye I. *J Biosciences Med.* 2015

869

In patients with a medical history of allergy, steatohepatitis is more frequent in Hashimoto thyroiditis (HT) than in Crohn's disease (CD) or multiple sclerosis (MS)

Donatini, B., Le Blaye, I.

Medicine Information Formation, Research, Cormontreuil, France

We compared the percentages of medical history of allergy in patients with dysimmune diseases. We investigated whether Nonalcoholic steatohepatitis (NASH) is more frequent in some subgroups which may suggest differences in liver metabolism and perhaps a role of gut microbiota.

Methods: All patients with CD, hemorrhagic recto-colitis (HRC), multiple sclerosis (MS), Hashimoto thyroiditis (HT), rheumatoid arthritis (RA) or ankylosing spondylitis or psoriatic polyarthritis (AS/PP) were prospectively enrolled into a 24-months cohort study before any treatment with immunosuppressive agents. NASH was identified with blood tests and liver elastography. Comparisons of percentages were performed with a Student's t-test.

Results: 247 patients with dysimmune diseases were enrolled. 38 NASH were detected. Anamnesis retraces allergic diagnoses in 74 patients.

The percentage of patients with a history of allergy differs according to diseases: CD (9.3% out of 86 cases), HRC (10.7% out of 28), MS (5.9% out of 34), RA (50.0% out of 18), AS/PP (65.9% out of 41), HT (62.5% out of 40). The difference was significant between CD or MS and RA, AS/PP or HT ($p < 0.01$). NASH was detected in 16 out of the 74 patients with a history of allergy (21.6%) versus only 22 out of 171 patients without allergy (15.8%): $p < 0.01$. NASH is never associated with CD. NASH exists in 26% of patients with HT plus a history of allergy.

Conclusions: Allergy rarely precedes CD or MS. It however frequently precedes RA, AS/PP or HT.

NASH is more frequent in patients with HT and a history of allergy.

870

Mannose receptor (MR) have a protective role in mannan induced psoriasis (MIP)

Hagert, C.¹, Sareila, O.¹, Jalkanen, S.¹, Holmdahl, R.^{1,2}

¹University of Turku, Turku, Finland, ²Karolinska Institutet, Stockholm, Sweden

Psoriasis and psoriasis arthritis are both poorly understood, but common diseases in human. They are induced by unknown

environmental factors and affects both skin and joints. Mannan induced psoriasis (MIP) is a novel mice model for psoriasis arthritis (induced by a single injection of mannan into mice) causing arthritic symptoms such as swelling and redness of the paws and the characteristic lesions of psoriasis. The model is dependent upon macrophage produced reactive oxygen species (ROS) and $\gamma\delta T$ cells. However, the receptor, important for the recognition and initiation of the disease, is unknown. This study focused on investigating one of the receptors binding mannan; the mannose receptor (MR). MR is a C-type lectin present on myeloid cells and lymphatics. To investigate its importance for MIP we utilized MR knock-out mice, showing that the lack of MR leads to more severe arthritis compared to wild type. We further concluded that a mutation leading to ROS deficiency will, as previously shown, exacerbate the disease. The importance of MR as a protecting pathway is diminishing if the mouse lacks ROS; either the protective pathway activated by MR is dependent upon ROS or the severity of MIP in a ROS deficient organism is too severe and the protective effect is therefore lost. In conclusion, these results indicate that MR scavenges mannan and thereby preventing it from binding to other receptors in the mouse, for example mannan binding lectin, hence protecting. Further studies are needed to conclude which receptor is important for the initiation of MIP.

Effect of gene delivery plasmid encoding Interleukin-19 on rat experimental autoimmune myocarditis

He, C.¹, Yan, W.¹, Jun, Z.²

¹Xiamen Cardiovascular Hospital, Medical College of Xiamen University, Xiamen, China, ²Medical College of Xiamen University, Xiamen, China

Objectives: To evaluate the effect of gene delivery plasmid encoding Interleukin-19 on rat Experimental Autoimmune Myocarditis (EAM) and possible mechanism.

Background: IL-19 is a novel, recently identified member of the IL-10 family, however, little is known about the exact biological role in immunological regulation.

Methods: The rat was immunized on day 0 and were injected with plasmid encoding IL-19 on day 6, all the rats were sacrificed on day 17. The effect of IL-19 gene delivery was evaluated by measuring of heart weight/body weight and myocarditis area, The relative gene expression levels of heart failure markers atrial natriuretic peptide (ANP) and brain natriuretic peptide (BNP) were detected by real-time RT-PCR. Cardiac Function were performed by Echocardiography. Furthermore, we examined the effect of serum containing IL-19 on the expression of immune-relevant genes in IL-1-stimulated Spleen cells cultured from EAM rats.

Results: IL-19 gene therapy was effective in controlling EAM as monitored by decreased ratio of heart weight / body weight and the myocarditis area, The level of ANP and BNP were significantly lower and cardiac function parameters improved in IL-19 treatment group than those in control group. The serum containing IL-19 significantly decreased the expression of IL-18, IL-1 β , IL-12p35, IFN- γ and upregulated IL-4 and IL-10 expression in IL-1-stimulated spleen cells cultured from EAM rats.

Conclusion: IL-19 effectively prevented progression of EAM by blocking related inflammatory immune genes expression. This might be a possible mechanism of the amelioration of EAM by IL-19 gene therapy.

872

Serum IL-18 as biomarker in predicting long-term renal outcome in pediatric-onset systemic lupus erythematosus

Wu, C.-Y.¹, Yang, H.-Y.², Yao, T.-C.¹, Liu, S.-H.³, Huang, J.-L.¹

¹Chang-Guang Memorial Hospital, Pediatrics, Taoyuan, Taiwan, Republic of China, ²Chang-Guang Memorial Hospital, Nephrology, Taoyuan, Taiwan, Republic of China, ³Chang-Guang Memorial Hospital, Family Medicine, Taoyuan, Taiwan, Republic of China

Introduction: An urge of biomarker identification is needed to better monitor lupus nephritis (LN) disease activity and predict patient's long-term outcome. With the pro-inflammatory effect and its association with inflammasomes, the significance of interleukin-18 (IL-18) among pediatric onset systemic lupus erythematosus (pSLE) patient, especially, its importance in predicting long-term renal outcome was investigated.

Methods: In a pSLE cohort of 96 patients with an average follow up period of 10.39 ± 3.31 years, data were collected at time of disease onset and 6 months after treatment. Through Cox regression analysis, the parameters at baseline and post treatment were carefully analyzed.

Results: Average age of all cases was 12.74 ± 3.01 years old and 65 of them suffered from LN. Nine subjects (9.38%) progressed to ESRD and 2 cases (2.08%) died during follow up. Serum IL-18 level 24 weeks post treatment was found to be the most hostile factor associating poor clinical outcome despite patient's initial renal status. In addition, the presentation of serum IL-18 in its correlation with SLE global disease activity as well as the presence and severity of LN were all significant ($p < 0.001$, $p = 0.03$ and $p = 0.02$). The histological classification of LN, however, was not associated with the level of IL-18 among the pSLE patients.

Conclusions: The role of serum IL-18 as biomarker in pSLE patient representing global disease activity and status of renal flares was assured. Additionally, we've identified IL-18 at 24 weeks post treatment a novel marker for long-term outcome prediction.

Antinuclear antibodies: quantitative prediction of Lupus-related and other morbidity and mortality

Bundell, C.^{1,2}, Preen, D.³, Lucas, M.^{1,2}, Hollingsworth, P.^{1,2}

¹PathWest Laboratory Medicine, Western Australia, Clinical Immunology, Nedlands, Australia, ²The University of Western Australia, School of Pathology and Laboratory Medicine, Crawley, Australia, ³The University of Western Australia, School of Population Health, Crawley, Australia

Background: The anti-nuclear antibody (ANA) indirect immunofluorescence assay is a screening test useful in the diagnosis and classification of SLE and other connective tissue/

rheumatic diseases. ANA results can be expressed in IU/lm, but are most commonly reported as titres and these are not standardised.

Aim: To determine the ability of ANA, precisely quantified in IU/ml, to predict inpatient morbidity and mortality in a Western Australian (WA) clinical cohort.

Method: Hospital morbidity and mortality data collected through the WA Department of Health were linked to PathWest Laboratory ANA data for individuals resident in WA who had their first ANA reported in the period 2000 - 2010 ($n = 58,700$). Multivariate logistic regression analysis was used to examine the relationship between ANA and morbidity and mortality adjusting for gender, Indigenous background, age at time of first ANA test and country of birth.

Results and conclusion: Hospitalisation for a diagnosis of systemic connective tissue disease (SLE, scleroderma, dermatomyositis and Sjogren's syndrome) was associated with an ANA level of $7 < 10$ IU/ml (OR=1.64; 95%CI 1.38-1.94) increasing to OR=21.91 (95% CI 18.07-26.57) for an ANA level of >30 IU/ml. Other conditions significantly associated with ANA included pulmonary embolism, pulmonary heart disease, chronic hepatitis, myasthenia gravis, glomerular disease and cancer of the oesophagus and of the lymph nodes. An ANA level of >30 IU/ml also predicted death (OR=1.69; 95% CI 1.35-2.11). ANA is quantitatively predictive of lupus and related connective tissue diseases and other morbidity and mortality.

874

Neonatal expression of IGRP is sufficient to induce lifelong protection from autoreactive IGRP-specific T cells in NOD mice

Selck, C., Jhala, G., Chee, J., Thomas, H.E., Kay, T.W.H., Krishnamurthy, B.

St Vincent's Institute, Immunology and Diabetes Unit, Melbourne, Australia

Autoimmune disorders result from the failure of immune tolerance mechanisms. Antigen-specific therapy constitutes an attractive approach to re-establish a tolerant state, but has so far not been successful in clinical settings. One of the major hurdles is the timing of intervention since, at the time of disease diagnosis, naive T cells have differentiated into antigen-experienced memory cells. Notably, we and others have shown that inducing tolerance to self-antigens during the neonatal period has long-lasting benefit suggesting that the initial wave of T cell differentiation may include self-reactive cells likely to cause future autoimmunity. To address the fate of a dominant CD8+ T cell population in this system, we generated non-obese diabetic (NOD) mice with tetracycline-controlled IGRP (islet-specific-glucose 6 phosphatase catalytic subunit related protein) expression in antigen presenting cells allowing induction of tolerance to IGRP in a temporally regulated manner. IGRP expression did not affect the immune infiltration of islets of Langerhans. However, using the tetramer enrichment assay, we detected a 100-fold reduction of IGRP₂₀₆₋₂₁₄-specific CD8+ T cells in mice where IGRP was expressed throughout the whole life compared to control NOD mice. Importantly, the same effect was observed in animals where tolerance to IGRP was induced only until weaning. Thus, our findings indicate that autoreactive T cells develop predominantly during the fetal and neonatal

period suggesting that antigen-based therapeutic approaches have lasting benefits when applied for a short period in early life.

875

Microbial fermentation product butyrate ameliorates autoimmune arthritis

Takahashi, D.¹, Yoshida-Hoshina, N.¹, Takahashi, Y.¹, Nakamura, M.¹, Tanabe, H.¹, Lockett, T.², Clarke, J.M.², Topping, D.L.², Suzuki, A.³, Morita, T.⁴, Komatsu, N.⁵, Takayanagi, H.⁵, Hase, K.¹

¹Keio University Faculty of Pharmacy, Minato-ku, Japan,

²Commonwealth Scientific and Industrial Research Organisation (CSIRO) Food and Nutritional, Preventative Health National Research Flagship, Adelaide, Australia, ³RIKEN Center for Genomic Medicine, Yokohama, Japan, ⁴Shizuoka University, Faculty of Agriculture, Shizuoka, Japan, ⁵University of Tokyo, Graduate School of Medicine and Faculty of Medicine, Bunkyo-ku, Japan

Gut microbiota and its metabolites have been implicated in autoimmune diseases, including rheumatoid arthritis (RA) and inflammatory bowel disease. We have been reported that a large bowel microbial fermentation product, butyrate, induces the differentiation of Foxp3-expressing regulatory T (Treg) cells in the colon, and ameliorate the development of mouse models of autoimmune colitis. Both systemic and organ-specific autoimmune diseases often result from an imbalance between Treg cells and pro-inflammatory IL-17-producing CD4⁺ T (Th17) cells. Treg cell functions to restrain excessive T-cell responses, while Th17 cell is a key player in the pathogenesis of autoimmune diseases. The aim of this study was to investigate the impact of butyrate on the development of collagen-induced arthritis (CIA) in mice, a model that shares many hallmarks with human RA. Here we show that mice fed butyrylated high amylose maize starch (HAMSB), which delivers butyrate to the colon in an effective manner, markedly suppressed the clinical and histologic signs in CIA. Treg cells were increased and Th17 cells were decreased in the draining lymph nodes of CIA mice fed HAMSB compared with CIA mice fed control diet. HAMSB also suppressed the production of collagen II-specific IgG. Adoptive transfer of Treg cells isolated from CIA mice fed HAMSB into CIA mice fed control diet followed by a booster immunisation prevented progression of the diseases. These data suggest that microbial metabolite butyrate play a key role in RA prevention and support that a potential protective role of butyrate in systemic autoimmune diseases.

876

Increased serum IL-21 in systemic lupus erythematosus patients with vitamin D deficiency

Hirigoyen, D.¹, Alvarez, A.¹, Montalva, R.¹, Naves, R.², Iruetagoien, M.¹, Burgos, P.¹

¹Pontificia Universidad Catolica de Chile, Departamento de Reumatología, Facultad de Medicina., Santiago, Chile,

²Universidad de Chile, Programa de Inmunología, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile

Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by aberrant B cell signaling. Vitamin D (VD)

deficiency is highly prevalent in SLE patients and has been associated with clinical activity, but the mechanisms implied are not fully understood. Interleukin 21(IL-21) signaling pathway is involved in B cell differentiation into plasma cells and antibody production and has been suggested to play a role in SLE. Consistently, deficiency of IL-21 receptor (IL-21R) improves clinical symptoms in a SLE mouse model. In this study, we assessed VD status, serum IL-21 levels and IL-21R expression in B cells obtained from Chilean SLE patients. Serum VD and IL-21 levels and IL-21R expression were determined in 19 SLE patients and 6 healthy controls by tandem mass spectrometry, ELISA and flow cytometry, respectively. Average vitamin D levels in SLE patients were 19.7±6.85 ng/ml and 13.58±4.74 ng/ml in controls. The prevalence of hypovitaminosis D (serum VD levels below 30 ng/ml) is 89.5% in SLE patients. We found significantly higher levels of IL-21 in serum of SLE patients (226.3±54.11 pg/ml) compared to controls with hypovitaminosis D (37.1±22.53 pg/ml)

(Mann Whitney, $p < 0.005$). We observed no significant differences in IL-21R expression in B cells from patients when compared to controls (MFI 25,65±3.812 vs. 29.52±5.653).

Chilean SLE patients analyzed present a high hypovitaminosis D prevalence and increased IL-21 levels compared to controls with hypovitaminosis D. Further studies are required to establish the role of vitamin D in IL-21 levels and SLE.

Supported by Fondecyt 1141211(PB) and 1140049(RN), and Conicyt Doctoral fellowship 21150777(DH).

Increased salt exposure affects both lymphoid and myeloid effector functions, influencing antibody-induced arthritis but not autoimmunity

Vaartjes, D.¹, Raposo, B.¹, Nandakumar, K.S.¹, Holmdahl, R.^{1,2}

¹Karolinska Institutet, Section for Medical Inflammation Research, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden, ²Southern Medical University, Section for Medical Inflammation Research, Guangzhou, China

Introduction: Salt is required to maintain the cell's homeostasis, helping to establish a membrane potential crucial for numerous cellular processes. In humans, high-salt intake is associated with elevated blood pressure, cardiovascular disease and insulin resistance. Recently, salt has been linked to the development of autoimmunity in mice. In the present study, we assessed how salt affects the activation and effector functions of murine lymphoid and myeloid cells in vitro, and how these effects can be translated in vivo using different models of inflammation.

Results: We show that a moderate increase in NaCl exposure significantly increases T cell proliferation while limiting the secretion of IFN- γ . After LPS stimulation of peritoneal macrophages, salt exposure reduced the production of pro-inflammatory cytokines as well as nitric oxide. Moreover, increased salt intake reduced the susceptibility to collagen antibody-induced arthritis, an acute arthritis model highly dependent on macrophage activation and inflammatory cell proliferation. However, a moderate increase of salt intake did not affect the development of the complex T cell dependent models of arthritis and multiple sclerosis.

Conclusion: Exposure of immune cells to moderate salt concentrations *in vitro* affects their proliferation capacity as well as their cytokine secretion profile. Even though salt had a suppressive effect on CAIA, its effects could not directly be translated into the T cell dependent models of autoimmunity CIA and EAE.

878

Collagen specific CD4+ T-cells restricted by HLA-DRB1*0101 are selected into the repertoire and expand in disease in mice and patients with inflammatory arthritis

Jansen, D.T.S.L.¹, Nel, H.J.¹, Ramnoruth, N.¹, Tesiram, J.¹, Nagl, L.¹, Benham, H.¹, Scally, S.², Reed, H.H.², Rossjohn, J.², Thomas, R.¹

¹University of Queensland Diamantina Institute, Woolloongabba, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia

The strong association between rheumatoid arthritis (RA) and HLA-DRB1, including HLA-DRB1*0101 and HLA-DRB1*0401 implicates autoreactive CD4+ T-cells in RA pathogenesis. Collagen-II is an arthritogenic autoantigen. Anti-collagen autoantibodies are present in 50% of early RA patients and bovine or human collagen-II is immunogenic in HLA-DRB1*0101-transgenic mice, with collagen₂₅₉₋₂₇₃ the dominant epitope. We characterized collagen₂₅₉₋₂₇₃-specific CD4+ T-cells using HLA-DRB1*0401- and HLA-DRB1*0101-collagen₂₅₉₋₂₇₃ tetramers. Collagen-specific CD4+ T-cells, binding tetramer with low affinity, were present at a frequency of 0.06% in blood, 0.11% in popliteal lymph node and 0.27% in spleen of naïve HLA-DRB1*0101-transgenic IA/IE^{-/-}B6xB10.BR mice. After bovine collagen immunization and onset of collagen-induced arthritis, the frequency of collagen-specific CD4+ T-cells almost doubled at each site, with expansion particularly among cells of higher binding affinity. High-affinity tetramer+ T-cells expanded markedly after *in vitro* stimulation of splenocytes from naïve or arthritic mice for 7 days with collagen₂₅₉₋₂₇₃. Expanded antigen-specific cells were CD4^{hi}CD44^{hi}CD62L^{lo} effector-memory T-cells. In peripheral blood of HLA-DRB1*0101+ or *0401+ RA patients, the frequency of collagen₂₅₉₋₂₇₃-specific CD4+ T-cells was 4-89/million PBMC. Tetramer+ cells were mostly CD45RO⁺CD69⁺CCR7^{+/+} and their frequency correlated with disease activity. These data indicate that collagen-specific CD4+ T-cells are selected into the repertoire of HLA-DRB1*0101 mice and are poorly controlled by peripheral tolerance mechanisms. Antigen-specific effector memory CD4+ T-cells expand with the development of autoimmune arthritis in mice and RA patients, associated with clinical inflammation. The collagen-specific CD4+ T-cells detected in RA patient blood at low frequency resemble CD4+ tissue-resident memory cells, likely trafficking between inflamed tissues.

IRF7-dependent IFN- β production in response to RANKL is crucial for bone metabolism in CAIA arthritis model

Zhang, D.¹, Yu, Q.-W.¹, Chen, X.-H.², Chen, N.-N.^{1,2}

¹Shanghai Institute of Immunology, Shanghai Jiaotong University School of Medicine, Shanghai, China, ²Ruijin Hospital, Shanghai, China

IFN- β has significant immunomodulatory properties in RA, and IFN gene transcription is activated by IFN-regulatory factors (IRF) in response to innate sensor recognition, it may be a reactive attempt to inhibit inflammation and plays a very significant role in bone balance via RANKL-RANK pathway, which is the essential signal for osteoclasts differentiation. We established CAIA model on IRF7^{-/-} mice which results in exacerbated arthritis and decreased IFN- β expression in the gene and protein level. IFN- β treatment of IRF7^{-/-} CAIA mice resulted in decreased arthritis to similar to WT CAIA mice, including attenuated bone damage and TNF- α protein and gene level. The IRF7^{-/-} mice showed no difference in T cell numbers compared with control mice, while IFN- β led to significant reduction in CD4⁺Foxp3⁺Treg cells infiltration in IRF7^{-/-} mice. There have a significant decrease in the number of osteoclasts in IRF7^{-/-} mice compared with WT *in vitro*. And IFN- β had the strongest inhibitory effect on day 2 in osteoclastogenesis. IFN- β treatment of FLS with leads to decreased MMP-1, IKK ϵ and c-FOS, while increased production of IRF-7, but has limited direct IRF3, RANKL, NF- κ B regulating function. The partly increased expression of IFN- β in RA, and low expression of IFN- β exacerbated arthritis while replacement treatment with IFN- β decreased arthritis severity in CAIA mice suggests IFN- β might be useful for some RA patients where endogenous IFN- β expression is low. IFN- β plays an immunomodulatory mechanism that could inhibit synovial inflammation and alleviate bone damage.

Atherosclerotic lesion regression is impaired in the K/BxN model of rheumatoid arthritis, independent of circulating cholesterol levels

Dragoljevic, D.^{1,2}, Whillas, A.^{1,2}, Kraakman, M.^{1,3}, Ngo, D.², Shihata, W.^{1,2}, van Doornum, S.⁴, Wicks, I.^{4,5}, Febbraio, M.^{1,6}, Chin-Dusting, J.^{1,2}, Murphy, A.J.^{1,2}

¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Monash University, Melbourne, Australia, ³Columbia University, New York, United States, ⁴Royal Melbourne Hospital, Melbourne, Australia, ⁵Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia, ⁶Garvan Institute of Medical Research, Sydney, Australia

Objective: Rheumatoid arthritis (RA) is associated with a ~2-fold elevated risk of mortality from cardiovascular disease (CVD). Chronic systemic inflammation is thought to be important but the precise mechanisms are not well understood. Peripheral blood in RA is often characterised by monocytosis and neutrophilia, which are known to play causal roles in atherosclerosis. We examined the effect of arthritis on atherosclerotic lesion regression when plasma cholesterol levels were controlled.

Methods: Low-density lipoprotein receptor knock-out mice were fed a high fat high cholesterol diet for 14wks to promote atherosclerotic lesion development. At 14wks, a subgroup of mice were sacrificed for baseline lesion characteristics and the remaining mice were placed on chow diet for 3 weeks to normalize plasma cholesterol and induce atherosclerotic regression. Simultaneously, a subgroup was rendered arthritic using passive transfer of K/BxN serum. Atherosclerotic lesion

size (H&E), lipid (Oil red O) and macrophage (CD68+) content were analysed. Flow cytometry was used to quantify leukocytes populations.

Results: RA impaired atherosclerotic regression, as lesions from the arthritic mice were larger than non-arthritic mice and appeared more rupture-prone as they contained more lipid and macrophages. This was independent of total serum cholesterol levels. Circulating monocyte levels were also elevated, predominantly the Ly6-Chi inflammatory subset that is considered more pro-atherogenic.

Conclusion: Inflammatory murine arthritis impaired atherosclerotic lesion regression. Enhanced monocyte production and entry into the atherosclerotic lesion may play a role in defective atherosclerotic lesion regression. Our findings suggest that control of lipid levels in RA patients is not sufficient in preventing atherosclerosis.

882

Type I interferon associated immune responses in STING associated vasculopathy with onset in infancy (SAVI) patients

Gul, E.¹, Kara Eroglu, F.², Surucu, N.¹, Yalciner, C.³, Gursel, I.², Ozen, S.⁴, Gursel, M.¹

¹Middle East Technical University, Ankara, Turkey, ²Bilkent University, Ankara, Turkey, ³Acibadem University, Istanbul, Turkey, ⁴Hacettepe University, Ankara, Turkey

Response to cytosolic DNA depends on the expression of the adaptor STING, culminating in type I IFN production. Gain-of-function mutations in STING has recently been shown to trigger an interferonopathy characterized by neonatal-onset systemic inflammation with severe cutaneous vasculopathy (STING-associated vasculopathy with onset in infancy, or SAVI) leading to extensive tissue loss and interstitial lung disease. Herein, we present data on immune activation status of 3 new cases of SAVI syndrome. Genetic analysis by direct sequencing revealed N154S mutation in one patient and a novel compound heterozygous mutation of V155E/L170Q in TMEM173 in 2 others. N154S mutation results in constitutive activation of the STING-IRF3. qRT-PCR results demonstrate that unstimulated PBMC of the patient with N154S mutation have significant upregulation of interferon stimulated genes (ISGs) compared to healthy controls, while patients with V155E/L170Q mutations showed moderate level of upregulation of ISGs, suggesting that differences in STING-TBK1-IRF3 axis may exist in various TMEM173 mutations that may affect clinical features of this disease. Similar results were found in plasma IP-10 levels where patients have significantly higher levels of IP-10 compared to healthy controls. To assess cGAS activity, monocytes from HSV DNA stimulated samples were co-cultured with a STING reporter cell-line and gap-junction-mediated intercellular cGAMP transfer was determined. Results showed that DNA transfection stimulated patient cells to synthesize and then transfer cGAMP to the reporter cells, suggesting that cGAS activity was not compromised in SAVI syndrome. Collectively, these results could contribute to our understanding of mechanisms that contribute to the pathogenesis of this rare disease.

883

Association of IL-27 gene polymorphisms (rs153109 and rs17855750) and its sera levels with risk of systemic sclerosis

Kamali Sarvestani, E.^{1,2}, Khalaj, F.^{1,2}, Nazarinia, M.A.³, Shenavandeh, S.³

¹Shiraz University of Medical Sciences, Autoimmune Diseases Research Center, Shiraz, Iran, Islamic Republic of, ²Shiraz University of Medical Sciences, Immunology, Shiraz, Iran, Islamic Republic of, ³Shiraz University of Medical Sciences, Rheumatology, Shiraz, Iran, Islamic Republic of

Introduction: IL-27 may play an important role in the pathogenesis of systemic sclerosis (SSc). Therefore, genetic variants and sera levels of IL-27 were studied in SSc.

Materials and methods: Two polymorphisms of IL-27p28 gene (rs153109 and rs17855750) were investigated in a total of 232 SSc patients and 234 controls by PCR-RFLP method. The IL-27 serum levels were also checked by ELISA.

Results: The rs153109-AA genotype and rs153109-A allele frequencies were significantly higher in patients compared to controls ($p=0.007$ and $p=0.002$, respectively). However, no significant differences were observed in genotype and allele frequencies of rs17855750 between patients and controls. In addition, after categorization of patients into rs153109-G and rs153109-non G carriers, rs153109-AA genotype was more frequent in patients with kidney involvements compared to cases without involvement ($p=0.03$). Moreover, AA carriers frequency was higher in CRP+ male patients compared to CRP- male patients ($p=0.03$). Furthermore, haplotype analysis showed AG haplotype was associated with increased SSc susceptibility ($p=0.001$) while GT was a protective haplotype ($p=0.007$). IL-27 serum levels showed an insignificant higher levels in patients compared to controls ($p=0.08$). Furthermore, IL-27 serum levels was higher in patients with increased FTP (>1 cm) compared to those with normal FTP (<1 cm, $p=0.003$).

Conclusion: In conclusion, functional SNP in IL-27p28 promoter (rs153109) and IL-27 levels may be associated with susceptibility and clinical manifestations of SSc.

884

Splenic long-lived plasma cells act as antigen-presenting cells preferentially driving the development of follicular helper T cells

Jang, E., Youn, J.

Hanyang University, Laboratory of Autoimmunology, Department of Anatomy and Cell Biology, College of Medicine, Seoul, Korea, Republic of

Long-lived plasma cells (LLPCs) develop under the help of follicular helper T (T_{fh}) cells and reside mainly in the bone marrow. However, these cells are unusually abundant in the spleen of several autoimmune models including K/BxNsf mice, yet their pathogenic impact remains unknown. To investigate a previously unappreciated role of splenic LLPCs, we sorted splenic plasma cells (PCs) from K/BxNsf and K/BxN mice, corresponding to LLPCs and conventional short-lived PCs, respectively, and compared their phenotypes and ability to

prime and induce the differentiation of naive CD4⁺ T cells into effector cells *in vitro* and *in vivo*. We found that K/BxNsf PCs had lower levels of the Ag presentation machinery and costimulators than K/BxN PCs, and also a lower CD4⁺ T cell priming capacity. Autoantigen-pulsed K/BxNsf PCs selectively polarized cognate CD4⁺ T cells toward the expression of molecules necessary for Tfh development and function. As a result, the K/BxNsf PC-primed CD4⁺ T cells were more effective in stimulating B cells to produce autoantigen-specific IgGs than K/BxN PCs or even dendritic cells. Adoptive transfer of K/BxNsf PCs, but not K/BxN PCs, to K/BxN mice increased numbers of Tfh cells in draining lymph nodes. These results propose that abnormal accumulation of LLPCs in the spleen of autoimmune models drives the differentiation of autoantigen-primed CD4⁺ T cells to Tfh cells. This positive feedback loop between splenic LLPCs and Tfh cells may contribute to the persistence of humoral autoimmunity.

Autoimmune evaluation in patients with idiopathic portal hypertension (IPH). Potential pathophysiological role and biomarkers

González-Navarro, E.A.^{1,2}, *Cerda Reyes, E.*^{2,3,4}, *Silva-Junior, G.*^{2,3,4}, *Seijo, S.*³, *Turon, F.*^{2,3,4}, *Baiges, A.*³, *Hernandez-Gea, V.*³, *Bosch, J.*³, *Juan, M.*^{1,2,5}, *García-Pagán, J.C.*^{2,3,4,5}

¹Hospital Clinic, Immunology Service, Barcelona, Spain, ²IDIBAPS, Barcelona, Spain, ³Hepatic Hemodynamic Lab. Liver Unit. Hospital Clinic, Barcelona, Spain, ⁴CIBERehd, Barcelona, Spain, ⁵Universidad de Barcelona, Barcelona, Spain

Background and aims: IPH is a rare clinical disorder consisting of intrahepatic portal hypertension in the absence of cirrhosis and other causes of liver disease. The pathophysiological mechanisms causing IPH remain largely unknown, although IPH is occasionally associated with autoimmune diseases (AD). This study evaluates the potential involvement of autoimmunity in the pathophysiology of IPH.

Methods: In serum samples prospectively collected from 39 patients with IPH and of 39 patients with liver cirrhosis (LC) matched by gender, signs of portal hypertension and liver function included as controls the 25 autoantibodies were determined. Antiendothelial cell antibodies (AECA) by CytoELISA (cell based ELISA using EA.Hy926 cells), immunohistochemistry (IH) and Western-blot on normal liver.

Results: Anti-TPO (Anti-Tiroperoxidase) and AECA were significantly more frequent in IPH patients than in patients with LC (41%vs10.3%;p=0.002 and 25.6%vs2.6%;p=0.003 respectively). These autoantibodies were represented in all IPH subgroups. Selectivity of AECA positivity was confirmed by IH showing reactivity against endothelial cells of normal livers. EA.Hy926 lysates were tested by Western blotting with serum samples, identifying a protein with a molecular weight of 68-72 kDa. Presence of anti-TPO and/or AECA had no prognostic value; patients had a similar clinical outcome during follow-up. In the current cohort of patients with portal hypertension (IPH+LC), presence of anti-TPO and/

or AECA had a specificity/sensitivity of 87.2%/64.1%; and a positive/negative likelihood ratio of 5/0.41 respectively for the diagnosis of IPH.

Conclusions: Our findings suggest a potential contribution of AECA and anti-TPO to IPH pathogenesis. and may be helpful for the diagnosis of IPH.

886

The role of CD8+ T regulatory cells in the development of autoimmune thyroid diseases (AITD) and thyroid eye disease (TED)

Al-Ansari, F., Lahooti, H., Edirimanne, S., Wall, J., Department of Medicine, Sydney Medical School, Nepean

Autoimmune thyroid diseases (AITD) are one of the most common autoimmune diseases. Approximately 40% of AITD patients develop a manifestation called thyroid eye disease (TED) alongside their thyroid condition that involves the inflammation of the extra-ocular muscles and the surrounding connective tissue. Despite the fact that AITD were along the earliest autoimmune diseases that were addressed, their pathogenesis remains unclear with poor scientific evidence for a link of these diseases to the orbital inflammation seen in TED patients. In this study, we aimed to see whether the number and/or function of CD8+ T regulatory cells (Tregs) within the thyroid and/or peripheral blood are affected in patients with AITD. We also aimed to assess whether the number and/or function of CD8+ Tregs is affected among AITD patients who have developed TED.

Thyroid mononuclear cells (mncs) were isolated with enzyme digestion and filtration of the thyroid tissue followed by Ficol-Hypaque density gradient. The same density gradient was also used to separate peripheral blood mncs. The isolated cells were analysed using flow cytometry to evaluate the number of CD8+ Tregs. To assess the function of CD8+ Tregs, after magnetic cell sorting, CD4+CD25- T-responder cells (Tresps) were cultured either alone or in combination with CD8+ Tregs. Flow cytometry was then used to detect the difference in the expression of activation markers by Tresps.

Our data suggest that the development of AITD may be related to a decreased number and function of CD8+ Tregs within the thyroid.

887

Immune mechanisms in chronic or relapsing autoimmune diseases investigated in the experimental rat model of autoimmune uveitis (EAU)

Experimental autoimmune uveitis (EAU) in rats is a model for human intraocular inflammatory disease. We can induce

either spontaneously relapsing-remitting disease with the interphotoreceptor retinoid-binding protein peptide R14 or a monophasic/chronic disease with the retinal S-Antigen peptide PDSAg. T cell lines were analyzed for gene and protein expression. Rats with EAU induced by both antigens were either treated with chemokine mutants or analyzed for intraocular T cell populations. Gene expression analysis revealed 26 genes upregulated in R14-specific T cells, all upstream or downstream of IFN-g signaling and belonging to pathways of wnt, antigen-presentation, secretion and cytokine expression. The role of IFN-g for recurrent disease was confirmed by synchronized relapses after intraocular injection of IFN-g in R14-mediated uveitis. PDSAg-specific T cell lines secreted more IL-6, IL-10, VEGF and CCL2. VEGF-secretion of PDSAg-specific T cells induced chorioretinal neovascularization as late complication in the monophasic uveitis. After application of CCL2- and CCL5-variants suppressive effects were only seen in PDSAg-, but not R14-induced EAU. During the course of EAU intraocular T cell populations co-express IFN-g, IL-17 and/or IL-10. Cells co-expressing these cytokines increased during monophasic and decreased during relapsing disease, and Foxp3-expression increased late in monophasic EAU. When rats were co-immunized with both antigens the monophasic EAU dominated with respect of the disease course and intraocular T cell populations. Analysis of autoreactive T cells in vitro, intraocular T cell populations in vivo and therapeutic responses revealed differences between both uveitis types and demonstrated that relapsing disease is strongly dependent on IFN-g.

Shared genetic and environmental risk factors for the autoimmune diseases type 1 diabetes mellitus and multiple sclerosis

Parnell, G.¹, Ong, L.¹, Swaminathan, S.², Vucic, S.², Barnett, M.³, Goodnow, C.⁴, Booth, D.¹, Stewart, G.¹

¹Westmead Institute for Medical Research, Centre for Immunology and Allergy Research, Sydney, Australia, ²University of Sydney, Westmead Clinical School, Westmead, Australia, ³University of Sydney, Brain and Mind Research Institute, Sydney, Australia, ⁴The Garvan Institute, Immunogenomics, Sydney, Australia

Multiple Sclerosis (MS) and type 1 diabetes (T1D) are both autoimmune diseases with inflammatory, auto-antigen-specific T-cell, and decreased T-cell suppressor components, but they affect different organs and have marked differences in pathogenesis and clinical manifestations. Despite this, they co-occur more often than expected by chance, pointing to shared susceptibility factors that override the known differences in HLA association including protection against T1D by the MS risk genotype, HLA-DRB1*1501. Low sun exposure and low vitamin D (vitD) levels are common risk factors. Genome-wide association studies and candidate gene studies have identified shared non-HLA genetic risk factors, including variants in the vitD pathway gene, CYP27B1. Also, both MS and T1D risk variants are over-represented in the vitD receptor (VDR) cistrome of myeloid cells ($p < 0.005$, FDR < 0.05).

We compared linkage disequilibrium (LD) regions around the MS and T1D associated SNPs to better define the shared risk

genes. Eight genetic loci were identified as shared, with 15 genes in the LD-blocks. These genes are expressed in multiple immune subsets including myeloid, B, NK, and T-cells. There is also evidence that 5 of these haplotypes affect gene expression in immune cells. Six shared genes have VDR binding sites within 20kb.

We sought rare variants that may be contributing to disease risk using whole genome sequencing of genomic DNA from individuals with both T1D and MS. Variants were filtered by multiple criteria, including likely involvement in the vitD pathway. These data implicate shared, specific immune dysregulation between T1D and MS, and common targets for therapeutic intervention.

Immune response to gingipain of *Porphyromonas gingivalis* in periodontitis and rheumatoid arthritis

Siao, S.-H.¹, Yen, J.-H.², Lee, Y.-H.², Sun, J.², Chang, Y.-C.³, Chen, J.², Lan, J.-L.², Tsai, J.¹, Zouali, M.⁴, Tsay, G.-J.²

¹Institute of Microbiology & Immunology, Chung Shan Medical University, Taichung, Taiwan, Republic of China, ²Division of Immunology and Rheumatology, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan, Republic of China, ³Chung Shan Medical University, Department of Oral Medicine, Taichung, Taiwan, Republic of China, ⁴Inserm & University Paris Diderot, Sorbone Paris Cité, Paris, France

Objective: Several studies indicate an epidemiologic association between rheumatoid arthritis (RA) and periodontitis (PD) even after adjusting for risk factor of smoking. The aim of the study was to investigate the humoral immune response to Arginine-gingipain (RgpA) of *Porphyromonas gingivalis* in PD and RA.

Methods: Hemagglutinin domain and catalytic domain of RgpA of *Porphyromonas gingivalis* were cloned respectively. Serum samples were tested for the IgG and the IgG subclass including IgG1, IgG2, IgG3 and IgG4 anti-RgpA antibodies in patients with PD, RA and normal control by ELISAs.

Results: RA patients had the antibodies to hemagglutinin domain of RgpA, but not to the catalytic domain of RgpA. Total IgG anti-RgpA were detected in 32/153 (20.9%) patients with RA, and 9/46 (19.1%) patients with PD. The titers of anti-RgpA hemagglutinin domain antibodies in both RA and PD patients were significantly higher than that of the healthy normal control group ($p < 0.05$). IgG1 of anti-RgpA hemagglutinin domain antibodies were increased in patients with PD only. IgG2 of anti-RgpA hemagglutinin domain antibodies were increased in patients with both PD and RA. Both IgG3 and IgG4 of anti-RgpA hemagglutinin domain antibodies were not increased in both diseases.

Conclusion: Our results showed that the antibody responses in PD and RA are predominantly directed to the RgpA hemagglutinin domain, not the catalytic domain. The IgG2 of anti-RgpA hemagglutinin domain antibodies play an important role in the pathogenesis of both PD and RA. The relationships between anti-RgpA hemagglutinin domain antibodies and rheumatoid arthritis need to be further elucidated.

890

Vaproic acid treatment suppresses autoimmune recurrence and allograft rejection in islet transplantation for type 1 diabetes

Lin, G.-J.¹, Lin, J.-R.¹, Yu, C.-C.¹, Huang, S.-H.^{1,2}

¹National Defense Medical Center, Department of Biology and Anatomy, Taipei, Taiwan, Republic of China, ²Tri-Service General Hospital, Department of General Surgery, Taipei, Taiwan, Republic of China

Type 1 diabetes mellitus (T1D) results from the destruction of insulin-producing β cells in the islet of the pancreas by leukocytes. It has been considered that T1D is a T cell-mediated autoimmune disease. CD4⁺ and CD8⁺ T cells are highly responsible for the destruction of β cells within the pancreatic islets of Langerhans. Previous studies have revealed that regulatory T cells (Tregs) play a key role in immune system homeostasis and tolerance to antigens, thereby preventing autoimmunity. Recent studies have found that HDAC inhibitor (HDACi) treatment *in vivo* increases the expression of forkhead box P3 (FOXP3), a critical transcription factor for Tregs, as well as the production and suppressive function of Tregs. Valproic acid (VPA), a branched short-chain fatty acid, is widely used as an antiepileptic drug and a mood stabilizer. Recently, VPA has been demonstrated to act as a HDAC inhibitor and VPA treatment increases Tregs function and decreases the incidence and severity of collagen-induced arthritis and experimental autoimmune neuritis. We treated a mouse model of islet transplantation in T1D (non-obese diabetic mice) with VPA. The survivals of the syngeneic and allogeneic islet grafts were significantly prolonged. This treatment increased the production of TGF- β in the splenocytes. Our study demonstrated a therapeutic potential of VPA treatment in islet transplantation for T1D.

891

Blockade of IL-7Ra alleviates collagen-induced arthritis via inhibiting Th1 cell differentiation and CD4⁺ T cell migration

Cai, L., Xu, H., Nie, H.

Shanghai Institute of Immunology, Shanghai JiaoTong University School of Medicine, Shanghai, China

IL-7/IL-7R axis shows the importance on CD4⁺ T cell response, including proliferation, differentiation, survival and migration. But whether blockade of IL-7/IL-7R axis can relieve rheumatoid arthritis and the treatment mechanisms have remained unclear. In this study, we established collagen-induced arthritis (CIA) model and observed the effect of IL-7Ra antibody in the treatment of CIA mice. The data showed IL-7Ra antibody treatment significantly alleviated clinical symptoms of CIA mice, accompanied by reduced number of CD4⁺ T cells in both spleen and joints. We found that CII-specific CD4⁺ T cell proliferation decreased and the mRNA expression of inflammatory cytokines reduced in the IL-7Ra antibody-treated mice. Subsequently, IL-7Ra antibody treatment *in vivo* reduced the percentage of Th1 and Th17 cells and the mRNA expression of T-bet and ROR γ t gene. Moreover, we found that IL-7 promoted Th1 differentiation *in vitro*, but no effect on Th17 differentiation. In addition, administration of IL-7Ra antibody reduced the

mRNA expression of chemokine receptors (CCR7, CXCR3, CXCR6 and XCR1) on CD4⁺ T cells and chemokine CXCL2 in joints. The results suggested that the treatment effect of IL-7Ra antibody on CIA was via the inhibition of CII-specific CD4⁺ T cell proliferation, reduction of Th1 differentiation and restraint of CD4⁺ T cell migration to joint lesion site. Our data indicated that IL-7Ra maybe a potential therapeutic target for rheumatoid arthritis. (This project is supported by grants from National Natural Science Foundation of China (81273307) and Shanghai Municipal Education Commission (14ZZ106).)

CXCR3 chemokine axis regulates T cell function in autoimmune cholangitis

Ma, H.-D., Liu, Q.-Z., Lian, Z.-X.

University of Science and Technology of China, Hefei, China

CXCR3 is a chemokine receptor that is highly expressed on effector T cells and plays an important role in T cell trafficking and function. Autoimmune cholangitis, primary biliary cirrhosis (PBC) among which, is a progressive autoimmune liver disease. As a mouse model of PBC, dnTGF- β R II mice fully mimic the clinical character of PBC patients. Our study aims at investigating how CXCR3 regulate the effector cells-T lymphocyte function in autoimmune liver disease. First, we detected that there is a high level of CXCR3 ligands-CXCL9 and CXCL10 in the liver of PBC model-dnTGF- β R II mice (TG mice). By flow cytometry we found that the frequency and number of CXCR3 expressing T cells are higher in liver of TG mice compared with wild type mice. In order to determine the role of CXCR3 in the progress of PBC, we crossed CXCR3 knockout mice with TG mice. Histological analysis showed that TGC3 (CXCR3^{-/-} dnTGF- β R II) mice have more severe infiltrations in the moderate portal vein in liver. Serological analysis showed that the level of anti-mitochondria antibody, which is the serological marker of this disease, and inflammatory cytokines are higher in TGC3 mice. Moreover, T cells, especially IFN- γ producing T cells and terminated KLRG1⁺ T cells increased after CXCR3 knockout in TG mice. From the above results, we know that CXCR3 chemokine axis may balance the choice between driving inflammation and dampening over-exuberant responses in liver tolerance. Further study is needed to illustrate the detailed mechanism of this regulation.

893

Unraveling autoimmune diabetes by using genetically modified mouse models: from mechanism dissection to clinical application

Sytwu, H.-K.

National Defense Medical Center, Microbiology and Immunology, Taipei, Taiwan, Republic of China

Autoimmune diabetes is a T cell-mediated autoimmune disease. To delineate the protective roles of some immune modulatory molecules, including soluble decoy receptor 3 (DcR3), cytotoxic T lymphocyte antigen 4 (CTLA4), program death ligand 1 and 2 (PD-L1 and 2), heme oxygenase 1 (HO-1), and chemokine receptor D6 in the autoimmune process and to search for potential preventive and/or therapeutic targets in this disease,

we have generated

(a) insulin promoter (plns)-sDcr3 transgenic non-obese diabetic (NOD) mice,

(b) plns-single chain anti-CTLA4 transgenic NOD mice,

(c) plns-single chain anti-4-1BB transgenic NOD mice,

(d) plns-PD-L1 transgenic NOD mice,

(e) plns-HO-1 transgenic NOD mice, and

(f) plns-D6 transgenic NOD mice and demonstrated their immunomodulatory potential and underlying mechanisms.

Meanwhile, to explore the modulatory potential of interleukin-12, 23 and 27 on autoimmune diabetes, we have generated following transgenic, knockout and knockdown NOD mice:

(1) Th1 and Th2 doubly transgenic

(2) IL-12 knockout

(3) IL-23 knockdown

(4) IL-27 knockdown NOD mice.

Our results revealed that 20% IL-12-deficient NOD mice still developed autoimmune diabetes, the diabetic incidence of IL-23 knockdown NOD mice is lower than that of control littermates, and the number and percentage of Th1 cells are dramatically decreased and Th17 cells are increased in IL-27 knockdown mice, indicating a differential role of IL-12 cytokine family in modulating Th1 and Th17 cell development during autoimmune diabetogenic process. Making full use of these unique mouse strains, we are quantitatively and qualitatively investigating the immunopathogenic mechanisms of autoimmune diabetes and providing valuable information for the development of novel immunotherapies.

894

CD1d and lipid regulation of Vdelta1 and Vgamma9 T cells in systemic sclerosis

Bank, L., Migalovich Sheikhet, H.

Sheba Medical Center, Ramat Gan, Israel

Vδ1+ T cell (TC) receptors recognize CD1d- presented lipids, and are activated oligoclonally in peripheral blood (PB) and organs in systemic sclerosis (SSc). To determine effects of the antigenic lipid (cardiolipin)- in SSc, mononuclear cells (MC) were isolated from PB of 12 SSc patients and 8 healthy controls (HC) and cultured in IL2C (RPMI-1640 with 10% FBS + 100 IU of IL-2), CARDC or OCHC [IL2C+cardiolipin 2.5µg/ml or OCH 50ng/ml (analogue of α-galactosyl ceramide) respectively]. Zoledronate (zol, 2µM), a Vγ9+ γδTC stimulant that induces their CD1d expression, was added to parallel cultures (labeled ILCzol etc.). Flow-cytometry (FC) after 4-5 day showed that Vδ1+ and Vγ9+TC consisted 11.85±2.0% and 14.7±3.5% vs 10.42±2.4% and 7.08±1.2% of the CD3+ TC in SSc and HC IL-2C respectively (not significantly different). In HC, %CD25+TC was not significantly altered by lipids absent of zol. However, IL2Czol increased CD25 expression, which was significantly further amplified on Vδ1+ TC in CARDCzol. In SSc, OCHC and CARDC slightly enhanced %CD25+Vδ1+TC versus IL2C whereas CARDC significantly suppressed %CD25+Vγ9+TC. In IL2Czol and CARDCzol, %CD25+Vγ9+TC increased. By contrast %CD25+Vδ1+TC decreased in IL2Czol relative to IL2C (p< 0.028) but increased in CARDCzol. 50-70% of SSc and HC

Vδ1+TC in IL2C reacted with native and OCH-bound CD1d tetramers, which was reduced in IL2Czol in SSc samples. Furthermore, blocking mAb against CD1d abolished CARDCzol induced elevated expression of CD25 in SSc Vδ1+ TC (n=5) specifically. Thus, CD1d mediated interactions with Vδ1+TC and lipid antigens may play a role in immune-dysregulation in SSc.

895

Development of a model for antigen-specific tolerising immunotherapy and response in NOD mice

Buckle, L., Steptoe, R.J., Thomas, R., Hamilton-Williams, E.E.

University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia

Type 1 diabetes (T1D) results from autoimmune destruction of insulin-producing pancreatic β cells, involving CD4+ and CD8+ T cells. Non-obese diabetic (NOD) mice are a model for human T1D. As islet-specific glucose-6-phosphatase catalytic subunit-related protein (IGRP) is a major diabetogenic antigen in NOD mice, we developed a model to test IGRP antigen-specific immunotherapy. We showed previously that liposomes co-encapsulating antigen and NF-κB inhibitor induced antigen-specific suppression of CD4+ T cells in mice. These liposomes passively target and deliver their payload to dendritic cells in lymphoid organs, suppressing NF-κB activation.

For the current model, we injected NOD mice with liposomes co-delivering IGRP₂₀₆₋₂₁₄ peptide and NF-κB inhibitor. After adoptive transfer of CTV-labelled IGRP-specific CD8+ T cells, we analysed proliferation in lymphoid organs, enumerated adoptively-transferred and endogenous antigen-specific T cells using K^d-IGRP tetramers, and measured IFN-γ effector function by intracellular staining ex vivo.

To induce antigen-specific T cell activation, mice were immunized with IGRP₂₀₆₋₂₁₄ peptide and adjuvant. 5 days after immunization, IGRP-specific CD8+ T cells dramatically expanded and production of IFN-γ increased. Twenty four hours after liposome injection to naïve mice, we observed uptake of liposomes specifically by antigen presenting cells (APCs). Delivered peptide was presented by these APCs as CTV-labelled IGRP-specific CD8+ T cells proliferated in draining lymph nodes after subcutaneous delivery of liposomes co-encapsulating IGRP₂₀₆₋₂₁₄ and NF-κB inhibitor.

These data establish a model in NOD mice for analysis of diabetogenic antigen presentation and response to antigen-specific liposome immunotherapy to complement studies of immunotherapy to prevent or treat diabetes.

896

CD40-pathway activation in ectopic lymphoid structure (ELS)-resident B cells contributes to disease pathology in primary Sjögren's syndrome

Wieczorek, G., Bigaud, M., Pfister, S., Hoersch, S., McMichael, K., Afatsawo, C., Hamburger, M., Texier, C., Cojean, C., Henry, M., Rush, J.

Novartis Institutes of Biomedical Research, Basel, Switzerland

T cell-dependent antibody responses are a key effector arm of the adaptive immune system. These responses often occur in germinal centers (GCs) within secondary lymphoid organs.

Similar GC-like structures can be found in affected tissue in various autoimmune diseases, including salivary glands of primary Sjögren's syndrome (pSS) patients. Previous work has implicated CD40 signalling in the regulation of GC function, and we wanted to investigate whether it also played a role in ELS maintenance and function in pSS. Histological analysis of salivary gland biopsies from pSS patients revealed evidence of CD40 and CD154 expression on ELS-resident B and T cells respectively. These results suggested that there might be ongoing T-B cell collaboration in these ELS and we subsequently examined whether there was evidence of CD40 pathway activation *in situ*. Using a published microarray dataset generated using pSS parotid gland biopsies we could demonstrate upregulation of a B cell-specific CD40 pathway gene signature, suggesting that the CD40 pathway was activated in ELS-resident B cells. To directly address the role of CD40-CD154 in pSS ELS, we used an anti-CD154 antibody in NOD mice, a preclinical model of pSS. Therapeutic treatment of NOD mice resulted in disaggregation of established ELS as well as a reduction in the frequencies of T and B lymphocytes and IgG secreting cells in salivary glands. Collectively our data indicate that CD40 pathway signalling is essential for the maintenance of salivary gland ELS, supporting the notion that blockade of CD40-CD154 interactions may provide therapeutic benefit in pSS patients.

897

Variants of the pro-inflammatory P2X7 receptor on platelets are associated with the acute attack of multiple sclerosis

Gu, B.¹, Krupa, M.², Ou, A.¹, Slee, M.², Wiley, J.¹

¹University of Melbourne, The Florey Institute of Neuroscience, Melbourne, Australia, ²Flinders Medical Centre/Flinders University, Department of Neurology, Adelaide, Australia

Multiple sclerosis (MS) is an autoimmune inflammatory disease of the central nervous system characterized by demyelination and neuronal death. In discovery cohorts of Australasian patients with multiple sclerosis (total 2941 patients, 3008 controls) we examined the associations of twelve functional polymorphisms of P2X7, a microglial/macrophage receptor with proinflammatory effects when activated by extracellular ATP. In discovery cohorts, rs28360457, coding for Arg307Gln was associated with MS and combined analysis showed a two-fold lower minor allele frequency compared with controls (1.11% for MS and 2.15% for controls, $p=0.0000071$). A meta-analysis of three Australasian and four European cohorts indicated that Arg307Gln confers a 1.8-fold protective effect on MS risk (OR 0.57, $p=0.0000024$) [1]. In contrast a gain of function variant of P2X7, Ala348Thr was associated with an increased risk of MS (OR 1.10, $p=0.0006$) [1]. Fresh human monocytes heterozygous for Arg307Gln have >85% loss of 'pore' function of the P2X7 receptor measured by ATP-induced ethidium uptake. Flow cytometric analysis of both resting and activated human platelets showed binding of the L4 mAb specific for the extracellular domain of the P2X7 receptor. Microvesicles derived from activated platelets have been shown in MS blood [2], and these may arise from the action of ATP on platelet P2X7 to induce cell blebbing. Our data show the protective effect against MS of a loss of function variant of P2RX7 and suggest a role for platelet P2X7-

function in the acute MS relapse.

High throughput screening co-culture assay to identify novel targets in IBD

Stallen, J.¹, Legent, A.¹, Schluep, D.¹, van Berge, L.¹, Kartono, A.¹, de Pril, R.¹, van Es, T.¹, Vandeghinste, N.², Brys, R.², Janssen, R.¹

¹Galapagos, Leiden, Netherlands, ²Galapagos, Mechelen, Belgium

Inflammatory bowel disease (IBD) is an autoimmune disease characterized by inflammation at the intestinal epithelium which acts as a barrier to antigens and bacteria in the gut lumen and is involved in immune cell regulation. Dendritic cells (DC) as antigen-presenting cells play an important role due to their function of antigen presentation to T cells and secretion of proinflammatory cytokines. As the interaction between intestinal epithelium, DC and the bacteria in the lumen is crucial, we developed a high throughput co-culture assay and screened this with our adenoviral shRNA library to identify novel targets inhibiting the proinflammatory response to DC cytokines in response to *E.coli*. Caco-2 cells, cultured in 96 well transwell plates until polarized, were either transduced with adenoviral shRNA constructs or not transduced for compound screening. Monocyte derived DC were added to the basolateral compartment and the system was triggered with UV irradiated *E.coli* in the culture medium at the basolateral compartment. Compound treatment was performed by apical and basolateral addition to the culture medium prior to trigger addition. Chemokines/cytokines were measured in both apical and basolateral supernatants on the Flexmap3D with CCL20 as primary readout. Barrier function was assessed using FITC labelled dextran leakage through the epithelial barrier. Several novel targets that inhibited CCL20 secretion and prevented barrier disruption were identified using adenoviral shRNA and/or compounds. A robust high throughput screening assay was developed to identify and validate targets in a disease relevant co-culture system for IBD. Known targets were confirmed and novel targets identified.

899

Identification of new therapeutic targets for the control of autoreactive plasma cells in inflamed kidneys in systemic lupus erythematosus

Natt, J.¹, Mathian, A.², Rucker-Martin, C.³, Amoura, Z.², Espéli, M.¹

¹UMR 996 - Inflammation, Chemokines and Immunopathology, Inserm, Univ Paris-Sud, Université Paris-Saclay, Clamart, France, ²Service de Médecine Interne 2, Centre de Référence National pour le Lupus et le Syndrome des Antiphospholipides, Institut E3M, Groupement Hospitalier Pitié-Salpêtrière, Assistance Publique-Hôpitaux de Paris, Paris, France, ³Centre Chirurgical Marie Lannelongue, Inserm UMR_S 999, LabEx LERMIT, Medical Research Department, Le Plessis-Robinson, France

Increased incidence of autoimmune diseases is a public health concern. Despite medical advances, they remain incurable and

are associated with a poor quality of life and vital prognostic. This is particularly true for systemic lupus erythematosus (SLE) that is a systemic autoimmune inflammatory disease involving several organs. One of the worst clinical manifestations of SLE is lupus nephritis (LN), where kidney damages progressively lead to an irreversible renal failure. Autoantibodies produced by autoreactive plasma cells (PCs) play a central role in the development of kidney inflammation. These autoreactive PCs are resistant to most therapies commonly used to treat autoimmune diseases. Moreover, we previously showed that they persist into specific niches within the inflamed kidneys. Controlling or eliminating autoreactive PCs within the inflamed kidney are thus promising therapeutic approaches for SLE.

Our project aims to identify and validate new therapeutic targets for the specific depletion of inflamed kidney PCs by focusing on their migratory potential and their survival niches. Firstly, we characterized the migratory barcode of PCs from SLE patients and a murine model of LN, the NZB/W F1 mice. Our current results highlight the potential role of two chemokine receptors. Secondly, we investigated the PC survival niche within the inflamed kidneys, with a specific focus on myeloid cells. We are currently determining the type of support, in particular the secretion of survival factors.

Altogether our results may open new therapeutic paths for the treatment of SLE and probably for other autoimmune diseases.

900

Regulation of murine lupus nephritis and nephritic T cell responses by Ox40/Ox40L

Sitrin, J., Suto, E., Chu, F., Austin, C.D., Lee, W.P., Behrens, T.W. Genentech, South San Francisco, United States

Ox40L locus polymorphisms are strongly linked with risk for systemic lupus erythematosus (SLE) in multiple ancestries. However, exactly where and how Ox40L contributes to SLE pathology remains unclear, limiting our understanding of the underlying biology and the potential clinical value in targeting this pathway as a therapeutic modality. In this study, we evaluated the contribution of the Ox40L and Ox40 receptor pathway using a combination of *in vivo* antagonist and agonist approaches in the classical spontaneous and interferon alpha-accelerated NZB/W murine model of SLE and lupus nephritis (LN). Ox40 was expressed by CD4⁺ T cells in the spleen and kidney on cells with an activated/memory phenotype, accumulating in a pattern correlating to disease severity. Administration of an antagonist Ox40:Fc reagent limited the pathogenicity of interferon alpha-accelerated disease, including a delayed onset of severe proteinuria and extended survival. Administration of an agonist anti-Ox40 monoclonal antibody provoked systemic and nephritic T cell responses, impacted the relative presence of glomerular and interstitial T cells, and exacerbated renal disease. Notably, the renal pathogenicity of anti-Ox40 treatment was limited to older mice with underlying mild renal disease. Both the antagonist and agonist approaches proceeded without altering serum dsDNA autoantibody titers. Collectively, these data support a scenario in which the Ox40/Ox40L pathway regulates LN and renal disease, likely by impacting nephritic T cell responses. Our findings support a pathogenic role for T

cells in SLE and LN, and highlight the potential clinical value in targeting the Ox40/Ox40L pathway as a therapy for SLE.

901

CD8⁺ T cells effect glomerular injury in experimental anti-myeloperoxidase glomerulonephritis

Ooi, J.D.¹, Chang, J.¹, Eggenhuizen, P.J.¹, O'Sullivan, K.M.¹, Holdsworth, S.R.^{1,2}, Kitching, A.R.^{1,2,3}

¹Monash University, Centre for Inflammatory Diseases, Clayton, Australia, ²Monash Health, Dept. of Nephrology, Clayton, Australia, ³Monash Health, Dept. of Paediatric Nephrology, Clayton, Australia

Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis is an autoimmune disease that manifests as focal and necrotizing glomerulonephritis and renal failure. Observations in patients suggest that CD8⁺ T cells participate in disease, but there is no experimental functional evidence of their pathological involvement. Myeloperoxidase (MPO) is a well defined autoantigen in ANCA-associated vasculitis and following ANCA-induced neutrophil localization, deposited MPO within glomeruli is recognized by autoreactive T-cells that contribute to injury.

The current studies test the hypothesis that CD8⁺ T-cells mediate disease in experimental ANCA-associated vasculitis. CD8⁺ T-cells were depleted in experimental murine anti-MPO glomerulonephritis using monoclonal antibodies. Candidate CD8⁺ T-cell epitopes were identified *in silico* using the IEDB and their immunogenic and cytotoxicity assessed using flow cytometric tetramer based and cytotoxicity assays. The pathogenicity of MPO-specific CD8⁺ T-cells was determined by transferring T-cell clones into *Rag1*^{-/-} mice.

CD8⁺ T-cell depletion in the effector phase of disease attenuated injury in murine anti-MPO glomerulonephritis. This was associated with decreased intrarenal IFN- γ and TNF- α , reduced inflammatory chemokines and fewer glomerular macrophages. A pathogenic CD8⁺ T-cell MPO epitope (MPO₄₃₁₋₄₃₉) was identified and transferred MPO₄₃₁₋₄₃₉-specific CD8⁺ T-cell clones exacerbated disease when co-transferred with MPO-specific CD4⁺ cells. Transfer of MPO₄₃₁₋₄₃₉-specific CD8⁺ T-cells, without CD4⁺ T-cells, could mediate glomerular injury when MPO was planted in glomeruli. These results demonstrate a pathogenic role for MPO-specific CD8⁺ T-cells, provide evidence that CD8⁺ T-cells are a therapeutic target in ANCA-associated vasculitis and suggest that a molecular hot spot within the MPO molecule contains important CD8⁺, CD4⁺ and B cell epitopes.

Elevation of serum Sema4A in neuromyelitis optica spectrum disorders (NMOSD)

Sakakibara, K.¹, Okuno, T.^{1,2}, Sakakibara, S.^{2,3}, Kikutani, H.^{2,3}, Mochizuki, H.¹, Kumanogoh, A.^{2,4}

¹Osaka University Graduate School of Medicine, Department of Neurology, Suita, Japan, ²World Premier International Immunology Frontier Research Center, Osaka University, Suita, Japan, ³Research Institute for Microbial Disease, Osaka university, Department of Molecular Immunology, Suita, Japan, ⁴Osaka University Graduate School of Medicine, Department of Respiratory Medicine, Allergy and Rheumatic Disease, Suita, Japan

Background: Sema4A is a class IV semaphorin, which plays an important role in the activation of Th cells. We previously established ELISA system to measure Sema4A and reported that serum Sema4A levels are significantly higher in patients with multiple sclerosis (MS) than those with other neurological diseases. Although Th cells as well as anti-aquaporin 4 antibodies (AQP4ab) play important roles in neuromyelitis optica spectrum disorders (NMOSD), the involvement of Sema4A in NMOSD remains to be elucidated.

Methods: Serum Sema4A levels were analyzed by ELISA in 38 patients with NMOSD and 129 patients with MS. All NMOSD patients were positive for serum AQP4ab. MS was diagnosed according to MacDonald criteria. We compared clinical characteristics of patients with high Sema4A levels to those with low Sema4A.

Results: The serum Sema4A levels were significantly higher in NMOSD patients than those with MS. The mean age of onset in patients with high Sema4A levels was significantly younger than those with low Sema4A levels. Patients with higher Sema4A levels had significantly less severe the Expanded Disability Status Scale (EDSS) score during exacerbations and remissions. Their relapse rate tended to decrease but this difference was not significant.

Conclusions: The levels of serum Sema4A in NMOSD is as high as those in MS, suggesting that Sema4A plays important roles in the pathogenesis of NMO.

903

Irradiation on NZBWF1 mice is an effective therapy for SLE-like morbidity

Fujita, K.^{1,2,3}, Kuwabara, T.⁴, Tome, Y.¹, Ito, K.^{1,2}, Tsukimoto, A.^{1,5}, Yoshida, Y.^{1,6}, Wang, B.³, Tanaka, K.³, Mikami, T.², Akasaka, Y.²

¹Tsukuba International University, Medical Technology, Tsuchiura, Ibaraki, Japan, ²School of Medicine, Toho University, Pathology, Tokyo, Japan, ³National Institute of Radiological Sciences, Research Center for Radiation Protection, Chiba, Japan, ⁴School of Medicine, Toho University, Immunology, Tokyo, Japan, ⁵Graduate School of Engineering, Chiba Institute of Technology, Narashino, Chiba, Japan, ⁶Graduate School of Comprehensive Human Sciences, University of Tsukuba, Doctoral Program in Sports Medicine, Tsukuba, Ibaraki, Japan

CD180 molecule expressed on mature B cells is a key regulator of cell proliferation and death, showing a protective effect against radiation-induced apoptosis *in vitro*. In SLE patients, the number of CD180-negative cells increased in peripheral blood, and appeared to be associated with the activity of SLE. Furthermore, production of autoantibodies was found by CD180-negative cells from SLE patients. We previously showed that CD180-negative cells were more radiosensitive than CD180-positive cells *in vivo*. In SLE-model NZBWF1 mouse, we also reported the increase in number of CD180-negative B cells in parallel with development of SLE morbidity, the production of autoantibodies by CD180-negative cells, and pathogenesis of lupus-like nephritis caused by CD180-negative cells. In the present study, we attempted to examine the effects of irradiation on CD180-negative cells in NZBWF1 mice. After the onset of symptoms, mice were paired according to their conditions. In each pair, one was irradiated

with 4 Gy, and the other was sham-irradiated. Compared to the sham-irradiated mice, the mean number of CD180-negative cells was significantly decreased, the mean life span was markedly extended, and the nephritis was suppressed in irradiated mice. The results suggest that radiation could effectively eliminate CD180-negative cells, leading to reduction of autoantibody production, and consequently relieve the SLE symptoms in the mouse. These findings suggest that the radiotherapy of autoimmune diseases associated with the expression of CD180-negative cells is a novel candidate for practical application.

Rethinking Rowell syndrome

Sacco, K.¹, Pongdee, T.²

¹Mayo Clinic, Internal Medicine, Jacksonville, United States, ²Mayo Clinic, Allergy and Immunology, Jacksonville, United States

Introduction: Patients meeting diagnostic criteria for systemic lupus erythematosus (SLE) but also having erythema multiforme-like lesions are diagnosed as suffering from Rowell Syndrome (RS). We present a case and review the literature discussing the relevance of this diagnosis to clinical immunology.

Methods: Case report (exempt from IRB approval) and literature review.

Case report: A 51 year old female presented with a 6 week history of a facial rash, oral ulcers, diffuse joint pain and malaise. She had no significant past medical history, no known allergies and family history was unremarkable. The rash was diffusely targetoid and superficially desquamative compatible with a diagnosis of erythema multiforme. Immunoserology was positive for ANA and anti-Sm antibodies. Thus the patient met American College of Rheumatology criteria for diagnosis of SLE. She was started on prednisone 40mg daily with a tapering regime, and hydroxychloroquine was added 1 week later with marked clinical improvement noted after 12 days.

Conclusion: RS typically affects middle-aged women similar to SLE. The majority of patients show a speckled anti-nuclear antibody pattern on autoantibody testing with rheumatoid factor and anti-Ro/anti-LA antibody positivity being reported to a lesser extent. Clinical remission is achieved with similar immunosuppressant medications used in SLE, namely prednisone, azathioprine, antimalarials and cyclosporine. No distinct immunopathogenesis or prognostic outcome between SLE and RS have been described to date. Thus, questions remain as to whether RS is an overlap syndrome, RS is a subset of SLE or a chance event, and if RS influences patient outcomes and disease morbidity.

Autoimmune associated missense mutation in the human gene *TNIP1* does not affect protein cellular localization

Simpfendorfer, K.R.¹, Armstead, B.E.¹, Diamond, B.², Lee, A.¹, Gregersen, P.K.¹

¹Feinstein Institute for Medical Research, Robert S. Boas Center for Genomics and Human Genetics, Manhasset, United States,

²Feinstein Institute for Medical Research, Center for Autoimmune and Musculoskeletal Diseases, Manhasset, United States

A risk haplotype (H1) spanning 30kb of the *TNIP1* gene is associated with risk for Myasthenia Gravis, Systemic Lupus Erythematosus and Systemic Sclerosis in genome-wide association studies. A missense mutation within the H1 risk haplotype is the lead candidate causal mutation and converts a proline to alanine at amino acid 151. Association of the *TNIP1* P151A mutation with multiple B-cell mediated autoimmune diseases across ancestral groups suggest that *TNIP1* P151A is involved in a common mechanism for B-cell mediated autoimmune disease. We confirmed that *TNIP1* is most highly expressed in B cells, compared to other leukocyte populations in human peripheral blood. The TNIP1 protein is reported to function as a co-regulator of NF κ B signaling, as well as a nuclear co-receptor with retinoic acid receptors RAR and PPAR. Amino acid 151 is located near a nuclear export sequence in the TNIP1 protein and substitution of amino acid 151 with an alanine is predicted to be deleterious to the stability of the TNIP1 protein. Given the differing functional roles of TNIP1 in the cytoplasm and nucleus we first investigated if the missense mutation 151A affects the localization of TNIP1 to the nucleus or cytoplasm, there was no difference. Our future studies will investigate the affect of the 151A mutation on NF κ B signaling in B cells from human peripheral blood.

906

TREM-1 knockout promotes lupus-like syndrome in mice

Sun, K.-H.¹, Liu, C.-J.²

¹National Yang-Ming University/Taipei City Hospital, Department of Biotechnology and Laboratory Science in Medicine/Department of Education and Research, Taipei, Taiwan, Republic of China,

²National Yang-Ming University, Department of Biotechnology and Laboratory Science in Medicine, Taipei, Taiwan, Republic of China

Systemic lupus erythematosus (SLE) is a multi-organ autoimmune disease. Inflammatory responses induced by innate immune system play important roles in disease pathogenesis. Triggering receptor expressed on myeloid cells-1 (TREM-1) is a novel innate immune receptor which amplifies TLR-induced inflammatory response. TREM-1 plays important role in many infectious diseases and aseptic inflammatory diseases. However the precise functions of TREM-1 in diseases remain controversial. Blockage of TREM-1 reduced the inflammation in mice with sepsis and collagen-induced arthritis (CIA) but promoted microbial-induced sepsis, pneumonia and liver abscess. Moreover, levels of soluble form of TREM-1 (sTREM-1) were found elevated in sera of SLE patients. These results suggest that TREM-1 may be involved in the progression of SLE. In this study, we established TREM-1^{-/-}.Lpr mice to investigate the role of TREM-1 in SLE. We found upregulated TREM-1 expression in spleen and lymph nodes of B6.Lpr mice. In addition, we found TREM-1^{-/-}.Lpr mice exhibited significantly lower survival rate and more severe syndromes, including higher spleen weight, lymph node weight, proteinuria, anti-dsDNA, anti-Sm/RNP antibodies, and renal immune complex deposition. Peripheral lymphocytes as well as myeloid dendritic cells, plasmacytoid dendritic cells, B cell and T cell subpopulations in both spleen and lymph nodes of TREM-1^{-/-}.Lpr mice were greatly increased. Importantly, the expansion of follicular B cells and plasma cells were consistent

with elevated serum B-cell activating factor (BAFF) levels in TREM-1^{-/-}.Lpr mice. The results suggest TREM-1 deficiency promotes lupus progression.

Department, Shiraz, Iran, Islamic Republic of

Hashimoto's disease (HD) is a archetypal organ specific autoimmune diseases. The substantial contribution from genetic factors in susceptibility to HD has been well-defined. The Fc receptor-like3 (FCRL3) gene is one of the genes that have recently shown a significant association with HD. To determine the possible role of FCRL3-169 C/T and FCRL3-110 A/G gene polymorphisms in the development of HD in Iranian patients, 220 HD patients and 302 healthy subjects were genotyped by polymerase chain reaction-restriction fragment length polymorphism. No significant difference was found in genotype and allele frequencies of FCRL3-169 C/T between patients and controls (Pv=0.55). In regards to position -110 A/G also no significant difference was found for genotype and allele (Pv= 0.6) between two groups of study. In conclusion, the results of this study showed no significant association between FCRL3-169 C/T and FCRL3-110 A/G polymorphism and susceptibility to HD.

908

Autophagy is suppressed by immune complex and TNF-alpha in glomerular endothelial cells

Wang, L., Law, H.K.W.

Hong Kong Polytechnic University, Department of Health

Technology and Informatics, Faculty of Health and Social Science, Hong Kong, China

Background: Lupus nephritis (LN) is a common complication of SLE. Glomerular endothelial cell (GEC) is one of the three components of the glomerular filtration barrier, which is the structural foundation of renal functions. However, GECs have been little studied and the precise mechanisms by which GECs are injured in LN remain unknown. Autophagy is a conserved metabolic process and shows protective roles in many cell types under stresses. Our previous results showed that heat-aggregated gamma globulin (HAGG), a substitute for immune complex, led to suppressed autophagy and injuries in GECs. TNF-alpha is elevated in serum and overexpressed in kidney in LN patients. Thus, in present study, we investigated the roles of TNF-alpha on GEC autophagy and dysfunctions.

Methods: GECs were incubated with TNF-alpha alone or in combination with HAGG. Proteins related to autophagy,

including LC3, p62, and mTOR, were determined by western blotting. Endothelial NOS (eNOS) expression was measured to evaluate endothelial function.

Results: TNF- α led to increased expressions of p62 and phosphorylated-mTOR (Ser2448) in GECs. Intriguingly, the ratio of LC3 II/I was slightly elevated. GECs were injured as phosphorylated-eNOS (Ser1177) expression was decreased. Co-stimulation of GECs with TNF- α and HAGG led to further decrease in phosphorylated-eNOS expression.

Conclusions: Our results showed that TNF- α suppressed autophagy in GECs through an mTOR-dependent pathway and led to cell injury. Co-stimulation of GECs with TNF- α and HAGG further damaged the cells. The suppressed autophagy in GECs may provide new insights for the mechanisms of renal impairments in LN patients.

Characterization of the Systemic Lupus Erythematosus associated single nucleotide polymorphism RS1143678 in integrin α M(CD11b) subunit

Ong, L.T., Tan, S.M.

Nanyang Technological University, School of Biological Sciences, Singapore, Singapore

Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that affects skin, joints, kidneys, brain and other organs. Genome wide analysis studies have identified single nucleotide polymorphisms in integrin α M β 2 (CD11bCD18) that are associated with SLE. Integrin α M β 2 is involved in various myeloid immune responses, including cell migration, phagocytosis, oxidative burst, and tolerance. Herein, we examined the single nucleotide polymorphism RS1143678 that substitutes Pro1146 to Ser in the cytoplasmic tail of integrin α M. Using reconstituted bone marrow-derived macrophages, we showed that integrin α MP1146S β 2 promoted cell adhesion and spreading, exhibited faster kinetics in terms of ERK1/2 phosphorylation and augmented IL-6 production in the presence of LPS compared with wild-type α M β 2 cells. Neutrophils expressing integrin α MP1146S β 2 also showed elevated adhesive capacity when stimulated with PDBu compared to cells expressing wild-type α M β 2. Inhibition of SFK and Syk pathways blunted integrin α MP1146S β 2 induced ERK1/2 activation. The different properties of integrin α MP1146S β 2 compared with wild-type α M β 2 may be attributed to a higher propensity of α MP1146S β 2 to cluster. Altogether, these data suggest that RS1143678 (integrin α MP1146S β 2) confers a pro-inflammatory property to myeloid cells.

The avidity of T cell receptor for self peptide-MHC complex dictates the diabetogenicity of CD8⁺ T cells in autoimmune diabetes

Yeh, L.-T., Chen, Y.-P., Sytwu, H.-K.

National Defense Medical Center, Taipei, Taiwan, Republic of China

Ptpn22 encodes PEST domain-enriched tyrosine phosphatase (Pep), a negative regulator of TCR proximal signaling molecules. We previously generated a T cell-specific *Ptpn22* transgenic

mouse model and demonstrate different modulation of *Ptpn22* in effector and regulatory T cells leads to attenuation of autoimmune diabetes in transgenic nonobese diabetic (NOD) mice. Recently, we observe that transgenic Pep attenuates the proliferation and diabetogenicity of CD8⁺ T cells in NOD mice but not in NOD8.3 TCR transgenic mice. Moreover, the TCR-induced cell proliferation of NOD8.3 CD8⁺ T cells is higher than that of NOD T cells, suggesting the regulatory potential of transgenic Pep on CD8⁺ T cells may be affected and/or masked by a selection bias of 8.3 TCR transgenic T cells. Recent studies demonstrate that the avidity of TCR for self peptide-major histocompatibility complex (self-pMHC) can be reflected in CD5 expression, further dictates the responses of naive T cells to foreign antigens. We observe a higher expression of CD5 in NOD8.3 CD8⁺ T cells than in NOD CD8⁺ T cells. Moreover, the CD5 expression on NOD CD8⁺ T cells positively correlates with the expressing profile of effector molecules and the response of cells to TCR stimulation, suggesting that the high self-recognition cells dominate the immune response to autoantigens in autoimmune diabetes. Taken together, the avidity of TCR for self-pMHC dictates the diabetogenicity of CD8⁺ T cells and masks the regulatory potential of transgenic *Ptpn22* in autoimmune diabetes.

Background: Hepatitis C virus (HCV) infection has been linked to systemic auto-immunity. This may have prognostic implications in the clinical management of HCV infection. Despite multiple observational studies, there does not appear to be any study that has systematically evaluated the prevalence rate of serological markers relevant to autoimmune manifestations in HCV infection compared to their prevalence in a general population.

Method: This study examines a panel of diagnostic autoantibodies (AABs) in subjects with chronic HCV infection (n=142) and age and gender matched general Australian population (n=198). AABs tested were: anti-nuclear antibodies (ANA), extractable nuclear antigen, anti-neutrophil cytoplasmic antibodies (ANCA), myeloperoxidase, proteinase 3, glomerular basement membrane, smooth muscle antibody (SMA), mitochondrial, liver kidney microsomal, β 2 glycoprotein I IgG/M/A, cardiolipin, tissue transglutaminase, parietal cell, intrinsic factor, thyroid peroxidase and cyclic citrullinated peptide.

Results: HCV subjects showed increased positivity for at least one autoantibody as compared to controls ($p < 0.0001$), with no additional gender effect. ANA followed by SMA were the most frequently detected autoantibodies within the HCV cohort. The SMA was commonly classified as mainly non-specific vessel and glomerular staining and not directed against the F-actin, which is specific for autoimmune hepatitis. ANCA were detected more frequently in the HCV cohort compared to the general population. Variation at IL-28B was not associated with AAB positivity.

Conclusion: A systemic comparison between two cohorts shows significant differences in autoimmune manifestations. However, due to the low level and lack of high specificity of some of the AABs they are unlikely to impact clinical outcomes.

912

Restraint of autoreactive T cell expansion is defective in female BALB/c ZAP70^{W163C} mutant (SKG) mice

Rahman, M.A., Montizaan, D., Bhuyan, Z.A., Rehaume, L.M., Thomas, R.
The University of Queensland Diamantina Institute, Brisbane, Australia

In the context of reduced TCR signaling in the BALB/c ZAP70^{W163C} mutant (SKG) mouse, auto-reactive CD4⁺ T cells are increased and female mice develop arthritis, psoriasis-like skin inflammation and ileitis within weeks after intra-peritoneal injection of microbial β -glucan (curdlan). Curdlan-triggered disease is mild in BALB/c mice and male SKG mice. It is not known how systemic adjuvant promotes T-cell-mediated tissue inflammation or the influence of gender. To elucidate where CD4⁺ T cells expand, syngeneic luciferase-expressing CD4⁺ T cells were adoptively transferred, and tracked *in vivo* post-curdlan in female SKG mice using *in vivo* bioluminescence imaging. Bioluminescence increased in spleen and inguinal lymph nodes 3 days post-curdlan, followed by focal signals from the ankles, tail, ears and abdomen at day 7, and wrists at day 10. Without curdlan, CD4⁺ T cells expanded to a lesser extent in lymph nodes and spleen by day 7, but did not traffic to joints. Signal from transferred SKG T cells increased at low level in spleen of curdlan-treated but not naive female BALB/c recipients from day 7-10 and subsequently disappeared. In male SKG recipients, signal from transferred SKG T cells increased at low level in spleen of curdlan-treated SKG but not BALB/c recipients. These data indicate that self-reactive SKG T cells spontaneously expand in lymphoid organs of female SKG mice. Systemic curdlan increases T cell activation and tissue infiltration in females, but autoreactive T cell activation is restrained in BALB/c hosts and male SKG host mice, implying deficient peripheral tolerance specifically in female SKG hosts.

913

Targeted delivery of withaferin-A incorporated mannosylated liposomes to the synovial macrophages suppresses the inflammatory immune response in adjuvant-induced arthritic rats - a potential therapeutic approach

Sultana, F., Rasool, M.

VIT University, School of BioSciences and Technology, Vellore, India

Rheumatoid arthritis is characterized by a chronic inflammation of the joint synovium where macrophages are activated and proliferate in an abnormal way, leading to the production of pro-inflammatory cytokines and inflammatory enzymes. To diminish inflammation and to prevent irreversible joint damage, selective counteraction of macrophage activation seems to be an appropriate approach. Therefore, our study was designed to explore whether withaferin-A, a steroidal lactone incorporated mannosylated liposomes are effective in suppressing the inflammatory immune response in the synovial macrophages of adjuvant-induced arthritic rats. Arthritis was induced by intradermal injection of complete Freund's adjuvant (0.1ml) into the right hind paw of the Wistar albino rats. The rats were treated intravenously with either withaferin-A incorporated mannosylated liposomes (10mg/kg/b.wt) for 3 days (11th, 14th, 17th day) or free withaferin-A alone (30mg/kg/b.wt) or saline for 8 days (from 11th to 18th day) after adjuvant injection. Withaferin-A incorporated mannosylated liposomes suppressed the paw swelling and levels of oxidative stress markers (ROS and NO) and pro-inflammatory cytokines (TNF- α , IL-6, and IL-1 β) in synovial macrophages of arthritic rats. Consistently, the expression of pro-inflammatory cytokines (TNF- α , IL-6, and IL-1 β), inflammatory enzymes (iNOS and COX-2) and transcription factor NF-kBp65 was also found downregulated at both the gene and protein level. These results indicate that the efficacy of withaferin-A incorporated mannosylated liposomes suppressed inflammatory immune response in arthritic synovial macrophages more effectively than the free drug withaferin-A.

914

The potential role of human endogenous retrovirus HERV-K10 in the pathogenesis of rheumatoid arthritis through molecular mimicry

Trela, M.¹, Nelson, P.¹, Ryland, P.²

¹University of Wolverhampton, Faculty of Science and Engineering, Wolverhampton, United Kingdom, ²Royal Wolverhampton New Cross Hospital NHS Trust, Wolverhampton, United Kingdom

Human endogenous retroviruses (HERVs) constitute 8% of the human genome and represent ancient retroviral infectious agents that have since been incorporated into our DNA. HERVs have then been inherited through successive generations in a Mendelian manner. Whilst many HERV families are defective, some can become activated and produce viral particles and products.

HERV-K10 is one such virus that has been linked with rheumatoid arthritis (RA). Preliminary analysis of HERV-K10 has identified a highly antigenic epitope within the Gag matrix region of this virus. Following the development of a representative synthetic

peptide (GKELK; defined as MAG1), significant IgG antibody reactivity to this epitope has been observed in patients with RA as compared to controls. A homologous region (GKEYK) within IgG1Fc, a key auto-antigen in RA, was revealed. On developing a polyclonal antibody (PAbMAG1) to the viral synthetic peptide, we have demonstrated immunological cross-reactivity in a range of immunoassays to IgG1Fc. We have also shown that the epitope on IgG1Fc, recognized by PAbMAG1, is targeted by Rheumatoid Factor (RF) auto-antibodies generated in RA.

These results confirmed immune reactivity to both virus and auto-antigen thus highlighting the potential for molecular mimicry between HERV-K10 Gag matrix and IgG1Fc. Consequently, HERV-K10 could trigger and/or augment reactivity to IgG1Fc in RA patients and provide a mechanism which contributes to RA pathogenesis.

Finally our results raise the possibility of HERV-K10 peptide or antibody as potential therapeutic blocking agents of rheumatoid factors which could transform patient therapy. A novel diagnostic/prognostic test for RA may also be provided.

915

Unravelling the multiple sclerosis complex disease trait through an immune transcriptional regulatory network approach

Jordan, M.A.¹, Gresle, M.², Laverick, L.², Stanley, D.³, Smith, L.¹, Spelman, T.², Field, J.⁴, Johnson, L.⁴, Butzkueven, H.², Baxter, A.G.¹

¹Comparative Genomics Centre, James Cook University, Molecular and Cell Biology, Townsville, Australia, ²University of Melbourne, Department of Medicine, Melbourne, Australia, ³Central Queensland University, Rockhampton, Australia, ⁴The Florey Neuroscience Institute, Melbourne, Australia

Multiple Sclerosis (MS), the most common disabling neurological disease affecting young adults in developed countries, is a complex genetic disease associated with both environmental and genetic risk factors. In most cases, the risk factors' individual associations with MS are so weak that any meaningful understanding of the disease will require the identification of molecular pathways that contribute to MS liability. We therefore hypothesised that the complex genetic phenotype is driven by a co-ordinated expression of transcriptional regulatory networks. To test this, we generated a weighted gene co-expression network based on 712 pooled Affymetrix Human Gene 1.0 ST array analyses of magnetic bead sorted B cells, CD4 and CD8 T cells, NK cells and monocytes, from 67 untreated relapsing/remitting MS patients and 102 Healthy Controls (HC). Sixteen relatively independent gene modules were identified. For each leukocyte population, the strength of differential expression between patients and HC was assessed, by ranking genes by Mann Whitney U test and ANOVA, and each transcript was tested across the network to identify modules of interest. A group of transcripts we named the "Black" module was most significantly associated with MS in monocytes & was strongly down-regulated in patients. Twelve highly differentially expressed genes with high centrality were identified and the top annotation clusters comprised the immune processes: Natural killer cell mediated cytotoxicity & Antigen processing and presentation. We propose that manipulating the module

as a whole may provide a new perspective on the aetiology of complex genetic diseases and offer novel therapies for MS.

916

Role of PD-L2 in B lymphocytes during the development of lupus

Hidalgo, Y.¹, Fuenzalida, M.J.¹, Roseblatt, M.², Sauma, D.¹, Bono, M.¹

¹Universidad de Chile, Biology, Santiago, Chile, ²Fundación Ciencia & Vida, Biology, Santiago, Chile

Introduction: Systemic lupus erythematosus is an autoimmune disease characterized by activation of autoreactive T and B lymphocytes, autoantibody production and immune complex deposition, which causes damage to various tissues and organs. Autoimmune diseases are caused by the loss of immunological tolerance. Tolerance is regulated by a balance between stimulatory and inhibitory signals between antigen presenting cells and T lymphocytes. PD-L2 is an inhibitory ligand expressed on antigen presenting cells that binds to PD-1 expressed in T lymphocytes.

Materials and methods: We evaluated the expression of PD-L2 in the B lymphocytes of mice susceptible to the development lupus (BWF1).

Results: Our results demonstrate that during the development of the disease there is an increase in the number of B cells in the spleen. Moreover, we observed a significant rise in the percentage of B cells in the thymus. In both, thymus and spleen, B cells show a reduced expression of PD-L2. To assess the role of PD-L2 on B cells in the development of lupus we compare the ability of B cells before and after the development of lupus to inhibit the proliferation of antigen-specific CD4+ T lymphocytes and their capacity to differentiate into cells secreting anti-DNA autoantibodies.

Conclusions: Together our results suggest that expression of PD-L2 in B lymphocytes exert a protective role in the development of lupus.

A novel drug targeting dihydroorotate dehydrogenase for treating inflammation and chorioretinal neovascularization in relapsing-remitting and chronic experimental autoimmune uveitis

Diedrichs-Möhrling, M.¹, Niesik, S.¹, Lebn, J.², Strobl, S.², Obermayr, F.³, Thurau, S.¹, Wildner, G.¹

¹Clinic of the University of Munich, Dept. of Ophthalmology, Section of Immunobiology, Munich, Germany, ²4SC Discovery GmbH, Planegg-Martinsried, Germany, ³Panoptes Pharma GmbH, Vienna, Austria

Experimental autoimmune uveitis (EAU) in rats is a suitable model for the respective intraocular inflammatory disease in humans. We investigated the effect of the dihydroorotate dehydrogenase inhibitor PP-001 in two EAU models: a spontaneously relapsing-remitting model and a monophasic/chronic disease resulting in chorioretinal neovascularization.

Daily oral applications of PP-001 after immunization with retinal S-Antigen peptide PDSAg (induces monophasic uveitis and neovascularizations) or the interphotoreceptor retinoid-binding protein peptide R14 (induces spontaneously relapsing-remitting EAU) abrogated both types of EAU. Uveitis was graded clinically and histologically.

Oral treatment after onset or peak of PDSAg-induced EAU significantly reduced neovascularizations (as determined by histology), and a significant reduction of the number and intensity of relapses in R14-induced EAU was observed when PP-001 treatment was initiated after resolution of the first attack of uveitis. Intraocular injection of PP-001 after resolution of R14-induced EAU also suppressed the number and intensity of relapses. PP-001 showed no toxic effect on rat eye tissues after intraocular injection.

Proliferation of autoantigen-specific rat T-cell lines and secretion of IFN- γ , IL-17, IL-10, IP10 and VEGF were efficiently suppressed by PP-001. PP-001 also suppressed proliferation and cytokine secretion of PHA-stimulated human PBL without affecting the viability of the cells. Treating the human retinal pigment epithelial cell line ARPE-19 with PP-001 no suppressive effect on proliferation, viability and VEGF production was observed.

Here we present a novel drug for systemic and local treatment of autoimmune uveitis without adverse effects on resident ocular cells.

The pemphigus-differentially expressed miR-223-3p induces p38 MAPK phosphorylation and IL-8 secretion possibly through direct inhibition of DUSP10

Cipolla, G.A.¹, Park, J.K.², Tadra-Sfeir, M.Z.³, Almeida, R.C.¹, Malheiros, D.¹, Souza, E.M.³, Roselino, A.M.⁴, Lavker, R.M.², Petzl-Erler, M.L.¹

¹Federal University of Parana, Department of Genetics, Curitiba, Brazil, ²Northwestern University Feinberg School of Medicine, Department of Dermatology, Chicago, United States, ³Federal University of Parana, Department of Biochemistry, Curitiba, Brazil, ⁴University of São Paulo, Division of Dermatology, School of Medicine of Ribeirão Preto, São Paulo, Brazil

MicroRNAs (miRNAs) are small non-coding RNAs that fine tune gene expression, being involved in virtually all signaling pathways. Pemphigus is an autoimmune skin disease characterized by IgG autoantibodies capable of activating different signaling pathways that ultimately lead to loss of keratinocyte intercellular adhesion, the disease hallmark. To understand the role of miRNAs in pemphigus, we first established the differentially expressed miRNAs between lesional and non-lesional skin biopsies of three pemphigus foliaceus (PF) patients through small RNA-sequencing. We identified miR-223-3p as the potentially most upregulated miRNA in PF lesions ($P=0.09$; fold change 7.58), and further confirmed this result in a larger sample ($n=7$) comprising also two pemphigus vulgaris biopsy pairs ($P=0.02$; fold change 6.77). Transfection of miR-223-3p mimic in HaCaT cells followed by western blot revealed that p38 phosphorylation was 5.5-fold increased. Downstream of p38 activation after

miR-223-3p transfection, we found increase of both HSP27 protein levels and IL-8 mRNA levels ($P<0.01$), the latter also being augmented in HaCaT culture media. IL-8 mRNA levels were rescued after miR-223-3p transfection in the presence of a well-known p38 inhibitor ($P=0.03$). We hypothesized that miR-223-3p downregulates a negative regulator of the p38 pathway and therefore tested protein levels of three dual-specificity phosphatases (DUSP) predicted to be direct targets of miR-223-3p. Preliminary results suggest DUSP10 as direct target of miR-223-3p. In conclusion, we show that miR-223-3p overexpression increases HSP27 and IL-8 production by inducing p38 MAPK phosphorylation, a key factor contributing to pemphigus onset/progression. Ultimately, this may allow development of miRNA-based pemphigus therapy.

Keywords: microRNA profiling; pemphigus; autoantibodies; miR-223-3p; p38 MAPK; HSP27; DUSP10.

Introduction: Approximately 20% of Caucasian population lacks Glutathione S-transferase Theta 1 (GSTT1), an enzyme involved in cellular detoxification that can induce the production of anti-GSTT1 antibodies in transplanted patients with GSTT1 mismatch between a positive donor and a null receptor. These antibodies may influence graft dysfunction in liver and kidney transplantation.

Aim: The aim of our study was to identify, retrospectively, whether the presence of anti-GSTT1 antibodies was associated to a higher risk of developing greater graft dysfunction and or rejection, compared to controls; and validate the ELISA test with the human GSTT1-recombinant protein, using indirect immunofluorescence (IIF) as gold standard method.

Methods: We included 26 (10 kidney and 16 liver) transplanted patients from Hospital Clínic, Barcelona, from 2010 until 2015, with no donor anti-HLA specific antibodies. Ten patients had a positive IIF characteristic pattern of anti-GSTT1 antibodies.

Results: Preliminary results showed that 1/4(25%) of anti-GSTT1 positive kidney transplant and 4/6(66.7%) of GSTT1 positive liver transplanted patients experienced graft rejection vs 2/6(33.3%) of kidney and 1/10(10.0%) liver control patients ($p=0.5320$ and $p=0.0216$ respectively). After adjust the cutoff, IIF positive samples were also positive through the ELISA.

Conclusion: Although the study group is small, a 100% correlation was obtained between IFI and ELISA detection of anti-GSTT1 antibodies, and the results confirm previous studies showing a higher risk of graft rejection in liver transplant patients with anti-GSTT1 antibodies and suggest that

monitoring the presence of anti-GSTT1 antibodies in recipients of GSTT1 mismatch liver transplant could help to predict liver graft rejection.

CD141⁺ CLEC9A⁺ dendritic cells are enriched in an active state in the inflamed synovium and contribute to synovial inflammation in rheumatoid arthritis

Canavan, M.¹, O'Rourke, M.², Orr, C.², Basdeo, S.³, Fletcher, J.³, Veale, D.², Fearon, U.¹

¹Trinity College Dublin, Trinity Biomedical Sciences Institute, Molecular Rheumatology, Dublin, Ireland, ²Centre for Arthritis and Rheumatic Diseases, St Vincent's University Hospital, Translational Rheumatology Research Group, Dublin, Ireland,

³Trinity College Dublin, Trinity Biomedical Sciences Institute, School of Immunology and Biochemistry, Dublin, Ireland

Studies identifying dendritic cell (DC) subsets in human disease are limited. Most focus on blood with few characterising DC from inflamed tissues. The aim of this work was to characterise DC from the synovium in Rheumatoid Arthritis. RA synovial fluid (SF), synovial tissue (ST) & whole blood (WB) were collected & used for DC characterisation. RA patients had significantly less mDC in WB compared to HC, suggesting these cells are recruited to the site of inflammation. Upon examination of DC in the synovium we identified an increase in CD11c⁺ HLADR⁺ myeloid cells in ST compared to WB. These cells had increased expression of CD80/CD40 & expressed monocytic markers CD64 & CD14. Additionally, upon examination of mDC in SF, they exhibited a more mature phenotype compared to WB (increased CD80/CD40). There was a significant increase in CD141⁺ DC within the SF compared to WB & these cells expressed the immune amplification receptor TREM1. SF CD141 DC expressed higher levels of CD80/CD86 & CD40 compared to WB & had a heightened response to TLR3 stimulation. To examine the effect of the synovial microenvironment on DC, MoDC were cultured in the presence of SF which induced a significant increase in CD80. Finally DC treated with SF & cocultured with CD4⁺ T cells had enhanced IFN γ production & proliferation. Our data suggests that unique DC subsets can be found in RA. These cells display a more activated phenotype than DC in blood & the inflammatory nature of the joint contributes to this activation.

Increased circulating follicular T helper (Tfh) cells in children with type I diabetes

Izad, M.¹, Arab, M.¹, Razzaghi-azar, M.², Salehi, Z.¹, Mehdi shekarabi, Maryam Keshavarz, Ensieh Nasli

¹School of Medicine, Tehran University of Medical Sciences, Immunology, Tehran, Iran, Islamic Republic of, ²Shariati Hospital, Tehran University of Medical Sciences, Endocrinology and Metabolism Research Center, Tehran, Iran, Islamic Republic of

Background: Type 1 diabetes (T1D) is an autoimmune disease resulting from the damage of pancreatic β -cells because of autoreactive CD4⁺ and CD8⁺ T cells activation. In recent years, follicular T helper (Tfh) cells have been recognized as

a subpopulation of CD4⁺ T cells providing help for B cells differentiation and antibody production. So far, several studies have been investigated the role of circulating Tfh cells in autoimmune diseases. In this study, we examined the frequency of circulating Tfh cells and aglutamic acid decarboxylase autoantibodies (GAD65) and islet cell autoantibodies (ICA) serum level in children with type I diabetes.

Methods: We analyzed the percentage of Tfh cells within peripheral blood mononuclear cells in T1D patients (\leq 300 days from disease onset; n=20; Mean age 6.8 ± 4.6 years) and healthy individuals (n=18; Mean age 8.8 ± 2.2 years) by flowcytometry. Anti-GAD and islet cell autoantibodies (ICA) level were determined using enzyme-linked immunosorbent assay (ELISA) and indirect immunofluorescence (IF) respectively.

Results: We found that the frequency of CD4⁺CXCR5⁺ and CD4⁺CXCR5⁺ICOS⁺ Tfh cells were increased significantly in the peripheral blood of patients, compared with that of healthy controls ($P < 0.0001$); Furthermore, an increased level of Anti-GAD and ICA was seen in Patients compared to controls ($P=0.001$ and $P=0.02$ respectively). There was no correlation between Tfh cells frequency and the autoantibody levels.

Conclusion: Our results demonstrated the possible involvement of Tfh cells in T1D and suggest that Tfh cells could be considered as a therapeutic target in type 1 diabetes.

922

Correlation of miR-146a and miR-155 with regulatory T cell in systemic lupus erythematosus patients

Rastin, M.¹, Mahmoudi, M.², Hasannejad, A.¹, Sahebari, M.³, Rezaei Yazdi, Z.³, Tabasi, N.⁴, Ekrami, Z.⁴, Jaber, S.⁴, Yazdanpanah, E.⁴, Esmaili, A.⁴, Khazaei, M.⁴

¹Bu Ali Research Institute, Faculty of Medicine, Mashhad University of Medical Sciences, Immunology Research Center, Mashhad, Iran, Islamic Republic of, ²Mashhad University of Medical Sciences, Immunology Research Center, Mashhad, Iran, Islamic Republic of, ³Rheumatic Disease Research Center, Internal Medicine Department, Ghaem Hospital, Faculty of Medicine, Mashhad University of Medical Sciences, Internal Medicine Section, Mashhad, Iran, Islamic Republic of, ⁴BuAli Research Institute, Faculty of Medicine, Mashhad University of Medical Sciences, Immunology Research Center, Mashhad, Iran, Islamic Republic of

Introduction: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by the presence of pathogenic autoantibodies. Dysregulated number and function of regulatory T cells are implicated in the pathogenesis of SLE. MicroRNAs are small noncoding RNAs that regulate the expression of the genes involved in immune responses regulation. These molecules are concerned as anticipant biomarkers for diagnosis, prognosis and treatment of SLE. In this study we purposed to investigate the expression of microRNAs and its association with regulatory T cell in systemic lupus erythematosus patients.

Materials and methods: In the current study, 20 healthy controls and 20 patients with SLE were studied. Their PBMCs were isolated, and regulatory T cells were analyzed by flow cytometry. MiRNAs was extracted, cDNA synthesized and the gene expression of miR-146a, and miR-155 were assessed by

Real-Time PCR method.

Result: in SLE patients the expression level of miR-146a decreased compared to controls (1.83 ± 2.1 versus 4.01 ± 5.26), while the expression of miR-155 increased significantly compared to controls (11.07 ± 4.51 versus 7.77 ± 3.72) ($p < 0.001$). Decreased expression of miR-146a had positive correlation with regulatory T cells ($p = 0.029$).

Conclusion: MicroRNAs could control cellular events such as cell growth, and differentiation. They have influence on the regulatory T cell population. It seems that by influencing regulatory cells these molecules can control immune responses in SLE patients.

923

Correlation of TLRs with autoantibodies profile in systemic lupus erythematosus patients

Rastin, M.¹, Mahmoudi, M.², Ekrami, Z.², Sahebari, M.³, Rezaei Yazdi, Z.³, Hasannejad, A.¹, Jaber, S.¹, Yazdanpanah, E.¹, Tabasi, N.¹, Esmaili, A.¹

¹BuAli Research Institute, Faculty of Medicine, Mashhad University of Medical Sciences, Immunology Research Center, Mashhad, Iran, Islamic Republic of, ²BuAli Sq, Ferdousi Sq, BuAli Research Center, Immunology Research Center, Mashhad, Iran, Islamic Republic of, ³Rheumatic Disease Research Center, Internal Medicine Department, Ghaem Hospital, Faculty of Medicine, Mashhad University of Medical Sciences, Internal Medicine Section, Mashhad, Iran, Islamic Republic of

Introduction: Systemic lupus erythematosus (SLE) is a severe systemic autoimmune disease with heterogeneous clinical manifestations. Recent experimental and clinical studies have placed new emphasis on the role of Toll-Like Receptors (TLRs) in the pathogenesis of SLE. TLRs are important innate immune receptors for the identification and clearance of pathogens. TLRs by deleting apoptotic cells play an important role in the control of the production of pathogenic autoantibodies and development of clinical features of SLE.

Materials and methods: In the current study, Peripheral Blood Mononuclear Cells (PBMCs) from 20 SLE patient and 20 healthy controls were separated. RNAs was extracted using Tripure, cDNA was synthesized, and the expression levels of TLR3, and TLR8 genes were assessed by Real-Time PCR method. Autoantibodies profile was screened on serum by using a commercial kit.

Results: The expression level of TLR3 was up-regulated in SLE patients compared to controls (5.96 ± 2.47 VS, 5.05 ± 3.44), while the expression of TLR8 was down-regulated (0.17 ± 2.89 VS, 3.18 ± 5.34) ($p = 0.03$). Ninety percent of SLE patients were ANA positive, and anti-SSA was the most prevalent autoantibody, followed by anti-dsDNA (59.1%) and anti-nucleosomes (57.9%). Our findings showed that the increased expression of TLR3 was significantly correlated with the presence of anti-nucleosomes autoantibodies in SLE patients ($p = 0.03$).

Conclusion: Our results showed that TLR3 and TLR8 has differential expressions in SLE patients compared to controls, we also showed that TLR3 may play an important role in the pathogenesis of SLE by power on the production of some autoantibodies.

924

In experimental autoimmune anti-glomerular basement membrane glomerulonephritis, HLA-DR15 inhibition blocks autoreactivity to the immunodominant T cell epitope, $\alpha 3_{135-145}$, and prevents disease

Huynh, M.¹, Eggenhuizen, P.J.¹, Olson, G.L.², Bhaskara Rao, N.², Self, C.R.², Sun, Y.², Holdsworth, S.R.^{1,3}, Kitching, A.R.^{1,3,4}, Ooi, J.D.¹

¹Monash University, Centre for Inflammatory Diseases, Clayton, Australia, ²Provid Pharmaceuticals, Monmouth Junction, United States, ³Monash Health, Department of Nephrology, Clayton, Australia, ⁴Monash Health, Department of Paediatric Nephrology, Clayton, Australia

Anti-glomerular basement membrane (GBM) disease is an autoimmune disease that manifests as rapidly progressive glomerulonephritis. It has a strong HLA association with the DR15 allele (odds ratio: 8.5) and the immunodominant, DR15-restricted T-cell epitope has been defined. A DR15 specific inhibitor, PV-267, has potential as a targeted therapy, as current treatments are non-specific and have detrimental side effects. Using humanised HLA transgenic mice expressing DR15, this study tests the hypotheses that administration of PV-267 will inhibit autoreactivity to the immunodominant T cell epitope, $\alpha 3_{135-145}$ and prevent disease in experimental autoimmune anti-GBM disease. Autoreactivity to $\alpha 3_{135-145}$ was determined by immunizing mice with $\alpha 3_{135-145}$, then measuring recall responses *ex vivo* 10 days later by [³H]-T proliferation and IFN- γ and IL-17 ELISPOTs. Experimental anti-GBM disease was induced by immunizing DR15 transgenic mice (backcrossed onto an Fc γ R11b^{-/-} background) with three weekly injections of $\alpha 3_{135-145}$, then functional and histological endpoints measured at 6 weeks.

Compared with mice that received vehicle control, DR15 transgenic mice that received PV-267 daily (30mg/kg) from day -1 developed markedly reduced $\alpha 3_{135-145}$ -specific proliferation (SI: 9.5 ± 0.9 vs 2.2 ± 0.5 , $P < 0.001$) as well as reduced numbers of IFN- γ and IL-17 spots. In experimental anti-GBM disease, DR15 transgenic mice that received PV-267 (30mg/kg) on alternate days from day -1 had markedly reduced 24 hour albuminuria (mg: 1064 ± 313 vs 42 ± 29 , $P < 0.01$) and reduced glomerular segmental necrosis and glomerular crescent formation. In conclusion, PV-267 effectively prevents experimental autoimmune anti-GBM disease, and highlights the potential for specific MHCII inhibitors as a targeted therapy for autoimmune disease.

925

Changes of MMP-2 and MMP-9 levels in arthritis rats after inhibiting of LOX

Liu, R.¹, Han, M.²

¹General Hospital of Ningxia Medical University, Department of Rheumatology and Immunology, Yinchuan, China, ²Ningxia Medical University, Department of Immunology, Yinchuan, China

Objective: Inhibiting lysyl oxidase (LOX) with β -aminopropionitrile (BAPN), detected the levels of the MMP-2 and 9 in spleen and thymus of arthritis arthritis rat.

Methods: The SD rats were divided into control, model

and intervention group, Rats in model group were injected intradermally bovine type II collagen with complete Freund's adjuvant into tail, back and paw to induce arthritis. Rats in intervention group were induced arthritis using the same way as the model group, injected BAPN 100mg/kg.day for 40 days intraperitoneally. Rats in the control group were injected with normal saline. The morphological changes of spleen and thymus were observed through HE staining. The levels of MMP-2 and MMP-9 in the Spleen and Thymus were determined by immunohistochemistry.

Results: Cells in the areas of cortex of thymus and white pulp of spleen become more in model group and intervention group. Levels of MMP-2 and MMP-9 in the spleen and thymus of model group and intervention group were significantly higher than the control group ($P < 0.05$). Expression of MMP-2 and MMP-9 in the spleen and thymus of the intervention group were significantly lower than the model group ($P < 0.05$).

Conclusion: High expression of MMP-2 and MMP-9 in the spleen and thymus of rats with arthritis, the levels of MMP-2 and MMP-9 were decreased after inhibiting LOX. Suggest that inhibition of LOX may reduce the pathological reaction that MMP-2 and MMP-9, and LOX may be as a new target for the treatment of arthritis.

The gluten-specific T cell repertoire is stable in coeliac disease irrespective of age

Hardy, M.Y.^{1,2}, Girardin, A.¹, Pizzey, C.^{3,4}, Cameron, D.J.^{3,5}, Watson, K.A.⁶, La Gruta, N.L.^{6,7}, Anderson, R.P.⁸, Tye-Din, J.A.^{1,2,4}

¹Walter and Eliza Hall Institute of Medical Research, Immunology Division, Melbourne, Australia, ²The University of Melbourne, Department of Medical Biology, Melbourne, Australia, ³Murdoch Childrens Research Institute, The Royal Children's Hospital, Melbourne, Australia, ⁴The Royal Melbourne Hospital, Department of Gastroenterology, Melbourne, Australia, ⁵The Royal Children's Hospital, Department of Gastroenterology, Melbourne, Australia, ⁶The Peter Doherty Institute for Infection and Immunity, Department of Immunology, Melbourne, Australia, ⁷University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ⁸ImmusanT, Inc, Cambridge, MA, United States

Antigen-specific approaches for the diagnosis and treatment of coeliac disease (CD) require detailed understanding of pathogenic CD4⁺ T cells. The pathogenic gluten peptides are well established in adults with CD, but few studies from children suggest the T-cell response is more diverse than in adults. We aimed to characterize the *in vivo* recall T-cell response following short-term oral wheat and/or barley challenge in paediatric CD. Children with HLA-DQ2.5⁺ CD (aged 3-17 years) consumed wheat bread or barley biscuits for 3 days. Peripheral blood was collected on day 6 and T-cell responses were measured by IFN- γ ELISpot to a set of wheat, barley, and rye peptides previously shown to be immunogenic in CD adults.

Gluten-specific responses were detected in 33/45 (73%) children. Recognition of peptides relevant in adults with CD

was highly consistent in children, and like adults, deamidation was important for bioactivity. Homozygosity for HLA-DQ2.5 was associated with response magnitude, but age and time since diagnosis was not. Gluten-specific T cells from children demonstrated comparable levels of cross-reactivity to wheat, rye, and barley peptides as those from adults. α -gliadin-specific T cells showed similar T cell receptor usage with biased TRBV7-2 expression, public CDR3 β sequences, and conserved Arg residues. In adults, public α - and ω -gliadin-specific CDR3 β 's were detected following challenge with two different grains (wheat and barley).

In paediatric CD, the peptide hierarchy, deamidation dependence, cross-reactivity, and T-cell repertoire induced by *in vivo* grain challenge are similar to adults, suggesting additional utility of peptide-based applications designed in adults with CD.

927

Methyltransferase Ash1l controls T cell autoimmunity by upregulating Smad3 to polarize iTreg cell generation

Xia, M.¹, Liu, J.², Liu, S.², Chen, K.³, Xue, Y.², Cao, X.¹

¹National Key Laboratory of Medical Molecular Biology & Department of Immunology, Institute of Basic Medical Sciences, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China, ²National Key Laboratory of Medical Immunology & Institute of Immunology, Second Military Medical University, Shanghai, China, ³Institute of Immunology, Zhejiang University School of Medicine, Hangzhou, China

Transforming growth factor- β (TGF- β)-dependent regulatory T (Treg) cells are important for maintenance of immune homeostasis and prevention of autoimmune diseases, but the mechanisms especially the epigenetic controls on their polarization still remain unclear. Here we report H3K4 methyltransferase Ash1l promotes TGF- β -mediated induced Treg (iTreg) cell generation. Less iTreg cells are generated from Ash1l-silenced CD4⁺ T cells, and Ash1l-silenced mice are more susceptible to T cell-mediated colitis with decreased iTreg cell generation. Mechanistically, Ash1l upregulates Smad3 expression by directly binding and modifying the Smad3 promoter. Furthermore, we identify a lncRNA, namely lnc-Smad3, which locates nearby the Smad3 promoter and silences its transcription at steady state. Under TGF- β stimulation, Smad3 suppresses lnc-Smad3 transcription, thereby recovering the Smad3 promoter accessibility to Ash1l. Our data add mechanistic insights into antagonistic crosstalk of histone modification and lncRNA in regulation of Treg cell fate by revealing the opposite role of Ash1l and lnc-Smad3 in epigenetic regulation of Smad3 expression.

928

Augmented AIRE expression paradoxically induces polymyositis-like autoimmunity in mice

Nishijima, H., Mouri, Y., Morimoto, J., Matsumoto, M.

Institute for Enzyme Research, Tokushima University, Tokushima, Japan

Autoimmunity is prevented by the function of transcriptional regulator Aire, which promotes the expression of wide

varieties of tissue-restricted antigens from medullary thymic epithelial cells (mTECs) and from a subset of peripheral antigen-presenting cells (APCs). We hypothesized that augmented expression of Aire would ameliorate autoimmune diabetes in NOD mice. We observed, in contrast, that mice overexpressing Aire developed muscle-specific autoimmunity associated with incomplete maturation of mTECs. This led to failure of deletion of autoreactive T cells together with dramatically reduced production of Tregs in the thymus. In peripheral APCs, costimulatory molecule expression was augmented by the additive Aire expression. Our results highlight the importance of coordinated action between central tolerance and peripheral tolerance under the common control of Aire. We suggest that autoimmune diseases develop not only by the loss of function of Aire but also by its augmented expression, which could occur in some forms of human autoimmune disease.

929

Impaired expansion of regulatory T cells in a neonatal thymectomy-induced autoimmune mouse model

Yamada, A., Ushio, A., Arakaki, R., Kudo, Y., *Ishimaru, N.*
Tokushima University Graduate School, Tokushima, Japan

Neonatal thymectomy (Tx) in certain mouse strains is known to induce organ-specific autoimmunity due to impaired functions of T cells, including Foxp3⁺ regulatory T (T_{reg}) cells in the thymus. The precise mechanism underlying the induction of autoimmunity by neonatal Tx remains unclear. One possibility is that depletion of T_{reg} cells breaks down peripheral tolerance. We examined the functions of T_{reg} cells by using a murine Sjögren's syndrome (SS) model, NFS/sld mice that underwent neonatal Tx. The ratio of T_{reg} cells to effector memory phenotype T cells in Tx mice was significantly lower than that of non-Tx mice. In addition, *in vitro* induction of peripherally induced T_{reg} cells by transforming growth factor- β (TGF- β) using naïve T cells from SS model mice was severely impaired. The mRNA expression of TGF- β receptor I, II, and Smad3 and -4 in the TGF- β -induced signal transduction pathway of T_{reg} cells in this SS model were lower than those of control mice. In addition, T_{reg} cells in this SS model exhibited an IFN- γ -producing Th1-like phenotype that resembled effector T cells. In conclusion, these results suggest that abnormal expansion and differentiation of T_{reg} cells and inflammatory cytokines produced by T_{reg} cells contribute to the development of autoimmunity.

931

Single cell gene expression studies in lupus patient monocytes reveal novel patterns reflecting disease activity, interferon, and medical treatment

Jin, Z.¹, Fan, W.², Jensen, M.A.¹, Dorschner, J.M.¹, Vsetecka, D.M.¹, Amin, S.¹, Makol, A.¹, Ernste, F.¹, Osborn, T.¹, Moder, K.¹, Chowdhary, V.¹, *Niewold, T.B.*¹

¹Mayo Clinic, Rochester, United States, ²Ren Ji Hospital, Shanghai Jiao Tong University, Shanghai, China

Background: Our previous studies have shown that different cell types from the same sample demonstrate diverse gene

expression, and important findings can be masked in mixed cell populations. In this study, we examine single cell gene expression in SLE patient monocytes and determine correlations with clinical features.

Methods: CD14⁺⁺CD16⁻ classical monocytes (CLs) and CD14^{dim}CD16⁺ non-classical monocytes (NCLs) from SLE patients were purified by magnetic separation. The Fluidigm single cell capture and RT-PCR system was used to quantify expression of 87 monocyte-related genes.

Results: Both CLs and NCLs demonstrated a wide range of expression of IFN-induced genes, and NCL monocytes had higher IFN scores than CL monocytes. Unsupervised hierarchical clustering of the entire data set demonstrated two unique clusters found only in SLE patients, one related to high disease activity and one related to prednisone use. Independent clusters in the SLE patients were related to disease activity (SLEDAI 10 or greater), interferon signature, and medication use, indicating that each of these factors exerted a different impact on monocyte gene expression that could be separately identified. A subset of anti-inflammatory gene set expressing NCLs was inversely correlated with anti-dsDNA titers ($\rho = -0.77$, $p=0.0051$) and positively correlated with C3 complement ($\rho = 0.68$, $p=0.030$) in the SLE patient group.

Conclusion: Using single cell gene expression, we have identified a unique gene expression patterns that reflect the major clinical and immunologic characteristics of the SLE patients which are not evident in bulk cell data, supporting the critical importance of the single cell technique.

932

Analysis of follicular helper T cells in a mouse model for Sjögren's syndrome

*Kunihiro, O.*¹, Masako, S.¹, Aya, U.¹, Takaaki, T.², Yasusei, K.¹, Rieko, A.¹, Naozumi, I.¹

¹Tokushima University Graduate School, Department of Oral Molecular Pathology, Tokushima, Japan, ²Tokushima University Graduate School, Department of Pathology and Laboratory Medicine, Tokushima, Japan

Objective: Follicular helper T cells (T_{fh}s) play a key role in the pathogenesis of various autoimmune diseases. T_{fh}s contribute to the formation and maintenance of germinal center (GC) in the lymphoid tissues or inflammatory lesions. Sjögren's syndrome (SS) is an autoimmune disorder that affects salivary and lacrimal glands. The precise mechanism of the onset of autoimmune lesions and autoantibody production through T_{fh}s in a SS model remains unclear. In this study, we evaluated how T_{fh}s contribute to the pathogenesis of SS to understand the differentiation of T_{fh}s, GC B cells, and autoantibody production in a SS model.

Methods: NFS/sld mutant mice thymectomized at 3 days after birth were used as SS model mice, and cervical lymph nodes (CLN), spleen (Sp) and sera were investigated by immunological and pathological analyzes such as flow cytometry, real-time RT-PCR, immunofluorescence staining, and ELISA.

Results: The proportion of CD4⁺CD62L⁻PD-1⁺CXCR5⁺ T_{fh}s and CD19⁺PNA⁺IgD⁻ GC-B cells in CLN and Sp of SS model was significantly increased compared with that of control mice in parallel with the upregulation of autoantibodies. In addition,

more enhanced GC formation in SS model was found by immunofluorescence analysis. Moreover, mRNA expression level of transcriptional factor Bcl-6, master regulator of GC reaction, in CLN and Sp of SS model was higher than that of control mice. **Conclusion:** These results suggest that Tfh₁ and GC-B cells might play an important role in the autoimmune response during the pathogenesis of SS.

933

Clozapine ameliorates experimental autoimmune encephalomyelitis in a CD4 independent fashion

Zareie, P.¹, La Flamme, A.^{1,2}

¹Victoria University of Wellington, Wellington, New Zealand,

²Malaghan Institute of Medical Research, Wellington, New Zealand

Recent research has revealed a neuroinflammatory component to psychiatric disorders including schizophrenia and depression, and this neuroinflammation has been shown to be reduced by several atypical anti-psychotics such as clozapine, which is used to treat schizophrenia. We have shown previously in mice that treatment with clozapine reduces disease severity in experimental autoimmune encephalomyelitis, an animal model for multiple sclerosis. In this study, we assessed the effect of treatment on CD4 T cells during EAE as a potential mechanism by which clozapine is able to reduce disease. We found that while clozapine treatment effectively ameliorated EAE, this protection was not associated with defective proliferation, expansion and encephalitogenicity of antigen-specific CD4 T cells. Instead our results suggest that clozapine may target myeloid cells as its mechanism of action in suppressing EAE.

934

Autoantigen microarray profiling identified IgA antibody clusters associated with autoimmune clinical manifestations in Systemic lupus erythematosus, systemic scleroderma and idiopathic inflammatory myositis

Li, Q.-Z.¹, Yan, M.¹, Zhao, H.², Zuo, X.²

¹University of Texas Southwestern Medical Center, Immunology,

Dallas, United States, ²Central-South University of China,

Rheumatology, Changsha, China

Systemic lupus erythematosus (SLE), systemic scleroderma (SSc) and idiopathic inflammatory myositis (IIM) are systemic autoimmune diseases characterized by autoantibodies (AutoAbs) against various self-antigens. In this study, we measured the serum IgA AutoAbs against 124 self-antigens in a cohort of 128 SLE, 73 SSc, 75 IIM and 140 healthy controls (HC) using autoantigen microarrays. Our result indicated that IgA AutoAbs were highly prevalent in SLE and SSc compared with IIM and NC. 58.4% SLE and 41.7% SSc have 5 or more IgA AutoAbs compared with 16% in IIM and 14.1% in NC. 9 IgA AutoAbs most significantly elevated in SLE were anti-DNA antigens including dsDNA (54.7%), ssDNA (51.1%), and chromatin (46%). 32 IgA AutoAbs were significantly increased in SSc with highest reactivity to Scl-70 (55.6%). IIM showed lower prevalence of IgA AutoAbs with highest in anti-Jo-1 (20%), anti-muscarinic receptor (8%) and anti-B2-microglobulin (6.7%). Significant correlation was observed between IgA and IgG isotypes on most

AutoAbs. 3 IgA autoAbs (anti-gDNA, anti-C1q and anti-dsDNA) positively correlated with SLEDAI Score, but only anti-C1q IgA was significantly elevated in lupus nephritis. 14 anti-nuclear IgA AutoAbs negatively correlated with serum complement C3 and/or C4 levels. Our study indicated that autoreactive IgA AutoAbs against nuclear components, in parallel with IgG AutoAbs, are highly prevalent in SLE and SSc patients. IgA AutoAbs could be used as biomarkers for diagnosis and prognosis of systemic autoimmune diseases, and the molecular mechanisms underlining IgA AutoAbs production in systemic autoimmune diseases warrant further study.

935

High-throughput discovery of T cell epitopes in type 1 diabetes using DNA barcode labelled peptide-MHC multimers

Lyngea, R.¹, Kai Bentzen, A.¹, Julie Overgaard, A.², Piciot, F.², Størling, J.², Reker Hadrup, S.¹

Fredriksberg C, Denmark, ²Copenhagen Diabetes Research Center,

University Hospital Herlev, Department of Pediatrics E, Herlev,

Denmark

Type 1 diabetes (T1D) is characterized by a CD8⁺ lymphocyte-mediated selective destruction of the insulin-producing β -cells causing clinical diabetes. Several autoantigens including glutamic acid decarboxylase 65kDa (GAD65), insulin, protein tyrosine phosphatase (IA-2) and zinc transporter 8 (ZnT8) have been identified based on reactivity in sera from T1D individuals. Here we investigate if post-translational deamination of arginine in the form of citrullination plays a role in T cell recognition of T1D autoantigens. Citrullination may lead to generation of neo-epitopes, which has been described as

T cell targets in other autoimmune diseases. We used netMHC prediction algorithm to identify 764 epitopes from Insulin, GAD65, IA-2 and ZnT8 restricted to HLA-A2, A24, B8 and B15. Among these 91 peptide sequences were susceptible for citrullination. We evaluate the MHC-affinity of both the citrullinated and non-citrullinated library, to identify potential neo-epitopes and to understand the impact of citrullination on MHC affinity. In parallel we will analyse peripheral blood lymphocytes from 50 T1D patients for immune reactivity against the full library. The large library screen will be conducted applying a novel technology where the selection of MHC-multimer binding T cells is followed by amplification and sequencing of MHC multimer-associated DNA barcodes revealing their recognition. This technique enables simultaneous detection of >1000 specificities. Identifying post translational modifications capable of eliciting autoreactive T cell responses in T1D patients is highly relevant for understanding the underlying mechanisms leading to T1D.

936

Abnormal germinal center (GC) reaction in autoimmunity*Saito, M., Otsuka, K., Ushio, A., Kurosawa, M., Yamada, A., Kudo, Y., Arakaki, R., Ishimaru, N.**Tokushima University Graduate School, Institute of Biomedical Sciences, Department of Oral Molecular Pathology, Tokushima, Japan*

The hallmark of follicular helper T cells (T_{FH}) is the ability to help B cell generation and induction of germinal center (GC) reactions, including production of high-affinity antibodies. Recent studies suggest that abnormal function of T_{FH} plays a crucial role in the generation of autoantibodies which inflict autoimmune pathology. However, the molecular mechanisms how T_{FH} promote GC formation and antibody production in autoimmune response remains unclear. Here we investigated the distribution and function of T_{FH} and GC-B cell using MRL/lpr, a mouse model of autoimmunity such as Rheumatoid arthritis and Sjögren's syndrome. The number of $CD4^+CD62L^-CXCR5^+T_{FH}$ and $CD19^+PNA^+IgD^-$ GC-B cell in MRL/lpr mice was significantly increased compared with that in MRL/+ control mice. In addition, higher expression levels of Egr2 in MRL/lpr mice, which is required for Bcl6 expression during T_{FH} cell differentiation, was observed comparing with that in control mice. Moreover, the expression of CXCL13, the ligand for CXCR5, and GC formation in the cervical lymph nodes of MRL/lpr mice were significantly enhanced compared with those in control mice together with increasing autoantibodies. These findings indicate that Egr2 and CXCL13 might positively regulate GC formation and promote the production of autoantibody following the onset of autoimmune disease.

937

Identification of self-reactive marginal-zone B cell like cells in lymph nodes of mice*Palm, A.-K.E., Friedrich, H.C., Kleinau, S.**Uppsala University, Cell and Molecular Biology, Uppsala, Sweden*

Marginal-zone (MZ) B cells represent a distinct subset of innate B cells that have been associated with autoimmunity in animal models. The MZ B cells express low-affinity polyreactive B cell receptors that recognize both foreign and self-structures. Murine MZ B cells have been confined to the spleen, but we demonstrate here that B cells with a MZ B-cell phenotype also exist in the subcapsular sinuses of lymph nodes of mice. The nodal MZ (nMZ) B cells display high levels of costimulators and toll-like receptors, and are represented by virgin and memory cells, with memory cells containing both IgM^+ and switched B cells. The frequency of nMZ B cells is about 1-6 % of nodal B cells depending on mouse strain, with higher numbers in older mice and a trend of increased numbers in females. Notably, there is a significant expansion of nMZ B cells following immunization with an autoantigen, but not after likewise immunization with a control protein or with the adjuvant alone. The nMZ B cells produce autoantibodies upon activation and can efficiently present autoantigen to cognate T cells in vitro, triggering T-cell proliferation, IFN- γ and IL-17 secretion. The existence of self-reactive MZ B cells in lymph nodes may be an additional

source of antigen-presenting cells that in an unfortunate environment may activate T cells leading to autoimmunity.

938

HtrA2 suppresses autoimmune arthritis and regulates activation of STAT3*Lee, S.H.¹, Moon, Y.-M.¹, Seo, H.-B.¹, Kim, S.-Y.¹, Kim, E.-K.¹, Nam, M.-K.², Rhim, H.², Cho, M.-L.¹**¹Rheumatism Research Center, Seoul, Korea, Republic of, ²College of Medicine, Catholic University of Korea, Department of Biomedicine and Health Sciences, Seoul, Korea, Republic of*

Rheumatoid arthritis (RA) is an autoimmune disorder inducing dysregulated inflammation. RA can result in promotion of Th17 cells secreting IL-17 associated with the activation of signal transducer and activator of transcription (STAT) 3. High temperature requirement protein A (HtrA) 2 is a serine protease involved in apoptosis and neurodegeneration. This protein is related with non-response to RA treatment. The aim of this study was to determine that HtrA2 overexpression may reveal therapeutic effects on RA. We observed that T helper cell (Th) 17 differentiation, osteoclastogenesis and lymphocyte activation is promoted in mnd2 mutant mice compared to wild type. Moreover, inhibitor of HtrA2 increases in T helper cell (Th) 17 differentiation. On the other hand, the overexpression HtrA2 induces cleavage of STAT3 and HtrA2 overexpression attenuates collagen-induced arthritis (CIA) in mice model. Additionally, HtrA2 overexpression inhibited development of plaque formation and differentiation of Th17 in ApoE^{-/-} mice with proteoglycan immunization for animal model of hyperlipidemia based RA. The therapeutic function of HtrA2 in inflammatory diseases is related with the targeting of Th17 development and STAT3 pathway in splenocytes. These results suggest that HtrA2 takes part in immunomodulatory activity and upregulation of HtrA2 may shed light on therapeutic approaches to inflammatory disorder such as RA and hyperlipidemia.

Natural killer cells are required for the development of imiquimod-induced psoriasis-like skin inflammation*Yang, S.-J.¹, Liu, M.-F.², Shieh, C.-C.³, Sytwu, H.-K.⁴, Wu, C.-L.⁵, Shiau, A.-L.⁶**¹National Cheng Kung University, Institute of Basic Medical Sciences, Tainan, Taiwan, Republic of China, ²National Cheng Kung University, Section of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Tainan, Taiwan, Republic of China, ³National Cheng Kung University, Institute of Clinical Medicine, Tainan, Taiwan, Republic of China, ⁴National Defense Medical Center, Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan, Republic of China, ⁵National Cheng Kung University, Department of Biochemistry and Molecular Biology, Tainan, Taiwan, Republic of China, ⁶National Cheng Kung University, Department of Microbiology and Immunology, Tainan, Taiwan, Republic of China*

Psoriasis is a common chronic immune-mediated inflammatory disease that causes erythema, scaling and thickening of the skin.

Th1- and Th17-mediated mechanisms have been demonstrated to be involved in the pathogenesis of psoriasis. However, the exact pathogenesis of psoriasis, which likely combines genetic, immunological and environmental factors, remains to be fully elucidated. Natural killer (NK) cells and macrophages, which play important roles in innate immunity, have been suggested to contribute to the pathogenesis of psoriasis. Whether NK cells are pivotal for the initiation/development of psoriasis still remains to be elucidated. Here, we used nonobese diabetic (NOD) mice, which are defective in innate immunity, to investigate the role of NK cells in the development of psoriasis-like dermatitis induced by imiquimod (IMQ). Our results show that while BALB/c mice treated with IMQ exhibited skin lesions resembling human psoriasis, NOD mice were protected from IMQ-induced psoriasis-like dermatitis. NOD mice had defects in the cytotoxic activity of NK cells and phagocytic activity of macrophages. Depletion of NK cells ameliorated IMQ-induced skin lesions in BALB/c mice. Taken together, our findings underline the importance of NK cells in the development of psoriasis and have implications for new therapeutic strategies targeting NK cells for psoriasis.

Toll-like receptors in primary Sjögren's syndrome

Karlsen, M.¹, Hansen, T.^{2,3}, Jakobsen, K.¹, Nordal, H.H.^{1,4}, Brun, J.G.^{2,4}, Jonsson, R.^{1,4}, Appel, S.¹

¹University of Bergen, Broegelmann Research Laboratory, Department of Clinical Science, Bergen, Norway, ²University of Bergen, Department of Clinical Science, Bergen, Norway, ³Haukeland University Hospital, Department of Immunology and Transfusion Medicine, Bergen, Norway, ⁴Haukeland University Hospital, Department of Rheumatology, Bergen, Norway

Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease of unknown etiology. It is characterized by chronic inflammation in salivary and lacrimal glands resulting in dry mouth and eyes, and the presence of autoantibodies. Many patients suffer from various additional symptoms due to extraglandular manifestations. The female to male ratio is 9:1, and the age of onset is usually between 40 and 60 years of age. We analysed Toll-like receptor (TLR) expression and function in peripheral blood mononuclear cells (PBMC), B cells and B cell subsets. TLR7 and -9 were expressed at similar levels in B cells of pSS patients and healthy controls. Naïve B cells expressed less TLR7 and -9 compared to memory and pre-switched memory B cells. We next analyzed the effect of B cell stimulation via TLR7 and -9. In general we found upregulated levels of surface markers and cytokines after stimulation with both TLR7 and -9 ligands in pSS patients and controls. B cells from pSS patients secreted higher amounts of IL-8, IL-15, IFN- α , IL-1RA, MCP-1 and IL-2R in both unstimulated and stimulated cells. We also found less intracellular IL-10 in pre-switched memory B cells in pSS patients compared to healthy controls. Evaluating expression levels of all ten TLRs in PBMC, we found that pSS patients expressed less TLR9 and more TLR8 at mRNA level, and less TLR5 and more TLR7 at protein level compared to controls. These results indicate that TLRs might indeed be involved in the pathogenesis of pSS.

941

Oligoclonally expanded CD4+ T cells recognising citrullinated vimentin in peripheral blood of rheumatoid arthritis patients

Law, S.C.¹, Nel, H.J.¹, Scally, S.W.², Mehdi, A.¹, Le Cao, K.-A.¹, Rossjohn, J.^{2,3}, Reid, H.H.², La Gruta, N.L.⁴, Thomas, R.¹

¹The University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia, ²Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ³Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom, ⁴Department of Microbiology and Immunology, The University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia

RA is strongly associated with HLA-DRB1, including the high-risk allele HLA-DRB1*0401, and with the development of autoantibodies specific for citrullinated-self-antigens. The preferential binding of citrullinated-vimentin to HLA-DRB1*0401, and a correlation between RA disease activity and the frequency of citrullinated-vimentin-specific T-cells suggests citrullinated-vimentin selects and expands autoreactive T-cells in HLA-DRB1*0401+ RA patients. Expanded CD4+ T cell clones have been identified in inflamed synovial compartment, however the antigen specificities of these clones are unknown. Furthermore, no studies have determined how presentation of citrullinated-vimentin shapes the T cell receptor (TCR) repertoire in HLA-DRB1*0401+ individuals, and the impact of RA on that process. We profiled TCR repertoire diversity among a total of 267 and 763 single peripheral blood (PB) vimentin₅₉₋₇₁-cit64-specific CD4+ T cells from 6 healthy controls (HC) and 7 recent-onset RA patients. We used pHLA tetramers and multiplex clonotypic analysis of single cells to simultaneously amplify expressed CDR3 α and CDR3 β segments from individual antigen-specific T cells. The repertoire encoding TCR α and TCR β among these was highly diverse and private in all individuals and included a large number of unique CDR3 sequences. Repeated sequences of individual clonotypes were observed in 2 patients, but no HC. This expansion was present pre- and post RA-treatment, and exclusively derived from CD25+CD127+ effector CD4+ T cells. These data demonstrate that a wide range of possible TCRs recognize the vimentin₅₉₋₇₁-cit64 epitope in PB CD4+ T cells of RA patients and HC. Repeated clonotypic sequences only among RA patients strongly suggest selective citrullinated self-antigen-driven effector T cell expansion in disease.

942

Elevated GITRL is associated with multi-organ involvement and increased disease activity of primary sjogren's syndrome (pSS) and promotes pathogenic Th17 differentiation

Gan, Y., Sun, X., Li, L., He, J., Li, Z.

Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China

Methods: 78 pSS patients and 44 healthy controls were recruited, and the serum GITRL level was measured by ELISA, and serum levels of IL-17A, IL-17E, IL-17F, IL-6, IL-22 and IL-23 were

determined by multiplex cytokine assays. CD4+T lymphocytes were isolated from PBMCs from healthy donors and cultured in TexMACS™GMP medium with anti-CD3 mAb, anti-CD28 mAb and rhIL-2. For Th17 differentiation and pathway exploration, CD4+T cells were treated either with recombinant-human GITRL or with the medium control. Surface marker, intracellular cytokine and phosphorylated signal protein were evaluated by flow cytometry.

Results: Serum levels of GITRL were significantly higher in pSS patients. There is a negative correlation between elevated levels of GITRL and WBC, Neutrophils, PLT, C3 and C4, and a positive correlation with Lymphocytes, IgG and RF. pSS patients with overt hypothyroidism showed higher level of GITRL comparing to those with subclinical hypothyroidism and normal thyroid function. pSS patients of moderate to high disease activity (ESSDAI \geq 5) showed higher level of GITRL. Moreover, Serum GITRL level was positively correlated with Th17-related cytokines, some of which had been shown to be the causal agents increasing autoimmunity and organ involvement in pSS. After GITRL treatment, we found the expansion of Th17 cells in vitro, and increased activation of mTOR and STAT5 and STAT3 signaling in Th cells.

Conclusions: Our results identified the clinical significance of GITRL in exacerbating disease activity in pSS patients and its pathogenic roles in enhancing the differentiation of Th17 cells and the possible involved signaling pathways.

943

Serum and intra-renal CD44 Levels correlate with disease activity in patients with lupus nephritis

Yung, S., Au, K.Y., Zhang, Q., Chau, M., Tse, W.W., Chan, T.M.

University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong

Lupus nephritis is a severe manifestation of systemic lupus erythematosus and often portends poor prognosis. CD44 is a cell surface receptor for hyaluronan and is involved in lymphocyte activation and extravasation, and tissue inflammation. We investigated serum CD44 level and its renal expression during lupus nephritis.

Serum CD44 level was measured in paired sera obtained during active disease and remission respectively from patients with biopsy-proven severe proliferative lupus nephritis using ELISA. Controls included patients with non-lupus glomerular diseases and healthy subjects. CD44 expression in human lupus nephritis kidney biopsies and NZBWF1 mice was assessed by cytochemical staining. Mesangial cells were isolated from NZBWF1 mice to investigate the mechanism of CD44 synthesis. Serum CD44 levels were significantly higher during active lupus nephritis compared with remission samples, the non-lupus glomerular disease group and healthy subjects ($P < 0.001$ for all). In lupus nephritis patients, serum CD44 level correlated with that of anti-dsDNA antibody ($r=0.43$, $P < 0.001$) and creatinine ($r=0.46$, $P < 0.0001$), and inversely correlated with C3 ($r=-0.45$, $P < 0.001$). Strong CD44 staining was observed in infiltrating and resident renal cells in glomeruli and renal tubules in human and murine active lupus nephritis renal specimens. In contrast, minimal CD44 expression was observed in healthy kidney tissue.

CD44 was constitutively expressed in cultured NZBWF1 mice mesangial cells, and its expression was significantly induced after adding exogenous hyaluronan, IL-6, IL-1 β and TNF- α .

Our data suggest that CD44 contributes to the pathogenesis of lupus nephritis through its effect on both infiltrating inflammatory cells and resident kidney cells.

944

An autoimmune disease-associated gene, Lnk/Sh2b3 controls inflammation in adipose tissue and reduces the risk for onset of diabetes

Mori, T., Yamazaki, N., Takaki, S.

Research Institute, National Center for Global Health and Medicine, Department of Immune Regulation, Research Center for Hepatitis and Immunology, Chiba, Japan

Lnk/Sh2b3 is an adaptor protein that regulates cytokine signaling in lymphohematopoiesis. In human, a nonsynonymous SNP in *LNK/SH2B3* has been reported as a risk variant for several autoimmune diseases including diabetes. We have shown that Lnk/Sh2b3 plays a role in preventing pathogenic expansion and activation of CD8⁺ T cells leading to intestinal tissue damage in the physiological levels of IL-15 (Eur J Immunol 44:1622-32, 2014). We also revealed that Lnk/Sh2b3 regulates DC production, and that the ability of DCs to support Th1 or Treg cells was altered by Lnk-deficiency in response to GM-CSF and IL-15 (J Immunol 193:1728-36, 2014). In this study, we investigated Lnk/Sh2b3 functions in tissues related to pathogenesis of diabetes. We found that adult *Lnk*^{-/-} mice showed slightly but significantly elevated blood sugar levels in steady state compared to WT mice. While serum insulin levels were not reduced, glucose tolerance and insulin sensitivity were impaired, indicating that *Lnk*^{-/-} mice spontaneously showed some symptoms observed in type2 diabetes. In adipose tissues of *Lnk*^{-/-} mice, CD45⁺ immune cells such as NK cells, CD8⁺ T cells and M1 macrophages were accumulated and inflammatory cytokines were up-regulated. When *Lnk*^{-/-} mice were crossed with *Il15*^{-/-} mice, NK cells disappeared, CD8⁺ T cells in adipose tissues decreased, and glucose intolerance and adipose inflammation were ameliorated. Thus, Lnk/Sh2b3 plays a role in preventing adipose tissue inflammation by controlling the expansion and function of IL-15-dependent cells, and maintains the threshold for onset of diabetes.

945

Serum acetate levels correlate with disease activity in patients with lupus nephritis

Chan, T.M., Au, K.Y., Zhang, Q., Chan, P.L., Chau, M., Yung, S.

University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong

Introduction: Lupus nephritis patients have impaired immune tolerance to self-antigens resulting in immune-mediated kidney injury. It is speculated that gut microbiota or its products are involved in the aetiology or pathogenesis of autoimmune diseases. Bacterial metabolites from the gut can enter the circulation and modulate inflammatory responses. Acetate is

a short-chain fatty acid produced by the gut microbiota. We measured serum acetate level and renal expression of its cell surface receptors GPR-41 and GPR-43 in lupus nephritis patients to investigate the potential relationship between the gut microbiota and serological and clinical parameters of disease activity.

Methods: Serum acetate, IL-6, IL-8, MCP-1 and LPS levels were measured in patients with biopsy-proven severe proliferative lupus nephritis, patients with non-lupus glomerular diseases and healthy controls. Renal expression of GPR-41 and GPR-43 was determined by cytochemical staining.

Results: Serum acetate level was higher in lupus nephritis patients compared with non-lupus renal disease group ($P < 0.05$) and healthy subjects ($P < 0.01$); and in lupus nephritis serum acetate level was higher during disease flare ($P = 0.04$ compared with remission). Furthermore, acetate level in lupus nephritis patients correlated with serum LPS ($r = 0.34$, $P < 0.0001$), MCP-1 ($r = 0.21$, $P < 0.0001$), and IL-8 levels ($r = 0.22$, $P < 0.0001$), and also proteinuria ($r = 0.29$, $P < 0.01$), but not serum IL-6 level. Renal GPR-41 and GPR-43 expression was markedly increased in active lupus nephritis kidney biopsies, and was predominantly detected in the tubulo-interstitium.

Conclusions: Our data suggest that acetate may contribute to the pathogenesis of lupus nephritis, and may have a role in tubulo-interstitial disease.

946

IFN- γ -receptor is required for intrafollicular localization of autoreactive marginal zone-B cells in the spleens of lupus-prone MRL+/+ mice

Machida, T.¹, Omori, T.¹, Sakamoto, N.¹, Zhang, X.², Gilkeson, G.², Sekine, H.¹

¹Fukushima Medical University, Department of Immunology, Fukushima, Japan, ²Medical University of South Carolina, Division of Rheumatology, Department of Medicine, Charleston, United States

It has been reported that IFN- γ and/or IFN- γ -receptor-1 (IFNGR1) is required for development of murine lupus-like disease, however, their role in auto-Ab production is not defined. We previously demonstrated that splenic marginal zone-B (MZ-B) cells of lupus-prone MRL+/+ mice express high levels of IFNGR1 compared to their follicular-B (FO-B) cells or MZ-B cells of non lupus-prone C57BL/6 mice. In this study, we further investigated the role of IFNGR1 in the development of autoreactive MZ-B cells and their localization in the spleens of MRL+/+ mice.

Flow cytometric analysis showed that MRL+/+ mice had significantly increased numbers of splenic MZ-B cells compared to C57BL/6 mice, while there was no difference in the numbers of FO-B cells between these strains. ELISPOT assay showed significantly increased frequency of anti-dsDNA IgM-producing cells in MZ-B cells of MRL+/+ mice compared to their FO-B cells. However, there was no difference in total numbers of MZ-B cells or frequency of anti-dsDNA IgM-producing MZ-B cells between WT and *Ifngr1*^{-/-} MRL+/+ mice. Strikingly, immunofluorescence analysis of spleen sections revealed significantly increased frequency of MZ-B cells inside the lymphoid follicles of WT MRL+/+ mice compared to *Ifngr1*^{-/-} MRL+/+ mice or C57BL/6

mice.

These results indicate that IFNGR1 contributes to intrafollicular localization of MZ-B cells in the spleens of MRL+/+ mice. From these results, we propose the hypothesis that the intrafollicular autoreactive MZ-B cells are involved in auto-Ab production by presenting auto-antigen to T_{FH} cells and/or differentiating into auto-Ab-producing cells in the spleens of MRL+/+ mice.

947

The decreased expression of miR-10a in mesangial cells treated with anti-dsDNA antibodies and in lupus nephritis kidney tissues

Thammasate, B.¹, Tangtanatakul, P.², Leelahavanichkul, A.¹, Avihingsanon, Y.³, Hirankarn, N.¹

¹Faculty of Medicine, Chulalongkorn University, Center of Excellence in Immunology and Immune Mediated Diseases, Department of Microbiology, Bangkok, Thailand, ²Chulalongkorn University, Medical Microbiology Interdisciplinary Program, Graduated School, Bangkok, Thailand, ³Faculty of Medicine, Chulalongkorn University, Center of Excellence in Immunology and Immune Mediated Diseases, Department of Medicine, Bangkok, Thailand

Lupus nephritis (LN) is a serious complication in systemic lupus erythematosus (SLE). It is a major cause of morbidity and mortality in SLE patients. MicroRNAs (miRNAs) are small non-coding RNAs that act as epigenetics regulator. In order to screen for the potential miRNA involved, primary human mesangial cells were incubated with anti-dsDNA IgG antibodies purified from LN patients (N=20) compared to pool normal IgG control (N=20). The stem-loop RT PCR result showed that anti-dsDNA IgG antibodies down-regulated miR-10a expression in mesangial cell significantly ($p < 0.05$). MicroRNA-10a (miR-10a) plays roles in cell proliferation and inflammatory pathway and founded to be decrease in kidney from ischemic reperfusion mouse model and SLE peripheral blood mononuclear cells (PBMCs). Next, we investigated the level of miR-10a in kidney tissues from LN patients. In order to test the hypothesis, 26 kidney-tissue samples from biopsy-proven active LN and 6 kidney-tissue samples from cadaveric donors as control were used. The RNAs were extracted and miR-10a was specifically amplified using real-time PCR normalized with RNU44 expression. The results showed that miR-10a expression in LN kidney tissue was significantly decreased compared to control group (fold change = 0.19, SD = 0.56; p -value = 0.01). However, the fold change of miR-10a expression in kidney was not correlated with creatinine clearance (CCr) ($n = 20$, $R^2 = 0.0247$; p -value = 0.508). Since miR-10a is important in regulating cell proliferation and inflammation, which are the main pathology in LN kidney, the use of miR-10a mimic to regain control might serve as a novel therapeutic target for LN.

948

Is generation of reactive oxygen species (ROS) in pristane induced lupus responsible for development of autoimmunity?

Minhas, U.^{1,2}, Bhatnagar, A.²

¹University of Allahabad, Biochemistry, Allahabad, India, ²Panjab University, Biochemistry, Chandigarh, India

Pristane induced murine model of lupus is a well established model of lupus like disease which is characterized by development of antibodies against nuclear antigens like dsDNA, ssDNA along with glomerulonephritis and arthritis. Reactive oxygen species are produced in huge amounts during inflammation and stress mediated through these reactive intermediates is being highlighted for their role in pathogenesis of autoimmune disorders. Oxidative Stress (OS) not only causes damage to cellular components but also induces cellular responses like gene activation which may contribute to pathogenesis of autoimmunity. The mechanism of disease development in pristane induced lupus is not completely understood and ROS mediated OS might play some role. We have recently reported generation of ROS in the peritoneal macrophages in response to pristane which remain high even six months after the pristane treatment. The persistent ROS generation during chronic inflammation might be the cause of weakening of antioxidant defense leading to oxidative stress. Oxidative modification of nuclear components may direct formation of neo-antigens which may further lead to production of autoantibodies against them. We propose that oxidative modification of DNA may lead to its mistaken identity as non self and thus the production of anti DNA antibodies in the model. The deposition of immune complexes is implicated in the pathogenesis of this systemic disorder.

949

Alphaviruses mediated arthritis in humans: a possible role for autoimmunity through molecular mimicry

Janakiraman, V., Nandakumar, A., Kannan, V.

Indian Institute of Technology Madras, Department of Biotechnology, Chennai, India

The mechanisms responsible for initiation and pathogenesis of autoimmune diseases remain unclear. Several theories have been proposed including infections. Microbial determinants that mimic host antigens can trigger self-reactive T cell clones and antibodies to destroy host tissue. Alpha virus infections are foremost in causing pathogenic conditions resulting in rheumatic arthritis like symptoms. The chronic stage of these infections is characterized by joint inflammation with arthritic like symptoms and the basis for this rheumatic outcomes is not clear. We have investigated the possible involvement of auto immune process in alpha viral induced disease pathogenicity through an *in silico* analysis. We have analysed the proteins from 23 characterized strains of alphaviruses (all of which had documented arthritic symptoms). Our results show presence of consensus regions of significant length in their proteomes that are conserved across the strains of arthritogenic alpha viruses only. Comparative analysis of these regions of consensus

with the human proteome identified some human proteins that shared homology with the structural and non-structural proteins of alpha viruses. Interestingly these proteins have also been implicated in auto immune responses. We have further mapped the plausible immunogenic domains on these regions of homology and have found that they harbour both T and B cell epitopes and are capable of binding to multiple HLA alleles. We speculate that these cross reactive epitopes between alpha virus proteins and human proteins could be responsible for inducing auto immune responses that might play a role in rheumatic like manifestations of arthritogenic alphaviral infections.

950

CD4+ T cells show a distinct epigenetic signature between disease states in Multiple sclerosis patients

Maltby, V.¹, Lea, R.², Miles, B.², Sanders, K.^{3,4}, Tajouri, L.⁴, Rodney, S.^{1,5}, Jeannette, L.-S.^{6,7}

¹University of Newcastle & Hunter Medical Research Institute, School of Biomedical Sciences and Pharmacy, Callaghan, Australia,

²Institute of Health and Biomedical Innovation, Brisbane, Australia,

³University of Newcastle & Hunter Medical Research Institute, Callaghan, Australia, ⁴Bond University, Faculty of Health Sciences

and Medicine, Gold Coast, Australia, ⁵Hunter Area Pathology Service, Molecular Genetics, Newcastle, Australia, ⁶University of Newcastle & Hunter Medical Research Institute, School of Medicine

and Public Health, Callaghan, Australia, ⁷John Hunter Hospital, Neurology, Newcastle, Australia

Background: Multiple Sclerosis (MS) is a T-cell mediated autoimmune disorder. Pathogenesis is due to a genetic predisposition triggered by environmental factors. Epigenetics, such as DNA methylation and non-coding RNA (ncRNA), provide a logical interface for environmental factors to influence the genome. Our previous work identified a differentially methylated region (DMR) at the HLA-DRB1 locus in CD4+ T cells of relapsing-remitting MS (RRMS) patients that was not present in CD8+ T cells or CD19+ B cells.

Aims:

1) Determine if these DMRs are also present in secondary progressive MS (SPMS).

2) Determine if there are changes in expression of ncRNAs between RRMS and SPMS patients.

3) Correlate these changes with clinical outcomes

Methods: DNA and RNA from CD4+ T cells was extracted from 28 RRMS, 21 SPMS patients and 40 healthy age and sex matched controls. DNA was bisulphite converted and hybridised to Illumina 450K arrays. RNA was hybridized to Illumina HumanHT12 expression arrays or used for microRNA Next Generation Sequencing (NGS) respectively.

Results and discussion: RRMS and SPMS patients have distinct and non-overlapping DNA methylation profiles, and the HLA-DRB1 DMR is unique to RRMS patients. Of the differentially methylated regions 63% are hypomethylated in RRMS patients, whereas 75% are hypermethylated in SPMS patients. This could be explained by a decrease of DNMT1 in RRMS patients and increase in DNMT3b in SPMS patients. Additionally, miR-29b, which targets DNMT3b, is downregulated in SPMS patients. In conclusion, we have demonstrated that differences in

epigenetic may be contributing to MS disease pathology and progression.

951

Defective regulatory T cell function results in autoimmune progression in New Zealand Black mice

Yang, W.C.^{1,2}, Kuo, Y.Y.¹, Chen, Y.Y.¹, Tan, Y.Y.^{1,3}, Chang, C.C.¹, Cho, Y.C.¹, Chan, T.H.¹, Liu, C.L.⁴, Hwang, Y.S.⁵, Shen, C.R.^{1,2,5}

¹Chang Gung University, Graduate Institute and Department of Medical Biotechnology and Laboratory Science, Taoyuan, Taiwan, Republic of China, ²Chang Gung University, Graduate Institute of Biomedical Sciences, Taoyuan, Taiwan, Republic of China, ³Chang Gung University, Department of Biomedical Sciences, Taoyuan, Taiwan, Republic of China, ⁴Ming Chi University of Technology, Department of Chemical Engineering and Graduate School of Biochemical Engineering, Taoyuan, Taiwan, Republic of China, ⁵Linkou Chang Gung Memorial Hospital, Department of Ophthalmology, Taoyuan, Taiwan, Republic of China

Simultaneous increment of Tregs in both numbers and frequencies with AIHA progression have been observed in New Zealand Black (NZB) mice, which spontaneously develop autoimmune hemolytic anemia (AIHA) as they age. However, supplement of CD4⁺CD25⁺ T cells from congenic mice helped ameliorating AIHA progression, implicating a defective role of Tregs in NZB mice during autoimmune progression. We designed both *in vitro* and *in vivo* suppression assay to understand the integrity of Tregs in NZB mice. Judging by the fluctuating percentages of Foxp3 expressing cells among CD4 T cells after anti-CD3 plus anti-CD28 antibody mediated stimulation *in vitro*, the expanded Tregs pool in NZB mice may result from the instable expression of Foxp3 within CD4 T cells after TCR engagement. In addition, enriched Tregs demonstrated inferior suppressive capabilities when suppressing Tregs *in vitro*. The defective phenotype of Tregs from NZB mice *in vivo* is evident by the decreased hematocrit values and increased Coombs' titers in the T cell deficient host receiving co-transferring of both Tregs and Tregs from NZB mice. Instead of Tregs from NZB mice, co-transferring of Tregs from BALB/c mice provided the recipients with effective protection against AIHA progression. We found the limited retention of Tregs from BALB/c mice when they were transferred into immune competent NZB mice may be the reason that the single infusion of Tregs provided the recipient with effective but temporal protection. Our study clearly demonstrated that the capabilities of Tregs from NZB mice in maintaining immune homeostasis is disrupted, thereby leading to autoimmune progression.

952

Opposing roles of tyrosine kinase receptors Mer and Axl determine clinical outcome in a mouse model of nephritis

Shao, W.

Temple University, School of Medicine, Medicine, Philadelphia, United States

Systemic lupus erythematosus (SLE) is an autoimmune disorder with unknown etiology. Lupus nephritis remains one

of the most severe manifestations of SLE, with considerable morbidity and mortality. There remains a major void in the successful management of lupus nephritis. TAM (Tyro-3, Axl and Mer) receptor tyrosine kinases play an important role in the maintenance of immune homeostasis. Mer is constitutively highly expressed on glomerular endothelial cells; Axl expression is inducible in kidney under inflammatory conditions. To investigate the functions of Axl and Mer in lupus nephritis, we induced glomerulonephritis in WT, Axl-KO, Mer-KO, and A/M-KO (Axl/Mer-double knockout) mice by injection of nephrotoxic serum (NTS). Mer-KO mice developed severe glomerulonephritis, with significantly decreased survival rate and increased blood urea nitrogen (BUN) levels as compared to WT mice given the same treatment. Two weeks after injection, necrotic cell death was evident in the glomeruli of Mer-KO mice. However, Axl-KO mice presented with significantly increased survival rate and reduced BUN as compared to the WT, Mer-KO and A/M-KO mice injected with the same serum. Interestingly, the A/M-KO mice developed kidney inflammation comparable to the WT mice. Western blot analysis revealed significantly increased Stat3 phosphorylation and caspase-1 activation in the kidney of Mer-KO mice after NTS injection. In contrast, Axl deficient NTS-injected mice developed decreased Akt phosphorylation and Bcl-xl upregulation. The reciprocal activation of Axl and Mer receptor tyrosine kinases may have a major impact on renal inflammation. Results from these studies may lead to novel therapeutic drug development targeted to lupus nephritis.

Deleting the BAFF receptor TACI protects against systemic lupus erythematosus without extensive reduction of B cell numbers

Figgett, W.¹, Deliyanti, D.², Fairfax, K.^{1,3}, Quah, P.S.^{1,2}, Wilkinson-Berka, J.², Mackay, F.¹

¹The University of Melbourne, Melbourne, Australia, ²Monash University, Melbourne, Australia, ³The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

B cell-activating factor of the TNF family (BAFF) is an essential B cell survival factor, however, high levels of BAFF promote systemic lupus erythematosus (SLE) in mice and humans. Belimumab (anti-human BAFF) limits B cell survival and is approved for use in SLE patients. Surprisingly, the efficacy of rituximab (anti-human CD20) in SLE remains controversial, despite depleting B cells more potently than belimumab. This raises the question of whether B cell depletion is really the mechanism of action of belimumab. In BAFF transgenic mice, SLE development is T cell-independent but relies on innate activation of B cells via TLRs, and TLR expression is modulated by the BAFF receptor TACI. Here, we show that loss of TACI on B cells protected against BAFF-mediated autoimmune manifestations, and B cells were retained. Therefore, B cell sparing blockade of TACI may offer a more specific and safer alternative to B cell depletion in SLE.

954
Next-generation sequencing demonstrates dynamic recirculation of B cell clones in ectopic lymphoid structures of Sjögren's syndrome

Murray-Brown, W.¹, Carlotti, E.¹, Floyd, J.¹, Sutcliffe, N.¹, Tappuni, A.², Vartoukian, S.², Fortune, F.², Mehr, R.³, Pitzalis, C.¹, Bomabardieri, M.¹

¹Queen Mary University of London, Experimental Medicine and Rheumatology, London, United Kingdom, ²Queen Mary University of London, Department of Oral Medicine, London, United Kingdom, ³Bar-Ilan University, The Mina and Everard Goodman Faculty of Life Sciences, Ramat-Gan, Israel

Sjögren's syndrome (SS) is characterised by immune cell infiltration in the salivary glands (SG) leading to xerostomia and exocrine dysfunction. B-cells play a central role in SS pathogenesis, whereby autoreactive B-cells populate ectopic germinal centres (EGC) in SS-SG and undergo somatic hypermutation (SHM) and class-switch recombination of the immunoglobulin (Ig) genes. However, the capacity of specific B-cell clones to seed EGC in different SG and undergo clonal diversification is unclear.

To unravel B-cell recirculation dynamics, we investigated immunoglobulin heavy-chain (IgH) gene rearrangements and patterns of SHM using a high-throughput next-generation sequencing approach for 4 pairs of mSG biopsies from 4 SS patients with high B-cell infiltration and EGC. Total RNA was used to generate Ig-specific cDNA for use in PCR library preparation and barcoded primers were used to allow multiplex sequencing and to assist in bioinformatic filtering of sequences.

In total, we generated ~166,000 reads >350bp, and we detected 1631 clonotypes (reads with same IgHV and IgHJ gene usage and equal CDR3 length). Between 5 and 9 shared clonotypes were observed among paired SG biopsies, demonstrating that B-cells can recirculate between different glands. Furthermore, lineage tree analysis revealed B-cells undergo further rounds of SHM in adjacent glands and highlight distinct patterns of B-cell circulation between biopsies. Finally, the level of B-cell recirculation appears to be related to the Ig-isotype, as IgG-rich samples appeared to recirculate less often. Although further study is needed to confirm these observations, these findings demonstrate the dynamic nature of B-cell affinity maturation in SS within EGCs.

955
Dendritic cells engineered for *de novo* synthesis of calcitriol and retinoic acid prime gut-homing regulatory T cells and rapidly arrest progression of ongoing experimental colitis

Xu, Y.¹, Cheng, Y.¹, Chan, C.¹, Chelliah, H.¹, Li, C.-H.¹, Wang, X.¹, Qin, X.^{1,2}, Lau, W.^{1,2}, Baylink, D.¹, Tang, X.¹

¹Loma Linda University, Medicine, Loma Linda, United States, ²Jerry L. Pettis Memorial Veterans Affairs Medical Center, Loma Linda, United States

Inflammatory bowel disease (IBD) is a chronic inflammatory disorder in gastrointestinal tract (GUT) and does not have a permanent cure. Recent immunological interventions, e.g. TNF- α and α 4 β 7 blockers, have improved specificity in the control of

gut inflammation and slowed disease progression. However, off target immune suppression is still causing unbearable adverse side effects, e.g. infections and cancers. Since deficiency of immune regulation in intestines is a major mechanism underlying IBD, this study aims to induce gut-homing regulatory T (Treg) cells in the peripheral lymphoid tissues such that Treg cells in the intestines of IBD patients are selectively augmented to further increase specificity of immunotherapy. Here we showed that enhanced generation of gut-homing Treg cells was achieved through immunization with dendritic cells engineered for *de novo* synthesis of both the active vitamin D metabolite and retinoic acid (RA). In addition, immunization with such engineered DCs rapidly arrested progression of experimental colitis induced by 2,4,6-trinitrobenzene sulfonic acid (TNBS).

956
Mild electrical stimulation with heat shock suppresses skin hyperplasia in imiquimod-induced psoriasis model

Tsurekawa, Y., Kai, Y., Morita, M., Takada, M., Moriuchi, M., Okita, G., Suico, M.A., Shuto, T., Kai, H.

Kumamoto University, Molecular Medicine, Kumamoto, Japan

Biophysical stimulations, such as shear stress, mild electrical current and heat shock (HS), affect various biological functions. We have comprehensively studied the biological effects of optimized combination treatment of mild electrical stimulation (MES) (0.1-ms pulse width, 55-pulse per second; pps) and HS at 42°C. Specifically, we have shown that MES+HS suppressed the production of inflammatory cytokines in mouse models of diabetes and chronic kidney disease (Morino, et al., *PLoS One*, 2008; Koga, et al., *PLoS One*, 2012). These findings prompted us to investigate the effects of MES+HS on skin inflammatory diseases such as psoriasis. In addition, our data from microarray analysis of healthy mouse skin tissues suggest that MES+HS may positively affect wound healing, and regulate cell proliferation and differentiation. Here, we examined the effect of MES+HS on the imiquimod-induced psoriasis mouse model. Interestingly, MES+HS treatment (10 min, daily) significantly suppressed skin hyperplasia in the psoriasis mouse model compared with the untreated group despite a minimal impact on the size of spleen and the mRNA expression of inflammatory cytokines in the skin tissue. Although the mechanism of MES+HS in ameliorating the progression of psoriasis still needs to be elucidated, our study provides information on the possible therapeutic application of MES+HS on psoriasis skin condition.

957
Blimp-1 deficiency exacerbates the pathogenic processes of autoimmune diabetes in NOD mice harboring islet antigen-specific TCR repertoire

Liu, Y.-W.¹, Lin, M.-H.², Fu, S.-H.³, Sytwu, H.-K.³

¹National Defense Medical Center, Taiwan International Graduate Program, Graduate Institute of Life Sciences, Taipei, Taiwan, Republic of China, ²Kaohsiung Medical University, College of Medicine, Institute of Medicine, Department of Microbiology and Immunology, Kaohsiung, Taiwan, Republic of China, ³National Defense Medical Center, Department and Graduate Institute of

Microbiology and Immunology, Taipei, Taiwan, Republic of China

Since Blimp-1 is a master suppressor in the terminal differentiation of T cell lineages, its deficiency in T cells tightly leads to the massive expansion of effector T cells (CD4^{hi}CD62L^{lo}) in peripheral lymphoid organs and further causes the development of severe inflammatory colitis. However, it is still elusive how Blimp-1 immuno-modulates the pathogenesis of autoimmune diabetes. In this study, to examine whether Blimp-1 ablation affects the pathogenesis of autoimmune diabetes, we currently established T cell-specific Blimp-1 conditional knockout (CKO) non-obese diabetic (NOD) mice to further investigate the underlying molecular mechanisms of disease. NOD mice spontaneously develop autoimmune diabetes, resulting from the autoreactive T cell-dependent destruction of insulin-producing islet cells of pancreas. Unexpectedly, Blimp-1 CKO NOD mice were completely resistant to the development of autoimmune diabetes. In contrast, these mice were highly susceptible to the pathogenesis of inflammatory colitis. Our accumulating results indicated that CKO NOD mice have increased amounts of Th1 (CD4⁺IFN- γ ⁺) and Th17 (CD4⁺IL-17⁺) cells in mesenteric lymph nodes (MLNs), pancreatic lymph nodes (PLNs) and spleen but not in pancreas-infiltrating lymphocytes (PILs). By the contrary, BDC2.5 Blimp-1 CKO NOD mice, bearing islets antigen-specific TCR repertoire, have massive amount of Th1 cells in PILs. Moreover, Treg cells (CD4⁺Foxp3⁺) in the PILs of BDC2.5 Blimp-1 CKO NOD mice are comparable to BDC2.5 control mice. In summary, islet antigen-specific TCR repertoire might drive the recruitment of Th1 cells in pancreas-infiltrating lymphocytes of Blimp-1 CKO mice and subsequently these inflammatory cells aggravated the pathogenesis of autoimmune diabetes of mice.

Effects of α 1-adrenergic receptor stimulation on pro- and anti-inflammatory cytokine production by dendritic cells

Back, C.¹, Stumbles, P.^{1,2,3}, Drummond, P.⁴

¹Murdoch University, Veterinary and Life Sciences, Perth, Australia,

²Telethon Kids Institute, Perth, Australia, ³University of Western

Australia, Perth, Australia, ⁴Murdoch University, Psychology and

Exercise Science, Perth, Australia

Adrenergic receptors (AR) include the α - and β - classes and their subtypes, and are targets for the catecholamines noradrenaline, adrenaline and dopamine. Adrenergic receptors are expressed on a range of peripheral tissues, and can influence immune cell function. To date, most studies have examined the role of β -AR on immune cell function, with less known regarding α -AR. However, animal models suggest a role for α 1-AR in inflammatory disease pathogenesis. Signalling through α 1-AR can modulate cytokine production by macrophages and monocytes, but their effect on dendritic cells (DC) remains unclear. As DC control immune responses in part by the cytokines they produce during T cell activation, we hypothesized that α 1-adrenoceptor signalling would alter pro- or anti-inflammatory cytokine production by DC dependent on the timing of signalling and

their maturation status. To examine this, DC were derived from the bone marrow (BMDC) of C57BL/6 mice by culture in GM-CSF, then pre-incubated with bacterial lipopolysaccharide (LPS) for 18h prior to the introduction of the α 1-adrenoceptor specific agonist phenylephrine (PHE) for 6h or 24h. Culture supernatants were then analysed by 27-plex immunomagnetic bead assay. Exposure to PHE inhibited the production of the pro-inflammatory cytokines IL-1 α , IL-12p70 and p40, KC, MIP-1 α and MIP-1 β by LPS matured BMDC after 24h (but not 6h), with the anti-inflammatory cytokines IL-10 and TGF β less affected. This is the first study to show inhibition of pro-inflammatory cytokine production by DC after α 1-AR signalling, and provides a basis for further investigations into the potential role of α 1-AR in treating inflammatory disease.

GSK-J4 a potent and selective inhibitor of the H3K27 demethylase JMJD3/UTX limits inflammation by favoring a tolerogenic potential in dendritic cells

Doñas, C.^{1,2}, Carrasco, M.^{1,2}, Fritz, M.^{1,2}, Prado, C.¹, Tejón, G.³, Osorio-Barrios, F.¹, Manriquez, V.³, Bono, M.R.³, Pacheco, R.¹, Loyola, A.¹, Roseblatt, M.^{1,2,3}

¹Fundación Ciencia & Vida, Santiago, Chile, ²Universidad Andrés

Bello, Santiago, Chile, ³Universidad de Chile, Santiago, Chile

Introduction: Epigenetic modifications on immune cells have been implicated in the development of several inflammatory diseases. Histone H3 lysine 27 (H3K27) demethylase JMJD3 plays an important role in the inflammatory response and appears as an interesting target for the treatment of inflammation. Recently, GSK-J4, a selective and potent JMJD3 inhibitor was synthesized, however, its effects on T cells and dendritic cells in the context of inflammation have not been reported.

Materials and methods: DCs purified from C57BL/6 mice and activated with LPS in the presence or absence of the drug were co-cultured with purified naïve CD4⁺ T cells from Foxp3-GFP mice under different polarizing conditions. DCs maturation and tolerogenic markers, as well as cytokines secretion were evaluated. C57BL/6 WT mice were treated with pMOG to induce EAE and subsequently treated with systemic administration of GSK-J4, with GSK-J4-generated Treg or with dendritic cells pre-treated with GSK-J4 and then, disease onset and severity were determined.

Results: GSK-J4 induced a tolerogenic phenotype on dendritic cells in vitro, increasing Treg generation and improving their phenotypic stability and suppressive function without affecting Th1 and Th17 differentiation. Administration of the drug in vivo ameliorates the severity of EAE. Moreover, adoptive transfer of Treg generated in the presence of GSK-J4 or of GSK-J4-treated DCs into EAE mice reduced the clinical manifestation of the disease.

Conclusions: Our data indicate that GSK-J4 attenuates inflammation through an effect on DCs. This drug may be a promising approach for the treatment of inflammatory diseases.

Individual and cocktails of TLR ligands influence APCs *in situ* in human skin explants*du Mez, E.¹, Feisst, V.^{1,2}, Locke, M.³, McIntosh, J.^{1,2}, Brooks, A.^{1,2}, Didsbury, A.^{1,2}, Graham, S.^{4,5}, Angel, C.^{1,2}**¹University of Auckland, School of Biological Sciences, Auckland, New Zealand, ²University of Auckland, Maurice Wilkins Centre, Auckland, New Zealand, ³University of Auckland, Department of Surgery, South Auckland Clinical Campus, Middlemore Hospital, Auckland, New Zealand, ⁴University of Auckland, Centre for Brain Research, School of Medical Sciences, Faculty of Medical and Health Sciences, Auckland, New Zealand, ⁵University of Auckland, Department of Pharmacology and Clinical Pharmacology, School of Medical Sciences, Faculty of Medical and Health Sciences, Auckland, New Zealand*

Antigen presenting cells (APCs) are the sentinel cells of the immune system and can initiate strong, directed immune responses against foreign pathogens. In humans, APCs are found at sites susceptible to pathogen infiltration, including the skin. Cutaneous APCs are therefore ideal vaccine targets as they are accessible by injection and can stimulate immune responses.

APCs can detect invading pathogens via Toll-like receptors (TLR), and recognition by these receptors enables APCs to stimulate an appropriate immune response to that pathogen. We can exploit this mechanism by including synthetic TLR ligands in vaccines to augment an immune response against vaccine antigens.

We have conducted immunohistochemical analyses of human skin, which demonstrates that CD1a⁺ and CD14⁺ dermal APCs express TLR3 and TLR7 proteins respectively, whilst both APC populations express TLR9 protein.

We next developed an intradermal injection protocol using human skin explants to test the response of APCs to TLR stimulation *in situ*. Initial experiments established which concentrations of individual or cocktails of TLR3 (Poly I:C), TLR 7/8 (R848) and TLR9 (ODN2006, ODN2216 and ODN2396) ligands induced minimal toxicity, and identified optimal timepoints. In subsequent experiments the influence of TLR ligand/s on migratory APCs was assessed using flow cytometry, and four-colour immunohistochemistry was used to study the APCs remaining in the skin. Our findings show that stimulation with TLR ligand/s affects the phenotype and distribution of APC subsets in human skin.

Collectively these findings identify TLR ligand/s that could be incorporated into vaccines targeting APCs in human skin.

961

T cell priming ability by activated, *Nlrc5*-deficient DCs is unaffected despite partially reduced MHCI levels*Rota, G.¹, Ludigs, K.¹, Siegert, S.², Tardivel, A.¹, Morgado, L.¹, Reith, W.³, De Gassart, A.¹, Guarda, G.¹**¹University of Lausanne, Epalinges, Switzerland, ²Ludwig Center for Cancer Research of the University of Lausanne, Epalinges, Switzerland, ³University of Geneva, Geneva, Switzerland*

NLRC5, a member of the NOD-like receptor protein family, has recently been characterized as the master transcriptional

regulator of major histocompatibility class I (MHCI) molecules in lymphocytes, in which it is highly expressed. However, its role in activated dendritic cells (DCs), which are instrumental to initiate T cell responses, remained elusive.

Using *Nlrc5*^{-/-} BMDCs, we showed that the increase of MHCI mRNA upon exposure to inflammatory stimuli is largely dependent on NLRC5. Despite the strong defect in transcript and intracellular protein levels of MHCI, surface display was nearly normal in *Nlrc5*^{-/-} DCs. Importantly, this discrepancy between a strong intracellular and a mild surface defect in H2-K levels was observed also in DCs with H2-K transcription defects independent of *Nlrc5*.

Hence, alongside with demonstrating the importance of NLRC5 in MHCI transcription in activated DCs, these data highlight a general, NLRC5-independent compensatory mechanism maintaining surface MHCI levels in cells with reduced MHCI mRNA.

Accordingly, with the decreased amount of neosynthesized MHCI, *Nlrc5*^{-/-} DCs exhibited a defective capacity to display endogenous antigens. However neither T cell priming by endogenous antigens, nor crosspriming ability were substantially affected in activated *Nlrc5*^{-/-} DCs.

Altogether, these data show that *Nlrc5*-deficiency, despite significantly affecting MHCI transcription and antigen display, is not sufficient to hinder T cell activation, underlining the robustness of the T cell priming process by activated DCs.

Studies in the laboratory are funded by the Swiss National Science Foundation (PP00P3_139094) and the European Research Council (ERC-2012-StG310890).

Distribution of the potential DC-markers DEC205, Langerin, DC-LAMP and DC-SIGN within tissues of Atlantic salmon (*Salmo salar* L.) and their response upon challenge with microbes*Eggestøl, H.Ø.¹, Wegeland, H.I.¹, Rønneseth, A.¹, Tollefsen, K.E.², Haugland, G.T.¹**¹University of Bergen, Department of Biology, Bergen, Norway, ²Norwegian Institute of Water Research (NIVA), Oslo, Norway*

In mammals, dendritic cells (DCs) are the sentinels of the body and the main organizers of the immune system essential for initiation and regulation of immune responses. Until recently, it was debated whether DCs are present in teleost fish, but functional and morphological studies from different species suggest that fish do indeed have DCs. However, little is yet known about the role of DCs in the fish immune system and in which organs and tissues they are present. We have, indirectly, by targeting the potential DC-markers DEC205 (CD205/Ly75), Langerin (CD207), DC-LAMP (CD208) and DC-SIGN (CD209A, D and E), studied the distribution of DCs within 17 tissues of Atlantic salmon (*Salmo salar* L.) using RT-qPCR. The highest level of DEC205 was detected in gut, but it was also abundant in head kidney, body kidney, thymus and gills. Surprisingly, high level of DEC205 was also measured in the brain. The highest level of Langerin and DC-LAMP was detected in spleen, but also in head kidney and epithelial surfaces like skin, gill and gut. Atlantic salmon has three DC-SIGN homologues. CD209A

was highest in PBL, spleen and the posterior part of the kidney, CD209D was highest in the kidney tissues while the expression of CD209E was evenly distributed in all organs. Further, we have investigated the response of these DC-markers, that all belong to the family of C-type lectin receptors (CLRs), upon challenge with virus, bacteria and fungus.

963
The phenotypical and functional effects of dendritic cells by calyx extract of a new variety *Hibiscus sabdariffa* with superior anthocyanin

Chuang, J.-J.¹, Tseng, H.-Y.¹, Chou, W.-M.²

¹National Chiayi University, Department of Microbiology, Immunology, and Biopharmaceuticals, Chiayi, Taiwan, Republic of China, ²National Chiayi University, Department of Biochemical Science and Technology, Chiayi, Taiwan, Republic of China

Dendritic cells (DCs) are professional antigen-presenting cells with high immunostimulatory abilities, can joint primary and secondary immune responses. Roselle (*Hibiscus sabdariffa*) possess rich anthocyanin, has recently been reported to induce multiple pharmacological effects. One γ -ray induced new roselle mutant designated Chia-yi Univ. 1 with extra superior anthocyanin was found in calyx extracts. In the present study we evaluated the effect of Chia-yi Univ. 1 on phenotype and function of dendritic cells. The toxicity of the calyx extract was first assessed by cytotoxicity assay. The result showed that roselle Chia-yi Univ. 1 expressed low toxicity to DCs. Under 0.5 mg/ml calyx extract could not induce the cell death of DCs. After analyzing cytokine production of treated immature DCs, we observed that the expression of TNF- α was relatively induced. Besides, the calyx extract of Chia-yi Univ. 1 obviously suppressed the ability of mature DCs to produce IL-10 and TGF- β and could increase the IL-6 in mature DCs. Additionally, after FACS analysis, we demonstrated that the expression of CD40, CD86 and IA/IE (MHC II) on mature DCs were further increased by Chia-yi Univ. 1. Thus, the results suggested that the effects of DCs by calyx extract of Chia-yi Univ. 1. The treated DCs may prove to be a potential tool for inducing of immunity control.

964
Investigating the role of dendritic cells in a mouse model of Myelodysplasia

Pooley, J.¹, Cafarella, M.¹, Guirguis, A.², Curtis, D.^{3,4}, O'Keeffe, M.¹

¹Monash University, Clayton, Australia, ²Brigham and Women's Hospital, Cambridge, United States, ³Australian Centre for Blood Diseases, Monash University, Melbourne, Australia, ⁴Alfred Health, Central Clinical School, Monash University Melbourne, Dept. of Clinical Haematology, Melbourne, Australia

NHD13 mice are a mouse model resembling human Myelodysplasia (MDS). NHD13 mice express the fusion protein NUP98-HOXD13 (NHD13) of the chromosomal translocation t(2;11)(q31;p15) which is expressed in hematopoietic cells under control of the *vav* promoter. Mice bearing this transgene develop leukemia resembling human Acute Myeloid Leukemia. The role of dendritic cells in MDS, inflammatory responses in MDS or in the progression of MDS to leukemia is unknown. However, DC are greatly reduced in the blood of patients with MDS and in the BM of patients with multiple different forms of MDS. We have determined that mice with Myelodysplasia have a reduced number of dendritic cells (DC) as early as 4 weeks of age. The DC present in young NHD13 mice are activated but in mice older than 6 months of age the DC are in an immature state relative to wildtype. We additionally show that the DC of NHD13 mice are functionally defective with respect to their production of cytokines including interferons.

965
Effect of past radiation exposure on the circulating dendritic cell populations in A-bomb survivors

Kajimura, J.¹, Lynch, H.E.², Geyer, S.³, Yamaoka, M.⁴, Shterev, I.²,

Kyoizumi, S.⁴, Sempowski, G.D.², Nakachi, K.⁴, Kusunoki, Y.⁴
¹Radiation Effects Research Foundation, Department of Molecular Biosciences, Hiroshima, Japan, ²Duke University Medical Center, Durham, United States, ³University of South Florida, Tampa, United States, ⁴Radiation Effects Research Foundation, Hiroshima, Japan

Previous A-bomb survivor studies suggested that radiation exposure might induce long-lasting immunological changes, such as enhancement of aging-related T-cell phenotypes, in the survivors. However, radiation effects on dendritic cells (DC) that may be a key factor behind the immunological changes remain unknown. In this study, we investigated numerical and functional alterations associated with radiation and aging in the circulating DC populations among A-bomb survivors.

Method and materials: Peripheral blood samples were collected with informed consent from 229 participants in the Adult Health Study at Radiation Effects Research Foundation. The two major DC populations, conventional DC (cDC) and plasmacytoid DC (pDC), were numerically analyzed and sorted by flow cytometry. The sorted cDC and pDC were stimulated with TLR3 and TLR7 ligands, respectively; and then, alterations in cytokine production levels and gene expression profiles of the DC populations were determined, using a bead-based multiplex assay and a PCR array, respectively.

Results and discussion: In female survivors, both the number

and functions of cDC decreased with age but not radiation dose, whereas the number of pDC decreased but function of pDC increased with age and radiation exposure dose. However, no significant numerical and functional changes associated with age or radiation dose were observed in male survivors. Our results suggest that aging-associated alterations in the DC populations, especially those in pDC, might be accelerated by past radiation exposure in a gender-dependent manner.

966

IRF8 dependent classical dendritic cells are essential for intestinal T cell homeostasis

Luda, K.M.¹, Joeris, T.^{1,2}, Persson, E.K.³, Rivollier, A.^{1,2}, Demiri, M.¹, Sitnik, K.M.², Pool, L.², Holm, J.B.⁴, Melo-Gonzalez, F.^{5,6,7}, Richter, L.⁸, Lambrecht, B.N.³, Kristiansen, K.⁴, Travis, M.A.^{5,6,7}, Svensson-Frej, M.¹, Kotarsky, K.¹, Agace, W.W.^{1,2}

¹Lund University, Lund, Sweden, ²Technical University of Denmark, Copenhagen, Denmark, ³Ghent University - VIB, Ghent, Belgium, ⁴University of Copenhagen, Copenhagen, Denmark, ⁵University of Manchester, Manchester, United Kingdom, ⁶Manchester Collaborative Centre of Inflammation Research (MCCIR), Manchester, United Kingdom, ⁷Wellcome Trust Centre for Cell-Matrix Research, Manchester, United Kingdom, ⁸Oslo University Hospital, Oslo, Norway

The role of dendritic cells (DCs) in intestinal immune homeostasis remains incompletely defined. Here we show that mice lacking IRF8 dependent DCs have reduced numbers of T cells in the small intestine (SI), but not large intestine (LI), including an almost complete absence of SI CD8ab⁺ and CD4⁺CD8aa⁺ T cells; the latter requiring b8 integrin expression by migratory IRF8 dependent CD103⁺CD11b⁻ DCs. SI homing receptor induction was impaired during T cell priming in mesenteric lymph nodes (MLN), which correlated with a reduction in aldehyde dehydrogenase activity by SI derived MLN DCs, and inefficient T cell localization to the SI. Finally, mice with a DC deletion in IRF8 lacked intestinal T helper 1 (Th1) cells, and failed to support Th1 cell differentiation in MLN and mount Th1 responses to *Trichuris muris* infection. Collectively these results highlight multiple non-redundant roles for IRF8 dependent DCs in the maintenance of intestinal T cell homeostasis.

967

Coordinate regulation of dendritic cell migration by the DOCK family of Rac guanine exchange factors

Kunimura, K., Fukui, Y.
Kyushu University, Division of Immunogenetics, Medical Institute of Bioregulation, Fukuoka, Japan

Dendritic cells (DCs) are specialized antigen presenting cells that play a critical role in initiation of adaptive immune responses. Upon antigen exposure, DCs phagocytose antigens in peripheral tissues, and migrate via the afferent lymphatic vessels into the draining lymph nodes to stimulate T cells. During this process, DCs switch their sessile sampling behavior to a highly migratory one, which is characterized by the acquisition of a polarized morphology. This morphologic polarity is regulated by Rac,

a member of the small GTPases that cycle between inactive GDP-bound and active GTP-bound states. Although Rac is activated by means of guanine exchange factors (GEFs), the Rac GEFs critical for DC migration remains to be determined. We found that DCs express all DOCK-A subfamily members, DOCK1, DOCK2 and DOCK5 that are known to act as Rac GEFs. By developing single, double and triple KO mice, we show in this study that DC migration is coordinately regulated by these DOCK family GEFs.

968

Identification of unique dendritic cell and macrophage subsets in human anogenital tissues

Bertram, K.M.¹, Botting, R.A.^{1,2}, Baharlou, H.^{1,2}, Sandgren, K.¹, Kim, M.¹, Cunningham, A.L.^{1,2}, Harman, A.N.¹

¹Westmead Institute for Medical Research, Centre for Virus Research, Westmead, Australia, ²University of Sydney, Medicine, Sydney, Australia

Dendritic cells (DCs) and macrophages present within anogenital tissues are two of the first cell types to encounter pathogens during sexual intercourse, which they detect via C-type lectin receptors (CLR) expressed on their surface. Furthermore, these cells play a direct role in transmission of some viruses such as HIV. Surprisingly however, very little human data is available regarding the specific DC and macrophage subsets that are present within different anogenital tissues.

We have established access to all the tissues that pathogens may encounter during sexual intercourse (labia, vagina, cervix, glans penis, foreskin, anus and rectum). Using complex multicolour flow cytometry we have determined the population frequency of all known DC and macrophage subsets within these tissues and also determined which CLR they express. We find that different anogenital tissues differ significantly in the subsets of these cells they contain and, importantly, we have identified several novel subsets. For example in foreskin and labia, in addition to Langerhans cells, we have identified an additional CD1a⁺ epidermal DC subset and two CD11c⁺ dermal myeloid subsets that can be discriminated by CD1c expression and are negative for all other DC and macrophage markers (CD1a, CD14, CD141 and CD123). In the anal epithelium we have identified a further epidermal DC subset that expresses langerin but not CD1a and these cells are also present in rectal but not anal lamina propria.

Identifying unique anogenital DC and macrophage populations and their CLR expression is important in understanding the transmission and immune control of sexually transmitted pathogens.

969

GMP-production of an allogenic DC-based cancer vaccine (INTUVAX) for treatment of patients with metastatic kidney- or primary liver cancer. Comparison of two production platforms for DC-generation

Adamson, L.¹, Andersson, B.², Kiessling, R.¹, Nasman-Glaser, B.¹, Karlsson-Parra, A.³

¹Karolinska Institutet, Dept of Oncology & Pathology, Stockholm,

Sweden, ²Gothenburg University, Immunology, Gothenburg, Sweden, ³Uppsala University, Dept of Immunology, Uppsala, Sweden

The aim of INTUVAX[®] phase I/II studies in patients with metastatic kidney- or primary liver cancer is to evaluate adverse effects and anti-tumor effects of a therapeutic vaccine-concept that is based on intratumoral injections of activated allogenic dendritic cells (DCs) produced from healthy donors. The strong allogenicity of such cells and their sustained production of pro-inflammatory mediators is expected to create a local inflammatory environment that promotes recruitment, antigen-loading and activation of endogenous DCs.

Clinical studies require protocols where a sufficient number of well characterized DCs are produced according to Good Manufacturing Practice (GMP) guidelines. We validated two different platforms for production of activated allogeneic DCs. In the COMBIG ("COMBined toll-like receptor Interferon-Gamma") GMP platform, ELUTRA[®] -enriched monocytes from leukapheresis products from healthy donors were used as starting material. In the other, CliniMACS[®] purified monocytes from pooled Buffy Coats were used as starting material. Collected fractions were phenotypically analysed for cell content by flow cytometry. The enriched monocyte fractions were differentiated into immature DC in culture bags using GM-CSF and IL-4 and matured for 18 hours using a cocktail of Poly-IC, R 848 and IFN γ . DC-generation was determined using phenotypic markers and expression of cytokines.

Our results show that these two COMBIG vaccine production platforms are comparable, very robust and reproducible resulting in high initial monocyte purity, high recovery and efficient differentiation/maturation of phenotypically and functionally mature DCs. Delivered frozen vaccine cells show a high and reproducible quality after thawing.

Ectromelia virus-induced down-regulation of genes associated with myeloid dendritic cell activation and maturation is mouse-strain independent

Szulc-Dabrowska, L.¹, Cymerys, J.¹, Toka, F.N.^{1,2}, Struzik, J.¹, Nowak, Z.³, Gierynska, M.¹

¹Warsaw University of Life Sciences-SGGW, Faculty of Veterinary Medicine, Department of Preclinical Sciences, Warsaw, Poland,

²Ross University School of Veterinary Medicine, Department of Biomedical Sciences, Basseterre, Saint Kitts and Nevis, ³Warsaw University of Life Sciences-SGGW, Faculty of Animal Sciences, Department of Genetics and Animal Breeding, Warsaw, Poland

Resistance and susceptibility to ectromelia virus (ECTV) infection in mice are controlled by many genetic factors and are associated with the preferential development of Th1 and Th2 cytokine immune responses, respectively. Myeloid dendritic cells (mDCs) isolated from various inbred mouse strains have a different ability to react to pathogen infection/exposure and, consequently, stimulate protective or non-protective Th immune responses. In the present study we evaluated the

effect of ECTV infection on transcriptional response of innate and adaptive immune genes in bone marrow-derived DCs (BMDCs) obtained from BALB/c (susceptible) and C57BL/6 (resistant) mice. Our results showed that ECTV similarly affects mRNA expression of chemokines and cytokines, and mRNA encoding proteins engaged in antigen uptake, processing and presentation in BMDCs generated from BALB/c and C57BL/6 mice. In both cases, ECTV does not stimulate genes, such as *cd80* and *cd86*, related to maturation of BMDCs, moreover it down-regulates several genes associated with their innate and adaptive immune functions, with the exception of *il10* that is significantly up-regulated. These data strongly suggest that *in vitro* modulation of BMDCs gene expression profile by a poxvirus occurs independently of the mouse strain susceptibility to infection. Inhibition of the activation and/or maturation of mDCs may be a strategy of immune evasion used by ECTV to reduce the capacity of mDCs to stimulate activation and proliferation of antigen-specific T lymphocytes. It is likely that this inhibitory effect is more pronounced in susceptible mouse strains under *in vivo* conditions.

Exosomes are nano-scale vesicles that are released from cells into the extracellular environment. There is increasing interest in the role of exosomal RNAs as mediators of intercellular communication, but there is minimal evidence that intercellular RNA transfer occurs *in vivo*. To explore this issue, we profiled exosomal RNAs from mouse dendritic cells (DCs) using RNAseq, and identified 230 exosome-enriched RNAs. Unexpectedly, the RNA that showed the greatest enrichment in exosomes (~200-fold) and was also the third most abundant exosomal RNA was the VL30 long noncoding RNA (lncRNA), which is derived from a mouse-specific endogenous retrovirus and has previously been shown to function as an important transcriptional regulator. Next, we tested whether VL30 lncRNA could be transferred to recipient cells *in vitro* by co-culturing DC-derived exosomes with various human cell lines. In each case, we found evidence of exosome-mediated VL30 lncRNA transfer. Finally, to determine

whether VL30 lncRNA can be transferred to recipient cells *in vivo*, we generated humanized mice whose T and B cells are of human origin and assessed whether VL30 lncRNA can be found in either the human T or B cells, whose genomes lack VL30 orthologs. Strikingly, VL30 was readily detected in human B cells from these mice, indicating that VL30 is also transferred *in vivo*. Taken together, this work suggests that VL30 lncRNA is being selectively loaded into exosomes and subsequently transferred to recipient cells. How this selective loading occurs and the functional consequences of VL30 lncRNA transfer are now being investigated.

The influence of immunosuppression on intraepithelial airway mucosal dendritic cell

Shevchenko, M.¹, Troyanova, N.¹, Servuli, E.¹, Fedorina, A.², Mirzoev, R.¹, Bolkhovtina, E.¹, Sapozhnikov, A.¹

¹Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry, Immunology, Moscow, Russian Federation, ²Lomonosov Moscow State University, Biology, Moscow, Russian Federation

Intraepithelial airway mucosal dendritic cells due to their location can sense inhaled pathogens, including conidia of opportunistic fungi *Aspergillus fumigatus*. Susceptibility to *Aspergillus*-induced infection is usually a result of immunosuppression that mainly leads to neutropenia, but also affects some other leukocyte populations.

In the present study we investigate whether immunosuppression influences intraepithelial airway mucosal dendritic cells.

BALB/c mice were subjected to immunosuppression by two ways: two injections of cyclophosphamide and cortisone acetate or one injection of anti-Gr-1 depletion antibodies. 24 hours after mice were sacrificed; main bronchi were microdissected and subjected to immunostaining and confocal imaging as whole-mount airways. Airway mucosal dendritic cells were identified according to MHCII expression, morphology - special dendritiform shape and location in a close proximity to epithelial cells. Specimens were scanned in Z-stack mode and intraepithelial airway mucosal dendritic cells were quantified per square millimeter of epithelium.

MHCII positive cells with dendritiform shape were identified in the airways of both intact mice and mice with induced immunosuppression. Statistical analysis revealed no significant differences between the numbers of intraepithelial dendritic cells per square millimeter of epithelium in intact mice (340±125), mice that received cyclophosphamide and cortisone acetate in combination (239±98) and mice that were injected with depletion antibodies (255±91).

Thus, immunosuppression does not influence morphology and number of intraepithelial airway mucosal dendritic cells. Functional analysis of the population in condition of immunosuppression is to be investigated.

Human and canine dendritic cell responses triggered by *Brucella canis* and *Escherichia coli* lipopolysaccharide

Pujol, M.¹, Arias, J.², Alvarez, C.², Rojas, L.², Ferreira, A.³, Vernal, R.²

¹Universidad de Chile, Facultad de Ciencias Veterinarias y Pecuarias, Santiago, Chile, ²Universidad de Chile, Facultad de Odontología, Santiago, Chile, ³Universidad de Chile, Facultad de Medicina, Santiago, Chile

The aim of this study was to evaluate the cytokine profile production by canine and human dendritic cells (DCs) when stimulated *in vitro* with *B. canis* Lipopolysaccharide (LPS) or *E. coli* LPS, as compared to the activating capacity of LPS purified from a naturally rough *Brucella*.

Brucella spp. can lead to chronic intracellular infections due to their low stimulatory activity on immune cells, in part mediated by their LPS. Naturally smooth *Brucella* LPS is several times less effective at inducing the innate immunity than enterobacterial LPS. However, there is much less knowledge about naturally rough *Brucella* LPS.

Monocytes were purified from canine and human blood samples, using magnetic cell sorting, and then differentiated to immature DCs, upon induction with GM-CSF and IL-4. DCs were stimulated with LPS purified from *B. canis* or *E. coli*. The mRNA expression levels for IL-1 β , IL-4, IL-5, IL-6, IL-10, IL-12p35, IL-17A, IFN- γ , TNF- α and TGF- β 1 were quantified by qRT-PCR.

Canine DCs stimulated with *B. canis* LPS increased expression of IL-6 and IL-12p35, while *E. coli* LPS increased IL-12p35 expression. *B. canis* LPS increased IL-12p35 expression in human DCs, while *E. coli* LPS increased IL-1 β and TNF- α expression, as compared with non-stimulated DCs.

No significant differences were detected in canine DCs stimulated with LPS from *B. canis* vs *E. coli*. However IL-1 β expression in human DCs with *E. coli* LPS was higher.

Dendritic cells (DC) are professional antigen-presenting cells that mediate immune responses. Important questions on the origins and differentiation paths of human DC populations remain unanswered. Here we combined two high-dimension techniques, single-cell mRNA sequencing and Cytometry by Time of Flight mass spectrometry to define and characterize

human DC precursors (pre-DC) present in blood. We showed that the previously-underestimated pre-DC population share several surface markers with plasmacytoid DC (pDC), and we revealed how some properties previously attributed to pDC are in fact restricted to pre-DC present in the same cultures. We also identified the whole DC lineage from BM to peripheral blood and revealed that pre-DC comprised of three distinct lineage-committed sub-populations, and demonstrated their presence and functional distinctions in peripheral blood. Hence, this opens promising new avenues for investigation of therapeutic potential of DC subset-specific targeting.

975

Modulation of dendritic cells by exosomes derived from human breast milk and plasma

Larssen, P., Eldh, M., Gabrielsson, S.

Karolinska Institutet, Department of Medicine, Translational Immunology Unit, Stockholm, Sweden

Exosomes are small extracellular vesicles, 30-100 nm in diameter, produced and secreted by most cells including immune cells. They are present in body fluids such as plasma and breast milk. Breast milk derived exosomes can induce foxp3 expression in PBMCs indicating that they may induce tolerance, thereby possibly influencing allergy development. It is not known how plasma- or milk exosomes affect dendritic cells. Therefore, we aimed to compare the immune modulatory properties of exosomes derived from human breast milk and plasma on monocyte derived dendritic cells (MDDC). We show that plasma-derived exosomes strongly increase the HLA-DR expression on MDDC, while breast milk-derived exosomes do not. Furthermore, plasma exosomes but not milk derived exosomes induced cytokine secretion such as; IL-10, IL-6 and TNF α , suggesting a more pro-inflammatory role of plasma exosomes. Instead breast milk exosomes may be important in regulation of immune responses towards induction of tolerance, which we will further investigate. We conclude that these exosomes have diverse immunological properties and this contributes to the understanding of the role of exosomes in immunological processes.

Introduction: Periodontal disease (PD) is one of the most common chronic inflammatory diseases in humans it involves many factors; mainly the composition of the microbes in the subgingival plaque, and the host immune response. A high rate of monocytes may be found in chronic lesions as T cells, B cells, macrophages and dendritic cells (DC). The role of DCs it's not well described in this pathological condition.

Methodology: Gingival biopsies samples were obtained from healthy individuals, patients with gingivitis and chronic periodontitis. HLA, CD11c, CD83 and CD80 were analyzed by flow cytometry. In other hand, one fraction of biopsies were oriented in Ployfreeze and frozen in liquid nitrogen and stored -80 °C to analyze CD1a, CD-80 and -83 by fluorescence IHC. Sub- and supra-gingival plaque were collected in order to characterize the microflora and make an association with the state of the cells.

Results: DCs CD11c+ were higher in healthy and gingivitis subjects (9.55 and 8.93%) whereas in periodontitis subjects are 6.17%. CD80+ were low expressed in periodontitis subjects (4.99%) and higher in gingivitis and healthy subjects (7.50 and 10.19%) by flow cytometry.

Conclusion: Due to the chronic inflammation DCs in a normal state remains low in periodontitis subjects. Sameway, activated DCs are low in periodontitis subjects which show that the labor of present antigen in DCs are not good under periodontitis.

977

Column-based untouched magnetic separation of human pDCs yields superior performance and functionally unaffected cells

Morrissey-Wettey, F.R., Angerer, C., Kurig, S., Richter, A., Dzionek, A. Miltenyi Biotec GmbH, Bergisch Gladbach, Germany

Plasmacytoid dendritic cells (pDC) play a crucial role in innate immune defense by recognition of conserved pathogen-associated molecular patterns (PAMPs). PAMPs activate pDCs via pattern recognition receptors such as Toll-like receptors (TLR). In particular, CpG motifs of bacterial DNA bind specifically either endosomal or lysosomal TLR9, thereby inducing secretion of IFN- α or proinflammatory cytokines and classical DC maturation, respectively. However, as observed in autoimmune settings, TLR9 also recognizes vertebrate CpG DNA-motifs as danger-associated molecular patterns (DAMPs) that activate pDCs. Routinely pDCs are isolated by indirect magnetic cell separation for *in-vitro* research. Here we describe the influence of the isolation method on the functionality of the purified pDCs. We compared Miltenyi Biotec's column-based with a column-free system from another supplier. Not only achieved the former a superior separation performance, it also enriched 10- and 30-fold less DNA-containing dead cells and debris, respectively. Both procedures yielded phenotypically comparable pDCs instantly after isolation. Whereas pDCs isolated using Miltenyi's procedure were functionally normal, cells isolated with the column-free system were pre-activated as evident from elevated expression of CD80, -83, -86 and HLA-DR and significantly increased IFN- α production after 24h of culture without stimulation. Moreover, upon stimulation with CpG-B pDCs isolated with the column-free method secreted extraordinary high amounts of IFN- α ,

whereas pDCs isolated with Miltenyi's system exhibited normal responses to CpG-A and CpG-B.

These results clearly demonstrate that unspecific enrichment of dead cells and debris may significantly influence the activation status of the isolated pDCs and therefore affect the results of downstream applications.

978

Importance of lung migratory DC in Influenza immunity

Ng, S.L., Ruedl, C., Erik Karjalainen, K.

Nanyang Technological University (NTU), Singapore, Singapore

Migratory CD103⁺ DC, which is specialized in cross-presenting extracellular antigen to cytotoxic T lymphocytes (CTLs), is indispensable for the induction of protective CTL response against Influenza A virus (IAV) infection. Using Clec9a-DTR transgenic mouse which allows us to specifically ablate CD103⁺ DCs upon DT administration, we aim to investigate the detailed mechanisms on how CD103⁺ DC-deficiency contributes to reduced accumulation of IAV-specific CTLs in the lung. We demonstrated in our Clec9a-DTR mouse that ablation of CD103⁺ DCs led to increased susceptibility to IAV infection and IAV-infected Clec9a-DTR mice harbored drastically fewer number of IAV-specific CTLs. Contrary to what we expected, in the absence of CD103⁺ DCs, the number of IAV-specific CTLs cells in the mediastinal lymph node (mLN) increased despite attenuated cross-presentation *in situ*. This observation suggests that efficient migration of CTLs from the mLN requires CD103⁺ DCs. Additionally our data showed that in IAV-infected Clec9a-DTR mouse, IAV-specific CTLs in the lung were less viable and adoptive transfer of CD103⁺ DCs improved the survival of these effector T cells suggesting direct involvement of CD103⁺ DCs in supporting CTLs survival. Moreover, our investigations also revealed significant reduction of memory CTL (KLRG1- IL7R⁺) number in the absence of CD103⁺ DCs and IAV-primed Clec9a-DTR mice were more susceptible to re-infection by serotypically distinct IAV strain. We reason that this reduction can be partially explained by the reduction in the frequency of CXCR3 (neg) effector CTLs in which these cells have been associated with high memory potential.

979

XCR1 expression by dendritic cells promotes NK cell activation during viral infection

Ghilas, S., Dalod, M., Crozat, K.

Centre d'Immunologie de Marseille-Luminy, Marseille, France

A subset of mouse dendritic cells (DCs) specifically express the chemokine receptor XCR1 and excels at priming CD8⁺ T cells including through cross-presentation. XCR1⁺ DCs are also highly efficient for the activation of natural killer (NK) cells and invariant NK T cells. XCL1, the ligand of XCR1, is selectively and strongly expressed by NK, NK T and activated or memory CD8⁺ T cells. Hence, we are investigating whether and how the XCL1/XCR1 axis regulates the cross-talk between cytotoxic lymphocyte subsets and XCR1⁺ DCs.

Here we examined whether XCR1 deficiency affected NK cell

responses to mouse cytomegalovirus (MCMV) infection. XCR1-deficient mice harbored high viral loads at day 5 after infection, at a time when viral replication had become undetectable in WT animals. XCR1-deficient mice also harbored diminished XCR1⁺ DC IL-12 production and NK cell responses. Finally, in infected XCR1-deficient mice, NK cells and XCR1⁺ DCs failed to cluster together in the marginal zone of the spleen. Hence, signaling through XCR1 may orchestrate in time and space the interactions between XCR1⁺ DCs and NK cells during MCMV infection, thereby promoting their mutual activation and the downstream control of the virus.

This work was funded by Aix Marseille Université (scholarship from the University President to S.G.), Association pour la Recherche sur le Cancer (ARC) and the European Research Council under the European Community's Seventh Framework Programme (FP7/2007-2013 Grant Agreement no. 281225 for the SystemsDendritic project).

Interferon response factor-3 is required for the pro-Th2 activity of mouse myeloid CD11b⁺ dendritic cells

Janss, T., Mesnil, C., Pirottin, D., Lemaitre, P., Schyns, J., Marichal, T., Bureau, F., Desmet, C.

University of Liège, Liège, Belgium

The transcription factors required for antigen-presenting cells (APCs) to induce T helper type 2 (Th2) responses are less well defined than for other types of T helper responses. Using mouse lung resident conventional CD11b⁺ dendritic cells (CD11b⁺ cDCs) in the context of house-dust mite (HDM)-driven allergic airway sensitization as a model, we aimed here to identify transcriptional events regulating the pro-Th2 activity of dendritic cells. Transcriptomic profiling of CD11b⁺ cDCs exposed to HDM *in vivo* revealed first that HDM triggered a prominent antiviral defense-like response and second that most of the HDM-induced transcriptional changes in CD11b⁺ cDCs depended on the transcription factor Interferon Response Factor-3 (Irf3). Validating the functional relevance of these observations, genetic deficiency in Irf3 diminished the pro-allergic activity of CD11b⁺ cDCs. The reduced pro-allergic activity of Irf3-deficient CD11b⁺ cDCs was not related to impaired antigen uptake or migratory activity. Instead, following direct contact with naive T cells, Irf3-deficient CD11b⁺ cDC induced less Th2, more regulatory T cell, and similar Th1 differentiation compared to their wild-type counterparts. The altered APC activity of Irf3 CD11b⁺ cDCs was associated with reduced expression of specific costimulatory molecules and was phenocopied by blocking the activity of the same molecules in wild-type CD11b⁺ cDCs. Altogether, these results establish Irf3, mostly known for its antiviral activities, as a transcription factor required for the induction of Th2 responses through appropriate costimulation in lung CD11b⁺ cDCs.

981

Gene profiling of murine splenic dendritic and myeloid subsets*Hey, Y.Y., O'Neill, H.C., O'Neill, T.J.**Bond University, Gold Coast, Australia*

Phenotype studies have been widely used to identify and characterise splenic myeloid and dendritic cell (DC) subsets. However, these studies are limited by the availability of antibodies, and the expression level, and specificity of markers. Multiple subsets can express the same marker. For example, F4/80, a red pulp macrophage marker, is also expressed on monocytes and DC. In order to delineate the lineages of DC and tissue macrophages more completely, recent studies have employed transcriptome analysis to generate gene profiles unique to macrophages and DC, respectively. A novel dendritic-like cell (L-DC) described recently resembles a myeloid cell on the basis of a CD11b^{hi}CD11c^{lo}CD43⁺MHCII⁻Ly6C⁻Ly6G⁻Siglec-F⁻CX3CR1^{lo} phenotype, but a DC on the basis of antigen presenting function. To fully elucidate the relationship between L-DC, conventional DC (cDC) and myeloid subsets, transcriptome analysis was undertaken. Principal components analysis showed close grouping of monocytes, L-DC and cDC in the first principal component, but separation of L-DC and monocytes from cDC subsets in the second principal component. In addition, hierarchical clustering indicates a close relationship between L-DC and resident monocytes, and then with inflammatory monocytes. Lists of common splenic cDC and monocytes genes were generated, respectively. L-DC expressed most of the common cDC and monocytes genes, suggesting that L-DC mirror both the cDC and monocyte lineages. Further analysis of L-DC gene profile also showed upregulation of genes reflecting both DC and myeloid lineages. Lastly, a comparison of gene profiles between L-DC and monocyte subsets, revealed CD300e to be a distinct marker for L-DC.

982

The role of inflammatory stimuli in dendritic cell biology*Tian, Z.¹, Villadangos, J.^{2,3}, Roquilly, A.⁴, Mintern, J.³, Jose Villadangos*

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²University of Melbourne, Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ³University of Melbourne, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ⁴University Hospital of Nantes, Nantes, France

Infection-induced inflammation drives direct DC activation by encountering pathogen associated/ danger associated molecular patterns (PAMPs/ DAMPs) directly, and indirect DC activation by encountering secondary inflammatory signals released by PAMPs/ DAMPs- exposed cells. Directly activated DC and indirectly activated DC are two distinct DC populations with differential characteristics and immunological roles. However, due to the lack of effective markers to discriminate these two DC populations, the study on the characteristics and immunological roles of the two DC populations is limited. This project aims to identify the membrane markers that discriminate directly vs.

indirectly activated DC, and to characterize the T cell response to indirectly activated DC, as well as to investigate the interest of antigen targeting to indirectly activated DCs to boost immune response during inflammation. Based on this study, we will be able to describe the specific phenotypes of directly vs indirectly activated DCs, to assess the immune functional properties of indirectly activated DC, as well as to assess the formation of directly and indirectly activated DCs *in vivo*, under both steady-state and inflammatory conditions. The results will also assist rational designing of vaccines to maximize the immune response, as well as strategies to minimize autoimmunity.

Stem Cells & Immunity

983

Increasing stem cell dose promotes immune reconstitution following stem cell transplant*Xu, N., Shen, S., O'Brien, T., Dolnikov, A.**Sydney Children's Hospital, Cord and Marrow Transplant Laboratory, Randwick, Australia*

Immunologic reconstitution following allogeneic stem cell transplantation is a critical component of successful outcome. The effect of stem cell dose on immune reconstitution was examined using immunocompromised NSG mice transplanted with different numbers of T-cell depleted cord blood derived CD34⁺ stem cells. Infusion of large numbers of stem cells promoted early B-, T- and myeloid cell engraftment and increased the magnitude of immune reconstitution at late stages post-transplant. Infusion of larger numbers of stem cells promoted CD8⁺ T cell differentiation and delayed late memory T cell skewing in expanse of naive T cells resulting in increased diversity in the T cell repertoire and stronger immune responses. We have also shown that the immune responses against xenografted leukaemia cells correlate with the magnitude of T-cell engraftment in stem cell reconstituted mice highlighting the importance of stem cell dose in the transplant to reduce the risk of leukaemia relapse particularly in T cell depleted haploidentical stem cell transplants. Additionally, increased expansion of adoptively transferred T cells generating potent anti-tumour effects against mismatched leukaemia cells was associated with higher stem cell engraftment. Therefore, increasing stem cell dose in the transplant prior to adoptive T cell transfer may promote graft-versus-leukaemia effect.

984

Investigating myeloid development in the context of a spleen microenvironment*Short, C., O'Neill, H., Tan, J.**Bond University, Robina, Australia*

The spleen contains multiple myeloid cell populations with varying functions in immunity and wound healing. The differentiation of hematopoietic stem cells (HSC) and progenitors into myeloid CD11b⁺CD11c^{lo} antigen presenting cells (APC) has been previously demonstrated *in vitro* in the context of a spleen stromal microenvironment. This same

subset is also produced indefinitely in spleen long-term cultures (LTC), suggesting they represent a spleen endogenous immune cell population derived from tissue-resident HSC. However, the precise correlation between culture-derived myeloid APC and naturally-occurring APC in spleen has been difficult to establish, although they are clearly distinct from conventional dendritic cells. This study now addresses whether common monocyte progenitors (CMoP) differentiate to give this distinct subset of myeloid CD11b⁺CD11c^{lo} APC in the context of a spleen stromal microenvironment, and whether these represent monocytes or a unique cell lineage. Findings will be presented demonstrating *in vitro* spleen stromal co-cultures of CMoP from sources including adult bone marrow, and adult and neonatal spleen. Co-cultures of HSC over spleen stroma, and cytokine-induced (SCF, LIF, IL-3 and IL-6) cultures of CMoP, will serve as controls which produce myeloid CD11b⁺CD11c^{lo} APC and CD11b⁺Ly6C^{hi} monocytes, respectively. Results from this study specifically allow the establishment of a relationship between co-culture and LTC-derived myeloid-APC, and cells arising from the monocyte lineage defined by the CMoP precursor.

985

Single cell sequencing reveals heterogeneity within murine bone marrow derived stem and progenitor population

Zalcenstein, D., Tian, L., Schreuder, J., Naik, S.

Walter & Eliza Hall Institute of Medical Research, Molecular Medicine, Parkville, Australia

In blood cell development (haematopoiesis) the prevailing paradigm is that haematopoietic stem cells (HSCs) generate multi-potent progenitors (MPPs) that later asymmetrically split to initiate the generation of cell type diversity. However, recent evidence suggests the classic 'tree' diagram of haematopoiesis is overly simplistic and, instead, HSC/MPP fate is highly heterogeneous and dictated by gene expression heterogeneity. Here, we isolated HSC/MPPs from mouse bone marrow, stained them with a panel of surface markers, and used single cell index sorting by FACS, which records each cell's phenotype, and then performed single cell RNA sequencing of the same cell. In this way, we have linked phenotypic and fate information per cell for hundreds of cells. Using novel computational methods, we could correlate gene expression heterogeneity to phenotypic heterogeneity. Differentially expressed genes between HSC/MPP subpopulations included both novel and known genes involved in lineage specification. This work is consistent with emerging evidence that lineage specification occurs much earlier in haematopoiesis than previously appreciated.

986

LL-37 upregulates genes related to stemness in breast cancer cells

Pinheiro da Silva, E., Martins de Lima, T., Tude Coelho Neto, G., Cesar Machado, M.

University of Sao Paulo, Emergency Medicine, Sao Paulo, Brazil

Introduction: Antimicrobial peptides (AMPs) are among the rare examples of very ancient molecules that emerged millions

of years ago and have been preserved during the evolutionary process of living organisms. Components of this large family of over 2,300 peptides can be found wherever there is life. Probably due to their prolonged existence in our planet, AMPs evolved a multitude of exquisite functions that go beyond our understanding. Indeed, despite their bactericidal capacity, AMPs have been intriguing the scientific community, since they are able to bind lipopolysaccharide (LPS) and other pathogen-associated patterns (PAMPs), bind membrane receptors, alter a variety of signaling pathways in different cell types, induce chemotactic responses, stimulate angiogenesis, promote wound healing, activate the inflammasome, trigger apoptosis and other mechanisms of cell death, such as NETosis, among other of their immunoregulatory and non-immune functions.

Objective: Investigate the role of LL-37 in cancer biology.

Results and discussion: Here, we show that LL-37 knockout in breast cancer cells (SKBr3) leads to down regulation of several genes related to stemness, such as Telomerase reverse transcriptase, Forkhead box D3 and Nestin and decreased production of mammospheres.

987

Delineation of cellular niches which support hematopoiesis in spleen

O'Neill, H.¹, Lim, H.K.², Tran, V.², Petvises, S.², Periasamy, P.², O'Neill, T.³

¹Bond University, Faculty of Health Sciences and Medicine, Robina, Australia, ²Australian National University, Research School of Biology, Canberra, Australia, ³Bond University, Business School, Gold Coast, Australia

Hematopoietic stem cell (HSC) niches in bone marrow have been described in terms of distinct cell types including osteoblastic, endothelial and perivascular reticular cells. However, niches which support extramedullary hematopoiesis in other sites like spleen remain to be elucidated. Previous studies have described splenic stromal cells which support hematopoiesis *in vitro* from purified HSC and multipotential progenitors (MPP) leading to the production of dendritic-like cells. Stromal cell lines were originally derived from splenocyte cultures, and later as freshly isolated stromal subsets prepared by enzymatic digestion and sorting. Transcriptome analysis has revealed that stroma which support hematopoiesis express many genes in parallel with perivascular cells described in bone marrow. They share a common mesenchymal lineage with perivascular cells in bone marrow, as well as mesenchymal progenitor cells and CXCL12-abundant reticular cells. They reflect osteoprogenitors in that cells can be induced to osteogenesis, although not adipogenesis or chondrogenesis, when cultured in defined media. Cell surface markers common to these cells include CD105, CD29, VCAM1, CD51, CD140a/b and CD90. A number of new markers and genes have been identified which delineate this cell type and determine their ability to support hematopoiesis. These studies have employed inhibitors and gene knockdown to block stromal cell signaling and interaction with HSC in order to identify novel regulators of *in vitro* hematopoiesis.

988

Combination of T-cell secreted cytokines promotes long-term muscle stem cell expansion

Fu, X., Xiao, J., Wei, Y., Gu, H., Wang, H., Hu, P.

Shanghai Institute of Biochemistry and Cell Biology, Shanghai, China

Muscle stem cells (MuSCs, satellite cells) are the major contributor to muscle regeneration. Like most adult stem cells, long-term expansion of MuSCs *in vitro* is difficult. The *in vivo* muscle regeneration abilities of MuSCs are quickly lost after culturing *in vitro*, which prevents the potential applications of MuSCs in cell-based therapies. Here, we found that muscle regeneration was delayed in Rag1 KO mice, which could be rescued by adoptive transfer of activated T cells. We further identified that the combination of four pro-inflammatory cytokines, IL-1 α , IL-13, TNF- α , and IFN- γ , secreted by T cells was able to stimulate MuSC proliferation *in vivo* upon injury and promote serial expansion of MuSCs *in vitro*. The expanded MuSCs can replenish the endogenous stem cell pool and are capable of repairing multiple rounds of muscle injuries *in vivo* after a single transplantation. The establishment of the *in vitro* system provides us a powerful method to expand functional MuSCs to repair muscle injuries (Cell Research, 2015, 25:655-73. Cover Story).

989

Study on the role of PPAR- γ in the immune regulatory activities during mesenchymal stem cell differentiation

Kuo, H.-L., Chiang, B.-L.

National Taiwan University, Department of Immunology, Taipei, Taiwan, Republic of China

Mesenchymal stem cells (MSCs) are self-renewable multipotent progenitor cells that can differentiate into a variety of cell types including adipocytes, osteocytes and chondrocytes. Recent studies have demonstrated that MSCs could exert an immunosuppressive activity. However, many obesity-related metabolic diseases such as type II diabetes are attributed to adipocyte-induced inflammation. Macrophages recruited by adipose tissue-derived hormones or chemokines, play the key roles on the chronic inflammation. We hypothesized that some mediators might be changed during adipogenesis of MSCs. Especially, the role of PPAR- γ in inflammation and anti-inflammation remain still unclear. Hence, this study was performed to examine the gene and cytokine profiles of MSCs in different differentiation process. Along with MSCs adipogenesis, more inflammatory cytokines, including IL-6, TNF- α , and *mcp1* were secreted and expressed. But the expression of IL-1Ra was negatively correlated with adipogenic process of MSCs. Furthermore, peroxisome proliferator-activated receptors (PPARs) can promote adipogenesis by inhibiting IL-1Ra expression. The results here provided rational mechanisms clarifying the role of adipogenesis-related genes and molecules in the differentiation and regulatory activities of MSCs.

Keywords: Mesenchymal stem cells; adipogenesis; inflammation; PPAR- γ ; IL-1Ra

Linking the gene expression profile of a cell with its fate

Creus, L., Naik, S., Schreuder, J., Zalcenstein, D.

Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia

In blood cell development the prevailing paradigm is that haematopoietic stem cells (HSCs) generate multi-potent progenitors (MPPs) that later asymmetrically split to initiate the generation of cell type diversity. However, recent evidence suggests the classic 'tree' diagram of haematopoiesis is overly simplistic and, instead, HSC/MPP fate is highly heterogeneous and dictated by gene expression heterogeneity. Linking the gene expression profile of a cell with its fate is challenging, because measurement of the first (e.g. through single cell RNA-seq) necessarily destroys the chance of testing the second (e.g. in clonal fate assays). Here we demonstrate that daughters of a single cell (a clone) when separated into separate mice, or wells in a tissue culture plate, largely inherit the same fate. This indicates that daughters can be used as surrogates of the mother. Therefore, we first sorted single HSC/MPPs, allowed a brief pre-expansion then tested daughter cells for B-, T-, DC- and myeloid potential separately, and some daughters for RNA-sequencing. In this way, we could link gene expression heterogeneity with fate heterogeneity. These preliminary results will be presented.

991

Lineage priming in early hematopoietic progenitors as revealed by *in vitro* clone splitting experimentsTran, J.¹, Schreuder, J.¹, Zalcenstein, D.¹, Kocovski, N.¹, Tian, L.²,Sargeant, T.², Alexander, W.², Metcalf, D.², Naik, S.¹¹WEHI, Naik Lab/Molecular Medicine, Parkville, Australia, ²WEHI, Parkville, Australia

Recent data has tabulated the nature of HSC and progenitor heterogeneity utilizing single cell transfers *in-vivo* or cellular barcoding technologies. While these studies valiantly examined cell fate *in-vivo* rather than *in-vitro*, these assays measure 'outcome' rather than 'potential', as it can be difficult to exclude the effects of niche where the cells engraft. Instead, we have performed large-scale clonal assays on total Sca1+CD117+ progenitors *in-vitro* across the B cell, T cell, dendritic cell and myeloid lineages. However, unlike examination of potential of single cells directly in a single condition, we first pre-expanded the progenitors for 3 days, then split the daughter cells into wells testing the potential of each lineage in replicate wells for each to exclude any stochastic effects. In this way we observed a large diversity in fate per clone. Also, paired wells were largely conserved in their fate, which indicates that the progenitor heterogeneity reflects an intrinsic and heritable program rather than a stochastic acquisition. In addition to splitting the daughter cells into the different lineage conditions, we also assessed some of these cells by RNA-seq. This made it possible to correlate the transcriptome of these progenitors to their fate; subsequently we were able to identify novel genes which might be involved in the earliest priming events.

Directing therapeutic stem cells to the inflamed CNS to augment repair and limit neuroinflammation in experimental MS

*Wilson, J., Foyle, K., Foeng, J., McColl, S., Comerford, I.
The University of Adelaide, Adelaide, Australia*

The potential for cell-based therapies to promote tissue repair and locally control immune responses in autoimmune and inflammatory neurodegenerative diseases such as multiple sclerosis (MS) is limited by restricted entry of transplanted cells to the injured central nervous system (CNS). Adult stem cell (SC) therapies have demonstrated anti-inflammatory, protective and reparative effects in a variety of experimental settings. However, SC-based therapies for MS are limited by entry of SCs into the inflamed CNS following systemic transplantation; a challenge for successful neural repair and local immunomodulation. To address this, we explored the utility of forced expression of chemokine receptors [CCR2 and CCR6] known to drive pathogenic leukocytes into the inflamed CNS, to redirect therapeutic SCs to this site in an experimental model of MS, experimental autoimmune encephalomyelitis (EAE). Expression of CCR6 by SCs significantly enhanced migration towards CCL20, a cognate chemokine ligand expressed at homeostasis and highly upregulated during inflammation within the CNS. An apparent redistribution of CCR6 expressing SCs into the inflamed CNS following systemic transplantation was accompanied by a significant inhibition in clinical EAE and pathogenic CD4⁺ T cells infiltrating the CNS. These findings suggest that conferring CNS tropism on adult stem cells enhances their anti-inflammatory and potentially neuroprotective effects in order to inhibit an important step in progression of EAE pathogenesis. This strategy advances the potential for cell-based immunotherapies tailored to redirect transplanted cells to target tissues defined by their inflammatory signatures; offering an additional level of control to halt the progression of inflammatory and autoimmune diseases.

993

Mesenchymal stem cell infusion modulates systemic inflammation in patients with chronic obstructive pulmonary disorder (COPD)

Armitage, J.^{1,2}, Tan, D.^{1,2}, Moodley, Y.^{1,2,3}

¹University of Western Australia, Medicine and Pharmacology, Perth, Australia, ²Sir Charles Gardiner Hospital, Institute of Respiratory Health, Perth, Australia, ³Fiona Stanley Hospital, Department of Respiratory Medicine, Perth, Australia

Background: COPD is characterised by chronic pulmonary and systemic inflammation. Recently, MSC infusions have shown success in clinical trials for improved several aspects of inflammatory-driven diseases including improving repair. Although promising, the reparative mechanisms by MSC and their acute effects post-infusion are poorly characterised, particularly in COPD. MSC possess anti-inflammatory properties, and have been shown to enhance the function of immunosuppressive T regulatory (Tregs) cells. Therefore, we hypothesise that

MSC infusion will alleviate chronic inflammation in patients with COPD.

Aims:

- 1) To assess trafficking of infused MSC by radiology
- 2) To evaluate inflammatory biomarkers following MSC infusion.
- 3) To assess phenotypic changes of Tregs post-infusion

Methods: Radiolabelled MSC were infused intravenously into 9 patients with stable COPD and tracked by CT scan across the first week post-infusion. Systemic inflammatory (sTNFR1, CRP, IL-6, IP-10) and oxidative stress (F2-Isoprostane) markers were measured in plasma across 7 days post-infusion by ELISA and GC-MS respectively. HLA-DR-expressing FoxP3+CD25⁺ Tregs were quantified by flow cytometry.

Results: MSC first localised in the lungs from 0-24 hours post-infusion and then trafficked to the liver and spleen at day 1-7. Levels of F2-isoprostanes, IL-6 and IP-10 were significantly lower, while CRP and sTNFR1 significantly increased after MSC infusion. HLA-DR⁺ Tregs were significantly higher after MSC infusion.

Summary and conclusions: We provide novel data showing MSC therapy in COPD patients modulating systemic inflammation within a week of infusion. Further characterisation of the systemic immunological changes will provide a deeper understanding of immune regulation during MSC therapy.

994

Enhanced immunoregulation of mesenchymal stem cells by IL-10-producing type 1 regulatory T cells in collagen-induced arthritis

Lim, J.-Y.¹, Im, K.-I.¹, Kim, N.¹, Nam, Y.-S.¹, Song, Y.J.¹, Jeon, Y.-W.^{1,2}, Cho, S.-G.^{1,2}

¹Institute for Translational Research and Molecular Imaging, The Catholic University of Korea College of Medicine, Seoul, Korea, Republic of, ²Department of Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St. Mary's Hospital, Seoul, Korea, Republic of

Mesenchymal stem cells (MSCs) possess immunomodulatory properties and have potential, however, there have been conflicting reports regarding their effects in rheumatoid arthritis (RA), which causes inflammation and destruction of the joints. Through a comparative analysis of regulatory T (Treg) and IL-10-producing type 1 regulatory T (Tr1) cells, we hypothesized that Tr1 cells enhance the immunoregulatory functions of MSCs, and that a combinatorial approach to cell therapy may exert synergistic immunomodulatory effects in an experimental animal model of rheumatoid arthritis (RA). A combination of MSCs and Tr1 cells prevented the development of destructive arthritis compared to single cell therapy. These therapeutic effects were associated with an increase in type II collagen (CII)-specific CD4⁺CD25⁺Foxp3⁺ Treg cells and inhibition of CII-specific CD4⁺IL-17⁺ T cells. We observed that Tr1 cells produce high levels of IL-10-dependent interferon (IFN)- β , which induces toll-like receptor (TLR) 3 expression in MSCs. Moreover, induction of indoleamine 2,3-dioxygenase (IDO) by TLR3 involved an autocrine IFN- β that was dependent on STAT1 signaling. Furthermore, we observed that production

of IFN- β and IL-10 in Tr1 cells synergistically induces IDO in MSCs through the STAT1 pathway. These findings suggest co-administration of MSCs and Tr1 cells to be a novel therapeutic modality for clinical autoimmune diseases.

995

Dental pulp stem cells inhibit encephalitogenic T cell responses and suppress disease in an animal model of multiple sclerosis

Foyle, K.^{1,2}, Wilson, J.¹, Koblar, S.², McColl, S.¹, Comerford, I.¹

¹University of Adelaide, School of Biological Sciences, Adelaide, Australia, ²South Australian Health and Medical Research Institute, Adelaide, Australia

Mesenchymal stem cells (MSCs) have been proposed as a potential therapy for autoimmune diseases due to their capacity to both participate in the tissue repair process and modulate immune responses. In the autoimmune disease multiple sclerosis (MS), encephalitogenic T cells enter the central nervous system (CNS) and initiate an inflammatory cascade that destroys neuron-insulating myelin and current therapies are limited. The therapeutic capacity of dental pulp-derived MSCs (DPSCs) is unexplored in the context of MS or its animal model, experimental autoimmune encephalomyelitis (EAE), and little is known about the immunomodulatory properties of DPSCs in autoimmune settings. DPSCs represent an abundantly available source of human MSCs for cell based therapy and may have particular utility in degenerative disorders of the nervous system. In this study we show that human DPSCs suppress MOG-induced chronic EAE and inhibit disease relapse in PLP-induced relapsing EAE. In chronic EAE, DPSC treatment led to a reduction in the emergence of CCR2⁺CCR6⁺ Th17 cells expressing GM-CSF in the spleen, a cell subset previously identified to be a key pathogenic T cell subset in EAE. Additionally, the CNS was infiltrated with fewer Th17 cells following DPSC-treatment and there was a corresponding reduction in frequency of activated microglia, indicative of less inflammation in the CNS. Therefore DPSCs are able to inhibit the differentiation of pathogenic T cell populations in EAE, which significantly suppresses development of disease. The molecular mechanisms enabling DPSCs to inhibit the pathogenic immune response in EAE are under investigation.

996

Autotaxin a cytokine modulator, is a critical regulator of satellite cell functions and skeletal muscle repair

Ray, R.^{1,2}, Raj, V.¹

¹Institute of Life Science, Vascular Immunology Group, Infectious Disease Biology Department, Bhubaneswar, India, ²Manipal University, Manipal, India

Satellite cells are a heterogeneous population of stem and progenitor cells that are required for the growth, maintenance and regeneration of skeletal muscle and possess noteworthy regenerative capacity for the repair of muscle damage in injuries or muscular disorders. Injury response in skeletal muscles is commenced by various cytokines secreted by

infiltrating immune cells, specifically IL-6 and are mediated by a network of myogenic transcription factors, including Pax3/7, Myf5, MyoD, and Myogenin. The endogenous phospholipid lysophosphatidic acid (LPA), a cytokine modulator generated by Autotaxin, regulates fundamental cellular processes and implicated in homeostatic and pathological conditions. Here we uncover, that Autotaxin dramatic expression and activity is essential for satellite cell differentiation and ATX-LPA regulated IL-6 release controls satellite cell compartment, myogenic differentiation. Ablation of ATX in satellite cells resulted in inhibition of differentiation process *ex vivo* affecting IL-6 release. The effects of ATX inhibition on cell fate and differentiation were conserved in human. Next, we demonstrate, Atx genetic deletion or intramuscular injection of ATX inhibitor resulted in a marked inhibition of muscle repair after cardiotoxin injury *in vivo* modulating IL-6. This study identifies ATX, as an essential master regulator in satellite cells, indispensable marker for muscle differentiation and its role in of ATX-LPA dependent IL-6 signalling may allow the development of novel strategies for the control of muscular dysfunctions.

997

Interplay between macrophages and human endometrial stem/stromal cells on mesh implants in a mouse model

Darzi, S.¹, Deane, J.¹, Edwards, S.², Gough, D.³, Werkmeister, J.², Gargett, C.E.¹

¹Monash University/Hudson Institute of Medical Research, Obstetrics & Gynaecology, Melbourne, Australia, ²CSIRO Manufacturing Flagship, Melbourne, Australia, ³Hudson Institute of Medical Research, Centre for Cancer Research, Melbourne, Australia

Pelvic Organ Prolapse (POP) is the herniation of pelvic organs into the vagina. POP is treated by mesh augmented surgery but the complication rate is unacceptable. Human endometrial mesenchymal stem cells (eMSC) are a new MSC, which are purified using SUSD2 antibodies. The anti-inflammatory properties of eMSC are poorly understood. Our aim was track eMSC delivered on novel polyamide/gelatin (PA+G) mesh to examine their modulatory role on macrophage phenotype in immunocompromised mice.

SUSD2⁺ eMSCs were isolated from endometrial biopsies by magnetic beads sorting. A mCherry lentiviral plasmid was used to permanently label eMSC. mCherry⁺SUSD2⁺eMSC were seeded onto PA+G mesh and implanted in an abdominal fascial defect. Tissues were harvested at 7, 14, 30 and 90 days. Macrophage markers used for immunofluorescence were F4/80 (Pan), CCR7 (M1) and CD206 (M2). ELISA was used to detect IL-1 β , IL-6 and TNF- α .

Transduction efficiency of eMSC was >80%. Small numbers of mCherry⁺ eMSC were identified in mouse tissue after 7, but not 14 days. Many M1 macrophages was observed around mesh filaments at 7 and 14 days but the M1/M2 ratio reduced at later time-points. Less IL-1 β was found in eMSC/PA+G explants than PA+G after 7 days, but TNF- α and IL-6 were similar for all time-points.

This study shows that human mCherry-labelled eMSC were traceable in-vivo and that their immunomodulatory effects on M1-macrophage mediated inflammation was limited by their

short lifespan in immunocompromised mice. Ongoing studies will evaluate the interaction between eMSCs and macrophages associated with the foreign body response to mesh.

998

Evaluation the capacity of immune tolerance induction on tissue-derived stromal cells in allogeneic setting

Chou, S.-H., Lee, W., Huang, B.-Y.

FU JEN Catholic University, Life Science, New Taipei, Taiwan, Republic of China

The induction of donor-specific tolerance in patients after allogeneic hematopoietic stem cell transplantation is major criteria for success of transplantation. One of the successes of allogeneic tolerance induction is determined on supported elements derived from the microenvironment during hematopoiesis. Health stroma elements have been reported that not only supporting donor cell hematopoiesis but also instruct tolerance to alloantigen. The purpose of this study is evaluating several tissue-derived stromal cells on allogeneic tolerance induction after allogeneic bone marrow transplantation. We first established stromal cell lines derived from spleen, thymus, bone marrow, two perinatal tissues (amniotic fluid and placenta) from C57BL/6 donor mice, respectively. The results of characterization on stromal cells indicated that all types of stromal cells positively expressed Sca-1, CD34, CD44, CD29, CD44 surface markers and exhibited different degrees of hematopoietic supportive activity. By used single injection of stroma cells into 13-14 day gestation BALB/c fetuses, bone marrow or perinatal-derived stromal cells are highly engrafted into thymus and bone marrow, the major tolerance education site. In addition, thymus, bone marrow or perinatal of stroma cells had shown the strong immunosuppressive activity in comparison to allogeneic positive control. In allogeneic HSCT murine model, co-injected bone marrow or perinatal-derived stromal cells enhance allogeneic donor cell engraftment. Importantly, results of donor skin graft, mixed leukocyte reaction, and adoptive cell transfer had showed that tissue-derived stromal cells may act as immune cell instructors during hematopoiesis. In conclusion, co-injection of bone marrow or perinatal-derived stromal cells with donor cells did induce the specific alloantigen tolerance.

A dual role for alveolar macrophages in mesenchymal stem/stromal cell therapy

Mendonca, S.¹, D'Rozario, J.¹, Payne, N.², Hammett, M.¹, Khong, S.¹, Mathias, L.¹, Siatskas, C.¹, Boyd, R.¹, Heng, T.^{1,3}

¹Monash University, Anatomy and Developmental Biology, Melbourne, Australia, ²Monash University, Australian Regenerative Medicine Institute, Melbourne, Australia, ³Monash Biomedicine Discovery Institute, Infection and Immunity Program, Melbourne, Australia

The reparative and immunomodulatory properties of multipotent mesenchymal stromal cell (MSCs) are currently being investigated in >350 clinical trials on various inflammatory conditions. The majority of trials utilize systemically infused

MSCs, which localize to the lungs and do not survive for long, raising the question of these cells mediate their anti-inflammatory effects elsewhere in the body. The broad use of MSCs without clear understanding of their immunogenicity and mechanisms of action has led to many controversies in the field. We therefore investigated the *in vivo* fate of infused MSCs to better understand how their immunogenicity and survival impact on their therapeutic effects. We found that MSCs disappeared shortly (~3 days) after intravenous administration in either immunocompetent or immunodeficient mice, discounting a role for the adaptive immune system in cell clearance. MSC survival is further influenced by the route of administration, as MSCs injected into the peritoneum showed increased survival. Despite the limited survival of MSCs, MSC infusion in a mouse model of allergic asthma led to a reduction in disease, even upon re-exposure to allergen several weeks later. Intranasal depletion of alveolar macrophages prolonged MSC survival in the lungs, but paradoxically abrogated the beneficial effects of MSCs on asthma. Our data suggest that alveolar macrophages act as a double-edge sword in limiting the survival of MSCs and activating downstream immune cells to inhibit asthma. Our studies provide insight into how MSCs modify the host response to therapeutic effect, which is crucial for the design of safer and smarter MSC-based therapies.

Probiotic-derived lactate accelerates intestinal stem cell-mediated epithelial regeneration and ameliorates injury

Lee, Y.-S., Kim, Y., Lee, S.-H., Yang, J.-Y., Kang, M.-H., Park, Y.-Y., Kweon, M.-N.

University of Ulsan College of Medicine/Asan Medical Center, Seoul, Korea, Republic of

The probiotics play an indispensable role in gut homeostasis but underlying mechanisms are still unveiled. In order to clarify an exact role of probiotic for intestinal stem cells (ISCs)-mediated epithelial regeneration, we fed mice for five days with human-use probiotics (VSL#3) including *Bifidobacterium*, *Lactobacillus*, and *Streptococcus spp.* Interestingly, short-term administration of probiotics significantly increases the growth of epithelium including expansion of Lgr5⁺ ISCs, paneth cells, and goblet cells. Similar results were found in *ex vivo* gut organoid culture in the presence of culture supernatant from probiotic. Among several candidates, we identified that lactate directly stimulated ISCs through Wnt/-catenin signals. In this regards, lactate receptor Gpr81 were highly expressed on the Lgr5⁺ ISCs in the steady-state condition and blockade of Gpr81 during gut organoid culture in the presence of lactate significantly reduced epithelial regeneration. Most importantly, pre-treatment with probiotic or lactate *in vivo* protected mice against intestinal injury provoked by treatment with irradiation and methotrexate. Our findings demonstrate that lactate produced by probiotics play a pivotal role to promote gut stem cell-mediated epithelial regeneration by direct stimulating Lgr5⁺ ISCs in Gpr81-dependent manner.

1001**Protective effect of phloroglucinol against gamma radiation-induced oxidative stress in hair follicle***Kim, A.¹, Bing, S.J.², Cho, J.², Herath, K.H.I.N.M.², Jee, Y.²**¹Jeju National University, Advanced Convergence Technology & Science, Jeju-si, Korea, Republic of, ²Jeju National University, Department of Veterinary Medicine, Jeju-si, Korea, Republic of*

When exposed to gamma-rays, hair follicle stem cells, immediately go through apoptosis, which injures their rapid differentiation essential for the regeneration of hair. Phloroglucinol (PG) is a phenolic compound of *Ecklonia cava*, brown algae abundant in Jeju island, Korea. Containing plentiful polyphenol, PG is known for its instructive effects by inhibiting apoptosis, scavenging oxygen radicals, and protecting cells against oxidative stress. In this study, we demonstrate that PG rescues radiosensitive hair follicle stem cells from gamma radiation-induced apoptosis and DNA damage. To identify the hair follicle protection capability of PG, we irradiated gamma-rays to the whole body of C57BL/6 mice at day 6 after depilation with or without PG. PG or EpiCeram® (EC) was applied once at 17.8 hours before irradiation. At 8 hours after gamma-rays irradiation, PG not only decreased apoptosis which was suppressed by radiation as shown in control but also decreased morphological changes of hair follicles. Our results suggest that PG presents radioprotective effects by inhibiting apoptosis of radiosensitive hair follicle stem cells and can PG protects hair follicle stem cells from gamma-ray induced damage. This research was a part of the project titled "Development of functional materials derived from marine living resources for regulation of immune diseases", funded by the Ministry of Oceans and Fisheries, Korea.

1002**Study on the nutrients on the adipogenesis and immune regulatory activities of mesenchymal stem cells***Wang, Z.T., Lin, B.F.**National Taiwan University, Taipei, Taiwan, Republic of China*

Introduction: Mesenchymal stem cells (MSCs) are multipotent stem cells, which can differentiate into adipocytes and osteocytes. Recently, MSCs are reported to have capacity to modulate the immune responses. During the adipogenic differentiation of MSCs, they might lose the ability of immunomodulatory function. Therefore, we investigated the effect of nutrients such as all trans-retinoic acid, 1 α , 25-(OH)₂D₃ and folate on the adipogenic differentiation and also immune modulatory ability of MSCs.

Materials and methods: MSCs were isolated from 4-week-old BALB/c bone marrow and characterized by surface marker. They were treated by different concentrations of all trans-retinoic acid (10, 100, 1000 nM), 1 α , 25-(OH)₂D₃ (0.1, 1, 10 nM) and folate (20, 200 μ M). Adipogenic differentiation of MSCs were determined on days 2, 7, 14, 21. Lipid accumulation and adipogenic genes expression of C/EBP α and PPAR- γ 2 were measured by Oil Red O staining and real-time PCR. The cytokines levels of IL-1 β , TNF- α and IL-6 were also detected.

Results: All trans-retinoic acid and folate inhibited adipogenic differentiation of MSCs

after 14 days induction. In addition, 1 α , 25-(OH)₂D₃ inhibited that after 7 days' culture. The results of C/EBP α and PPAR- γ 2 gene expression were downregulated by folate, all trans-retinoic acid and 1 α , 25-(OH)₂D₃. We will further clarify that IL-1 β , TNF- α and IL-6 of MSCs would also be decreased by all three nutrients.

Conclusion: These data showed that trans-retinoic acid, 1 α , 25-(OH)₂D₃ and folate affected the adipogenic differentiation of MSCs. We will further assay all these nutrients on the immune regulatory activities of MSCs.

T Cell Development

1003**TCR induced transcription factors RelA and IRF4 co-operatively regulate the differentiation of effector T_{reg} cells***Vasanthakumar, A.¹, Yang Laio, Y.¹, Gloury, R.¹, Sidwell, T.¹, Teh, P.¹, Mielke, L.¹, Belz, G.¹, Shi, W.¹, Grigoriadis, G.², Banerjee, A.², Kallies, A.¹**¹The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ²Hudson Institute of Medical Research and Monash University, Melbourne, Australia*

TCR signaling is pivotal for the development of Foxp3⁺ regulatory (T_{reg}) T cells in the thymus. These cells continue to require TCR signals in the periphery for their homeostasis and function. Since TCR signaling and NF- κ B transcription factors are linked, we interrogated the role of NF- κ B family members in peripheral Treg cells. Surprisingly, deletion of c-Rel or NF κ B1/p50 did not have a major impact on Treg homeostasis and function. In contrast, RelA deficiency in T_{reg} cells led to fatal multi-organ autoimmune pathology, accompanied by the expansion of inflammatory adaptive and innate immune cells. Transcriptional profiling of RelA deficient T_{reg} cells revealed the loss of a gene signature associated with the development of activated or effector Treg (eT_{reg}) cells. In agreement with this notion, RelA-deficient T_{reg} cells failed to differentiate into eT_{reg} cells. We have previously shown that the TCR-induced transcription factor IRF4 is required for eT_{reg} cell differentiation in a non-redundant manner. Although neither RelA nor IRF4 were transcriptional targets of each other, the set of genes regulated by either of these transcription factors in T_{reg} cells largely overlapped. Together our observations suggest that the transcription factors RelA and IRF4 co-operate to establish the eT_{reg} cell differentiation program in a TCR dependent manner.

1004**Apoptosis regulates thymic progenitor fitness and progression to T cell acute lymphoblastic leukemia***Policheni, A.¹, Grabow, S.², Boulliet, P.³, Strasser, A.³, Gray, D.⁴**¹Melbourne University, Medical Biology, Melbourne, Australia, ²The Walter and Eliza Hall Institute of Medical Research, Molecular Genetics of Cancer, Melbourne, Australia, ³The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ⁴The Walter and Eliza Hall Institute, Melbourne, Australia*

Cell competition is a process whereby "new" or "fit" cells replace "old" or "unfit" cells to maintain tissue integrity. Cell competition

among thymic T cell precursors was recently found to be essential for suppression of malignancy. Disruption of thymic cell competition can be achieved by grafting thymi from wildtype mice into immunodeficient mice, creating a situation where host progenitors are incapable of displacing donor. The ensuing reliance upon self-renewal of 'old' thymic progenitors for T cell differentiation leads to cancer with the cellular and molecular hallmarks of T cell acute lymphoblastic leukemia (T-ALL). The processes that govern competitive fitness or displacement in the thymus are unknown. We explored whether the intrinsic pathway of apoptosis in thymic progenitors plays a role in cell competition and leukaemogenesis.

Thymic lobes from mice deficient in the pro-survival proteins BCL-2 (*Bcl2*^{-/-}) or MCL-1 (*Mcl1*^{+/-}) were grafted into immunodeficient *Rag2*^{-/-}/*gC*^{-/-} mice to measure whether reducing donor cell survival would diminish progenitor fitness and restore competition to prevent T-ALL. Surprisingly, we found that these mice succumbed to T-ALL at an accelerated rate (average latency of 100 days and 100% penetrance) as compared to *Rag2*^{-/-}/*gC*^{-/-} mice grafted with wildtype thymi (average latency of 250 days). Furthermore, we have identified a cellular phenotype associated with "fit" and "unfit" thymic progenitors that will aid dissection of the cellular processes leading to T-ALL in situations of disrupted cell competition. This study implicates the intrinsic pathway of apoptosis as a major regulator of thymic progenitor cell competition and subsequent leukaemia development.

1006

Apoptosis regulates thymic progenitor fitness and progression to T cell acute lymphoblastic leukemia

Policheni, A.^{1,2}, Grabow, S.^{1,2}, Bouillet, P.^{1,2}, Strasser, A.^{1,2}, Gray, D.^{1,2}

1007

The histone acetylase HBO1 directs expression of the autoimmune regulator AIRE in thymic epithelial cells

Heinlein, M.^{1,2}, Jain, R.^{1,2}, Voss, A.^{2,3}, Thomas, T.^{2,3}, Gray, D.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research, Molecular Genetics of Cancer, Melbourne, Australia, ²The University of Melbourne, Department of Medical Biology, Melbourne, Australia, ³The Walter and Eliza Hall Institute of Medical Research, Development and Cancer Division, Melbourne, Australia

The autoimmune regulator, AIRE, induces the transcription of a panoply of peripheral tissue self-antigens in thymic epithelial cells (TECs). This activity mediates self-tolerance via the clonal deletion of auto-reactive thymocytes and/or the selection of Foxp3⁺ regulatory T cells. The molecular mechanisms by which AIRE orchestrates transcriptional regulation in TECs remain poorly defined. Post-translational modifications of histone proteins, such as acetylation, play an important role in the transcriptional regulation of genes. HBO-1 is a histone acetylase that can promote or repress transcription at a range of loci, prompting us to examine whether HBO-1 plays a role in the epigenetic regulation of transcription in TECs. We took a conditional genetic deletion approach, ablating a floxed allele of *Hbo1* specifically in TECs using *Foxn1*^{Cre}. Functional deletion of HBO-1 was confirmed by the complete loss of histone 3 lysine 14 acetylation only in TECs from these mice. Young *Foxn1*^{Cre} *Hbo1*^{fl/fl} mice exhibited thymic hypo-cellularity but without a major reduction in overall TEC numbers. Yet, there was a substantial reduction in medullary TEC subsets, coincident with an increase in the cortical TEC subset. AIRE-positive medullary TECs were greatly diminished in *Foxn1*^{Cre} *Hbo1*^{fl/fl} mice and there was a reduced level of AIRE expression in this population. Increased T cell activation in young *Foxn1*^{Cre} *Hbo1*^{fl/fl} mice and mild lymphocytic infiltration of the lung in older mice suggested tolerance was perturbed. Together, these data reveal a role for histone 3 lysine 14 acetylation mediated by HBO-1 for establishing a normal thymic microenvironment, AIRE expression and the establishment of self-tolerance.

1008

EGF regulation of MCL-1 is indispensable for thymic epithelial cell survival and thymic function

Jain, R.^{1,2}, Sheridan, J.^{1,2}, Policheni, A.^{1,2}, Kupresanin, F.¹, Fu, N.Y.^{2,3}, Hollander, G.⁴, Strasser, A.^{1,2}, Gray, D.^{1,2}

Kingdom

The differentiation of haematopoietic precursors into functional T cells that are tolerant of self-tissues is driven by interactions with thymic epithelial cells (TEC). Despite the importance of TEC for adaptive immunity and tolerance, very little is known about the molecular control of TEC function and dysfunction. We aim to understand the molecular mechanisms that govern life and death decisions in TEC, with a view to developing new strategies to restore thymic function in immunodeficiency. Guided by expression profiling, we created conditional genetic models deleting various pro-survival genes only in TEC using *Foxn1^{Cre}*. We found that, although the pro-survival proteins BCL-2 and BCL_x_l were dispensable for TEC homeostasis and thymic function, TEC-specific loss of MCL-1 (i.e. *Mcl-1^{ΔFoxn1}* mice) caused early thymic involution, with near complete loss of the thymus in 2 month-old mice. Loss of thymic function in *Mcl-1^{ΔFoxn1}* mice reduced their peripheral T cell compartment by two thirds. Defects in TEC composition of *Mcl-1^{ΔFoxn1}* mice were evident early in life, with the progressive loss of Aire⁺ medullary TEC, followed by disruption of other TEC subsets. In a screen of TEC trophic factors in thymic organ cultures, we found that only EGF upregulated MCL-1, providing a molecular mechanism for mesenchymal support of TEC. We conclude that MCL-1 is essential for TEC survival and function, highlighting an important mesenchymal/epithelial signalling axis with bearing on thymic involution and injury.

Homeostatic proliferation maintains recent thymic emigrants' phenotype of naïve T cells and TCR signaling affects «thymic» phenotype of memory T cells in hemoblastosis patients

Batorov, E., Tikhonova, M., Kryuchkova, I., Sergeevicheva, V., Batorova, D., Sizikova, S., Ushakova, G., Gilevich, A., Ostanin, A., Chernykh, E.

Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

Numerous studies have shown that chemotherapy and autologous hematopoietic stem cell transplantation (AHSCT) led to a profound immunodeficiency in hemoblastosis patients. Thymus begins to fill up T cell repertoire approximately from the 6th post-transplant month. We evaluated thymic activity by measuring amounts of CD31⁺ naïve T cells, i.e. "recent thymic emigrants" (RTEs).

87 patients underwent AHSCT. Circulating CD4⁺CD45RA⁺CD31⁺ and CD4⁺CD45RO⁺CD31⁺ cells were evaluated by flow cytometry before AHSCT and during 1st post-transplant year. Mononuclear cells (MNCs) were cultured separately with IL-2, IL-7, αCD3.

Pre-transplant count of CD4⁺CD45RA⁺CD31⁺ T cells was lower comparing to controls and did not reach donors' values during 12-month period. We found high levels of CD4⁺CD45RA⁻ T cells expressing CD31 in patients, since this molecule was infrequent on memory subsets in healthy controls. Amount of CD4⁺CD45RA⁻CD31⁺ T cells highly correlated with CD4⁺CD45RO⁺CD31⁺ population. CD4⁺CD45RO⁺CD31⁺ T cells recovered intensively, reached pre-transplant level during the 1st month and remained

it for the observation period. *In vitro* studies showed the growth of CD4⁺CD45RA⁺CD31⁺ T cells counts upon stimulation of donors and patients MNCs with IL-7 (homeostatic proliferation trigger) but not IL-2 (peripheral expansion trigger) or anti-CD3 (TCR trigger). CD4⁺CD45RO⁺CD31⁺ T cells elevated upon stimulation with anti-CD3 but not IL-2 or IL-7.

Homeostatic proliferation might decrease the significance of CD4⁺CD45RA⁺CD31⁺ T-cells as a marker of RTEs. The biological role of CD31 on memory T cells remained unclear. Presumably, lymphocyte stimulation through CD31 might prevent their hyper-reactivity by increasing the activation threshold of TCR signaling and thus provide their survival.

Assessing the role of CXCR4 in the CD8+ T cell response to vaccinia virus with mathematical modeling

Körber, V.¹, Wencker, M.², Djebali, S.², Arpin, C.², Marvel, J.², Graw, F.¹

¹Heidelberg University, Center for Modeling and Simulation in the Biosciences (BIOMS), BioQuant-Center, Heidelberg, Germany,

²International Center for Infectiology Research (CIRI), INSERM U 1111, Lyon, France

Migration and motility are essential properties of the cellular immune response, playing an important role for development and effective function. Genetic defects affecting chemokine receptor (CR) expression can lead to inappropriate migratory patterns of developing and mature immune cells resulting in ineffective immune responses, increased sensitivity to infections and autoimmune diseases. However, the exact interplay between cell differentiation and CR expression has not been determined so far.

Using a mouse model with a gain-of-function mutation in CXCR4, we studied the role of this CR on the dynamics of CD8+ T cell responses following infection with Vaccinia Virus. We found that overexpression of CXCR4 leads to a shift in the generation of memory CD8+ T cell subsets, as well as a delayed appearance of CD8+ T cells in the blood during acute infection. Using a mathematical model, we estimated a delayed dynamics of ~1 day.

In order to assess the role of CXCR4 in more detail, we developed an agent-based model following individual cell proliferation, differentiation and migration in the lymph node (LN) and the blood, explicitly accounting for LN structure. Testing different hypotheses our model suggests that the observed altered CD8+ T cell phenotype dynamics in the blood can be explained by a changed dwell time of cells within the LN medulla, or by a smaller pool of naïve T cells in the LN at the start of infection.

Our model provides a systematic framework for an integrative analysis of cell differentiation and migration in the context of the CXCR4-receptor.

1011**Superior activation of human naïve CD27^{hi}CD45RA⁺CD8⁺ T cells in the presence of CD27 co-stimulation**

Grant, E.¹, Nussing, S.¹, Bird, N.¹, Jaworowski, A.², Schuessler, A.³, Smith, C.³, Khanna, R.³, Al-Shamkhani, A.⁴, Bharadwaj, M.¹, Kedzierska, K.¹

¹The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ³QIMR Berghofer Medical Research Institute, Brisbane, Australia, ⁴University of Southampton, Faculty of Medicine, Southampton, United Kingdom

CD27 is constitutively expressed on naïve and majority of circulating memory-T cells in humans at any stage of life. While it is well-known that CD27 co-stimulation enhances primary, secondary and recall CD8⁺ T-cell responses in murine models, little is known about the effect of CD27 co-stimulation on human T-cells. Using a combination of *ex vivo* phenotypic staining and stimulation, we firstly assessed the functional capacity of different human T-cell subsets, as defined by CD27 and CD45RA. We found that CD27^{lo}CD45RA⁻ and CD27^{lo}CD45RA⁺ T-cells have superior polyfunctional and cytotoxic potential, respectively. Interestingly, quantitation of gene expression in these CD8⁺ T-cells using qPCR revealed novel gene expression profiles in CD27^{hi} and CD27^{lo} CD8⁺ T-cells. To understand the activation of CD27^{hi} CD8⁺ T-cells subsets, we performed a comprehensive kinetic analysis to directly assess the effect of CD27 co-stimulation on human CD8⁺ T-cells over time. CD8⁺ T-cell populations were stimulated by anti-CD3 cross-linking alone, or with additional co-stimulation using plate bound CD70 (CD27 ligand) or anti-CD28 (pCD70/pCD28, respectively) for up to 7 days. Co-stimulation with pCD70 was required for naïve CD27^{hi}CD45RA⁺CD8⁺ T-cell proliferation and accelerated Granzyme B acquisition. Furthermore, pCD70 co-stimulation enhanced phenotypic plasticity of naïve and central-like memory CD27^{hi}CD45RA⁺CD8⁺ T-cells and their cytokine secretion potential. The effect of anti-CD27 stimulation was superior in comparison to anti-CD28 stimulation in human T-cells. As expected, CD27^{lo}CD8⁺ T-cells were unaffected by pCD70 or pCD28 co-stimulation. Overall, these data provide new evidence that CD27 co-stimulation mediates superior activation of human CD27-expressing naïve CD8⁺ T-cells.

1012**Although Gtf2h4 is highly expressed in double positive thymocytes there is no fundamental role regarding negative selection and T cell development**

Beil-Wagner, J.¹, Prazeres da Costa, O.², vom Berg, J.¹, Specht, S.¹, Heikenwälder, M.³, Buch, T.¹

¹University of Zurich, Institute for Laboratory Animal Sciences, Schlieren, Switzerland, ²Technische Universität München, ²Institute for Medical Microbiology, Immunology and Hygiene, Munich, Germany, ³Deutsches Krebsforschungszentrum, Heidelberg, Germany

During T cell development negative selection facilitates elimination of self-reactive thymocytes. It is controlled by the

avidity of the interaction between the TCR and the self antigen which means that cells which interact with a low avidity to self antigen can survive and those with a high avidity die by apoptosis. However, the exact molecular pathway enabling negative selection is not yet known. Therefore we were looking for candidate transcription factors that are highly expressed at the double positive stage of T cell development. Microarray analyses and RT-PCR identified, besides others, Gtf2h4 as candidate gene. To analyse its role in T cell development we followed two approaches: First, we cloned it under the control of the CD4 promoter to generate a mouse line overexpressing Gtf2h4 in T cells specifically. Second, by using the CRISPR/Cas9 we generated a knockout strain. Both mouse strains were deeply analysed with regard to T cell development by flow cytometry and histology. Unexpectedly, homozygous knockout mice were found to be embryonic lethal. Heterozygous mice did not show any alterations. Also the overexpression strains did not present with changes in T cell development. In summary, although Gtf2h4 is expressed at remarkable height at the double positive stage compared to other thymic development stages it does not seem to play a key role in T cell development and specifically negative selection.

1013**CD4⁺CD8⁺ double-positive T-cells regulate CD8⁺ single-positive T cell function in the skin**

Gonzalez Cruz, J.L.¹, Overgaard, N.H.^{1,2}, Bridge, J.A.¹, Jung, J.-W.¹, He, J.¹, Nel, H.J.¹, Watson, K.³, Frazer, I.H.¹, La Gruta, N.L.³, Steptoe, R.J.¹, Wells, J.W.¹

¹The University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia, ²National Veterinary Institute, Technical University of Denmark, Copenhagen, Denmark, ³The University of Melbourne and The Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia

CD4⁺CD8⁺ double-positive mature peripheral T-cells (DPs) are detectable in a variety of tissues. However, despite their relevant implications in autoimmune and malignant skin disorders, such as atopic dermatitis and cutaneous T-cell lymphoma, very little is known about their role or function; likely due to their very low abundance. Additionally, technical difficulties that confound distinguishing DP single-cells from CD4⁺CD8⁺ T-cell aggregates makes them difficult to study. We have overcome these issues using a novel isolation strategy which allows us to obtain >95% pure DPs. To determine whether peripheral DPs arise from CD4⁺ T-cells, we adoptively transferred highly purified single-positive T-cells into Rag1^{-/-} mice. Under these conditions we observed that subsets of CD4⁺ T-cells become DP T-cells with the peculiarity that these cells express CD8 α but not CD8 β , which is in contrast to DPs isolated from wild-type mice. To study the effect of DPs on the regulation of skin CD8⁺ T-cells, we used a skin graft rejection model in which skin engineered to express Ovalbumin (OVA) under the K5 promoter was grafted onto wild-type recipient mice. As expected, grafts were rejected from untreated recipients around 20-30 days post-grafting. However, transfer of a low number of DPs, but not CD4⁺ or CD8⁺ single-positive T-cells, suppressed CD8⁺ T-cell

dependent rejection of OVA-expressing grafts. Interestingly, the DP inhibitory phenotype depended on their activation status since only activated and not naïve DPs prevented skin graft rejection. Our data suggests a powerful immunoregulatory role for DPs in controlling CD8⁺ T-cell function in the skin.

1014

CBAP promotes thymocyte negative selection by facilitating T cell receptor proximal signaling

Ho, K.-C.¹, Chiang, Y.-J.¹, Lai, A.¹, Liao, N.S.², Chang, Y.J.¹, Yang-Yen, H.-F.², Yen, J.¹

¹Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, Republic of China, ²Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan, Republic of China

T cell receptor (TCR)-transduced signaling is critical to thymocyte development at the CD4/CD8 double-positive stage, but the molecules involved in this process are not yet fully characterized. We previously demonstrated that GM-CSF/IL-3/IL-5 receptor common β -chain associated protein (CBAP) modulates ZAP70-mediated T cell migration and adhesion. Based on the high expression of CBAP during thymocyte development, we utilized a CBAP knockout mouse to investigate the function of CBAP in thymocyte development. CBAP-deficient mice showed normal early thymocyte development and positive selection. In contrast, several negative selection models (including TCR transgene, superantigen staphylococcal enterotoxin B, and anti-CD3 antibody treatment) revealed an attenuation of TCR-induced thymocyte deletion in CBAP knockout mice. This phenotype correlated with a reduced accumulation of BIM upon TCR crosslinking in CBAP-deficient thymocytes. Loss of CBAP led to reduced TCR-induced phosphorylation of proteins involved in both proximal and distal signaling events, including ZAP70, LAT, PLC γ 1, and JNK1/2. Moreover, TCR-induced association of LAT signalosome components was reduced in CBAP-deficient thymocytes. Our data demonstrate that CBAP is a novel component in the TCR signaling pathway and modulates thymocyte apoptosis during negative selection.

1015

C-Myc regulation by Notch signaling modulates T cell differentiation

Song, J., Haque, R., Song, X., Lei, F.

Penn State University College of Medicine, Hershey, United States

Notch signaling is essential for T lineage commitment and further required during early phases of thymocyte differentiation. Active Notch signaling during early stages of T cell development inhibits other lineage potentials, such as B cell and myeloid cell (e.g., dendritic cell) potentials. However, the intracellular signaling pathways by which Notch signaling regulates T cell differentiation remain unknown. Here we show that the transcriptional factor c-Myc is controlled by Notch signaling which regulates T cell differentiation. In a well-established *in vitro* differentiation of T lymphocytes from stem cells, Notch signaling directly controls c-Myc expression. Overexpression of active c-Myc promotes while dominant-negative (dn) c-Myc

inhibits early cell differentiation. Moreover, c-Myc expression mediated by Notch signaling modulates survivin, an inhibitor of apoptosis (IAP) protein, which is crucial for T cell development. Overexpression of active c-Myc increases while dn c-Myc reduces survivin expression, which corresponds to T cell differentiation within the *in vitro* differentiation system. These results identify c-Myc, together with survivin, as regulators of the differentiation of T cells from Notch signaling.

1016

Two waves of thymic deletion distinguished by differential dependence on thymic antigen-presenting cell subsets

Yap, J.Y.¹, Howard, D.R.¹, Wirasinha, R.C.^{1,2}, Goodnow, C.C.^{1,3}, Daley, S.R.²

¹The Australian National University, The John Curtin School of Medical Research, Department of Immunology, Canberra, Australia, ²Monash University, Clayton Campus, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ³Garvan Institute of Medical Research, Immunology Division, New South Wales, Australia

Distinct antigen-presenting cell (APC) types cooperate to delete strongly self-reactive thymocytes to establish central tolerance. Here, we ascertained deletion defects caused by perturbing bone marrow (BM)-derived APCs (BM-APCs), and/or Aire, which drives expression of certain self-antigens in non-BM-derived APCs. Deletable thymocytes, identified by Helios expression, were resolved into two subsets: immature Helios⁺ CCR7⁻ cells characterised as wave 1 of thymic deletion, and mature Helios⁺ CCR7⁺ cells as wave 2. Wave 1 deletion was reduced 40% by MHCII-deficiency within BM-APCs versus 18% by Aire-deficiency within non-BM-derived APCs. Aire contributes to wave 1 indirectly in a mechanism requiring BM-APCs. However, Aire-dependent direct presentation deletes thymocytes at wave 2, including thymocytes that escape wave 1, and ~35% of wave 2 requires Aire. The different stage and extent of impairments caused by perturbing BM-APCs versus Aire shows that thymic deletion is not confined to a single stage of thymocyte development in the natural TCR repertoire.

1017

Tespa1 regulates late thymocyte development through interacting with inositol 1,4,5-triphosphate (IP3) receptors

Liang, J., Lv, J., Zheng, M., Li, D., Lu, L., Jun Lv, Mingzhu Zheng, Dan Li and Linrong Lu

Zhejiang University, School of Medicine, Hangzhou, China

T cell antigen receptor (TCR) ligation on the surface of DP thymocyte induces the formation of TCR proximal LAT signalosome complexes in the cell, which is critical for mediating subsequent signal transduction pathways that direct its late stage development into Single positive cells. We've previously shown that, Tespa1, a newly- identified adaptor protein, is also recruited to the LAT signalosome and participate to the activation of ERK kinases and calcium flux. However, the precise function of Tespa1 remains to be elucidated. Here we found that Tespa1 interacted with the N-terminal of IP3R1 through its PFF domain, which enable it to recruit IP3R1 to the TCR complexes after TCR stimulation. We also found that

the recruitment of IP3R1 by Tespa1 enabled the membrane-proximal phosphorylation of IP3R1 on tyrosine 353 by Fyn and was critical for optimal TCR-proximal calcium flux signaling. Disruption of Tespa1-IP3R1 interaction by mutagenesis led to substantial decrease of calcium flux signals. Finally, we proved that the interaction between Tespa1 and IP3R1 was essential for the positive selection of thymocytes in Teaps1 PFF mutant transgenic mice. In sum, our work uncovered a new molecular mechanism that regulates the calcium signaling in T cells.

1018

Different extracellular regions of Notch ligands, DII1 and DII4, are necessary for supporting T cell development

Hozumi, K., Hirano, K.-I.

Tokai University School of Medicine, Immunology, Isehara, Japan

We have shown that DII4 is absolutely necessary and efficiently induces T cell development. However, it has not been clarified what is unique characteristics in DII4 among NotchLs. It was known that the DOS motif, observed into the 1st and 2nd EGF repeats of the extracellular region, is widely conserved in NotchLs from invertebrates to mammals, but mammalian DII4 does not possess this motif. To investigate and compare the significance of DOS motif with another functional region, DSL, we make six chimeric molecules between DII1 and DII4 and check their abilities. The improvement of their function is only found in DII4-derived molecules with DOS region of DII1, which effectively induces the signaling and supports T cell development in vitro. These results indicate the significance of DOS motif for the functional modification of DII family members, but suggest that the superiority of DII4 cannot be explained by the difference in DSL/DOS regions. On the other hand, we reveal that the N-terminus (MNNL) of DII4 is critical for DII4, but not for DII1, to trigger the signaling and support T cell development. Taken together, it is demonstrated that different components of the extracellular region of DII family members are required to function, and that MNNL region of DII4 can be linked with the superiority of DII4 over DII1.

1019

CXXC finger protein 1 is critical for T cell intrathymic development through regulating H3K4 trimethylation

Wang, L., Cao, W., Guo, J., Wen, X.

Zhejiang University School of Medicine, Institute of Immunology, Hangzhou, China

T cell development in the thymus is largely controlled by an epigenetic program involving in both DNA methylation and histone modifications. Previous studies have identified Cxxc1 as a regulator of both cytosine methylation and histone 3 lysine 4 trimethylation (H3K4me3). However, it is unknown whether Cxxc1 plays a role in thymocyte development. Here we show that T cell development in the thymus is severely impaired in Cxxc1-deficient mice. Furthermore, we identify genome-wide Cxxc1 binding sites and H3K4me3 modification sites in wild-type and Cxxc1-deficient thymocytes. Our results demonstrate that Cxxc1 directly controls the expression of key genes important

for thymocyte survival such as ROR γ t and for TCR signaling including Zap70 and CD8, through maintaining the appropriate H3K4me3 on their promoters. Importantly, we show that ROR γ t, a direct target of Cxxc1, can rescue the survival defects in Cxxc1-deficient thymocytes. Our data strongly support a critical role of Cxxc1 in thymocyte development.

1020

T cell receptor recognition of the non-classical MHC molecule HLA-E

Sullivan, L.¹, Nguyen, O.¹, Kedzierska, K.¹, Cai, Z.¹, Gray, J.¹, Widjaja, J.¹, Gras, S.², Farenc, C.², Malmberg, K.³, Rossjohn, J.², Brooks, A.¹

¹Peter Doherty Institute for Infection and Immunity, The University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ²Biomedicine Discovery Institute, Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia, ³Karolinska University Hospital, Department of Hematology, Stockholm, Sweden

The non-classical MHC class I molecule (MHC-I) HLA-E has a restrictive peptide-binding groove; largely binding peptides derived from the leader sequences of other MHC-I. The human cytomegalovirus glycoprotein UL40 contains a sequence that is identical to the HLA-E-binding peptide found in many HLA-C alleles and the HLA-E/UL40 peptide complex is recognised by the T cell receptor (TCR) of a subset of CD8⁺ T cells (UL40-specific T cells). The ability of UL40-specific TCR to recognise the UL40 peptide represents a potential specificity challenge for the immune system. In order to avoid self-reactivity, UL40-specific TCR must distinguish between the UL40 peptide (VMAPRTLIL) and near-identical self-peptides (e.g. VMAPRTLVL encoded by HLA-A2), which may differ by only a single methyl group. Limited knowledge exists on how TCRs are capable of such discrimination or how TCRs recognise HLA-E in general. We used single-cell multiplex-nested RT-PCR to assess the TCR $\alpha\beta$ repertoire diversity of UL40-specific TCR in healthy donors. We showed that the TCR repertoire capable of recognising HLA-E/UL40 was highly restricted, with repeated selection of TRBV14 in several unrelated donors. Furthermore, we generated soluble recombinant forms of these TCRs and assessed their ability to bind to HLA-E in complex with the UL40 peptide and self-HLA derived peptides by surface plasmon resonance (SPR). SPR analysis indicated that the affinity of the TCRs for HLA-E/UL40 was consistently higher than the affinity of TCRs for HLA-E-self peptide complexes. These findings provide fundamental insights into the generation of the T cell repertoire, self/non-self discrimination and the requirements for activation.

1021

A critical role for proper fucosylation in T cell development

Yabas, M.^{1,2}, Roots, C.M.², Goodnow, C.C.^{2,3}, Enders, A.²

¹Faculty of Engineering, Trakya University, Department of Genetics and Bioengineering, Edirne, Turkey, ²The John Curtin School of Medical Research, The Australian National University, Department of Immunology and Infectious Disease, Canberra, Australia, ³Immunology Division, Garvan Institute of Medical Research, Sydney, Australia

Fucosylation, a type of glycosylation, is the attachment of a fucose residue to *N*-glycans, *O*-glycans and glycolipids, and is critical for posttranscriptional regulation of many essential pathways. The defects in the genes encoding enzymes involved in the GDP-fucose synthesis have been implicated in Notch-dependent lymphoid cell development in the immune system. Here we describe a mouse strain with an *N*-ethyl-*N*-nitrosourea (ENU)-induced point mutation in the gene encoding an enzyme involved in fucosylation. The mutant mice displayed growth retardation and increased postnatal mortality with a median survival of 5 weeks. Despite the presence of normal numbers of double negative (DN) thymocytes mutant mice at 3 weeks of age had reduced numbers of double positive (DP), CD4 single positive (SP) and CD8SP cells. Interestingly, the presence of B cells, T cells and myeloid cells in the spleen of mutant mice at 3 weeks of age seemed to be normal. Analysis of thymi from *Rag1*^{-/-} chimeras reconstituted with mutant bone marrow cells revealed a partial arrest at the DN stage of T cell development with an approximately two-fold reduction in thymocyte numbers compared to WT *Rag1*^{-/-} control chimeras. Furthermore, mixed bone marrow chimera experiment demonstrated that mutant cells were unable to compete with wild-type cells from the DP stage of T cell development in the thymus onwards. This inability to compete results in a complete absence of mutant derived peripheral T cells in the recipient mice. These findings highlight an important role for proper fucosylation in T cell development.

1022

PP2A C subunit isoform α (PP2Ac) is essential for early T cell development

Zheng, M., Li, D., Lu, L.

Institute of Immunology/Zhejiang University, Hangzhou, China

The development of T cells is critically dependent on signaling through the TCR and can be disrupted by deficiencies in the receptor itself and in many signaling molecules and mediators. Protein phosphatase 2A is a highly regulated serine/threonine phosphatases family implicated in cell growth and signaling, which contains three subunits: A(scaffold subunit), B(regulatory subunit) and C(catalytic subunit). T cells from SLE patients express high levels of PP2Ac. However, the function of PP2Ac that mediates the maturation, differentiation and activation in T cells remained undefined. Here we generated T-cell-specific PP2Ac conditional knockout mice. We found that *Ppp2ca* gene deletion in the T-cell-lineage resulted in aberrant thymocytes development including reduced number of total thymocytes, T-cell arrest from DN4 to DP. PP2Ac deficient thymocytes showed decreased proliferation and enhanced apoptosis *in vivo*. Thus our results indicate that PP2Ac is a critical component involved in the T cell developmental program and maturation.

1023

Elucidating T cell fate using microfabricated cell culture platforms

Charnley, M.^{1,2}, Ludford-Menting, M.², Pham, K.², McArthur, S.¹, Russell, S.^{1,2}

¹Swinburne University of Technology, Melbourne, Australia, ²Peter

MacCallum Cancer Centre, Melbourne, Australia

An effective immune response depends upon the coordinated proliferation and differentiation of T cells, with each cell performing its own designated role. Current research indicates that this diversification is controlled by asymmetric cell division (ACD); a process that orchestrates fundamental aspects of stem and immune cell biology and is disrupted in cancer. ACD occurs when there is intracellular polarity in a dividing cell resulting in two daughter cells with different molecular compositions. My group has definitively revealed for the first time that ACD also controls the differential inheritance of cell fate determinants in T cell precursors (thymocytes).

This project aims to tease out the external cues responsible for the initiation of ACD. To achieve this I have developed a simple and robust model using functionalised surfaces to individually present proteins to the thymocytes. With this model I can study the effect of different cues on the development of individual immune cells in real time. Excitingly, the Notch-1 ligand, Delta-like-1 (DL-1), induced the polarisation of cell fate proteins during interphase and mitosis. On-going work is focused on exploring the synergistic interactions between the molecular players that control ACD and its impact on cell development. Thus, this approach provides unique opportunities to hone in on the mechanisms by which the microenvironment can influence cell fate. This is expected to impact on our understanding of the immune response and will have profound implications for the development of therapeutic and diagnostic solutions for immune disorders, improved vaccination, and T cell leukaemias.

1024

The Redox function of apurinic/apyrimidinic endonuclease1/redox factor-1 (Ape1/Ref-1) modulates helper T cell response through antigen presenting cells

Akhter, N.¹, Takeda, Y.¹, Nara, H.¹, Araki, A.¹, Asao, N.², Ishii, N.³, Asao, H.¹

¹Yamagata University, Faculty of Medicine, Immunology, Yamagata, Japan, ²Tohoku University, Advance Institute for Material Research, Sendai, Japan, ³Tohoku University Graduate School of Medicine, Immunology, Sendai, Japan

Ape1/Ref-1 is a multifunctional protein possessing DNA repair, redox control and transcriptional regulatory activities. In immune system Ape1/Ref-1 is essential for immunoglobulin class-switch recombination and for CD40-mediated B cell activation. However, specific roles of Ape1/Ref-1 in helper T cell response are largely unknown. In this study, the function of Ape1/Ref-1 redox control activity in helper T cell immune response was analyzed using an Ape1/Ref-1 redox specific inhibitor, E3330. When OT-II cells, which are CD4⁺ T cells with ovalbumin (OVA) specific TCR, were activated with OVA-pulsed antigen presenting cells (APC) in the presence of E3330, IFN- γ -producing OT-II T cells were significantly increased. E3330 doesn't enhance IFN- γ producing CD4⁺ T cells, which were activated with anti-CD3 and anti-CD28 antibodies without APC. Moreover, E3330-pre-treated and OVA-pulsed APC could enhance IFN- γ production from OT-II T cells. These results suggest that E3330 enhances Th1 response through the modification of

APC function. E3330 has no effect on CD80/CD86 and MHC-II expression in APC. Therefore, we focused on the IL-12. E3330 up-regulated the *Il12a* and *Il12b* gene activation in TLR ligand-stimulated APC and increased IL-12 surface expression on APC, but decreased the secretion. These data were confirmed with Ape1/Ref-1 knockdown APC. Next, to elucidate the mechanisms how Ape1/Ref-1 modulates APC functions, we examined the signal transduction. Amusingly E3330 augmented TLR ligand-induced p38 MAPK activation suggesting that the activated p38 MAPK may enhance the IL-12 gene activation. This is the first study to demonstrate that the redox function of Ape1/Ref-1 modulates APC function and inhibits Th1 cell differentiation.

1025

MiR-205 maintains T cell output from the thymus by positively regulating Foxn1 expression

Hoover, A.¹, MacLeod, J.¹, Dozmorov, I.¹, de la Morena, M.T.^{2,3}, van Oers, N.^{1,4}

¹UT Southwestern Medical Center, Immunology, Dallas, United States, ²UT Southwestern Medical Center, Pediatrics, Dallas, United States, ³Childrens Health, Allergy and Immunology, Dallas, United States, ⁴UT Southwestern Medical Center, Microbiology, Dallas, United States

T cells are a critical component of the adaptive immune system, developing within the thymus. Immature thymocytes interact with an interconnected meshwork of thymic epithelial cells (TECs) to establish the T cell repertoire. This developmental process is extremely stress sensitive, with the thymus undergoing a rapid involution in response to inflammatory and endocrine mediators. The type of stress predicates whether TECs and/or thymocytes mediate this process. Several microRNAs (miRs) have been identified in the thymus based on their ability to mitigate stress damage. We identified miR-205 as a stress responsive miR specifically expressed in TECs. The conditional ablation of miR-205 in TECs results in an age and sex-dependent thymic hypoplasia in mice beginning at 8 weeks. During type I interferon responses (dsRNA mimic; polyI:C), the TEC-miR-205 deficient mice displayed a severe thymic atrophy compared to littermate controls, including a delayed recovery of single positive CD4 and CD8 thymocytes. qPCR and gene expression comparisons revealed a number of putative miR-205 targets with significant changes in chemokine/chemokine receptors and antigen processing pathways. The addition of miR-205 mimics in fetal thymic organ cultures lacking miR-205 restored normal levels of Foxn1, the master regulator of TEC development and function. Interestingly, miR-205 is encoded within a long non-coding RNA (lncRNA), 4631405K08Rik. Current experiments will reveal the mechanisms by which the miR and lncRNA are transcriptionally regulated, and how these affect Foxn1 expression to support thymopoiesis.

1026

Scribble is an important regulator of T cell development

Novita, N.¹, Dew, A.¹, Durrant, M.¹, Johnson, C.¹, Walkley, C.R.^{2,3}, Purton, L.E.^{2,3}, Darcy, P.K.¹, Ellis, S.L.¹

¹Peter MacCallum Cancer Centre, East Melbourne, Australia, ²St Vincent's Institute, Fitzroy, Australia, ³University of Melbourne, Department of Medicine at St Vincent's Hospital, Fitzroy, Australia

As a scaffolding protein, Scribble regulates multiple intracellular signalling pathways that control cell proliferation, migration, and apoptosis. Scribble is pivotal to the development of epithelial tissues and its deregulation has been linked to multiple epithelial cancers. Scribble's role in haematopoiesis and haematopoietic malignancies is an exciting area of burgeoning interest. Using multiple approaches, we show that Scribble is expressed in haematopoietic stem and progenitor cells (HSPC) and their differentiated progeny, implying a putative role for Scribble in blood production. We investigated the effect of Scribble loss in haematopoiesis through two inducible knockout mouse models and an extensive phenotyping labelling regime in conjunction with multi-color flow cytometry. Surprisingly, we observed no effect of loss of Scribble on either the proportion or numbers of HSPC, or cells from the B, myeloid, or erythroid lineages. Mature differentiated cells in the peripheral blood were also unaffected by loss of Scribble. However, mice lacking Scribble had a significantly smaller thymus compared to controls, which was caused by a significant decrease in the number of DN1, DN2, DN3, single positive and double positive thymocytes. Our data suggests Scribble may regulate thymocyte development and/or the migration of the early progenitors from the bone marrow to the thymus. We are currently investigating these hypotheses and the underlying mechanism/s involved. Our research will improve the understanding of T cell development and will form the basis of future studies aimed at investigating how Scribble impacts T cell leukaemia.

Screening of mouse mutagenesis pipeline for cytotoxic T lymphocyte function

Barton, P., Smart, E., Griffiths, G., Wellcome Trust - 3i Consortium CIMR, Cambridge, United Kingdom

As part of the 3i consortium - an expansion of the immunological phenotyping carried out at the Mouse Genetics Project at the Wellcome Trust Sanger Institute (WTSI) - we have developed a screen to assess cytotoxic function of CD8+ T-cells in mutant mouse lines. CD8+ T cells kill target cells through the polarised release of cytotoxic granules¹, the contents of which initiate apoptosis and the subsequent release of lactate dehydrogenase (LDH) from the target cell. Release of LDH from target cells can be quantified to ascertain the cytotoxicity of T cells². Furthermore, the presence of the lysosomal associated proteins LAMP1 and 2 (CD107a and CD107b), proteins found within the cytolytic granule membrane, can be detected at the cell surface using flow cytometric quantification to indicate the level of cytolytic degranulation³. Combining cytotoxicity and degranulation assays, alongside a flow cytometric analysis of

the ratio of CD4⁺:CD8⁺ cells within the cultured population allows for a comprehensive screen of T cell function from these mutant mouse lines, in order to identify novel T cell phenotypes.

Quantification of the peripheral T cell repertoire that escapes negative selection due to attenuated TCR signalling

Wirasinha, R.C.^{1,2}, Singh, M.³, Archer, S.⁴, Daley, S.R.^{1,2}

¹Monash University, Infection and Immunity Program, Monash Biomedicine Discovery Institute, Clayton, Victoria, Australia,

⁴Monash University, Monash Bioinformatics Platform, Clayton, Victoria, Australia

Genetic mutations that attenuate intracellular TCR-signalling are associated with T-cell lymphopaenia, immunodeficiency and autoimmune disease. During T cell development in the thymus, TCR-signalling thresholds play a critical role in central tolerance. T cells that receive no TCR signal undergo death by neglect, weak TCR signals drive positive selection and strong TCR signals trigger negative selection. One suspected cause of autoimmune disease invokes shifting of these T-cell signalling thresholds, whereby strong TCR binding is incorrectly interpreted and transmitted as a weak intracellular TCR signal. This "selection shift" hypothesis proposes that TCR binding events that would normally trigger negative selection instead induce positive selection. The fraction of the peripheral T cell repertoire composed of negatively-selectable TCRs due to the selection shift has not been examined. To address this, we cell sorted thymic and peripheral T cell subsets from fixed TCR-beta chain, wild-type or TCR-attenuated mouse strains bearing hypomorphic alleles of genes encoding Zap70 or SIp-76, and performed deep-sequencing of the TCR-alpha chain repertoire. Negatively-selectable thymocytes were identified as CCR7⁺ CD4^{lo}CD8^{lo}PD-1^{hi}. We found that < 5% of wildtype peripheral naive CD4⁺ T cells were negatively-selectable, versus up to 70% in TCR-attenuated mutants. Further analysis of TCR-attenuated strain peripheral effector/memory CD4⁺, regulatory T cells and naive CD8⁺ splenocytes, were also enriched in negatively-selectable TCRs, albeit to a lesser extent than naive CD4⁺ splenocytes. These findings are the first quantitative estimate of the selection shift, and strongly support that attenuated TCR signals can lead to negatively-selectable TCRs dominating the repertoire exported from the thymus.

Bone morphogenetic protein type-II receptor mutation affects circulatory T cell subsets but is dispensable for B cell development in mouse models of pulmonary arterial hypertension

Jafri, S.¹, Moore, S.D.¹, Morrell, N.W.¹, Ormiston, M.L.²

¹University of Cambridge, Department of Medicine, Cambridge, United Kingdom, ²Queens University, Departments of Biomedical and Molecular Sciences, Kingston, Canada

Bone morphogenetic protein (BMP) signalling is involved in lymphocyte development. Mutations in BMP type-II receptor (BMPRII) predispose to pulmonary arterial hypertension (PAH), which is also associated with immune dysfunction. We aimed to investigate the effect of a disease-relevant BMPRII mutation on mouse T and B cell development.

Wild type (WT) and *Bmpr2*^{+/R899X} mice, bearing a PAH-associated premature stop mutation, were exposed to chronic hypoxia (21 days, 10% O₂) as a model of pulmonary hypertension. T and B cell development was characterised in bone marrow, spleen, thymus and blood by flow cytometric analysis. *Bmpr2*^{+/R899X} mice spontaneously develop pulmonary arterial hypertension with age, and these were also used to characterise T and B cell development.

Naïve *Bmpr2*^{+/R899X} mice do not have altered T or B cell development compared to WT. Hypoxic *Bmpr2*^{+/R899X} mice exhibit an expansion of absolute circulating CD8⁺ memory T cells. This is accompanied with increased follicular splenic B cells. However, no early stage T or B cell differences are observed between mice genotypes. Aged *Bmpr2*^{+/R899X} mice also trend towards increased circulating CD8⁺ memory T cells, manifest unaltered B cell subsets, and an increase in the common lymphoid progenitor population in bone marrow.

Our data show a PAH-relevant BMPRII mutation does not considerably affect mouse B cell development, even with hypoxia as a trigger. However, an expansion of circulating CD8⁺ memory T cells, particularly in *Bmpr2*^{+/R899X} mice following hypoxia, suggests that elevated T cell activation secondary to BMPRII dysfunction may contribute to disease development.

1030

Functional analysis of a developmental stage specific enhancer in the CD4 locus

Fujii, C.¹, Littleton, S.¹, Kasapi, M.¹, Zapatero, Z.¹, Sarafova, S.^{1,2}

¹Davidson College, Biology, Davidson, United States, ²Duke University, Immunology, Durham, United States

CD4 helper T cells coordinate the immune response and are highly dependent on the expression of the *Cd4* gene for proper development and function. The function of a promoter, an enhancer and a silencer have been well documented and together explain how the *Cd4* gene gets turned on in CD4 T cells and off in CD8 T cells. However once turned on, the amount and timing of *Cd4* expression varies during T cell development and activation. This modulation of CD4 surface levels is essential for proper lineage specification and T cell function. Yet, how subtle changes of CD4 expression are regulated remains unclear. We have recently identified a novel positive

cis-acting transcriptional regulatory element (NCE) in the *Cd4* locus that is inactive at the double-positive stage and becomes activated during positive selection. Here we investigate the *in vivo* function of NCE by introducing modified versions of the CD4 locus as a BAC transgene into mice deficient for CD4 and beta-2 microglobulin and look for deviations from the normal T cell development program. In addition we have generated a version of the BACs that contain a destabilized version of EGFP as a reporter, so we can observe the changes in transcription level directly. This set of mice will allow us to interrogate the transcriptional regulation of CD4 in other cells that express CD4, such as NKT and CD4+ DCs.

Poly(A) shortening of ASK1 mRNA contributes to positive selection of thymocytes through impairment of TCR-induced stress response

Kureha, T.¹, Akiyama, T.², Morita, M.³, Ichijo, H.⁴, Yamamoto, T.⁵

¹Okinawa Institute of Science and Technology Graduate University, Cell Signal Unit, Okinawa, Japan, ²Institute of Medical Science, University of Tokyo, Department of Cancer Biology, Tokyo, Japan, ³McGill University, Department of Biochemistry, Montreal, Canada, ⁴The University of Tokyo, Laboratory of Cell Signaling, Tokyo, Japan, ⁵Okinawa Institute of Science and Technology Graduate University, Cell Signal Unit, Onna-son, Japan

The CCR4-NOT complex is the major deadenylase that removes poly(A) tails from mRNAs. Recently, we found that the number of mature T cells was reduced in mice hetero-deficient for CNOT3, a subunit of the CCR4-NOT complex. The data suggest an involvement of CNOT3 in T cell development and/or maintenance. To clarify the role of CNOT3 in T cell, we generated mice devoid of CNOT3 in T cell specific manner (T-CNOT3^{-/-} mice). We found fewer mature thymic CD4⁺ and CD8⁺ T cells in T-CNOT3^{-/-} mice than in wild type mice. To identify the stage at which thymocyte development is first affected in T-CNOT3^{-/-} mice, we quantified cells at five distinct developmental stages defined by the expression of CD3 and the activation marker CD69. We found that numbers of immature CD3^{lo}CD69^{lo} and CD3^{int}CD69^{lo} cells did not differ between T-CNOT3^{-/-} mice and control mice. However, we observed fewer CD3^{int}CD69^{high}, CD3^{hi}CD69^{hi} and CD3^{hi}CD69^{lo} cells in T-CNOT3^{-/-} mice. Furthermore, we found the survival defect occurred in the presence of TCR stimulation. These results indicated that the defect of DP differentiation in T-CNOT3^{-/-} mice was caused by the cell death after TCR stimulation. We found that the CCR4-NOT complex post-transcriptionally attenuates expression of ASK1, thereby preventing prolonged activation of Jnk and p38 after TCR stimulation, which leads TCR-induced cell death of DP thymocytes. Our results identified the CCR4-NOT complex-mediated deadenylation of mRNAs is a critical factor during the positive selection of DP thymocytes.

The impact of the selecting MHCI molecule on epitope-specific CD8 T cell repertoire and function

Sng, X.Y.X.^{1,2}, Quinn, K.M.^{1,2}, Guan, J.^{1,2}, La Gruta, N.L.^{1,2}

¹Monash University, Biochemistry, Melbourne, Australia, ²University of Melbourne, Microbiology and Immunology, Melbourne, Australia

Up to 10% of naïve CD8 T cell precursors (CTLps) are known as alloreactive cells that recognise major histocompatibility complex class I (MHCI) variants that are not expressed during thymic selection. This indicates that MHCI restriction is not absolute, however the degree to which non-restricting MHCI affect epitope-specific T cell repertoire and function is not well delineated. We used naïve tetramer enrichment to characterise H-2D^b restricted epitope (influenza A virus derived PA₂₂₄)-specific CTLps in mice lacking H-2D^b (the restricting MHCI) or H-2K^b, the non-restricting MHCI. CTLps were enumerated, their clonal composition determined and their function assessed on a single-cell level. Intriguingly, although D^bPA₂₂₄-specific CTLp numbers were substantially lower in H-2D^b KO compared to wildtype and H-2K^b KO, they were reproducibly present, indicating the ability of H-2D^b reactive cells to be selected on H-2K^b.

The median fluorescence intensity of tetramer straining on CTLps from H-2D^b KO mice was lower, suggesting poorer avidity of TCR-MHCI interactions. Assays for intrinsic and TCR dependent functionality will be performed to further dissect TCR-MHCI avidity. TCR repertoire analysis revealed similar TRAV usage across the different mouse strains but markedly diminished TRBV29 usage in H-2D^b KO. Altogether, these data demonstrate that epitope-specific CTLps

- (i) can be selected on distinct MHCI alleles,
- (ii) are largely defined by their selecting MHCI ligand, and
- (iii) are intrinsically poorer at epitope recognition when selected on mismatched MHCI molecule, thus likely affecting their functionality.

These data have implications for clinically significant diseases (e.g. GvHD) and treatments mediated by alloreactive CD8 T cells.

CRTAM is differentially regulated in naïve CD4 T-cells by IL-6 and IL-27

Liu, X., Twohig, J.P., Cardus, A., Andrews, R., Jones, G.W., Jones, S.A.
Cardiff University, Infection and Immunity, Cardiff, United Kingdom

Aim: Class-I MHC-restricted T-cell associated molecule (CRTAM) is an activation-induced surface receptor that regulates T-cell development and proliferation. CRTAM+CD4+ T-cells secrete IFN- γ and express cytotoxic T-cell-related genes. Currently, the mechanism of CRTAM regulation remains unknown. Here, using an unbiased transcriptomic approach, we investigated the role of IL-6 and IL-27 on CRTAM expression in CD4+ T-cells and examined the impact of CRTAM+CD4+ T-cells in inflammatory arthritis.

Methods: Naïve CD4 T-cells were stimulated with plate-bound anti-CD3 and anti-CD28 antibodies in the presence or absence of IL-6 or IL-27. Changes in CRTAM together with markers of

T-cell activation, cytokine release and proliferation/survival were analysed by flow cytometry, qPCR and ELISA. The in vivo regulation of CRTAM was monitored by immunofluorescence of joint sections from antigen-induced-arthritis treated mice.

Results: Activation of naïve CD4 T-cells caused a temporal increase in CRTAM surface expression. Maximal expression was observed 18hrs post-stimulation. Treatment with IL-6 significantly impaired CRTAM expression (50-60%). A similar early inhibition of CRTAM expression was also observed using IL-27, however in contrast to IL-6, IL-27 promoted a later induction of CRTAM (48-96hrs post-stimulation). Here, regulation of CRTAM by IL-6 and IL-27 was associated with a differential control of Zeb1, a negative regulator of CRTAM. Data will be presented showing the in vivo regulation of CRTAM in synovitis from IL6r^{-/-} and IL27r^{-/-} mice.

Conclusions: Our findings highlight the differential regulatory effects of IL-6 and IL-27 on CRTAM expression in naïve CD4 T-cells and provide the first evidence of CRTAM+CD4⁺ T-cells within the inflamed synovium.

CD4 T cell help for a more potent CD8 T cell response against hepatocyte-expressed antigens

English, K.^{1,2,3}, Sierro, F.^{1,2,3}, Tay, S.S.^{1,2,3}, Wood, N.A.W.^{1,2,3}, McGuffog, C.^{1,2,3}, McCaughan, G.W.^{1,2,3}, Bowen, D.G.^{1,2,3}, Wong, Y.C.^{1,2,3}, Bertolino, P.^{1,2,3}

¹Centenary Institute, Liver Immunology Program and AW Morrow Gastroenterology and Liver Centre, Camperdown, Australia, ²Royal Prince Alfred Hospital, Camperdown, Australia, ³University of Sydney, Camperdown, Australia

CD4 T cell help is required to elicit potent CD8 T cell responses to clear liver-tropic pathogens. The kinetics of the CD4 T cell responses and mechanism by which CD4 T cell help enhances liver-specific CD8 T cell responses are, however, unknown. We developed a recombinant adeno-associated viral vector system to express a fusion protein containing both CD4 and CD8 T cell epitopes in mouse hepatocytes. Using this approach, we investigated the CD4 T cell response against the hepatocyte-expressed antigen and how it affects the antigen-specific CD8 T cell response at different time points in liver, lymph nodes (LNs), spleen and blood.

While activation of antigen-specific CD8 T cells was initiated in both liver and LNs, naïve CD4 T cells were preferentially activated and proliferated in the liver-draining LNs. These activated CD4 T cells re-circulated to the liver and all secondary lymphoid organs (SLOs) and their numbers peaked at 7 days post antigen exposure. Although activated CD4 T cells did not influence the early proliferation of CD8 T cells in the liver and SLOs, they promoted a 5-15 fold increase in the number of antigen-specific CD8 T cells at day 7. These 'helped' CD8 T cells also displayed an enhanced functionality.

Our results suggest that CD4 T cells increase both the number and function of antigen-specific CD8 T cells after recirculation to the liver, an effect that will likely promote faster clearance of antigen-expressing hepatocytes. This model will help to induce a better CD8 T cell immunity against hepatotropic infections.

Drinking Jeju ground water containing vanadium leads to immune activation in chronically stressed mice

Cho, J.¹, Bing, S.J.¹, Ha, D.¹, Joo, H.¹, Kim, M.J.¹, Kim, A.², Herath, K.H.I.N.M.¹, Jee, Y.¹

¹Jeju National University, Department of Veterinary Medicine, Jeju-si, Korea, Republic of, ²Jeju National University, Advanced Convergence Technology & Science, Jeju-si, Korea, Republic of

Vanadium, an essential trace element for mammals, has been studied frequently in recent time cause its biological and pharmacological properties. We previously demonstrated that low doses of ammonium metavanadate (NaVO₃) activate peripheral immune system. It is well known that immune system, which protects host bodies from foreign invaders, is influenced by stress. Exposure to stress, through the action of stress hormones, has detrimental effects on immune function by reducing NK cell activity, lymphocyte populations, lymphocyte proliferation and antibody production. In this study, we aimed to investigate the immunomodulatory effects of Jeju water containing vanadium (Jeju water) on immunosuppression in stressed mice. We used various stressors such as physical exercise (swim), environmental factors (heat, sound), deprivation of freedom (restraint) and supplied mice with tap water (control) or Jeju water of varying vanadium concentrations for 28 days; S₁(vanadium 24.0 ± 2.0 µg/L), and S₂(vanadium 26.0 ± 2.0 µg/L). All Jeju water drinking groups showed increased single-positive (CD4⁺CD8⁻ or CD4⁺CD8⁺) thymocytes compare to control. Cell proliferation of splenocytes showed significant increase in Jeju water drinking groups, and the numbers of CD4 positive T cells, B cells, macrophages and granulocytes in spleen were also increased. Additionally, Jeju waters promoted IgG production in splenocytes of stressed mice. Taken together, Jeju waters promote T cell development in thymus and immune activation against immunosuppression by stress through the enhancement the splenocyte proliferation and its function. This research was supported by Jeju Special Self-Governing Province Development Corporation (JPDC) in 2016.

Acute influenza A virus (IAV) infection in humans leads to expansion of highly diverse CD8 T cell repertoires crossreactive with persistent Epstein Barr virus (EBV)

Gil, A., Mishra, R., Aslan, N., Selin, L.

University of Massachusetts Medical School, Pathology, Worcester, United States

The competence of T cell responses predominantly depends on how efficient T cell receptors (TCRs) are at recognizing antigenic epitopes. We show here that during acute severely symptomatic IAV infection there was an expansion of IAV-M1/EBV-BRLF1 and IAV-M1/EBV-BMLF1 double-tetramer+ cells directly ex-vivo in 5 HLA-A2+ patients. We questioned whether this expansion specific to these two different crossreactive responses would lead to alterations in the TCR repertoire of the IAV-M158, EBV-BRLF1109 and -BMLF1280 from before, during and following

acute IAV infection. Using staining with VB mAb we found that T cell responses generated to these epitopes became surprisingly more polyclonal, with the sharing of Vb between M1, BMLF1 and BRLF1 populations which is not seen in healthy donors and which decreased 2 months later consistent with crossreactive expansion. Furthermore, by using single-cell analysis of TCR α and TCR β repertoire of tetramer sorted IAV-M1 cells we showed dramatic changes in specific clonotype usage and in JA and JB family usage during acute IAV infection compared to before infection. In summary, these changes in TCR repertoire during acute symptomatic IAV infection suggest that during severe infection there is a preferential expansion of highly diverse crossreactive responses between IAV and the persistent virus, EBV, which leads to permanent changes in TCR repertoires to both of these two viruses (NIH AI049320 and NIH AI109858).

1037

The molecular basis of CD4 help during CD8⁺ T cell memory formation

Cullen, J., Olshansky, M., Turner, S.

Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia

A long-lived pool of memory cells is the defining feature of adaptive immunity. Memory CD8 T cells offer protection for the life of the host due to their unique capabilities to survive in the absence of antigen and respond rapidly to secondary challenge. Therefore, effective CD8 T cell memory is the goal of cell-mediated vaccination strategies. While it is well established that CD4 help is required for CD8 T cell memory formation, it is unclear when during CD8 differentiation this help is required. Further, the affect that CD4 help has on the transcriptional profiles of CD8 T cells and the molecular pathways they use during the generation of memory CD8 T cells remains elusive. Using a mouse model of Influenza infection, where priming occurs in the presence or absence of CD4 T cell help, we have pinpointed that help is required for priming of CD8 T cells, and not during memory maintenance or recall. Genome wide RNA-sequencing analysis of the transcriptional signatures between resting "helped" and "unhelped" memory CD8 T cells reveals few differentially expressed genes. However, upon reactivation, "helped" memory CD8 T cells exhibited greater transcriptional up regulation than "unhelped" counterparts, and utilization of alternate molecular pathways. Our analysis revealed that CD4 help during initial priming is essential for establishing a memory cell pool with enhanced transcriptional potential. Thus, CD4 T cell dependent programming likely underpins rapid responsiveness, a key characteristic of memory CD8 T cells. Analysis into intriguing metabolic differences based on this RNA-sequencing data are underway.

Antigen-specific CD8⁺ human memory stem T-cell clones: decoupling T-cell differentiation and division

Verdon, D.J.^{1,2}, Brooks, A.E.S.^{1,2}, Sheppard, H.M.¹, Ho, Y.J.¹, Dunbar, P.R.^{1,2}
¹University of Auckland, School of Biological Sciences, Auckland, New Zealand, ²Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand

Memory stem T-cells (T_{SCM}) have recently been characterised in mice, non-human-primates and humans as the least-differentiated subset of antigen-experienced T-cells, retaining a naive-like phenotype and proliferative potential. *In vivo* T_{SCM} can both self-renew, to retain a T_{SCM} pool and give rise to diverse memory and effector progeny. These characteristics make T_{SCM} the most potent and efficacious cellular resource for adoptive cell therapy in the treatment of cancer and protection from latent viruses.

In this study we describe the development of a cytokine regimen for reliably generating CD8⁺ T_{SCM} clones specific for epitopes derived from tumour-associated- and cancer-testis-antigen-derived epitopes. T-cell clones generated retained T_{SCM} phenotype, polyfunctional cytokine production and homeostatic cytokine responsiveness through serial expansions and ≤ 40 population doublings. Interestingly, these characteristics were lost during matched expansion in IL-2 alone. Dynamic tracking of memory-phenotype-associated cell surface markers revealed that these T_{SCM} clones do enter an 'effector phase' post-stimulation, but regain T_{SCM} phenotype following cessation of expansion, without evidence of population contraction. T_{SCM} clones do not constitutively express all cytotoxic granule proteins, but are able to rapidly upregulate these proteins and lyse epitope-matched melanoma cells on co-culture, without the need for prior cell division.

This study represents the first description of *in vitro*-generated epitope-specific CD8⁺ T_{SCM} clones and provides important insights into the regulation of T-cell memory phenotype-associated protein expression. Analysis of the surface phenotype and effector function of T_{SCM} populations throughout expansion and maintenance demonstrates that T-cell differentiation status is not determined by proliferative history, but is cytokine-responsive.

A novel IL-17-dependent positive control loop influencing human Th17 physiology and cutaneous inflammation

Pascoal Ramos, M.I.¹, Kakeda, M.², Paul-Gilloteaux, P.³, Hivroz, C.³, Puel, A.^{4,5,6}, Casanova, J.L.^{4,5,6,7,8}, Iezzi, G.⁹, Yawalkar, N.², Padovan, E.¹⁰

¹Instituto Gulbenkian de Ciencia, Oeiras, Portugal, ²Inselspital - Dermatology, Bern, Switzerland, ³Institut Curie, Paris, France, ⁴France Imagine Institute, Paris, France, ⁵Descartes University, Paris, France, ⁶Necker Hospital, Paris, France, ⁷St. Giles Laboratory, New York, United States, ⁸The Rockefeller University and HHM Institute, New York, United States, ⁹Basel University Hospital and University of Basel, Basel, Switzerland, ¹⁰University of Basel, Basel, Switzerland

IL-17 immunity is required for host immune protection, but can also be pathogenic. In our studies, we observed a decreased

frequency of blood-circulating Th17 cells in a patient lacking functional IL-17RA. Furthermore, by studying plaque psoriasis as skin disease model, we observed that psoriatic lesional skin, contained IL-17+ and CD3+ cells conjugated with CD68+/IL-6+ Macrophages (Mf). Based on these observations, we hypothesized that IL-17 cytokine could contribute to Th17 memory responses through a bidirectional interaction between M ϕ and Th17 cells. We demonstrated that pro-inflammatory M1 Mf were powerful inducers of Th17 responses, as compared to anti-inflammatory M2 Mf. We further showed that M1 Mf responded to activated Th17 by releasing IL-6. CD40 crosslinking on M1 Mf with sCD40L was necessary for IL-6 induction, but concomitant stimulation with IL-17A enhanced Mf cytokine release. The presence of Mf lacking functional IL-17RA and antibody blocking IL-17 hampered IL-6 release and Th17 expansion from memory T cell precursors. Moreover, conditioned media from M1 Mf activated by sCD40L and IL-17 consistently expanded Th17 cells from CD4+ T lymphocytes activated through CD3. Contrary to M1 cells, M2 Mf responded to activated Th17 cells by producing IL-10 and had no effect on Th17 expansion. Collectively, we demonstrated that IL-17, in synergy with CD40L, feeds back M1 Mf establishing a positive control loop on Th17 responses, thus identifying new pathways for the fine-tuning of IL-17 immunity and the maintenance skin homeostasis *in vivo*.

Effect of gain-of-function mutations in PI3 kinase p110d on the phenotype and function of EBV-specific CD8⁺ T-cells

Edwards, E.S.J.^{1,2}, Cole, T.³, Wong, M.⁴, Uzel, G.⁵, Tangye, S.G.^{1,2}

¹Garvan Institute of Medical Research, Immunology Division, Darlinghurst, Australia, ²St Vincent's Clinical School, University of New South Wales, Sydney, Australia, ³Royal Childrens Hospital Melbourne, Department of Allergy and Immunology, Melbourne, Australia, ⁴Childrens Hospital at Westmead, Department of Allergy and Immunology, Sydney, Australia, ⁵NIAID, NIH, Immunopathogenesis Section, Laboratory of Clinical Infectious Diseases, Bethesda, United States

CD8⁺ T-cells are largely responsible for controlling infection caused by the common herpes virus EBV. Due to the efficacy of CD8⁺ T-cells, primary EBV infection in healthy individuals is often asymptomatic. However, individuals with primary immunodeficiencies characterised by uncontrolled EBV viremia have been identified. These include patients with heterozygous, germline gain-of-function mutations in *PIK3CD* (which encodes the p110d catalytic subunit of PI3-kinase). *PIK3CD* is predominantly expressed in leukocytes and is critical for lymphocyte function. Previous studies reported an altered CD8⁺ T-cell phenotype in patients, with a skewing towards a T_{EM}/T_{EMRA} phenotype, at the expense of naïve CD8⁺ T-cells, consequent with hyperactivation of the PI3K-Akt-mTOR pathway. In order to understand how *PIK3CD* GOF mutations contribute to EBV susceptibility, we have utilized polychromatic FACS to enumerate the functional and phenotypic attributes of total and EBV-specific CD8⁺ T-cells in patients and healthy controls. Results show that EBV-specific CD8⁺ T-cells are present at similar frequencies in patients and controls. Total and EBV-specific CD8⁺

T-cells are hyperactivated in patients, as indicated by significant upregulation of regulatory markers CD95, CD160 and 2B4, as well as cytotoxic marker Granzyme B. In addition, CD57 and PD-1 are overexpressed indicating immunosensence of CD8⁺ T-cells. Preliminary experiments suggest dysregulated cytokine and cytolytic marker expression in affected individuals, and by extension suspected dysfunction of cytotoxicity towards EBV-infected targets. Further investigation will provide new insights into the generation and function of CD8⁺ T-cells in the control of EBV, which will be important in the treatment of EBV-associated diseases, and EBV vaccine development.

1041

Tissue resident memory T cells closely interact with a 3D macrophage network for immune surveillance of salivary gland

Thelen, F.¹, Ficht, X.¹, Stolp, B.², Page, N.³, Merkler, D.³, Stein, J.V.¹

¹University Bern, Theodor Kocher Institut, Bern, Switzerland, ²Universitätsklinikum Heidelberg, Ruprecht-Karls-Universität Heidelberg, Infektiologie, Heidelberg, Germany, ³University of Geneva, Pathology and Immunology, Geneva, Switzerland

After clearing of infections, distinct memory T cell populations persist in the host for efficient protection upon pathogen re-encounter. Re-activation of resident CD8⁺ memory T cells (T_{RM}) is particularly relevant for a fast response to viral and microbial infections on a tissue level. However, the requirements for efficient tissue protection by T_{RM} are not fully understood. Here, we used multiphoton intravital imaging, confocal imaging and light sheet microscopy of submandibular salivary glands (SMG) to dissect memory-mediated tissue surveillance during acute and memory phase of lymphocytic choriomeningitis virus (LCMV) infections in mice. SMG is an exocrine gland with ductal and acinar structures, which are anchored via extracellular matrix (ECM) sheets. We discovered in SMG and lacrimal glands an extended tissue macrophage network, which facilitates migration of T_{RM} between different epithelial and stromal compartments by extending protrusions through ECM and densely packed epithelial cells. These protrusions create gaps in the ECM layer that are used by T_{RM} as guidance cues for efficient scanning of ductal and acinar structures. Depletion of the macrophage network resulted in significantly reduced T_{RM} motility and patrolling ability. After viral re-challenge of the SMG, we found that the macrophage network was essential for fast clearance of infected cells by T_{RM}. In sum, we describe a close cooperation between the resident macrophage network and T_{RM} in exocrine glands that ensures effective tissue surveillance by granting T cell access to epithelial structures sheathed by ECM.

1042**CD8⁺ T cells require LFA-1 to patrol the liver and protect against hepatic pathogens***McNamara, H.A., Cai, Y., Enders, A., Cockburn, I.A.**Australian National University, John Curtin School of Medical Research, Canberra, Australia*

CD8⁺ T cells in the liver play a critical role in protection against pathogens such as Hepatitis C and malaria. However, the behaviour of CD8⁺ T cells within the liver has yet to be clearly defined. Using multiphoton microscopy we imaged the behaviour of effector and memory CD8⁺ T cells following immunization with the malaria parasite *Plasmodium*. At early time points most CD8⁺ T cells in the liver were found to be temporarily trapped in the liver or flowing in the blood stream. However by 28 days post-immunization the majority of CD8⁺ T cells had adopted a characteristic patrolling behaviour within the hepatic sinusoids. Flow cytometry analysis of CD8⁺ T cells at memory time points revealed a population of tissue resident memory-like cells which were CD69^{hi} CXCR3^{hi}, KLRG1^{lo}. Intriguingly these cells also expressed exceptionally high levels of LFA-1 (CD11a/CD18). We therefore investigated whether LFA-1 was critical for the migration and homing of T cells in the liver. We found that antibody blockade of ICAM-1 - a major LFA-1 ligand - reduced the migratory speed of CD8⁺ T cells in the liver. Furthermore, CD8⁺ T cells deficient in LFA-1 did not exhibit patrolling behaviour and failed to home efficiently to the liver. Finally, we found that cells deficient in LFA-1 were unable to efficiently protect against malaria parasite challenge despite retaining cytotoxic activity. Collectively these observations demonstrate a clear role for LFA-1 in CD8⁺ T cell patrolling of the hepatic sinusoids, and their ability to protect against liver pathogens.

1043**Reduction in pathogen-specific memory responses after antibiotic treatment increases susceptibility to secondary infection***Benoun, J.¹, Fogassy, Z.¹, McSorley, S.^{1,2}*¹*University California, Immunology, Davis, United States,*²*University California, Department of Anatomy, Physiology and Cell Biology, School of Veterinary Medicine, Davis, United States*

Salmonella enterica serovar Typhi causes recurrent and relapsing infection in antibiotic-treated individuals, suggesting that rapid bacterial clearance hinders the development of adaptive immunity. We have developed an antibiotic-treatment model in mice to examine this issue. This model demonstrates poor secondary protection after antibiotic treatment and allows the use of antigen-specific reagents to examine this issue in detail. Infection with *Salmonella* Typhimurium (BRD509-2W1S) caused expansion of *Salmonella*-specific CD4 T cells that were detected in peripheral blood, lymphoid tissues, and various non-lymphoid tissues. In contrast, antibiotic-treated mice had lower CD4 clonal expansion that persisted for months after infection. This reduced clonal frequency of *Salmonella*-specific CD4 T cells correlated with diminished protective immunity to secondary infection. In order to examine the protective contribution

of circulating and non-circulating CD4 T cells, parabiosis experiments were performed whereby mice previously infected with BRD509-2W1S were paired with naïve mice for 30 days. Previously infected mice were more capable of controlling secondary infection compared to naïve parabionts or naïve control mice, indicating that protection is dependent upon the tissue resident memory cells. Current experiments are focused on examining tissue resident memory cells in antibiotic-treated and untreated mice. Greater understanding of how antibiotics hinder CD4 memory development may allow for therapeutics to boost protective immunity to secondary or relapsing *Salmonella* infections. (Funding: NIH 5P01AI056172-09).

1044**Protein tyrosine phosphatase non-receptor type 2 regulates development and function of tissue resident memory T cells***Hochheiser, K.¹, Wiede, F.², Tigani, T.², Gebhardt, T.¹*¹*University of Melbourne, Microbiology and Immunology, Melbourne, Australia,* ²*Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia*

T cells play a central role in immune protection against pathogens. Upon resolution of an infection, memory T cells provide enhanced immune surveillance and recall responses towards re-infection. Central memory T cells (T_{CM}) and effector memory T cells (T_{EM}) circulate through secondary lymphoid organs or non-lymphoid tissues, respectively. Recently, a distinct subset of memory T cells was discovered, which permanently remains in tissues after infection without recirculation through the blood. These tissue resident memory T cells (T_{RM}) provide a high degree of protection against localized infection. However, they may also drive aberrant immune responses associated with autoimmunity. Here, we investigated the role of the Protein tyrosine phosphatase non-receptor type 2 (ptpn2) in T_{RM} formation and function in a model of Herpes simplex virus skin infection. We observed a profound defect in ptpn2-deficient T cells to form a stable T_{RM} population in vivo. Related to this, we found a relative reduction of KLRG1⁺ T_{RM} precursors after priming. This defect was reversed by in vitro instead of in vivo activation, a situation that exclusively induces KLRG1⁺ cells. In vitro activated ptpn2-deficient T cells were able to form T_{RM} when lodged into the skin and reacted more strongly towards viral challenge in comparison to ptpn2-competent T cells. Our study reveals a dual role for ptpn2 in skin T_{RM} promoting T_{RM} development by enhancing precursor frequencies and regulating potentially detrimental effector functions.

1045**CCR2 Is critical for memory CD8 T cell generation following influenza A virus infection***Fenix, K.¹, Kara, E.¹, Bastow, C.¹, Gregor, C.¹, McKenzie, D.¹, Norton, T.¹, Seilet, C.², Alsharifi, M.¹, Belz, G.², Comerford, I.¹, McColl, S.^{1,3}*¹*The University of Adelaide, Adelaide, Australia,* ²*Walter and Eliza Hall Institute of Medical Research (WEHI), Parkville, Australia,*³*Centre for Molecular Pathology, Adelaide, Australia*

Memory CD8⁺ T cells are important for controlling reinfection

against intracellular pathogens, yet the migratory signals required for CD8⁺ T cell memory formation are poorly understood. In this study, we show that the chemokine receptor CCR2 is expressed on CD8⁺ T cells following influenza A infection. CCR2-deficient antigen-specific CD8⁺ T cells displayed normal effector cell differentiation and cytokine production but impaired development of memory precursor effector cells (MPECs). Furthermore, CCR2^{-/-} CD8⁺ T cells had reduced proliferation during the late stages of infection. This led to enhanced CD8⁺

T cell contraction alongside a cell intrinsic defect in the formation of central and tissue-resident memory CD8⁺ T cells. Consistent with these observations, CCR2^{-/-} memory CD8⁺ T cells failed to efficiently control secondary infection against intracellular pathogens. These data uncover a novel CCR2-dependent pathway critical for generating memory CD8⁺ T cells.

Molecular control of tissue resident memory T cell generation in the liver

Yang, K.^{1,2}, Mackay, L.K.², Prosser, A.³, Liao, Y.¹, Man, K.^{1,2}, Lucas, M.³, Shi, W.¹, Gisbergen, K.V.⁴, Kallies, A.^{1,2}

¹Walter and Eliza Hall Institute of Medical Research, Molecular Immunology, Melbourne, Australia, ²University of Melbourne, Department of Medical Biology, Melbourne, Australia, ³The University of Western Australia, School of Pathology and Laboratory Medicine, Crawley, Australia, ⁴AMC, Department of Experimental Immunology, Amsterdam, Netherlands

CD8 memory T cells can be classified into three types, central memory T cells (T_{cm}), effector memory T cells (T_{em}) and resident memory T cells (T_{rm}). While T_{cm} and T_{em} recirculate through secondary lymphoid organs, T_{rm} reside predominantly in non-lymphoid tissues, and do not enter circulation or get replenished from blood or lymphoid tissues. T_{rm} in most tissues, in particular T_{rm} associated with epithelia, express a set of surface molecules including CD69 and CD103 that prevent egress and mediate retention in the tissue. We have characterized the phenotype and transcriptional profiles of multiple circulating and resident memory T cell populations, isolated from various lymphoid and non-lymphoid tissues, including the skin, gut and liver.

In the course of this work we identified a population of memory CD8 T cells in the liver with T_{rm}-like properties. Similar to other T_{rm}, this memory T cell population expressed CD69 and CD49a and was dependent on the transcription factors Hobit and Blimp1. Indeed, transplantation experiments revealed that these cells resided long-term in the liver and were in disequilibrium with circulating memory T cells. However, in contrast to T_{rm} in the skin or intestine, liver T_{rm} did not express CD103, and had access to the blood. Importantly, liver T_{rm} can protect locally against viral infection. We are now testing the molecular requirements and functional properties of liver T_{rm} generation.

1047

Infection of mice with influenza A virus generates a dichotomy of long-term, local immunity and local immune tolerance of antigen-specific T cells

Eriksson, M., Grönvik, K.-O.

National Veterinary Institute, Department of Microbiology, Uppsala, Sweden

Aim: To study localization and function of influenza virus-specific memory T cells and of APCs.

Methods: Mice were infected intranasally with a sublethal dose of H1N1 PR8 influenza A virus. Between 3 - 17 months post challenge with a lethal dose of homologous virus T cells and APCs from mediastinal lymph nodes (MLNs), lungs and spleens were obtained from sacrificed mice. Viral RNA in tissues was detected by RT-PCR. Purified T cells and infected APCs were co-cultured in vitro. Cytokines in cell-free culture supernatants were determined with Gyrolab Bioaffy, and cell proliferation by uptake of 3H-thymidine.

Results: Replicating influenza virus was restricted to sensitive tissues of the respiratory tract such as MLNs and lungs whereas no viral RNA was detected in spleen. At 12 - 17 months post infection localization of infected, autologous APCs determined immunity versus immune tolerance of influenza-virus specific memory T cells. Immune T cells of MLNs produced significantly less TH1 cytokines when co-cultured with infected, autologous APCs of MLNs than co-culture with infected, autologous APCs of spleen. Conversely immune spleen T cells produced significantly less TH1 cytokines upon stimulation with infected APCs of spleen than when co-cultured with infected APCs of MLNs.

Conclusions: Long-term memory T cells display a localization into different lymphoid organs in a similar way to the localization of differentiated $\gamma\delta$ -T cells into different tissues. This may be an important mechanism for maintenance of peripheral immunological tolerance and for establishing a more energy-efficient state of tissue-resident, memory T cells.

Pulmonary immunization with recombinant influenza A virus stimulates *M. tuberculosis*-specific CD4⁺ tissue resident memory T cells in the lung

Flórido, M.¹, Muflihah, H.¹, Lin, L.¹, Stambas, J.², Palendira, M.¹, Britton, W.J.^{1,3}

¹Centenary Institute, Tuberculosis Research Program, Newtown, Australia, ²Deakin University, School of Medicine, Geelong, Australia, ³University of Sydney, Sydney Medical School, Camperdown, Australia

The recently identified tissue resident memory T cells (TRMs) are retained within tissues and are phenotypically and functionally distinct from the circulating effector and memory T cells. They have been associated with protection against several pathogens. We have determined that pulmonary immunization of mice with recombinant influenza A virus (rIAV) expressing the p25 CD4⁺ T cell epitope of the *Mycobacterium tuberculosis* (*Mtb*) Ag85B protein (PR8.p25) induced strong p25-specific CD4⁺ T cell responses and protected mice against *Mtb* challenge. Using adoptive transfer of P25 TCR transgenic CD4⁺ T cells

and intravascular staining, we found that p25-specific T cells induced by PR8.p25 vaccine persist in the lung parenchyma long after the virus is cleared. After 6 wk, more than 90% of the P25 T cells were present in the lung parenchyma and expressed higher levels of CD69, a marker of TRMs, compared to P25 cells in the vasculature. The presence and location of these cells in the lungs following PR8.p25 immunization were confirmed by 2-photon imaging. Moreover, transcriptional analysis of the CD69⁺ P25 T cells isolated from the lungs 6 weeks after PR8.p25 immunization revealed down-regulation of the TRM-associated transcription factors, Klf2 and S1pr1, as compared to splenic effector or naïve P25 CD4 T cells. Thus, immunization with PR8.p25 stimulates retention in the lungs of *Mtb*-specific CD4⁺ T cells with the characteristics of TRMs. One potential advantage of the pulmonary delivery of TB vaccines is the induction of protective CD4 TRMs at the site of *Mtb* infection in the lung. Support: NHMRC.

Memory CD8 T cells confer increased protection upon pathogen re-encounter. The level of protection provided depends on the numbers, functional abilities, and location of memory cells present at the time of re-infection. While primary memory CD8 T cells can be maintained for life, the extent of phenotypic and functional changes that occur over time after initial antigen (Ag) encounter remains poorly characterized. We show that critical properties of circulating primary memory CD8 T cells, including location, phenotype, maintenance, Ag-driven secondary proliferation and generation of secondary memory, mitochondrial function, and inflammation-induced bystander activation change with time after initial infection. Interestingly, phenotypic and functional alterations in the memory population are not due solely to shifts in the ratio of effector (CD62L^{lo}) and central memory (CD62L^{hi}) cells, but also occur within defined CD62L^{hi} memory subsets. CD62L^{hi} memory cells retain the ability to efficiently produce cytokines with time after infection. However, the gene expression profiles of CD62L^{hi} memory cells change, phenotypic heterogeneity decreases, and mitochondrial function and proliferative capacity in either a lymphopenic environment or in response to cognate Ag increase with time. Importantly, protection provided against chronic LCMV clone-13 infection increases over time for both circulating memory CD8 T cell populations and for CD62L^{hi} memory cells. Taken together, the data reveal that memory CD8 T cells continue to change with time after primary infection and suggest that the outcome of vaccination strategies designed to elicit protective memory CD8 T cell responses using single or prime-boost immunizations depends upon the timing between antigen encounters.

1050

Distinct recirculation potential of phenotypically disparate CD69⁺CD103⁻ and CD103⁺ thymic memory T cells

Park, S., Mackay, L., Gebhardt, T.

Peter Doherty Institute for Infection and Immunity at The University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia

Unlike central and effector memory T cells that transit through blood, non-recirculating tissue-resident memory T (T_{RM}) cells permanently occupy peripheral and lymphoid tissues where they confer superior protection against infection. Whilst epithelial CD8⁺ T_{RM} cells co-express CD69 and CD103, CD103⁻ memory cells have been described in diverse organs and are often presumed non-recirculating based on their expression of CD69 alone. We found that both CD69⁺CD103⁻ and CD69⁺CD103⁺ memory cells populated the thymus upon transfer of CD8⁺ effector T cells into uninfected recipients, demonstrating that these subsets can form in the absence of both local antigen and inflammation. Transcriptionally and phenotypically, CD103⁺ thymic cells resembled non-lymphoid T_{RM} cells whereas CD69⁺CD103⁻ cells displayed an intermediate profile more closely related to recirculating cells, indicating that these memory subpopulations are fundamentally distinct. Although CD69 was required for optimal CD103⁺ T_{RM} cell formation, its expression alone did not identify permanently resident cells, as the CD69⁺CD103⁻ subset was largely eradicated from the thymus following antibody-mediated depletion of recirculating cells. In contrast, CD69⁺CD103⁺ thymic cells were selectively retained despite antibody treatment, confirming that they are *bona fide* T_{RM} cells. Our findings highlight a distinct migration potential of phenotypically divergent thymic CD8⁺ memory T cells and emphasise the inadequacy of CD69 as an absolute marker of tissue residency.

Background: CD8⁺ T cells typically recognize infected cells through viral peptides presented on HLA class I. However, class II-restricted CD8⁺ T cell responses have been reported

in CD4 knockout mice and in a macaque AIDS vaccine model. This raises a critical question: do class II-restricted CD8+ T cell responses exist in natural HIV-infection?

Methods: We detected class II-restricted CD8+ T cells in 3% of treatment-naive HIV-infected individuals (3/101 screened) using a novel 'CD8 HLA-DR ELISpot'. CD8+ T cells targeted HIV Gag37 or Gag41 peptides presented by LCL stably expressing recombinant human DR01 and DR11, respectively. Antibody blocking of class I and II, and flow cytometric staining with class II tetramers confirmed the restriction. TCR sequencing was conducted from tetramer-sorted cells.

Results: Class II-restricted CD8+ T memory cells exist in HIV-infection. Although rare, in one individual it was the most immunodominant CD8+ response encompassing 12% of total CD8+ T cells directly ex vivo. These CD8+ TEMRA cells were Perforin+GranzymeB+ and efficiently lysed autologous HIV-infected CD4+ T cells and macrophage targets ($p < 0.01$). Furthermore, HLA-DR-restricted CD8+ T cells showed atypical patterns of TCR usage, characterized by two distinct co-expressed TCR alpha chains (TRAV26 and TRAV6), and a single TCR beta clonotype shared with CD4+ T cells targeting the same HLA-DR-epitope. Indeed, TCR beta clonotype TRBV2 was shared between 100% of CD8+ and 73.9% of CD4+ T cells targeting DR11-Gag41.

Conclusions: HLA-DR-restricted antigen-specific CD8+ T cells exist in natural HIV infection, demonstrating that the established T cell recognition paradigms are not absolute.

Immunological memory is important for vaccinations and the suppression of neoplasia, yet it remains unclear how this memory function is maintained in the long term. Stem cell memory T (T_{SCM}) cells have recently been proposed as a novel memory T cell population which possesses the potential of long lifespan, self-renewal and the ability to produce large number of effector T cells. However, methods of T_{SCM} cells generation from effector T cells for clinical use have not been established. In this study, we have developed a method for the *in vitro* generation of induced T_{SCM} -like (iT_{SCM}) cells and characterized their function in antitumor immunity. We found that Notch signaling can generate iT_{SCM} cells from CD4+ or CD8+ activated effector T cells. iT_{SCM} cells not only supplied effector, classical central and effector memory T cell populations (T_{CM} and T_{EM}) by antigen re-stimulation, but also possessed long-lived and self-renewing potentials. Both CD4+ and CD8+ iT_{SCM} cells suppressed tumor growth much more efficiently than did T_{CM} or effector T cells in mouse models. Notch signaling also converted peripheral memory T cells to more potent antitumor iT_{SCM} cells. Our data suggest that Notch signaling confers "stemness" to effector T cells, and converts them into potent anti-tumorigenic T cells.

During pregnancy a semi-allogenic foetus develops within the uterus of its HLA mismatched mother. The decidua is able to secrete a milieu of cytokines and growth factors that ultimately permits development of the highly immunogenic foetus through potent immune suppression, whilst also preparing the foetus' immune system for subsequent challenge. Previous studies have highlighted the role of a number of important cytokines in establishing and maintaining pregnancy, as well as in foetal immune priming. The majority of this work however has focused on the functions of these molecules acting individually or in simple combinations. To date, detailed immune phenotyping at the decidua and in newborns has not been undertaken. Here, we performed high definition profiling using T cell pathway-focused gene profiling that quantified markers of survival, apoptosis, transcription, migration, adhesion, differentiation and effector function. We combined this phenotypic analysis with massive parallel sequencing of the human TCR repertoire. We identified atomically specific signatures in both gene profiling and TCR repertoire composition at different anatomical sites. Identifying immune "baselines" in different human tissues could be expanded in future to define immune correlates of disease in pregnancy-related complications where altered T cell cytokine expression has already been implicated.

1054

Signaling through PD-1 on CD8 T cells is critical for antigen-independent maintenance of immune memory

Yuzefpolskiy, Y.¹, Baumann, F.M.², Penny, L.A.², Kalia, V.^{3,4}, Sarkar, S.^{3,4}

¹Penn State University, Seattle, United States, ²Penn State University, University Park, United States, ³University of Washington School of Medicine, Seattle, United States, ⁴Seattle Children's Research Institute, Seattle, United States

PD-1 is highly expressed on CD8 T cells during activation, both in acute and chronic viral infections. Inhibitory signaling in cytotoxic T cells through the PD-1 axis is well characterized during chronic infections and has led to the development of potent blockade therapies that restore function to otherwise exhausted CD8 T cells. However, the functional significance of transiently increased PD-1 expression on CD8 T cells early after activation and its rapid down-regulation following clearance of antigen during acute infections, remains to be characterized. The enigma is - expression of PD-1 (an immunological brake) during activation temporally coincides with rapid proliferation and production of copious amounts of signature effector

cytokines (IFN- γ and TNF- α). We generated PD-1^{-/-} antigen-specific CD8 T cells to study its cell-intrinsic role during acute infection with LCMV. Unexpectedly, PD-1^{-/-} cells did not exhibit increased proliferation early during infection, or enhanced accumulation at the peak of expansion. PD-1^{-/-} CD8 T cells were also unaltered in their polyfunctionality and granzyme B expression. Despite robust effector properties, PD-1^{-/-} CD8 T cells underwent precipitous contraction, leading to near ablation of the memory pool. Mechanistically, *in vivo* analysis of PD-1^{-/-} memory cells showed a severe defect in antigen-independent homeostatic proliferation due to decreased sensitivity to IL-2, -7, and -15 signals, without evident change in the expression of common gamma-chain cytokine receptors. These studies demonstrate a previously unrecognized role of PD-1 signaling in programming of memory CD8 T cell maintenance and could make it a novel target for manipulating vaccine-induced memory T cell longevity.

Differentiation of resident memory CD8⁺ T cells in the liver

Wong, Y.C.^{1,2,3}, Sierro, F.^{1,2,3}, Lu, B.⁴, Tay, S.S.^{1,2,3}, Wood, N.A.W.^{1,2,3}, McGuffog, C.^{1,2,3}, McCaughan, G.W.^{1,2,3}, Bowen, D.G.^{1,2,3}, Bertolino, P.^{1,2,3}

¹Centenary Institute, Liver Immunology Program and AW Morrow Gastroenterology and Liver Centre, Camperdown, Australia, ²Royal Prince Alfred Hospital, Camperdown, Australia, ³University of Sydney, Camperdown, Australia, ⁴St. Vincent's Hospital, Melbourne, Australia

Tissue-resident memory T cells (T_{RM}) have been identified in different organs including skin and lung. Whether T_{RM} can differentiate in the liver is unknown. To induce intrahepatic CD8⁺ T cell responses, recipient mice were transferred with OVA-specific transgenic T cells and treated with recombinant adeno-associated viral vectors (rAAV) that target mouse hepatocytes to induce de novo OVA expression in the liver. We have recently shown that a low rAAV dose induced a low antigen load and allowed the development of intrahepatic effector T cells. We investigated here whether these cells differentiated into T_{RM}. When 1-5% of hepatocytes expressed OVA, functional memory OVA-specific CD8⁺ T cells expressing CD69, a common T_{RM} marker, were established in the liver. Intra-vital multi-photon microscopy experiments revealed that these memory cells moved slowly and against the blood flow, suggesting that they were patrolling the hepatic sinusoids. To test the ability of these cells to recirculate, livers containing memory T cells were transplanted into naive recipients. Most donor memory CD8⁺ T cells were detected within the transplanted livers and very few recirculated into lymphoid tissues, suggesting that they were liver resident. Importantly, when OVA presentation was restricted to hepatocytes, naive CD8⁺ T cells became effectors but failed to develop into T_{RM}.

In summary, low numbers of antigen-expressing hepatocytes promote the differentiation of liver CD8⁺T_{RM}. Although hepatocytes are critical in providing antigen, the differentiation of intrahepatic CD8⁺ T_{RM} requires non-hepatocyte antigen-presenting cells. Our results have important implications for vaccine development and for the treatment of hepatotropic infections.

CRTAM instructs the CD4⁺ cytotoxic T lymphocyte lineage

Takeuchi, A.¹, Gadelhaq Badr, M.E.S.¹, Miyauchi, K.², Kubo, M.^{2,3}, Saito, T.^{1,4}

¹RIKEN Center for Integrative Medical Sciences, Laboratory for Cell Signaling, Yokohama, Japan, ²RIKEN Center for Integrative Medical Sciences, Laboratory for Cytokine Regulation, Yokohama, Japan, ³Tokyo University of Science, Research Institute for Biomedical Science, Division of Molecular Pathology, Chiba, Japan, ⁴Osaka University, WPI Immunology Frontier Research Center, Osaka, Japan

Naïve T cells differentiate into various effector T cells including CD4⁺ helper T cell subsets and CD8⁺ cytotoxic T cells (CTL). Cytotoxic CD4⁺T cells (CD4⁺CTL) also develop from naïve T cells, but the mechanism of development is elusive. Class-I restricted T cell associated molecule (CRTAM) is an activation-induced surface receptor molecules predominantly expressed on activated CD8⁺T cells. However, tiny fraction of activated CD4⁺T cells also express CRTAM and has characterized these unique CD4⁺T cells. Micro array data revealed that the CRTAM⁺ CD4⁺T cells have the characteristics of both CD4⁺ and CD8⁺T cells. These cells particularly secrete IFN γ , express CTL-related genes such as eomesodermin (Eomes), granzyme B and perforins, and exhibit cytotoxicity after cultivation. These results suggest that CRTAM⁺ T cells are the precursor of CD4⁺CTL. Furthermore, ectopic expression of CRTAM in T cells also induced the production of IFN γ , expression of CTL-related genes, and cytotoxic activity. This result indicates that the induction of CD4⁺CTL and IFN γ production requires CRTAM-mediated intracellular signaling. CRTAM⁺ T cells traffic to mucosal tissues and inflammatory sites, and developed into CD4⁺CTL. These cells are involved in mediating protection against infection as well as inducing inflammatory response, depending on the circumstances, through IFN γ secretion and cytotoxic activity. These results reveal that CRTAM is critical to instruct the differentiation of CD4⁺CTL through the induction of Eomes and CTL-related gene.

Using immunodeficiency patient cells in *in vitro* cultures to provide insight into T-helper cell differentiation

Pillay, B.A.^{1,2}, Ma, C.S.^{1,2}, Casanova, J.L.³, Uzel, G.⁴, Tangye, S.G.^{1,2}

¹The Garvan Institute of Medical Research, Immunology Division, Darlinghurst, Australia, ²The University of New South Wales, St Vincent's Clinical School, Sydney, Australia, ³The Rockefeller University, Laboratory of Human Genetics of Infectious Diseases, Rockefeller Branch, New York, United States, ⁴NIAID, NIH, Laboratory of Clinical Infectious Diseases, Bethesda, United States

CD4⁺ T-cells play a broad role in host protection against disease. To achieve this, specialised subsets of effector CD4⁺ T-cells have evolved to orchestrate the diverse jobs required. These include defence against viruses, bacteria and fungi, as well as being involved in immune regulation and providing "help" to B-cells for their differentiation into memory and antibody-secreting

plasma cells. It is believed that all CD4⁺ T-cell subsets originate from a common precursor: the naïve CD4⁺ T-cell. Upon receipt of signals provided by specific antigen, antigen-presenting cells and the priming microenvironment, naïve T-cells differentiate into effector subsets via a process that is regulated by specific transcription factors induced by these stimulatory signals at the time of T-cell activation.

Our study of monogenic primary immunodeficiencies caused by mutations in cytokine receptors (*IL21R*, *IL12RB1*, *IL12RB2*, *IFNGR1*, *IFNGR2*) and proteins involved in downstream signalling (*STAT1*, *STAT3*, *DOCK8*) showed a CD4⁺ memory compartment with increased production of cytokines characteristically produced by Th2 cells (IL4, IL5, IL13). The intrinsic nature of this apparent Th2 skewing has been explored using *in vitro* cultures to polarise naïve CD4⁺ T-cells towards Th1, Th2 and Th17 differentiation pathways and assessing transcription factor and cytokine expression.

We found that the ability of some of these patient cells to differentiate into Th1 and Th17 cells in an *in vitro* system was unaffected and this suggests that *in vivo* an element of the environment during differentiation is responsible for Th2 skewing. Further investigation is being undertaken to elucidate the nature of this environmental element.

Immunological signature predictive of rituximab response in a subgroup of focal segmental glomerulosclerosis patients

Chan, C.Y.^{1,2}, Liu, I.D.^{1,2}, Resontoc, L.P.^{1,2}, Ng, K.H.^{1,2}, Chan, Y.H.³, Lau, Y.W.^{1,2}, Than, M.^{1,2}, Jordan, S.C.⁴, Lam, K.P.^{1,5}, Yeo, W.S.^{1,2}, Yap, H.K.^{1,2}

¹National University of Singapore, Paediatrics, Singapore, Singapore, ²Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore, ³National University of Singapore, Biostatistics Unit, Singapore, Singapore, ⁴Cedars Sinai Medical Center, CA, United States, ⁵Bioprocessing Technology Institute, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore

Rituximab has been used with variable success in focal segmental glomerulosclerosis (FSGS) patients, but the immunological basis of its efficacy is poorly characterized. This study aimed to characterize T-cell subsets in FSGS patients in order to identify an immunological signature predictive to favourable rituximab treatment.

Twenty-two FSGS patients (median age 14.4 years, range 6.2-25.0 years) were recruited prospectively to receive rituximab and were followed up longitudinally. Clinical parameters and immunological subsets were monitored at baseline and followed up until relapse. Baseline immunological subsets were compared to 22 patients with minimal change nephrotic syndrome (MCNS) in relapse and 30 healthy controls, and subsequently examined for association with response to rituximab.

Of the 22 patients, 12 (54.5%) responded to rituximab therapy. *In-vivo* expression of baseline B-cells, T-cells, natural killer cells, helper T-cell, cytotoxic T-cell and regulatory T-cell in FSGS rituximab responders were comparable to non-responders. However, mitogen-stimulated CD154⁺CD4⁺CD3⁺, IFN- γ ⁺CD3⁺

and IL-2⁺CD3⁺ expressions before rituximab were significantly lower in responders compared to non-responders and controls. The IFN- γ ⁺CD3⁺ and IL-2⁺CD3⁺ expressions in FSGS rituximab responders were also significantly lower compared to MCNS in relapse. At six months post-rituximab treatment, T-cells activation level in the responders were restored. Using ROC curve analysis, activated CD154⁺CD4⁺CD3⁺ (AUC 0.81, 95% CI 0.61-1.01), IFN- γ ⁺CD3⁺ (AUC 0.90, 95% CI 0.75-1.05) and IL-2⁺CD3⁺ (AUC 0.78, 95% CI 0.57-0.98) were good predictors of response to rituximab.

We have identified prognostic markers which define a subgroup of FSGS patients bearing an immunological signature of hyporesponsiveness to T-cell stimulation, with good response to rituximab therapy.

Innate effector function of Th2 cells is regulated by EGF-R expression

Zaiss, D., Minuti, C., Blair, N., Maizels, R.

University of Edinburgh, Institute of Immunology and Infection Research, Edinburgh, United Kingdom

Host resistance to helminth infection is critically dependent on cytokine production at the site of infection, mediated by both innate immune cells and cells of the adaptive immune system. Recently, it was revealed that Th2 cells contribute to helminth resistance, both in an antigen-dependent and - independent manner; however, to which either mechanism contributes to helminth resistance remains unknown.

Here we show that EGF-R expression on activated Th2 cells critically contributes to host resistance to helminths, and directly correlates with IL13 production at the site of infection in mice. IL33 induces "innate" IL13 production in Th2 cells, dependent on the formation of a signaling complex between T1/ST2, the IL33-R, and EGF-R. T cell transfer into MHC-II deficient mice confirmed that the innate capacity of Th2 cells to expel helminth infections was dependent on EGF-R expression. In addition, while EGF-R expression in activated Th2 cells was i) transient, ii) induced by either antigen or STAT5-signalling inducing cytokines, and iii) rapidly lost upon drug-induced pathogen clearance or transfer of Th2 cells into naïve mice, T1/ST2 expression was stable over time of infection.

Taken together, these data suggest a mechanism by which pathogen-specific Th2 cells are activated in an antigen-specific manner within draining lymph nodes, which results in an up-regulation of the EGF-R. This EGF-R expression then opens a window of opportunity within which activated Th2 cells can secrete IL13 at the site of infection in an antigen-independent way upon exposure to IL-33, and so contribute to helminth expulsion.

1060**MINK1 kinase suppresses Th17 cell differentiation and autoimmune inflammation via inhibition of the TGF- β pathway***Fu, G., Lu, L.**Zhejiang University, Hangzhou, China*

T-helper type 17 (Th17) cells that produce the cytokines interleukin-17A (IL-17A) and IL-17F are implicated in the pathogenesis of several autoimmune diseases. The differentiation of Th17 cells is instructed and critically regulated by different cytokines, which drives intracellular signaling cascades and transcriptional signatures that determines the cell fate. We report that MINK1, a germinal center kinase (GCK) family kinase, is a negative regulator of IL-17A production in the periphery. Mice deficient in MINK1 developed exacerbated inflammation during EAE. MINK1 directly phosphorylated SAMD2 at T324 residue, which inhibited the activation of SMAD2 and suppressed the induction of Th17 cells. Antioxidants have been shown to compromise the activation of MINK1 in other cells. Here we show that antioxidant N-acetyl cysteine (NAC) boosts Th17 cells generation *in vitro* in a MINK1-dependent manner. Moreover, mice with NAC treatment develop a more severe form of EAE through a cell-intrinsic mechanism. These data identify MINK1 as a suppressor of Th17 cells and provide a molecular insight into a mechanism by which an antioxidant (health product) such as continued NAC supplementation triggers Th17 development and promotes autoimmunity.

1061**Promotion of mouse autoimmune arthritis via TLR4/ICOS/IL-17 axis by mycoplasma superantigen***Mu, H.-H., Nourian, M., Jiang, H.-H., Wang, J., Cole, B.**University of Utah School of Medicine, Salt Lake City, United States*

Mycoplasma arthritidis mitogen (MAM), a potent superantigen (SAg) secreted by *M. arthritidis*, is known to contribute to mouse arthritis models that are related to the pathogenic Th17 cells. We previously demonstrated that IL-17 mobilizes, recruits and activates inflammatory cells to increase local inflammation in arthritic mice infected with *M. arthritidis*, and an early engagement of TLR4 by MAM is necessary for the enhanced disease severity that is associated to the increased IL-17. ICOS, with its counterpart ICOS ligand (ICOSL) that is expressed on activated T cells. In the present study, we found injections of MAM to a collagen-immunized mice aggravated collagen-induced arthritis (CIA), initiating an early onset of disease, enhancing incidence and severity of arthritis. The increased arthritis was accompanied by an increase in anti-CII Ig levels. Enhanced level of ICOS expression was observed in the inflamed synovial tissue as well as in the draining lymph nodes (LNs) that are associated with increased IL-17 and Th17-associated cytokines and chemokines. Furthermore, blocking antibody against ICOSL significantly ameliorated arthritis in the joints. The number of T cells expressing ICOS in lymphoid tissues were remarkably reduced by the anti-ICOSL treatment. Serum anti-CII IgG1, IgG2a, and IgG2b levels were also reduced. Our results demonstrates a beneficial effect of the ICOSL blockade on mouse

arthritis through suppression of Th17-mediated pathogenic effect, suggesting that the ICOS/ICOSL co-stimulatory pathway plays an important role in the pathogenesis of inflammatory/autoimmune arthritis and thus the targeting of this pathway can be a useful therapeutic strategy for treating human rheumatoid arthritis.

1062**Itk is required for Th9 differentiation via TCR-mediated induction of IL-2 and IRF4***Gomez Rodriguez, J.¹, Meylan, F.², Handon, R.¹, Hayes, E.², Anderson, S.¹, Kirby, M.¹, Siegel, R.², Schwartzberg, P.¹**¹NIH/NHGRI, Bethesda, United States, ²NIH/NIAMS, Bethesda, United States*

T helper 9 (Th9) cells produce IL-9, a cytokine implicated in allergic asthma and autoimmunity. We show that Itk, a mediator of T-cell receptor signalling required for Th2 immune responses and the development of asthma, is a positive regulator of Th9 differentiation *in vivo* and *in vitro*. In a papain-induced model of allergic lung disease, Itk-deficient mice have reduced pulmonary inflammation and decreased IL-9 production by T cells and innate lymphoid type 2 cells (ILC2), despite normal early induction of ILC2s. *In vitro*, naive *Itk*^{-/-} CD4⁺ T cells essentially fail to produce IL-9 and have reduced levels of IRF4, a critical transcription factor for effector T-cell function. Both IL-9 and IRF4 expression are rescued by either IL-2 or expression of constitutively-active STAT5, but not NFATc1. We further find that STAT5 binds the *Irf4* promoter, indicating one mechanism by which IL-2 can rescue weakly-activated T cells. Interestingly, naive WT CD4 T cells cultured in presence of the Itk inhibitor show very high levels of IL-9 production when IL-2 is added to the cultures, suggesting complex effects of Itk inhibitors. Thus, inhibiting Itk as a therapeutic strategy for treating or preventing symptoms of asthma and other diseases in which IL-9 participates still remains an important question.

1063**Th17 plasticity and transition towards a pathogenic cytokine signature is regulated by Cyclosporin after allogeneic-SCT***Gartlan, K.H.^{1,2}, Varelias, A.^{1,2}, Koyama, M.¹, Markey, K.¹, Kuns, R.¹, Raffelt, N.¹, Olver, S.¹, Lineburg, K.¹, Teal, B.¹, Cheong, M.¹, Smyth, M.¹, Tey, S.-K.¹, Macdonald, K.¹, Hill, G.¹**¹QIMR Berghofer, Immunology Department, Brisbane, Australia,**²University of Queensland, School of Medicine, Brisbane, Australia*

Th17 cells have been widely implicated as drivers of autoimmune disease. In particular, Th17 cytokine plasticity and acquisition of an IL-17A⁺IFN γ ⁺ cytokine profile is associated with increased pathogenic capacity. Donor Th17 polarization is known to exacerbate GVHD after allogeneic stem cell transplant (allo-SCT), however donor Th17 cytokine co-expression and plasticity have not been fully characterized. Using IL-17 'fate-mapping' reporter mice, we identified IL-6-dependent Th17 cells early after allo-SCT, characterized by significantly elevated expression of pro-inflammatory cytokines, IL-17A, IL-22, GM-CSF and TNF. This

population did not maintain lineage fidelity, with a marked loss of IL-17A and IL-22 expression late post-transplant. Th17 cells could be further segregated based on IFN γ co-expression and IL-17A⁺IFN γ ⁺ Th17 displayed an enhanced pro-inflammatory phenotype. This cytokine plasticity and IFN γ production was critically dependent upon donor derived IL-12/IL-23 and calcineurin inhibition via Cyclosporin treatment regulated this differentiation pathway. This observation was highly concordant with clinical samples from recipients receiving Cyclosporin-based immune suppression where although the IFN γ negative-Th17 subset predominated, IFN γ ⁺-Th17 cells remained present. In sum, Th17 polarization and ensuing differentiation are mediated by sequential inflammatory signals which are modulated by immunosuppressive therapy, leading to distinct phenotypes within this lineage.

1064

IFN-g and IL-21 producing Th1 cells dependent IgG2 responses gave a protection to H5N1 pandemic influenza virus

Miyauchi, K.¹, Ishige, A.², Takahashi, Y.³, Takemori, T.², Kubo, M.^{1,4}

¹RIKEN Center for Integrative Medical Sciences, Laboratory for Cytokine Regulation, Yokohama, Japan, ²RIKEN Center for Integrative Medical Sciences (IMS), Drug Discovery Antibody Platform Unit, Yokohama, Japan, ³National Institute of Infectious Diseases, Department of Immunology, Tokyo, Japan, ⁴Research Institute for Biomedical Science, Tokyo University of Science, Division of Molecular Pathology, Chiba, Japan

Two major distinct helper T cell subsets, Tfh and Th1 cell are developed with influenza A virus infection. The contribution of Tfh on producing neutralizing antibody, which takes a pivotal role in virus protection, has become a consensus. However, Th1 cell's contribution in protective humoral response is controversial. The mice carrying loxP-flanked Bcl6 exon allele and crossing with cd4-cre (Bcl6f/fCd4cre), Tfh deficient mice, give us an opportunity to ask about Th1 function in anti-viral IgG induction. Vaccinated Bcl6f/fCd4cre mice showed normal protection against H1N1 seasonal and H5N1 pandemic virus that relied on virus specific IgG2 antibodies. Thus, Tfh cells are dispensable in virus specific IgG2 response. Further experiments revealed that IFN-g and IL-21 from Th1 cells were required for anti-virus IgG2. Moreover, the transfer of IL-21 producing Th1 cells augmented anti-virus IgG2 titer. Taken together, the distinct Th1 subset producing IFN-g and IL-21 takes significant roles in influenza virus specific humoral responses. Plasticity and lineage decision of Tfh and Th1 cells are also debatable. In our experimental setting, transferred Th1 cells retained Th1 signature for two weeks, which suggests that Th1 and Tfh lineage are rather independent. Th1 induction could be a promising strategy in novel vaccine design to tackle H1N1 and H5N1 influenza virus pandemic.

1065

Vaccination induced ICOS⁺ circulating memory T_{FH} cells share similar characteristics to T_{FH} cells but are dysfunctional and Th2 skewed in chronic HIV-1 infection

Abudulai, L.¹, Hunter, M.^{2,3}, Post, J.^{2,3}, French, M.^{1,4}, Fernandez, S.¹

¹The University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia, ²University of New South Wales, Prince of Wales Clinical School, Sydney, Australia, ³Prince of Wales Hospital, Department of Infectious Diseases, Sydney, Australia, ⁴Royal Perth Hospital and PathWest Laboratory Medicine, Department of Clinical Immunology, Perth, Australia

HIV infection increases the risk of pneumococcal disease, probably related to B-cell and/or T follicular-helper (T_{FH}) cell dysfunction. We have shown that decreased production of pneumococcal polysaccharide (PcP)-specific IgG2⁺ antibody secreting cells (ASC) in HIV patients 7 days after vaccination with unconjugated PcPs is associated with impaired expansion of ICOS⁺ circulating memory (cm)T_{FH} (CD4⁺CD45RA⁻CD27⁺CXCR5⁺PD-1⁺) cells. Here, we sought to further characterise these cells in antiretroviral therapy (ART)-treated (n=27) and ART-naive (n=11) HIV patients and non-HIV subjects (n=20). Intracellular expression of Bcl-6, Blimp-1 and BATF, and surface expression of CCR6, CCR7, CXCR3, BTLA and IL-6Ra were examined in unstimulated cells while production of IL-21 and IFN- γ were assessed following *in vitro* stimulation. After vaccination, ICOS⁺ cmT_{FH} cells in HIV patients and non-HIV subjects displayed characteristics of canonical T_{FH} cells, with BTLA, IL-6Ra and Bcl-6 expression and IL-21 production all observed. However, IL-21 production by ICOS⁺ cmT_{FH} cells was decreased in ART-naive (p=0.02) and ART-treated (p=0.03) patients compared to non-HIV subjects. Furthermore, production of IgG2 ASCs specific for PcP serotypes 4, 6B, 9V and 14 correlated with ICOS⁺ cmT_{FH} cells that displayed a Th1 phenotype (CXCR3⁺CCR6⁻) in non-HIV subjects (R \geq 0.42, p \leq 0.06) but a Th2 phenotype (CXCR3⁻CCR6⁻) in ART-treated HIV patients (R \geq 0.44, p \leq 0.02). Thus, after vaccination with PcPs, ICOS⁺ cmT_{FH} cells were skewed from Th1 to Th2 and displayed impaired production of IL-21 in ART-treated HIV patients. These findings provide new evidence that impaired antibody responses to PcPs, and possibly other antigens, in HIV patients receiving ART may result from residual T_{FH} cell dysfunction.

Bach2-Batf interactions control Th2-type immune response by regulating the IL-4 amplification loop

Yamashita, M.¹, Ochi, M.¹, Sawasaki, T.², Kuwahara, M.¹

¹Ehime University, Department of Immunology, Graduate School of Medicine, Toon, Japan, ²Ehime University, Proteo-Science Center, Matsuyama, Japan

Although Bach2 plays an important role in regulating the Th2-type immune response, the underlying molecular mechanisms remain unclear. We herein demonstrate that Bach2 associates with Batf family transcription factors and binds to the regulatory regions of the Th2 cytokine gene loci, which contain AP-1 motifs. The Bach2-Batf complex antagonizes the recruitment of the Batf-Irf4 complex to AP-1 motifs and suppresses Th2 cytokine production. Furthermore, we found that Bach2 also regulates

the *Batf* and *Batf3* expressions via two distinct pathways. First, the Bach2-Batf complex directly binds to the *Batf* and *Batf3* gene loci and reduces transcription by interfering with the Batf-Irf4 complex. Second, Bach2 suppresses IL-4-induced augmentation of the *Batf* and *Batf3* expressions through the inhibition of IL-4 production. These findings suggest that IL-4 and Batf family transcription factors form a positive feedback amplification loop to induce Th2-type immune response, and Bach2-Batf interactions block formation of this amplification loop.

Multivariate modeling of human T helper differentiation

Grandclaudeon, M., Perrot, M., Trichot, C., Raieli, S., Soumelis, V.
Institut Curie, Paris, France

In the past decade, 2 main levels of complexity have emerged in the field of T helper (h) differentiation: the multiplicity of "input" signals interacting together to control Th differentiation, and the multiplicity of secreted "output" Th cytokines. In this work, we studied the mechanisms that control T helper cell differentiation taking into account these 2 levels of complexity. We built a statistical model on 600 single observation points of 42 T cell "inputs" measured on dendritic cells (DC) and 19 "outputs" measured on Th cells, in human heterologous DC - naïve CD4 T cells co-cultures. From this dataset we derived a sparse partial least square 2 model able to predict the outputs based on the input dataset with a low error score assessed computationally by 10 fold cross-validation. Such an unbiased modeling strategy was able to identify known regulators of T helper cell differentiation, for instance, IL-12 inducing Th1 or IL-23 inducing Th17. This strategy also led to the identification of several new input-output relationships that are currently investigated for functional validation. Multivariate modeling already enabled us to test novel hypotheses in silico and will bring new insights into the mechanistic understanding of Th cell differentiation. Ultimately, our strategy will help to identify optimal vaccine and immunotherapy strategies in order to induce specific Th cytokine profiles.

Peripheral memory OX40⁺CXCR5⁺PD-1⁺ Bcl6⁺ Flu-specific T follicular helper cells elicited by vaccination correlated with anti hemagglutinin antibody responses in healthy individuals

Brezar, V.^{1,2,3}, Dahlke, C.⁴, Wiedemann, A.^{1,2,3}, Hani, L.^{1,2,3}, Godot, V.^{1,2,3}, Tcherakian, C.^{5,6}, Lelièvre, J.D.^{1,2,3,7}, Addo, M.⁴, Lévy, Y.^{1,2,3,7}, Seddiki, N.^{1,2,3}

¹INSERM U 955 Eq 16, Créteil, France, ²Université Paris-Est Créteil, Faculté de Médecine, Créteil, France, ³Vaccine Research Institute (VRI), Créteil, France, ⁴University Medical Center Hamburg - Eppendorf, Hamburg, Germany, ⁵Service de Pneumologie, Hôpital Foch, Suresnes, France, ⁶UFR des Sciences de la Santé Simone Veil, Université de Versailles Saint-Quentin-en-Yvelines, Montigny-Le-Bretonneux, France, ⁷AP-HP, Hôpital H. Mondor - A. Chenevier, Service d'Immunologie Clinique et Maladies Infectieuses, Créteil, France

OX40 signals promote memory CD4⁺ to express Tfh-cell molecules and become functional B-cell helpers.

We have previously shown that peripheral memory Ag-specific CD4⁺ can be detected by their dual expression of OX40 and CD25 after stimulation with cognate Ag. These cells include effector cells and CD39⁺Foxp3⁺ Ag-specific regulatory T cells (Tregs). Here we report that CD4⁺CD25⁺OX40⁺ also include Tfh cells.

By using blood samples from 15 healthy individuals prior and after (3, 7, 14 and 50 days) post-seasonal influenza (Flu) vaccination, our data reveal the presence of Flu-specific OX40⁺CD25⁺CXCR5⁺PD-1⁺ Tfh expressing the transcription factor Bcl6; these cells peaked at day 7 post-vaccination. CD4⁺OX40⁺ CD25⁺CXCR5⁺PD-1⁺Bcl6⁺ Flu-specific Tfh but not *ex vivo* bulk CD4⁺CXCR5⁺PD-1⁺CCR7^{low}Tfh, correlated significantly with Hemagglutinin inhibition (HI) titers ($r=0.4$, $p=0.04$ and $r=0.04$, $p=0.8$, respectively), suggesting that the former subset is associated with vaccine responses. Moreover, we show the presence of OX40⁺CD25⁺CXCR5⁺PD-1⁺-cells expressing both Bcl6 and Foxp3 transcription factors, which indicate their T-follicular regulatory (Tfr) phenotype. The proportion of Tfr varies between days 7, 14 and 50 post-vaccination with a decrease at day-7. More characterization of these cells is under way. Moreover, current co-culture experiments will demonstrate whether Flu-specific OX40⁺CD25⁺CXCR5⁺PD-1⁺Bcl6⁺ Tfh are able to help memory B-cells to produce immunoglobulins. Taken together our data demonstrate for the first time the presence of Flu-specific peripheral memory OX40⁺CD25⁺CXCR5⁺PD-1⁺ Tfh that express Bcl6. These cells peak at day-7 post-vaccination and contain low proportions of dual Bcl6⁺Foxp3⁺ Tfr as compared to day-0 or day-50 post-vaccination. Other vaccine models are currently tested in this context.

1069

Non-cognate stimulation of CD4 T cells contributes to the resolution of intracellular bacterial infections

Pham, O.H.¹, O'Donnell, H.², Li, L.¹, Mooney, J.³, Kerrinnes, T.³, Tsois, R.³, Davies, H.⁴, McSorley, S.J.¹

¹University of California, Center for Comparative Medicine, Davis, United States, ²Pastuer Institute, Paris, France, ³University of California, Department of Medical Microbiology and Immunology, Davis, United States, ⁴University of California, Division of Infectious Diseases, Irvine, United States

Salmonella-specific CD4 T cells acquire the ability to rapidly produce IFN- γ in response to non-cognate stimuli during active infection. Treatment of *Salmonella*-infected mice with PAMPs caused increased production of multiple cytokines, as detected by ELISA, Luminex array, or DNA microarray. Mixed bone marrow chimera experiments indicate that IL-18 and IL-33 are essential for optimal IFN- γ production while several other cytokines are dispensable. T cell-intrinsic MyD88 signaling was required for maximal IFN- γ production and optimal clearance of *Salmonella*, *Chlamydia*, and *Brucella* infection, demonstrating the importance of non-cognate stimulation in vivo. Interestingly, Th1 cells generated by immunization did not respond to non-cognate stimuli in vivo, despite surface expression of IL-18R.

Together, these data suggest that non-cognate activation of CD4 T cells occurs in a variety of infectious disease models and contributes to the resolution of infection. Current studies are exploring how non-cognate stimulation contributes to in vitro background responses and whether this information can be utilized to uncover target antigens of *Salmonella*-specific T cells in vitro.

1070

Long noncoding RNAs: new players in plasticity and new therapeutic opportunities in human immune system

Panzeri, I.¹, Lorenzo, M.¹, Gruarin, P.¹, Dardanelli, A.¹, Marchesi, S.¹, Ranzani, V.¹, Arrigoni, A.¹, Bonnal, R.J.¹, Rossetti, G.¹, Abrignani, S.², Pagani, M.²

¹Fondazione INGM, Milan, Italy, ²Fondazione INGM - University of Milan, Milan, Italy

The human genome encodes thousands of long non-coding-RNAs that are emerging as key molecules in modulating differentiation events and maintenance of cell identity in different cellular contexts. As little is known on long intergenic non-coding-RNAs (lincRNAs) in the human immune system, we investigated lincRNAs in thirteen T and B lymphocyte subsets by RNA-seq analysis and de-novo transcriptome reconstruction. Hundreds of new lincRNAs were identified and lincRNAs signatures were described. Expression of linc-MAF-4, a chromatin associated TH1 specific lincRNA, was found to anti-correlate with MAF, a TH2 specific transcription factor, and down-regulation of linc-MAF-4 associated to skewing of T cell differentiation toward TH2 phenotype. We demonstrated a long distance interaction between linc-MAF-4 and MAF regions, and found specific association of linc-MAF-4 with LSD1 and EZH2, suggesting linc-MAF-4 regulated MAF transcription by recruiting chromatin modifiers on MAF promoter. Our findings further support the key role of lincRNAs in regulating lymphocyte differentiation. As immune mediated diseases often arise from an imbalance among the different subsets in the immune system, we are now investigating the possibility to exploit lincRNAs as new therapeutic targets to modulate T cell plasticity and to restore immune system function in pathological settings. In this perspective, we are mainly focusing on lincRNAs specifically expressed in human CD4+ regulatory T cells, which have a prominent role in the etiology of such diseases. We are therefore applying several parallel approaches to investigate the functional role of signature Treg cell lincRNAs in both auto-immune and tumor contexts.

1071

GITRL enhances p38 MAPK/STAT3 signaling to promote Th17 cells differentiation in autoimmune arthritis

Tang, X.¹, Xu, H.², Wang, S.³

¹Affiliated People's Hospital of Jiangsu University, Zhenjiang, China,

²Jiangsu University, Zhenjiang, China, ³Affiliated People's Hospital of Jiangsu University, Clinical Laboratory, Zhenjiang, China

The glucocorticoid-induced TNFR family-related protein (GITR) and its ligand play a critical role in the pathogenesis of

autoimmune arthritis by enhancing the Th17 cell response, but their molecular mechanisms remain largely unclear. This study aims to define the role of p38 mitogen-activated protein kinases (MAPK) and signal transducer and activator of transcription 3 (STAT3) signaling in GITRL-induced Th17 cells in autoimmune arthritis.

We found that the p38 phosphorylation was enhanced by GITRL in activated CD4⁺T cells, and the p38 inhibitor restrained the GITRL-induced Th17 cell expansion in a dose-dependent manner. Moreover, there was decreased STAT3 activity on Tyr705 and Ser727 with the p38 inhibitor in vitro. Notably, the p38 inhibitor could prevent GITRL-treated arthritis progression and markedly decrease the Th17 cell percentages. The phosphorylation of the Tyr705 site was significantly lower in the GITRL-treated CIA mice treated with the p38 inhibitor. A significantly higher phosphorylation of p38 was detected in RA patients and had a positive relationship with the serum level of anti-cyclic citrullinated peptide (anti-CCP) antibody.

Taken together, these findings indicate that GITRL could promote Th17 cell differentiation by p38 MAPK and STAT3 signaling in autoimmune arthritis, which is considered a central pathogenesis of autoimmune disorders.

1072

TGFb induces fractalkine receptor CX3CR1 expression during T cell polarization

Dong, L., Hertel, B., Haller, H., von Vietinghoff, S.

Hannover Medical School, Nephrology and Hypertension, Hannover, Germany

Background: Fractalkine receptor CX3CR1 is the only known CX3 cytokine receptor with a single known ligand, fractalkine. Monocytes have the highest absolute expression levels and their response to fractalkine has received most interest over the last years. However, its expression on other leukocytes including T cells is well documented. We here investigated T cell CX3CR1 expression during T cell polarization.

Methods: Murine splenocytes were polarized towards TH1, TH17 and TREG phenotypes on plate-bound purified anti-CD28 and anti-CD3 with IL-12 and anti-IL-4 or IL-6, TGFb and IL-23 or TGFb and IL-2. Polarization was assessed by flow cytometry after intracellular staining for IFN γ , IL-17A and FoxP3, respectively. Cell proliferation was assessed by CFSE dilution. CX3CR1 expression was investigated by reporter gene expression in CX3CR1gfp/gfp and mRNA expression in wildtype cells. TGFb signaling was inhibited by SMAD3 inhibitor SB431542.

Results: TH17 polarization or stimulation with TGFb alone increased T cell CX3CR1 reporter gene expression. TGFb induced CX3CR1 mRNA expression in wildtype cells in a dose and time dependent manner. This was reverted by SMAD3 blockade. Less TH17 cells were obtained from CX3CR1^{-/-} than wildtype splenocytes by in vitro polarization.

Conclusion: T cell CX3CR1 can be induced by TGFb during both TH17 and TREG polarization.

1073**The RNA-binding protein HuR is necessary for IL-2 homeostasis and CD4⁺ T cell differentiation**

Atasoy, U., Glascock, J., Techasinta, P., Ellis, J., Ridenhour, S. University of Missouri, Surgery, Molecular Microbiology and Immunology, Columbia, United States

The RNA binding protein, HuR, (ELAVL1), controls gene expression in activated T cells by interacting with 3' UTR AU-rich elements (AREs) and altering transcript stability or translation. IL-2 and many Th2 cytokine mRNAs contain AREs. We hypothesized that HuR may play a critical role in early CD4⁺ T cell differentiation by regulating IL-2 signaling pathways. We conditionally ablated HuR in CD4⁺ T cells (distal Ick-Cre ROSA HuR^{fl/fl}) to test this hypothesis. HuR KO T cells developed and normally egressed from the thymus, but upon activation were unable to shut off IL-2 production and had defects in both Th2 differentiation and cytokine expression. HuR null T cells displayed proliferation defects, decreased p-stat5, and reductions in CD25 and blimp-1, which is involved in IL-2 transcriptional repression. In the absence of HuR, *Il2ra* (CD25) mRNA recruitment to heavy polysomes is reduced, resulting in decreased protein translation. This suggests that HuR regulates T cell activation and IL-2 homeostasis by controlling CD25 expression. Activated HuR KO cells still expressed IL-2 (97%) on day 5 with large increases in both *IL-2* mRNA (30 fold) and protein (7 fold) but scant amounts of Th2 cytokines. We investigated other T cell lineages in HuR null T cells. Under Treg, Th17, and Tfh differentiation conditions, HuR KO T cells had reduced levels of transcription factors Foxp3, RoRyt, and Bcl6, as compared to controls. Thus, we conclude that HuR plays an indispensable role in normal IL-2 homeostasis and CD4⁺ T cell differentiation via influencing CD25 mRNA translation.

1074**Vitamin D modulates the expression of HLA-DR and CD38 after in vitro activation of T lymphocytes**

Aguilar-Jimenez, W., Villegas-Ospina, S., Gonzalez, S.M., Rugeles, M.T.

Grupo Inmunovirologia, Facultad de Medicina, Universidad de Antioquia UdeA, Medellin, Colombia

The steroid hormone Vitamin D (VitD) acts as an immunomodulatory molecule through specific responsive sequences on genes of the immune response. VitD modulates several cell populations towards an anti-inflammatory state while promoting pathogens clearance. Contrary to that anti-inflammatory effects, previous evidence show that VitD induces the activation marker CD38 under certain stimuli; in addition, the HLA-DR gene carries VitD responsive sequences in its promoter. However, the direct effect of VitD on the expression of these activation markers remains unclear. We studied the effects of its active form, calcitriol, at three concentrations (10⁻¹¹M, 10⁻⁹M and 10⁻⁷M), on the expression of these activation markers in PHA/IL-2-activated CD4⁺ and CD8⁺ T lymphocytes. When analyzed individually, a significant dose-dependent increase of CD38⁺ cells was seen in both CD4⁺ and CD8⁺ T cells and a decrease of HLA-DR⁺ cells within CD8⁺ T cells.

The coexpression of these markers showed a dose-dependent increase of CD38⁺HLA-DR⁻ and a decrease of CD38⁺HLA-DR⁺ subpopulations in both CD4⁺ and CD8⁺ cells, as well as decreases in the CD4⁺CD38⁺HLA-DR⁻ and CD8⁺CD38⁺HLA-DR⁺ subpopulations. Furthermore, calcitriol treatment significantly increased in a dose-dependent manner the number of CD38 molecules per cell within the CD38⁺HLA-DR⁺ and CD38⁺HLA-DR⁻ subpopulations of CD4⁺ and CD8⁺ T cells, as measured by their mean fluorescence intensity. Our results support the role of calcitriol as a modulator of the immune activation, by inducing CD38 while reducing HLA-DR on T lymphocytes. These results highlight the potential of the VitD as an alternative therapeutic strategy in pathogenic immune disturbances.

1075**RORgt and RORa signature genes in human Th17 cells**

Castro, G.¹, Liu, X.², Ngo, K.², De Leon, A.², Xue, X.², Zhao, S.², Fourie, A.², Fung-Leung, W.-P.³

¹Janssen Research and Development, LCC, San Diego, United States, ²Janssen R&D, Immunology, San Diego, United States,

³Janssen Research and Development LCC, San Diego, United States

Retinoid-related orphan nuclear receptor *gt* (RORgt) is a transcription factor involved in the differentiation of IL-17 producing, pro-inflammatory T helper 17 (Th17) cells. These cells have been implicated in the pathology of autoimmune diseases such as psoriasis, and novel therapeutics targeting IL-23 or IL-17A have shown benefit in reducing disease in psoriasis patients. RORgt is therefore a novel oral therapeutic target of interest for psoriasis treatment. The goal of our study was to identify a RORgt specific gene signature that could be used to develop biomarkers for studying RORgt modulators in clinical studies as well as to explore additional disease indications where RORgt modulation could be beneficial. We studied the global gene expression profile of human CD4⁺ T cells activated under Th17-skewing conditions and examined the effects of treatment with either specific siRNAs to knock down RORgt expression or antagonistic RORgt compounds. In addition to RORgt, RORa has been suggested to participate in Th17 cell differentiation and we therefore also included RORa specific siRNAs in our studies. Gene expression of human T cell samples at the mRNA level was profiled using Affymetrix DNA microarrays, RNA-sequencing, and quantitative RT-PCR. Cytokine production from Th17 cells was measured with Luminex multiplex assays. Our studies identified RORgt and RORa specific signature genes. These results support an important role for RORgt in Th17 cell differentiation and cytokine production and provide critical information to inform biomarker strategies for studying RORgt modulators in patients.

1076**CD155 (PVR/Necl5) mediates a costimulatory signal in CD4⁺ T cells and regulates allergic inflammation**

Yamashita-Kanemaru, Y.¹, Bernhardt, G.², Shibuya, A.¹, Shibuya, K.¹

¹University of Tsukuba, Tsukuba, Japan, ²Hannover Medical School, Hannover, Germany

Although Th1 and Th2 cells are known to be involved in allergic inflammatory diseases, the molecular mechanisms underlying their differentiation are incompletely understood. Here, we identified CD155 as a costimulatory molecule on CD4⁺ T cells. Importantly, CD155-mediated signaling induced Th1 development in both humans and mice, as evidenced by production of interferon- γ and upregulation of *Tbx21* transcription; these effects were independent of interleukin-12 but dependent on NF κ B-induced autocrine interferon- γ that triggered positive-feedback via STAT1 activation. Mice genetically deficient in CD155 or treated with anti-CD155 antibody exhibited attenuated Th1-type contact hypersensitivity. Thus, CD155 plays an important regulatory role in helper T-cell differentiation and allergic diseases.

Zika

Zika Virus Program at Butantan Institute

Kalil, J., Ho, P., Precioso, A. R.

Instituto Butantan

Zika vírus (ZIKV) has recently aroused global attention due to its rapid spread since its first detection in May 2015 in Brazil to 22 other countries and other territories in the Americas. ZIKV outbreak in Brazil, has also been associated with a significant increase in the number of notifications of newborn with microcephaly and neurological disorders, and has been declared a "Global Emergency" by the World Health Organization. Instituto Butantan in other to contribute to overcome the challenges posed of the explosive spread of ZIKV in Brazil has developed the following strategic programs: 1) Development of ZIKV vaccines and vaccination strategies: a) Pentavalent live attenuated vaccine (4 dengue serotypes+zika virus): Partnership between NIH and Butantan; b) Inactivated vaccine: Butantan R&D program; 2) Development of serum against ZIKV (horses immunization); 3) Development of ZIKV live attenuated vaccine: Butantan R&D program; 4) Diagnostic assays: Development of sensitive, specific, and rapid clinical diagnostic tests for ZIKV: Butantan R&D program;) Development of animal model to study ZIKV pathogenesis and evaluate candidate therapeutics and vaccines; 6) Development and manufacturing of neutralizing human anti-zika monoclonal antibodies. To aid Brazil in developing a vaccine to protect people from Zika virus infection, U.S. Department of Health and Human Services (HHS) is joining the World Health Organization (WHO) and international public health groups in providing funding and technical assistance to Butantan Institute to produce ZIKV inactivated vaccine. Biomedical Advanced Research and Development Authority (BARDA), part of the HHS Office of the Assistant Secretary for Preparedness and Response (ASPR), will work along with Butantan Institute providing not only financial support, through its existing cooperative agreement with the World Health Organization, but also technical assistance whenever it is required.

B Cells

Control of B-cell immunity and leukemia by the transcription factor Pax5

Busslinger, M., Smeenk, L., Malin S., Schindler, K.

Research Institute of Molecular Pathology (IMP), Vienna Biocenter, Vienna, Austria

B-cell commitment and development depend on the transcriptional factor Pax5. Conditional inactivation identified a critical role for Pax5 in maintaining B-cell identity and function in late B-lymphopoiesis. At the molecular level, Pax5 represses B-lineage-inappropriate genes and activates B-cell-specific genes. PAX5 is also a prominent tumor suppressor gene in B-cell acute lymphoblastic (B-ALL) leukemia, while chromosome translocations in a subset of leukemia patients generate novel PAX5 fusion proteins. By analyzing a PAX5-ETV6 mouse model, we could demonstrate that this fusion protein arrests early B-cell development, regulates genes implicated in pre-B cell receptor signaling and cooperates with loss of the Cdkn2a/b tumor suppressor in promoting B-ALL development. Hence, PAX5-ETV6 is a potent oncoprotein. By investigating the role of Pax5 in late B-lymphopoiesis, we could show that B-1, marginal zone, follicular (FO) and germinal center B-cells are rapidly lost upon Pax5 inactivation, whereas follicular (FO) B-cells tolerate the loss of Pax5 for some time. Pax5-deficient B-cells furthermore fail to generate plasma cells, indicating that all B-cell immune responses are lost in the absence of Pax5. Upon stimulation with anti-CD40 and IL-4, Pax5-deficient FO B-cells undergo normal proliferation, whereas they fail to proliferate in response to anti-IgM plus IL-4 stimulation. Unexpectedly, B-cell receptor signaling pathways from the cell surface to the nucleus are largely normal in the absence of Pax5. However, many immediate early genes are only minimally induced in Pax5-deficient

Instructive selection of germinal center B cells into the memory compartment

Kurosaki, T.

WPI Immunology Frontier Research Center, Osaka University

The germinal center (GC) B cells undergo one of two terminal fates; differentiation into memory B cells and plasma cells that provide protection against recurrent infection. The mechanism of how these memory B cells are selected and generated remains unclear. Here, we show that light zone GC B cells with lower affinity BCRs express relatively high Bach2 expression, being prone to enter memory B cell pool. Conversely, inhibition of Bach2 expression led to suppression of memory B cell generation. The levels of Bach2 in GC cells are inversely correlated with the strength of T cell help. Thus, we propose an instructive model in which weak T cell help maintains relatively high expression of Bach2, thereby predisposing GC cells to enter the memory pool.

Inflammation

Innate and adaptive IL-17-secreting T cells in autoimmunity

Mills, K.H.G., Edwards, S.C., McGinley, A.M., McGuinness, N.C., Raverdeau, M., Sutton, C.E.

School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute Trinity College

Cells of the adaptive immune system, especially IL-17-secreting CD4+ T cells (Th17 cells), are considered to be the key pathogenic lymphocytes in mediating inflammatory pathology in autoimmune diseases, such as multiple sclerosis, psoriasis and rheumatoid arthritis. However, there is increasing evidence that innate-like lymphocytes, including $\gamma\delta$ T cells, NK cells, NKT cells and innate lymphoid cells (ILC) play a key role in the pathogenesis of many autoimmune diseases. We have shown that IL-1 β and IL-18 produced by TLR- and NLR-activated dendritic cells and macrophages synergize with IL-23 to activate IL-17A, IL-17F, IL-21 and GM-CSF production by $\gamma\delta$ T cells without TCR engagement. We found that $\gamma\delta$ T cells are key IL-17-producing T cells in the CNS of mice with experimental autoimmune encephalomyelitis (EAE). We have also discovered a novel subset of V γ 4+ T cells that play a protective role in infection and are pathogenic in EAE by providing an early source of IL-17A and related cytokines. IL-17A is pathogenic in EAE, not the effector stage, but in promoting the induction of Th17 cells. Furthermore, early IFN- γ from NK cells plays a role in the induction phase of EAE by promoting M1 macrophage activation and VLA-4 expression on CD4+ T cells, thus conferring encephalitogenic activity on T cells. Rather than acting as effector cytokines, it appears that the primary function of IL-17A and IFN- γ produced by innate cells early in inflammatory responses is to promote the induction of pathogenic Th17 and Th1 cells.

Immunodeficiency

Dysregulated PI3K signaling causes primary immunodeficiencies

Durandy, A., Deau, M.C., Heurtier, L., Kracker, S.

INSERM U 1163, Institut Imagine, Université Sorbonne, Paris Cité, Paris, France

We herein show that hyperactivation of the PI3K signaling in lymphocytes causes an autosomal dominant primary immunodeficiency, affecting mostly, but not only, antibody production. Gain-of-function mutations in PIK3CD, the gene encoding the catalytic subunit of PI3K δ , p110 δ , lead to activated PI3 kinase delta syndrome (APDS1) whereas heterozygous mutations in PIK3R1, the gene encoding the regulatory subunit p85a, although they do not impair either p110 δ -p85a interaction or p110 δ stability, are responsible for a similar phenotype (APDS2). Both syndromes have a very variable clinical and immunological expression, from subtle defect in immunoglobulin subclass through common variable immunodeficiency- or hyper-IgM-like syndromes to combined immunodeficiency. Respiratory infections leading in some cases to bronchiectasis are the main feature of the disease.

Massive lymphoproliferation in spleen or lymph nodes, autoimmunity and development of B cell lymphomas are frequent complications. Extra-immunological features (short stature, neurodevelopmental delay) can also be observed. The immune deficiency is mainly characterized by decreased levels of IgG and IgA, B lymphopenia (with decreased numbers of switched B cells and expansion of transitional B cells), defective naïve T CD4 and CD8 T cells' counts with expansion of effector memory CD8 T and senescent CD57 T cells. Hematopoietic stem cell transplantation, shown to be successful in a few cases, is a therapeutical option in severe forms. Immunosuppressive treatment using rapamycin, an inhibitor of the mTOR pathway, is largely used with efficacy in patients presenting with lymphoproliferation. Administration of specific p110 δ inhibitors could be a possible first choice treatment in a near future.

Intrinsic functional defects in human lymphocytes: insights into disease pathogenesis of primary immunodeficiencies

Tangye, S.

Garvan Institute of Medical Research

Intracellular signaling pathways induced by interactions between surface receptors and their cognate ligands facilitate the generation of successful immune responses. This underlies the efficient neutralization and clearance of pathogens, and the establishment of long-lived immunological memory. The corollary of this is that perturbations to signaling pathways compromise the differentiation and effector function of immune cells, underlying the clinical features of, and disease pathogenesis in, primary immunodeficiencies.

We have been studying lymphocyte development, differentiation and effector function in individuals with monogenic mutations resulting in the loss- or gain-of of function of the encoded protein. These genetic lesions render affected individuals susceptible to infection with specific pathogens, as well as impaired long-term humoral immunity. This has provided an opportunity to ascribe non-redundant and lineage-specific functions of defined genes, and to identify defects in lymphocyte biology caused by specific disease-causing mutations. Our studies reveal the value of examining "Experiments of Nature" to not only delineate signaling pathways required for human lymphocyte differentiation and effector function and to understand disease etiology in primary immunodeficiencies, but more importantly provide a framework to identify molecules and signaling pathways that could be targeted for intervention to improve immune function in affected individuals.

HBV inhibits LPS-induced NLRP3 inflammasome activation and IL-1 β production

Yu, X.¹, Han, Q.¹, Zhang, J.¹, Tian, Z.², Zhang, C.¹

¹*Institute of Immunopharmacology & Immunotherapy, School of Pharmaceutical Sciences, Shandong University, Jinan, China,*

²*Institute of Immunology, School of Life Sciences, University of Science and Technology of China, Hefei, China*

Hepatitis B virus (HBV) constitutes a global public health problem involving chronic infection of the liver, which can cause liver disease and is linked with liver cancer. Although HBV has developed multifaceted strategies to evade the surveillance of immune responses, the precise mechanisms involved remain unclear. In the current study, by utilizing an HBV-persistent mouse model, it was demonstrated that Kupffer cells expressed a considerable amount of NLRP3 and IL-1 β after LPS stimulation; whereas, chronic HBV infection not only suppressed LPS-induced NLRP3 and pro-IL-1 β expression, but also repressed caspase-1 activation and IL-1 β maturation. Furthermore, by utilizing differentiated THP-1 cells, it was found that inhibitory activity is mediated by HBeAg, but not by HBsAg, and is involved in NF- κ B signal pathway inhibition. Additionally, the inhibitory effect of HBeAg was confirmed in patients with chronic hepatitis B and hepatocellular carcinoma by comparing the levels of IL-1 β and NLRP3-related proteins in para-carcinoma tissues from HBeAg-positive or negative patients. Moreover, chronic HBV infection increases the susceptibility of mice to *S. typhimurium* infection, possibly via inhibiting the activation of NLRP3 inflammasome and the production of IL-1 β . The present study provides a novel mechanism of HBV-mediated suppression of innate immune responses and identifies new therapeutic targets for chronic HBV infection and related diseases.

The inflammatory response that follows vaccination has an important role in immunity. However, the mechanism by which it influences the adaptive response is not fully understood. In this work we characterised the role of lymph node (LN) subcapsular sinus macrophages (SSM) as inducers of the inflammatory mechanism that is triggered following vaccination with inactivated influenza virus. We found that, in response to vaccination, SSM undergo inflammasome-independent necrosis-like death that is reliant on MyD88 expression. Activated SSM produced IFN- β that induced the secretion of IL-1a by LN-resident dendritic cells (LNDC). We found that IL-1a activates DC and induces the expression of IL-6, which in turn promotes the expression of the secreted form of IL-1R antagonist that limits the duration and intensity of the effect of IL-1a. Importantly, macrophage depletion affected the capacity of LNDC to capture virus and limited their ability to present antigen to CD4+ T cells. We also observed that upon SSM death, germinal centre DC migrated to the subcapsular sinus, in a mechanism that involved the upregulation of the CCR2 receptor in this cells and the secretion of MCP-1.

Tissue-resident macrophages are found in all organs of the body where they are adapted to perform numerous functions required for tissue homeostasis. Contrary to most immune cells, they develop prenatally from embryonic progenitors, have self-renewal mechanisms and exist, at least in most tissues, independently of adult hematopoietic stem cells (HSCs). These insights have undermined the concept of the mononuclear phagocyte system, where the circulating monocyte was seen as the central progenitor of all tissue macrophages. Importantly, despite their common origin, tissue-resident macrophages are highly specialised to the tissue of residence. However, macrophages that develop from adult HSCs after irradiation neither display the full gene signature of their embryonic counterparts. Here, using a new model of selective diphtheria toxin-mediated depletion of Clec4F-positive liver-resident Kupffer cells, we found that short-lived circulating adult monocytes engrafted in the adult liver following both full and partial depletion of embryonically-derived Kupffer cells. These monocytes differentiated into bona fide self-renewing Kupffer cells, which adopted the full transcriptional profile of the depleted tissue-resident Kupffer cells, as well as

their morphological and functional features. Highlighting the physiological relevance of our findings we found that, contrary to recent studies, bone marrow-derived monocytes engrafted in the liver and spleen during the period of normal organ growth in the first weeks of life. Thus in conclusion, we find that nurture by the tissue, rather than nature of the progenitor, is the principal factor controlling macrophage life-span and organ-specific functions. This concept paves the way for monocyte-based cellular therapy.

Helminth parasites trigger polarized Th2-type immune responses in their hosts. These worms have been recently used to ameliorate ongoing inflammatory conditions. Although the anti-inflammatory mechanism is poorly understood, a role for alternatively activated macrophages (AAMφs) has been suggested. We previously demonstrated that the helminth *Taenia crassiceps* induces a population of AAMφs in mice. Here, we aimed to define the origin of these AAMφs and their potential role in modulating experimental autoimmune encephalomyelitis (EAE). We first established the phenotypic profile of AAMφs from C57BL/6 and CX3CR1^{EGFP/+} mice infected with *T. crassiceps*. To determine the origin of these AAMφs, we transferred Ly6C⁺ monocytes from a CX3CR1^{EGFP+/-}/CD45.1 mice into a C57BL/6/CD45.2 mice infected with *T. crassiceps*, and determined their differentiation into AAMφs. To assess the role AAMφs in modulating autoimmune diseases, we transferred AAMφs into EAE induced C57BL/6 mice and monitored clinical scores. Our results showed two populations of AAMφs after *T. crassiceps* infection, PDL1⁺ PDL2⁻ cells that did not express chemokine receptors CX3CR1 or CCR2 and PDL1⁺ PDL2⁺ cells that expressed both CCR2 and CX3CR1 receptors. These data suggested that whereas AAMφs PDL1⁺ PDL2⁻ may originate from resident macrophages, AAMφs PDL1⁺ PDL2⁺ subpopulation originated from blood-derived monocytes. This later hypothesis was confirmed by adoptively transferring of Ly6C⁺ monocytes, which gave rise only to AAMφs PDL1⁺ PDL2⁺ in *T. crassiceps* infected mice. Strikingly, adoptive transfer of AAMφs PDL1⁺ PDL2⁺ into EAE induced mice, completely prevented the clinical signs of disease, indicating these cells play a critical role in the regulation of autoimmune disorders.

Tissue-resident macrophages as a front line of defense in *Plasmodium* infection

Gupta, P., Lai, S.M., Ruedl, C.

Nanyang Technological University (NTU), School of Biological Sciences, Singapore, Singapore

Tissue-resident macrophages exhibit diverse functions, ranging from the maintenance of tissue homeostasis, including clearance of senescent erythrocytes and cell debris, to modulation of inflammation and immunity. However, their contribution to the control of blood-stage malaria infection is unclear. Here, we show that tissue-resident macrophages regulate the outcome of *Plasmodium berghei* ANKA (PbA) infection by restraining the parasite burden and dramatically decreasing malarial-related pathology and morbidity. In the absence of tissue-resident macrophages, PbA infection results in significantly increased parasite sequestration leading to vascular occlusion, leakage and augmented tissue deposition of the malarial pigment hemozoin. This leads to widespread tissue damage, including in the lung, liver, heart, kidney and brain, culminating in multiple organ inflammation and failure. Thus, the capacity of tissue-resident macrophages to contain the parasite burden and its sequestration into different tissues is crucial to their role in mitigating malaria infection and pathogenesis.

This work was supported by National Medical Research Council grant NMRC.1307.2011 to C.R.

A tissue-resident macrophage specific coinhibitory molecule promotes regulatory T cell differentiation and stability

Fu, W., Yuan, X., Dong, Y., Yang, B.-H., Sanogo, F.

University of California San Diego, La Jolla, United States

CD4⁺ Foxp3⁺ regulatory T (Treg) cells are key players in immune tolerance and tissue homeostasis. Their impact on tissue homeostasis has been further reinforced by recent studies showing that Tregs in tissue control non-immunological processes. However, how Treg cell differentiation and function are influenced by tissue-derived signals remain poorly understood. We here show that a specific subset of tissue-resident macrophages can promote the differentiation and stability of Tregs. This subset of tissue-resident macrophages distinctively express complement receptor of the immunoglobulin superfamily (CRIg). The phenotype of these macrophages are F4/80^{hi} CRIg⁺. We find that in addition to dampening effector T cell proliferation, CRIg promotes the conversion of induced Treg cells, by synergizing with TGFβ signaling. CRIg also stabilizes Foxp3 expression in induced Tregs. In vivo CRIg-Ig fusion protein treatment increases Treg proportion, particularly in tissue (islets) of NOD mice, a commonly used animal model for autoimmune diabetes. Together, these data reveal a novel mechanism of shaping Treg pool and function by tissue-resident macrophages. CRIg may represent a novel means to generate 'stable' iTregs, which remains unmet need in Treg-based therapy.

Hypoxia reprograms human macrophages towards a proinflammatory direction*Raggi, F.¹, Pelassa, S.¹, Pierobon, D.², Giovarelli, M.², Cangelosi, D.¹, Varesio, L.¹, Bosco, M.C.¹**¹G.Gaslini Institute, Laboratory of Molecular Biology, Genova, Italy, ²Cerms, AUO Città della Scienza, Department of Molecular Biotechnology and Health Sciences, Torino, Italy*

Mononuclear phagocytes are recruited from the circulation as primary monocytes to sites of infection, inflammation, and tumor growth, where they undergo terminal differentiation into macrophages. Macrophages can be polarized into classically activated macrophages (M1) or alternatively activated macrophages (M2) which are characterized by a proinflammatory or an anti-inflammatory phenotype, respectively. M1 and M2 polarization is regulated by microenvironment factors. A common feature of pathologic situations is represented by hypoxia. Little is known about the impact of hypoxia on M1/M2 polarization. To address this issue, M1 (CD80⁺) and M2 (CD206⁺) macrophages were generated by culturing human monocytes with LPS or IL4 for 24h under normoxia (20%O₂) or hypoxia (1%O₂). We present data showing that hypoxia amplifies the proinflammatory state of M1 macrophages and reprograms M2 macrophages towards a proinflammatory direction by increasing the production of inflammatory and proangiogenic M1 type cytokines/chemokines. The hypoxic pathologic microenvironment can finely tune the expression of immunoregulatory signaling (IRS) receptors, whose deregulated expression may result in amplification of inflammation or establishment of immune escape situations. We demonstrate that hypoxia strongly upregulates the expression of one of such receptors, TREM-1, in both M1 and M2 macrophages. Engagement of TREM-1 by agonist Ab triggers further production of M1-type cytokines/chemokines in both macrophage populations. These results suggest the role of the hypoxic environment present at pathologic sites in skewing macrophages towards a M1-like proinflammatory phenotype by inducing TREM-1, highlighting the potential of targeting TREM-1 as a strategy to counteract inflammation in inflammatory disorders and in tumors.

Elucidating the molecular mechanism of apoptotic cell disassembly for drug targeting*Atkin-Smith, G., Tixeira, R., Jiang, L., Paone, S., Caruso, S., Poon, I. La Trobe University, Biochemistry and Genetics, Melbourne, Australia*

Apoptosis (programmed cell death) occurs in essentially all tissues as part of development, homeostasis, and pathogenic processes including infection and cardiovascular disorders. Apoptotic cells often disassemble into smaller membrane-bound particles called apoptotic bodies (a process known as apoptotic cell disassembly). Under normal physiological conditions, the generation of apoptotic bodies during apoptosis can facilitate efficient removal of apoptotic cells by phagocytes, to prevent intracellular factors leaking from dying cells and

promoting unwanted inflammation. However, under certain pathological conditions, cellular materials such as cytokines, cell surface molecules and microRNA can be packaged into apoptotic bodies as a mechanism to regulate immunity and tissue repair. Since billions of cells undergo apoptosis daily, the importance of apoptotic cell disassembly and clearance for health and disease is fundamental, yet the mechanisms involved in the formation of apoptotic bodies are poorly understood. These mechanisms also represent attractive targets for the development of novel therapeutics. Here, we describe two new mechanisms of cell disassembly by apoptotic T lymphocytes and monocytes via the formation of a novel membrane protrusion called apoptopodia. Mechanistically, we have identified ROCK1 kinase and pannexin 1 membrane channels as key regulators of apoptotic cell disassembly. Additionally, we have identified a novel selection of drugs that can modulate apoptotic body formation. Understanding the mechanistic basis of this process will generate fundamental knowledge of the downstream consequence of cell death and has significant implication in health and diseases.

712

M3 switch macrophage phenotype: implication in the cancer immunotherapy*Malyshev, I., Lyamina, S., Kalish, S.**Moscow State University of Medicine and Dentistry, Pathophysiology, Moscow, Russian Federation*

The presentation will describe key phenomena of macrophage reprogramming, analyze signalling mechanisms of reprogramming and give an idea of the specific features of these mechanisms, which provides a fundamental characteristic of macrophages and immune response in general - plasticity. Macrophages play the key role in carcinogenesis. Depending on the microenvironment macrophages acquire or, in other words, reprogram themselves into either a pro-inflammatory, antitumor M1 phenotype or an anti-inflammatory, protumor M2 phenotype. Many tumors produce anti-inflammatory cytokines, which reprogram the antitumor M1 phenotype into the protumor M2 phenotype. We have hypothesized that the problem of protumor macrophage reprogramming could be solved using a special M3 switch phenotype. The M3 switch phenotype, in contrast to the M1 phenotype, should respond to anti-inflammatory cytokines by increasing production of proinflammatory cytokines to retain thereby its antitumor properties. The aim of the study was to verify this hypothesis.

Results:

1. Activation of M1 reprogramming pathways and inhibition of M2 reprogramming pathways programs the M3 phenotype of macrophages,
2. M3 macrophages exerted an effective anti-tumor effect *in vitro* and *in vivo* and
3. The antitumor effect of M3 macrophages was due to an anti-proliferative rather than a cytotoxic effect, and accompanied by pro-inflammatory reprogramming of tumor microenvironment.

Conclusion: Development of new biotechnologies for restriction of tumor growth using in vitro reprogrammed M3 switch macrophages is very promising.

Unprimed, M1 and M2 macrophages differentially interact with *Porphyromonas gingivalis*

Lam, R., O'Brien-Simpson, N., Holden, J., Lenzo, J., Fong, S.B., Reynolds, E.

The University of Melbourne, Oral Health CRC, Carlton, Australia

Tissue macrophages are likely to be one of the first immune cells to encounter to *Porphyromonas gingivalis*, a major pathogen associated with chronic periodontitis in humans. Naïve macrophages (M0) differentiate into a classical inflammatory (antibacterial) M1 macrophage upon IFN- γ priming and TLR ligation or anti-inflammatory (tissue-repair) M2 macrophage upon IL-4 priming. Previous work has shown that *P. gingivalis* infection induced M1 macrophages phenotype. The aims of this study were to determine the ability of M0, M1 and M2 macrophages (different subsets) to phagocytose *P. gingivalis* and investigate how this interaction affects both the bacterial cell and the macrophage. M1 and M2 macrophages were found to have enhanced phagocytic capacity compared to unprimed (M0) macrophages, however only the M0 and M1 macrophages were able to produce a respiratory burst in phagosome to clear the bacteria. *P. gingivalis* was found to persist in M2 macrophages for 24 hours, however not at the same levels of persistence as *S. Typhimurium*, a bacterium well known for survival inside macrophages. Phagocytosis of *P. gingivalis* also induced high levels of TNF- α and IL-27 in M1 macrophages, but not in M0 or M2 macrophages. Furthermore, infection of macrophages with *P. gingivalis* at high bacteria to cell ratios, while inducing an inflammatory response, was also found to be deleterious to macrophage longevity, with high levels of apoptotic death found in macrophages after infection. The activation of M1 macrophages observed in this study would contribute to the initiation and maintenance of a pro-inflammatory state during chronic periodontitis.

Therapeutic potential anti-CD137 mAbs in multiple myeloma

Guillerey, C.^{1,2}, de Andrade, L.F.^{1,3}, Miles, K.¹, Vuckovic, S.⁴, Chesi, M.⁵, Bergsagel, L.P.⁵, Geoffrey R., H.⁴, Martinet, L.^{1,6}, Smyth, M.J.^{1,2}

¹QIMR Berghofer, Immunology in Cancer and Infection Lab, Herston, Australia, ²The University of Queensland, School of Medicine, Herston, Australia, ³Dana-Farber Cancer Institute, Department of Cancer Immunology and AIDS, Boston, United States, ⁴QIMR Berghofer, Bone Marrow Transplantation Lab, Herston, Australia, ⁵Mayo Clinic, Comprehensive Cancer Center, Scottsdale, United States, ⁶Cancer Research Center of Toulouse, INSERM UMR 1037, Toulouse, France

Multiple myeloma (MM) is a blood cancer that arises in the bone

marrow from malignant plasma cells. MM remains an incurable disease responsible for approximately 80 000 deaths per year worldwide. CD137 is a costimulatory molecule expressed on activated T cells and NK cells. Here, we report that early treatment with agonist monoclonal antibodies (mAbs) against CD137 (Rat IgG2a, clone 3H3) significantly reduces tumour burden and improves survival in the V κ^* myc mouse model of MM. We demonstrated that anti-CD137 mAb therapeutic activity requires the presence of both CD8 T cells and NK cells but is independent of Fc receptors. We found that anti-CD137 mAb treatment loses efficacy when given more than 3 weeks after V κ^* MYC cell injection. The depletion of CD4 cells or Foxp3⁺ Tregs restored the efficacy of late anti-CD137 mAb treatment, indicating that Treg-mediated suppression is a major hindrance. In line with these data, a single injection of anti-CD137 mAbs stimulated Treg proliferation and led to a rapid increase in spleen Treg numbers. Interestingly, we observed higher levels of TNF and IFN- γ and lower levels of IL-10 in the serum of responders compared with non-responders to late anti-CD137 mAb treatment. Finally, we established that, when combined with the chemotherapeutic bortezomib, anti-CD137 mAbs achieve high efficacy against late MM without adverse event. Collectively, our data emphasize the therapeutic benefit of anti-CD137 mAbs and suggest that low doses of anti-CD137 mAbs combined with chemotherapy could allow efficient anti-tumour responses at late MM stages with limited toxicity.

Growth regulation of chronic lymphocytic leukemia by IL-10 produced constitutively by leukemic cells

Bondada, S.¹, McKenna, M.K.¹, Rangnekar, V.R.^{1,2}, Byrd, J.C.³, Muthusamy, N.⁴, Alhakeem, S.S.¹

¹University of Kentucky, Microbiology, Immunology, and Molecular Genetics and Markey Cancer Center, Lexington, United States, ²University of Kentucky, Radiation Medicine, Lexington, United States, ³Ohio State University, Internal Medicine and Comprehensive Cancer Center, Columbus, United States, ⁴Ohio State University, Internal Medicine and Comprehensive Cancer Center, Lexington, United States

B-cell chronic lymphocytic leukemia (B-CLL) is characterized by a slow and progressive accumulation of abnormal lymphocytes in blood, bone marrow and secondary lymphoid organs. There is evidence for immunosuppression in CLL. We studied the basis of this immunoregulation using the transgenic E μ -Tcl1 mouse, which spontaneously develop B-CLL due to a B-cell specific expression of the oncogene, Tcl1. We showed that E μ -Tcl1 CLL cells constitutively produce IL-10, an anti-inflammatory cytokine. Here we studied the role of IL-10 in CLL cell survival *in vitro* and the development of CLL *in vivo*. Neutralization of IL-10 using anti-IL-10 antibodies or blocking the IL-10 receptor (IL-10R) using anti-IL-10R antibodies did not affect the survival of CLL cells *in vitro*. Adoptively transferred E μ -Tcl1 cells grew at a slower rate in IL-10R KO mice vs. wild type (WT) mice. There was a significant reduction in CLL cell engraftment in the spleen, bone marrow, peritoneal cavity and liver of the IL-10R KO compared to WT mice. IL-10 appeared to be playing a role in the tumor microenvironment possibly by affecting anti-tumor immunity.

There was a reduction in the activation of CD8⁺ T cells as well as a significantly lower production of IFN- γ by CD4⁺ T cells purified from WT mice compared to the IL-10R KO mice injected with CLL. Currently, we are testing if neutralization of IL-10 with monoclonal anti-IL-10 antibody in WT mice will have similar enhancement of anti-leukemic effects. These studies support the concept that CLL cells suppress host anti-tumour immunity via IL-10 production.

Tumour-infiltrating T cells leave tumours to provide effector functions in draining lymph nodes

Torcellan, T.^{1,2}, Hampton, H.R.^{1,2}, Bailey, J.¹, Tomura, M.³, Brink, R.^{1,2}, Chtanova, T.^{1,2}

¹Garvan Institute of Medical Research, Department of Immunology, Sydney, Australia, ²St. Vincent's Clinical School, UNSW Australia, Sydney, Australia, ³Osaka Ohtani University, Laboratory of Immunology, Faculty of Pharmacy, Osaka, Japan

Tumour-infiltrating T cells are a key component of the tumour microenvironment and their presence within the tumour can dramatically alter anti-tumour responses. While CD8⁺ T cells can have an anti-tumour role and destroy tumour cells, regulatory T cells (Treg cells) play a pro-tumour role and promote tumour growth by impairing anti-tumour immunity. Despite their impact on tumour growth, the fate of tumour-infiltrating cells is largely unknown. We hypothesise that tumour-infiltrating cells leave primary tumour deposits and play a key role in tumour immunity in draining lymph nodes.

Using Kaede photoconvertible mice we developed a method to label and track tumour-infiltrating cells and showed that these cells leave primary tumours and accumulate in draining lymph nodes. Flow cytometric analysis revealed that over 60% of tumour-egressing cells in draining lymph nodes are T cells, of which 80% are antigen experienced. While Treg cells represented a minor fraction of the migratory population, $\gamma\delta$ T cell subsets were enriched substantially. Compared to total lymph node T cells, tumour-egressing T cells showed enhanced effector functions: $\gamma\delta$ T cells showed increased IL17A⁺ and decreased IFN- γ ⁺ proportions, whereas CD8⁺ T cells had enriched IFN- γ ⁺ proportions and expressed increased cytotoxicity marker CD107a. Finally, tumour-conditioned T cell migration to draining lymph nodes involved G protein-coupled receptors but was not dependent on CCR7 or CD62L alone.

In summary, we demonstrate for the first time that tumour-infiltrating T cells leave tumour sites and migrate to the draining lymph node to perform effector functions that may modulate anti-tumour immune responses.

D133p53 isoform - a novel adjuvant for tumour vaccination

Braithwaite, A., Slatter, T., Wilson, M., Baird, M.
University of Otago, Dunedin, New Zealand

p53 is widely known as a tumour suppressor that responds to DNA damage by causing cell cycle arrest and repair, senescence or apoptosis. However, recent data from our lab has shown

that p53 is required to generate a protective response against B16 melanoma using a prophylactic vaccine model¹. Bone marrow derived APCs from p53 null mice pulsed with tumour antigen (BMAPC/tumour Ag) fail to generate in vivo cytotoxicity and prevent tumour growth, due to a lack of IL-12 expression. These data suggest that p53 plays an important role in tumour suppression by regulating the production of key cytokines. The p53 gene also encodes a number of transcriptional variants (isoforms) due to alternate promoter usage and splicing. We created a transgenic mouse model of human D133p53 isoform, designated D122p53². These mice express constitutively high levels of pro-inflammatory cytokines and upregulate the NF κ B pathway in response to pathogens³. BMAPC from these mice have a pro-inflammatory phenotype so we investigated the protective effect of a D122p53 BMAPC/tumour Ag prophylactic vaccine against melanoma. Consistent with the constitutive elevation of cytokines, we found that this vaccine not only provoked an antigen-specific anti-tumour immune response, but also induced a marked degree of non-specific protection. These results suggest that augmentation of antigen presentation using pro-inflammatory D133p53 BMAPC might be a useful adjuvant in anti-cancer vaccines.

Langerhans cell histiocytosis (LCH) is an inflammatory neoplasm that damages tissues by accumulating death-resistant dendritic cells (DCs) and giant cells. Death resistance of lesional DCs is both controlled by BRAFV600E mutation and the microenvironment. Monocyte-derived DCs (Mo-DCs) are one possible source for pathological DCs. Because we have previously demonstrated that IL-17A induces survival and fusion of Mo-DCs, we investigated whether inhibiting IL-17A may represent a new

strategy to optimize chemotherapy in LCH.

Using ELISA, significant higher levels of plasma IL-17A were detected in young patients with LCH compared to healthy donors. Plasma from LCH patients with sequelae contained higher IL-17A levels than plasma from LCH patients without sequelae, suggesting that IL-17A may be pathogenic. In Mo-DCs from LCH patients, we observed abnormal and correlated intracellular expressions of IL-17A and BCL2A1, a pro-survival BCL2 family member. Both proteins correlated to DC survival, while MCL1, the myeloid pro-survival BCL2 member, did not. *In vivo*, BCL2A1 expression was highly detected by immunohistofluorescence in CD1a-positive pathogenic DCs and giant cells of LCH granulomas. Neutralizing IL-17A impaired both BCL2A1 expression and survival in Mo-DCs from LCH patients. Vinblastine is the main cytotoxic compound of the current front-line standard of care of LCH. Vinblastine had no effect on IL-17A and BCL2A1 expression, while it can decrease MCL1 and depolymerize microtubules in Mo-DCs, depending on doses. Vinblastine synergized with IL-17A neutralization to kill Mo-DCs from LCH patients. These results strongly suggest that targeting IL-17A may represent an interesting strategy to improve efficiency of chemotherapy in LCH.

Cancer immunotherapy: translation from mice to human clinical trials

Berzofsky, J.A., Terabe, M., Wood, L.V.

National Cancer Institute, National Institutes of Health, Vaccine Branch, Bethesda, United States

We have developed cancer immunotherapeutic vaccines dependent on either CD8⁺ T cells or antibodies, and translated these from mice to human clinical trials with promising early results. We modified epitopes of the TARP prostate cancer antigen to increase binding to HLA-A2, and elicited human T cells that killed human tumor cells. These peptides were tested in stage D0 prostate cancer patients, whose tumors have been removed but have rising PSA indicative of recurrence. Minimal disease is an ideal setting for cancer vaccine efficacy, but usually not amenable to measuring tumor regression. In D0 prostate cancer, the rate of change of PSA is a validated predictor of clinical outcome. Of 29 patients immunized with TARP peptides assessable at 48 weeks, 74% had a reduced PSA slope compared with their pretreatment slope ($p = 0.0004$). Based on this unexpectedly strong effect, we have opened a randomized placebo-controlled phase II trial that will be discussed. We also developed an adenovirus vaccine expressing HER2 extracellular/ transmembrane domains, which cured large 2-cm established mammary tumors and lung metastases in mice, dependent on antibodies that inhibited HER2 phosphorylation, not FcR binding like trastuzumab. This vaccine is being tested in a clinical trial in patients with various advanced metastatic cancers expressing HER2. A high frequency of objective responses have been seen in the second and third dose levels. Thus, mouse immunotherapeutic cancer vaccines dependent on either T cells or antibodies can be successfully translated to human cancer patients with promising clinical results.

Melanoma cell lysosome secretory burst neutralises the CTL-mediated cytotoxicity at the lytic synapse

Khazen, R.¹, Müller, S.¹, Gaudenzio, N.^{1,2}, Espinosa, E.¹, Puissegur, M.-P.¹, Valitutti, S.^{1,3}

¹Inserm, U 1043, Toulouse, France, ²Stanford University School of Medicine, Department of Pathology, Stanford, United States, ³Institut Universitaire du Cancer-Oncopole de Toulouse, Department of Pathology, Toulouse, France

Human melanoma cells express various tumor antigens that are recognized by CD8⁺ cytotoxic

T lymphocytes (CTL) and elicit tumor-specific responses *in vivo*. However, natural and therapeutically enhanced CTL responses in melanoma patients are of limited efficacy. The mechanisms underlying CTL effector phase failure when facing melanomas are still largely elusive.

Here we show that, upon conjugation with CTL, human melanoma cells undergo an active late endosome/lysosome trafficking, which is intensified at the lytic synapse and is paralleled by cathepsin-mediated perforin degradation and deficient granzyme B penetration. Abortion of SNAP-23-dependent lysosomal trafficking, pH perturbation or impairment of lysosomal proteolytic activity restores susceptibility to CTL attack.

Inside the arsenal of melanoma cell strategies to escape immune surveillance, we disclose a self-defense mechanism based on exacerbated lysosome secretion and perforin degradation at the lytic synapse. Interfering with this synaptic self-defense mechanism might be instrumental to potentiate CTL-mediated therapies in melanoma patients.

Predicted neoantigens serve as attractive targets for tumor infiltrating lymphocytes in pediatric leukemias

Zamora, A.¹, Dash, P.¹, Abdelsamed, H.¹, Dallas, M.², Geiger, T.³, Carter, R.⁴, Youngblood, B.¹, Thomas, P.¹

¹St. Jude Children's Research Hospital, Immunology, Memphis, United States, ²St. Jude Children's Research Hospital, Bone Marrow Transplantation and Cellular Therapy, Memphis, United States, ³St. Jude Children's Research Hospital, Pathology, Memphis, United States, ⁴St. Jude Children's Research Hospital, Computational Biology and Bioinformatics, Memphis, United States

The use of tumor-reactive T lymphocytes as a means of adoptive immunotherapy has emerged as a promising therapeutic against various cancers. Currently, several approaches towards achieving tumor specificity are beginning to bear fruit, including the use of: tumor infiltrating lymphocytes, chimeric antigen receptor and T cell receptor engineered T cells. In this study, we aimed to determine the clonality, differentiation status, and phenotype of tumor infiltrating lymphocytes from pediatric patients with acute lymphoid leukemia (ALL) and acute myeloid leukemia (AML). Additionally, we generated a list of predicted neoantigens and determined the HLA-binding potential of each of these neoantigens using computational algorithms. We next determined the tumor-associated T cell receptor repertoire with single cell resolution, allowing us to determine the structure of

tumor-associated TCR repertoires and their propensity to target neoantigen. Finally, we tested which predicted neoantigens elicited the best T cell responses measured by TCR activation. Our results expand on studies aiming to better characterize the phenotypic and developmental changes that enhance the efficacy of adoptive T cell therapies and provide a platform for designing therapeutic interventions, including engineered T cells, against identified neoepitopes, which serve as attractive anti-tumor targets.

⁵Nantes Hospital, Nantes, France

Therapeutic strategies using anti-PD-1 antibody reported unparalleled effectiveness for cancer immunotherapy. Understanding mechanisms involved in clinical benefit remains crucial to improve patients' management.

Despite its negative role in anti-tumor immunity, PD-1 first identifies reactive tumor-specific T-cells. We previously demonstrated that PD-1^{pos} melanoma specific T-cell clones exhibited a better functional avidity than their PD-1^{neg} counterpart. We further documented *in vitro* that PD-1 blockade during the selection and amplification process of melanoma specific T-cells from patients' PBMC, resulted in the proliferation of specific T-cells with a biased TCRVbeta repertoire exhibiting a better functional avidity (*Simon et al., Oncoimmunol, 2016*).

We assumed that this bias in antigen specific T-cell repertoire also occurs *in vivo* for patients treated with anti-PD-1 antibody. We compared Melan-A specific T-cell repertoire diversity from melanoma patients before and after anti-PD-1 therapy. We documented, for all patients tested, a bias in Melan-A-specific T-cell repertoire after treatment with the preferential amplification of clonotypes highly expressing PD-1. We characterized the most represented Vb subtypes (reactivity against melanoma cell lines and functional avidity) and analyzed results according to the expression of additional inhibitory receptors to allow discriminating between highly reactive and exhausted T-cells.

We are currently correlating experimental results with clinical outcomes of treated-patients to identify new biomarkers associated with anti-PD-1 therapy efficiency.

In addition to the emergence of neo-antigen specific T-cells previously documented upon anti-PD-1 therapy, our work describes qualitative and quantitative changes within an antigen-specific T-cell repertoire and offers new prospects for the monitoring of patients upon anti-PD-1 therapy.

A thymus-sparing conditioning regime for tolerance induction in aged recipients

Anticevic, C.¹, Morison, J.¹, Hammett, M.¹, Lister, N.¹, Homann, J.¹, Barbuto, J.¹, Boyd, R.¹, Heng, T.^{1,2}

¹Monash University, Department of Anatomy and Developmental Biology, Melbourne, Australia, ²Monash Biomedicine Discovery Institute, Infection and Immunity Program, Melbourne, Australia

Allograft tolerance induction avoids the need for long-term dependence on immunosuppressive drugs. A promising approach being explored clinically is mixed chimerism via graft-matched haematopoietic stem cell (HSC) transplantation. Aged recipients, however, exhibit reduced engraftment of transplanted HSCs, which is further compounded by poor T cell recovery due to age-related thymic atrophy. We therefore investigated minimal conditioning regimes that would mitigate the damage to the thymus and allow for long-term allogeneic tolerance in aged mice. In contrast to low-dose irradiation or cyclophosphamide, busulfan caused only minimal damage to the thymus and facilitated highly efficient engraftment of donor HSCs for durable mixed chimerism. Chimeric mice were tolerant to full MHC-mismatched donor skin grafts and rejected third-party grafts, indicating immune tolerance and competence. Surprisingly, thymectomy did not prevent the establishment of mixed chimerism and tolerance in this model. Instead, tolerance induction was associated with an expansion in Gr-1⁺CD11b⁺ myeloid-derived suppressor cells and Foxp3⁺ regulatory T cells; depletion of the latter affected donor graft integrity. Thus, our conditioning protocol operates via peripheral regulation and donor-specific tolerance could be induced despite thymic atrophy and immunosenescence. Whilst busulfan-based conditioning was less effective in aged mice compared to young, we established a transplantation threshold for donor HSC dose and further determined that host HSC mobilisation could increase the sensitivity of aged HSCs to busulfan treatment. Our findings are especially relevant for the clinical application of chimerism-based transplantation tolerance in older patients, which the majority of transplant recipients.

Metabolic and epigenetic mechanisms of age-related functional defects in naïve CD8 T cells

Quinn, K.M.^{1,2}, Russ, B.E.^{1,2}, Dagley, M.^{3,4}, Olshansky, M.^{1,2}, Saunders, E.^{3,4}, Sng, X.Y.X.^{1,2}, Harland, K.², Fox, A.², McConville, M.J.^{3,4}, Turner, S.J.^{1,2}, La Gruta, N.L.^{1,2}

¹Monash University, Biomedical Sciences, Clayton, Australia, ²University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ³University of Melbourne, Department of Biochemistry, Melbourne, Australia, ⁴Bio21, Melbourne, Australia

Immune dysfunction occurs with ageing, and particularly impacts upon primary CD8 T cell responses that are needed to control novel intracellular infections and cancers. Ageing causes a decrease in the number of naïve CD8 T cells, an increase in

the proportion of these cells exhibiting a semi-differentiated “virtual memory” phenotype and a decrease in their intrinsic functionality. We have recently defined the dynamics of epitope-specific CD8 T cell loss (Quinn et al., 2016, PNAS), and we now examine molecular mechanisms that underpin the phenotypic shift and loss of function. To this end, we assessed metabolic, epigenetic and transcriptional differences across true naïve (T_N) and virtual memory (T_{VM}) CD8 T cells from young and aged mice. We found that aged CD8 T_{VM} cells were the least functional, with aberrant cytokine production and minimal proliferative capacity. These cells had metabolic indicators of diminished functionality, including lower glucose uptake, high rates of reactive oxygen species production and minimal induction of glycolytic pathways upon activation. Upon adoptive transfer of cells, the phenotypic and functional profiles of young and aged T_N and T_{VM} were stable regardless of the age of their environment, suggestive of epigenetic programming. We performed ChIP-Seq of T_N and T_{VM} cells from young and aged mice, targeting H3K9 acetylation, to define this program and will correlate this with the transcriptional profile of the cells. These data highlight the molecular constraints, both metabolic and epigenetic, on aged CD8 T_{VM} cells and suggest cellular targets to improve function.

Rules governing homeostasis, repertoire mobilization and protective immunity change with old age

Nikolich-Zugich, J.¹, Uhrlaub, J.¹, Pulko, V.¹, Rudd, B.², Davies, J.¹, Renkema, K.³, Li, G.¹, Padilla, J.¹, Nikolich-Zugich, D.¹, Contreras, N.¹, Smithey, M.¹

¹University of Arizona, Immunobiology, Tucson, United States,

²Cornell University College of Veterinary Medicine, Immunology, Ithaca, United States, ³University of Minnesota Medical School, Laboratory Science, Minneapolis, United States

Age-related defects in production, maintenance and function of lymphocytes are commonly described in quantitative terms, as a reduction in molecules, cells and/or processes that govern various facets of the immune function. Qualitative changes often also ensue from these quantitative changes, most frequently in the form of insufficient or dysregulated immune responses that lead to sickness and/or death. The opposite is also possible, so that qualitative alterations of cells and molecules and of their spatial arrangement can lead to quantitatively diminished responses.

Results presented here will provide evidence for the third possibility - that the very rules that govern maintenance and function of the adult immune system change with age, and therefore orchestrate different types of responses. Specifically, such results will illustrate age-related changes in

- (i) homeostatic rules that enforce selection of different types and classes of naïve T cells with aging;
- (ii) epigenetic changes that drive the process of selection and survival of some, but not other T cell clones during the primary immune response; and
- (iii) changes in polarization of the immune response against acute viral infection. Broader implications of such “rule breakers” associated with immune aging will be discussed.

793

A tumor suppressor Menin controls CD8 T cell senescence by regulating energy metabolism

Suzuki, J.^{1,2}, Kuwahara, M.², Yasukawa, M.¹, Yamashita, M.²

¹Ehime University, Department of Hematology, Clinical Immunology and Infectious Diseases, Graduate School of Medicine, Toon, Japan, ²Ehime University, Department of Immunology, Graduate School of Medicine, Toon, Japan

Age-induced alterations of immune system are designated as immunosenescence, which is involved in increasing the susceptibility of elderly individuals to infectious diseases and certain cancers. We previously reported that deficiency in Menin, a tumor suppressor protein, induces premature senescence of CD4 T cells. In this study, we investigated the role of Menin in the regulation of CD8 T-cell senescence. The characteristic features of cellular senescence including the early cycle arrest, increased expression of the inhibitory receptors, augmented expressions of pro-inflammatory factors and increase in SA- β -Gal activity were rapidly induced in the *Menin*-deficient activated CD8 T cells. It has been recently reported that the change of the metabolic pathways and the induction of cellular senescence are intimately connected. We performed a metabolic profiling of 116 metabolites and found that *Menin*-deficient activated CD8 T cells had higher rate of anaerobic glycolysis and glutaminolysis than that in the WT activated CD8 T cells. Furthermore, premature CD8 T cell senescence in *Menin*-deficient CD8 T cells was partially inhibited by the treatment with rapamycin or inhibitors for glutamine metabolism. These results suggest that Menin controls CD8 T-cell senescence in part by regulating the energy metabolism.

1870

Significance of age-associated changes in miRNA expression regarding human CD4+ T cells

Frackowiak, J.E.¹, Wicik, Z.², Lisowska, K.A.¹, Jasiulewicz, A.¹, Mikosik, A.¹, Ruckemann-Dziurdzinska, K.³, Bartoszewski, R.⁴, Witkowski, J.M.¹

¹Medical University of Gdansk, Department of Pathophysiology, Gdansk, Poland, ²Mossakowski Medical Research Centre, Polish Academy of Sciences, Department of Human Epigenetics, Warsaw, Poland, ³Medical University of Gdansk, Department of Pathology and Experimental Rheumatology, Gdansk, Poland, ⁴Medical University of Gdansk, Department of Biology and Pharmaceutical Botany, Gdansk, Poland

Successful aging depends on a number of factors. A healthy immune system is of vital importance for this process. The phenotype of immune cells in the context of aging undergoes multiple changes which reflects in their function. CD4+ T helper cells modulate the function of other types of immune cells and are therefore especially important as they shape immune response. Activation and subsequent proliferation of CD4+ T cells accompanied by cytokine production is pivotal to their function. The impact of miRNAs on differentiation and function of human immune cells has recently been described in several publications. Furthermore, these small RNA species have been associated with human aging. Our research is among the few

which study miRNAs in an extreme age range.

Using Next Generation Sequencing (Illumina) we established the expression profile of mature miRNAs in FACS-sorted peripheral resting CD4+ cells obtained from Polish centenarians and three healthy control age groups: below 35 years of age, in their 60s and individuals aged 70-89.

Data analysis revealed significant age-associated changes in the expression profile of miRNAs. miRNA target prediction using *in silico* algorithms and ontological analysis revealed pathways significantly affected by age, including GNRHR, Wnt, CCKR and EGF receptor signaling. We also singled out several miRNAs, including miR-432-3p, for further study in qRT-PCR experiments. The studied miRNAs may influence homeostasis in resting cells and their sensitivity to T cell receptor activation, resulting in age-related changes in CD4+ T cell function.

1745

The visceral adipose tissue contributes to the generation of pro-inflammatory B cell subsets in aging mice and humans

Frasca, D., Diaz, A., Romero, M., Vazquez, T., Blomberg, B.

University of Miami Miller School of Medicine, Microbiology and Immunology, Miami, United States

Age-related decrease in B cell function is associated with chronic low-grade systemic and metabolic inflammation and with an increase in visceral adipose tissue (VAT). Adipocyte-derived chemokines are involved in the chemotaxis of immune cells which infiltrate the VAT and contribute to the inflammatory process. To identify contributors to the phenotypic and functional changes observed in aged B cells, we studied B cells in the VAT of obese mice and humans (epididymal and abdominal VAT, respectively). We found macrophages, B cells and T cells in VAT in a ratio of 1:3:5. As to B cells, we measured the major B cell subsets and found higher percentages of pro-inflammatory and less percentages of anti-inflammatory B cell subsets in VAT as compared to peripheral B cells. B cells isolated from VAT express higher levels of inflammatory immune activation markers (TNF- α /IL-6/IL-8), significantly higher NF- κ B activation and phospho-STAT3, and secrete higher amounts of Ig antibodies specific for fat antigens as compared to peripheral B cells. To evaluate the ability of adipocytes from the VAT to promote inflammation and induce pro-inflammatory B cell subsets, we co-cultured adipocytes from the VAT with peripheral B cells. Results show that co-culture for 72 hrs significantly changed the relative percentages of the B cell subsets, leading to a higher percentage of pro-inflammatory B cell subsets, similar to what we have observed in the fat. Moreover, we found that the adipocytes produce several pro-inflammatory chemokines. These results are the first to show a direct effect of adipocytes on pro-inflammatory B cells.

3499

Respiratory syncytial virus targets a fetally developed B cell population with regulatory functions which predicts disease severity

Zhivaki, D.¹, Lemoine, S.¹, Rameix-Welti, M.-A.², Lim, A.¹, Descamps, D.³, Eleouet, J.-F.³, Riffault, S.³, Zhang, X.⁴, Tissières, P.⁵, Lo-Man, R.¹

¹Institut Pasteur, Immunology, Paris, France, ²Hôpital Ambroise Paré, Boulogne-Billancourt, France, ³INRA, Jouy-en-Josas, France, ⁴Institut Pasteur of Shanghai, Chinese Academy of Sciences, Molecular Virology and Immunology, Shanghai, China, ⁵Hopital Bicetre, Kremlin Bicetre, France

Human Respiratory Syncytial Virus (RSV) is the commonest viral cause of severe lower respiratory tract infection in children under 5 years of age, leading to over 3 million hospitalizations related to severe bronchiolitis. Newborns and very young infants are highly susceptible to infections and poorly responsive to vaccines with a biased T cell response towards Th2 polarization in response to RSV infection. We analyzed neonatal blood for B cell population, including regulatory B cells (nBregs) and analyzed their susceptibility to infection and their impact on T cell immune responses *in vitro* and *in vivo* in infected human newborns.

We identified a fetally developed B cell population with regulatory properties and with a biased Ig repertoire. Using a recombinant RSV expressing the red fluorescent Cherry protein, we showed that RSV infects the neonatal B cells, with Breg cells subset in particular being the most permissive to RSV infection. Gene expression microarray analysis revealed an activation signature of Breg population upon RSV stimulation involving the BCR pathway. We also described an immunoregulatory mechanism by which upon RSV exposure, these nBregs can modulate neonatal CD4 Th1 development through the production of a high level of IL-10. These *in vitro* data were confirmed in patients suffering of acute bronchiolitis in which high nBregs frequency correlated with disease severity. Thus, we uncovered neonatal regulatory B cells as new target for RSV and how hijacking the newborn immune system contributes to disease severity and reduced viral clearance.

2011

What role do immune cells play in preterm newborn brain injury?

Zhang, X., Jabin, D., Zhou, K., Nazmi, A., Zhu, C., Mallard, C., Wang, X.

University of Gothenburg/Department of Neuroscience and Physiology, Gothenburg, Sweden

Infants with sepsis have increased incidence of brain abnormalities, and these are especially common in low birthweight newborn infants. Immune cells derived from the systemic circulation are a key feature of many diseases of the central nervous system. The aim of this study was to investigate whether or not immune cells contribute to the development of preterm brain injury using a mouse model of sepsis.

C57BL/6J wild-type (WT), T-cell receptor delta knockout (deltaTCRKO), and TCR beta knockout (betaTCRKO) mice were subcutaneously administered sterile saline or

lipopolysaccharide (LPS) (5 mg/kg) at postnatal day (PND) 2. Mouse brains were examined at PND12. Motor function and anxiety were evaluated at PND 26-30, using DigiGait analysis and an elevated plus maze.

LPS causes the loss of brain white-matter volume in WT and betaTCRKO mice, compared to that of the saline-treated group. However, deltaTCRKO mice did not have any white-matter tissue loss after LPS compared to the WT controls. The different treatments and genotypes had no effect on anxiety behavior in mice as determined with the elevated plus maze. DigiGait analysis showed that there were increases in stance, stride, and stride length and a decrease in stride frequency after LPS treatment in the WT and betaTCRKO mice, but no such effect was observed in the deltaTCRKO mice.

LPS causes sepsis-induced damage to the white matter in the mouse brain. Gamma/delta T cells, but not alpha/beta T cells, contribute to sepsis-induced brain injury and mild motor abnormalities in early life.

3753

Interleukin-22Ra1 signaling attenuates the severity of necrotizing enterocolitis and enhances expression of antimicrobial peptides

Good, M.¹, Parks, O.², Hodzic, Z.², Ma, C.¹, Kumar, P.², Horne, W.², Kolls, J.²

¹University of Pittsburgh School of Medicine/Children's Hospital of Pittsburgh, Pediatrics/Newborn Medicine, Pittsburgh, United States, ²University of Pittsburgh School of Medicine/Children's Hospital of Pittsburgh, Pediatrics, Pittsburgh, United States

Necrotizing enterocolitis (NEC) is the leading cause of death from gastrointestinal disease in premature infants and is characterized by an exaggerated inflammatory response, intestinal epithelial barrier disruption and impaired mucosal healing. Recently, interleukin (IL)-22 signaling has proven to play a critical role in attenuating intestinal inflammation, maintaining the gut barrier and promoting intestinal wound healing. Thus, we hypothesized that IL-22Ra1 signaling plays an important role in NEC pathogenesis. To test this hypothesis, we subjected wild type (WT) and IL-22Ra1 intestinal specific knock out mice (*villin-cre x IL22Ra1^{fl/fl}*, termed IL-22Ra1^{ΔIEC}) to an experimental model of NEC using gavage formula feeds and intermittent hypoxia. Mice were administered rIL-22 (4ug IP daily) and NEC severity was assessed by intestinal mucosal expression of pro-inflammatory markers, IL-6 and iNOS and histology. NEC resulted in disruption in the intestinal mucosal architecture and upregulation of pro-inflammatory cytokines and IL-22Ra1^{ΔIEC} mice demonstrated earlier NEC-related mortality than WT mice. Strikingly, administration of rIL-22 attenuated NEC severity and decreased pro-inflammatory markers. To determine the mechanisms involved, mouse primary intestinal stem cell enteroids were isolated and cultured with or without rIL-22. rIL-22 enhanced the growth of enteroids *ex vivo* and RNA sequencing on these enteroids demonstrated upregulated gene expression of antimicrobial peptides and defensins. Taken together, these data suggest IL-22 signaling may play an important role in attenuating the immune response in NEC pathogenesis and raise the possibility of novel therapeutic

approaches to this devastating disease by exploring the efficacy of IL-22 treatment for NEC and further defining the mechanisms involved.

Regulatory T cells (Tregs) control immune homeostasis by preventing inappropriate responses to self and non-harmful foreign antigens. Tregs use multiple mechanisms to control immune responses, all of which require Tregs to be near their targets of suppression, but how Treg-to-target proximity is controlled is unknown. We found that Tregs produce chemokines to attract CD4⁺ and CD8⁺ T cells close to their proximity *in vitro* and *in vivo*. Mouse and human lineage committed Tregs, as well as murine *in vitro* induced Tregs, produced CCL3 and CCL4 at message and protein level. Chemokine producing Tregs had an activated Treg phenotype with high expression of multiple proteins associated with suppressive function. Furthermore the human CCL3 and CCL4 promoter could be transactivated by FOXP3. *In vitro* and *in vivo* migration experiments indicated that CCR5 was the major receptor required by target cells. CCL3 and CCL4 deficient Tregs were impaired in their ability to prevent experimental autoimmune encephalomyelitis or islet allograft rejection, but suppressive in a standard *in vitro* assay. Moreover, Tregs from subjects with established type 1 diabetes were impaired in their ability to produce CCL3 and CCL4. These results demonstrate a previously unknown facet of Treg function and suggest that chemokine secretion by Tregs is a fundamental aspect of their *in vivo* function and therapeutic effect in autoimmunity and transplantation.

Italy, ⁶Fondazione INGM - University of Milan, Milan, Italy

T cell immunity is key to protective immune responses against tumors; however, antitumor immunity is often compromised by the recruitment in the tumor microenvironment of immunosuppressive regulatory cells. Discoveries regarding regulation of T cell responses have provided key principles for the development of promising immunomodulatory strategies in antitumor therapies, however characterization of the immune landscapes in different tumor contexts is still largely incomplete. Here we provide the first comprehensive RNA-sequencing analysis of CD4⁺ effector cells (Th1 and Th17) and regulatory T cells (Treg) infiltrating colorectal cancer (CRC) and non-small cell lung cancer (NSCLC). These data were integrated by transcriptomic data obtained from the same subsets isolated from adjacent healthy tissues to obtain the expression landscape of transcription factors, membrane receptors, cytokines and immune checkpoints of tumor infiltrating lymphocytes in NSCLC and CRC samples. We show that tumor infiltrating Treg cells display the more pronounced difference between normal and tumor tissues and are described by the expression of a subset of specific signature genes. Single-cell gene expression analysis show distinct expression frequencies between Treg cells infiltrating CRC and NSCLC suggesting an underlying heterogeneity in tumor infiltrating Treg cells that cannot be appreciated at the population level. These findings illustrate the importance of studying Treg cells contextually at tumor sites to better elucidate the underlying mechanisms of localized immune responses and to optimize the efficacy of current immune-based cancer therapy.

Molecular control of Foxp3⁺ regulatory T cell survival and death during chronic viral infection

Gray, D.^{1,2}, Teh, C.^{1,2}, Preston, S.^{2,3}, Ebert, G.^{2,3}, Strasser, A.^{1,2}, Pellegrini, M.^{2,3}

¹The Walter and Eliza Hall Institute of Medical Research, Molecular Genetics of Cancer, Melbourne, Australia, ²The University of Melbourne, Department of Medical Biology, Melbourne, Australia, ³The Walter and Eliza Hall Institute, Infection and Immunity Division, Melbourne, Australia

The immunosuppressive function of Foxp3⁺ regulatory T (Treg) cells prevents immune-mediated damage from autoimmunity and chronic viral infections; however, the death and survival programs that control the Treg cell pool during these states are unknown. We examined how two major pathways of apoptosis (the intrinsic and extrinsic pathways) impinge upon Treg cell homeostasis and function under steady-state conditions and during chronic inflammatory conditions.

We generated mice with Treg cell-specific deletion of key mediators of the intrinsic (*Bax* Δ ^{FoxP3}*Bak*^{-/-}) or extrinsic (*Casp8* Δ ^{FoxP3}) apoptotic pathways. Unexpectedly, Treg cell-specific ablation of either resulted in a marked expansion of Treg cell number, mainly among FoxP3⁺ Treg cells with an effector phenotype (CD62L^{low}PD1^{hi}ICOS^{hi}), suggesting that dual control mechanisms maintain Treg cell homeostasis. Infection with the fast-replicating chronic lymphocytic choriomeningitis virus

(LCMV) Docile strain triggered massive expansion in the Treg cell population in wild-type and *Bax* Δ ^{FoxP3}*Bak*^{-/-} mice eight days post-infection. By contrast, infection of *Casp8* Δ ^{FoxP3} mice resulted in a striking loss of Treg cells and increased CD8⁺ and CD4⁺ cell activation, indicating a pro-survival role for this caspase in Treg cells only during chronic inflammation. We explore the role of necroptosis in this cell death switch in Treg cells, to better understand the divergent roles of the apoptotic pathways in the control of Treg cell function during chronic inflammation. Understanding how these pathways alter Treg cell homeostasis and the immune response is pivotal because drugs that target these pathways are currently in clinical trials for treatment of cancers and autoimmune disease.

Low-dose interleukin-2 selectively modulates CD4⁺ T cell subsets in SLE

He, J.¹, Zhang, X.¹, Wei, Y.², Yu, D.³, Li, Z.¹

¹Peking Univ. People's Hospital, Beijing, China, ²Shandong Analysis and Test Center, Shandong Academy of Sciences, Shandong, China, ³Monash University, Melbourne, Australia

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multi-system involvement. We hypothesized that low-dose IL-2 treatment of SLE would result in selective expansion of regulatory CD4⁺ T (Treg) cells, while suppressing follicular helper T (Tfh) cells and IL-17-producing helper T (Th17) cells.

Methods: Forty patients with active SLE were recruited to a prospective open label study. The primary end points were the SLE Responder Index (SRI) and safety at week 12. Secondary end points were the effects of the therapy on Treg, Tfh and Th17 cells.

Results: An SRI response was seen in 34/38 patients (89.5%) at week 12. At week 12, resolution of clinical activity present at baseline was observed in multiple domains, including rash (20/24 patients), alopecia (13/14), arthritis (10/11), fever (3/3), leukopenia (18/19) and thrombocytopenia (4/4). No severe adverse events were observed. Significant reductions of anti-dsDNA titres ($p < 0.001$) and proteinuria ($p = 0.005$), and increased levels of C3 ($p < 0.001$) and C4 ($p < 0.001$), were observed at week 12. Immunological analysis revealed that low-dose rhIL-2 administration was associated with selective expansion of Treg cells and conversely with reductions of Tfh and Th17 cells ($p < 0.001$).

Conclusion: Low-dose IL-2 was well tolerated in active SLE, and was associated with improvements in disease activity accompanied by selective modulation of CD4⁺ T cell subsets.

Regulatory T cells modulate dendritic cell maturation and function at a transcriptional level*Mavin, E., Nicholson, L., Dickinson, A., Wang, X.-N.**Institute of Cellular Medicine, Haematological Sciences, Newcastle, United Kingdom*

Regulatory T cells (Treg) are able to prevent effective T cell priming through modulation of dendritic cell function, arresting them in a semi-mature status. However, little is known about the molecular mechanisms underlying this effect. Using microarrays, we examined the gene expression profile of LPS-stimulated monocyte-derived dendritic cells either with Treg treatment (Treg-moDC), or without (mat-moDC) and compared them to unstimulated immature moDC (imm-moDC) controls. Hierarchical clustering showed a significant difference between all three DC populations at a global gene expression level. Treg-moDC had reduced levels of NFκB signalling genes and decreased phosphorylation of the Ser536 residue of the RelA subunit, suggesting attenuation of the NFκB signalling pathway which is essential for DC maturation. We also observed Treg-DC had intermediate levels of the NFκB-regulated genes CD80, CD86, CD83 and CD38, which was then confirmed by qPCR and flow cytometry. Treg-moDC had a distinct morphology, resembling that of imm-moDC with an impaired ability to uptake antigen. Functional analysis demonstrated that Treg-moDC skewed naïve T cell polarisation from a Th1 to a Treg-type response, possibly due to their increased surface expression of TGFβ and decreased secretion of IL-12p70 and IL-6. Furthermore Treg-moDC had an impaired ability to induce allo-reactive CD8+ T cell activation and proliferation. Using a unique human skin explant model of graft-versus-host reactions we demonstrated the clinical relevance of Treg modulation of DC function. This study provides the first evidence that Treg modulation of DC function occurs, at least in part, through attenuation of NFκB signalling.

Suppression by human FOXP3⁺ Treg cells requires FOXP3/TIP60 interaction*Bin Dhuban, K.¹, d'Hennezel, E.¹, Xiao, Y.², Nagai, Y.², Ben-Shoshan, M.³, Mazer, B.³, Ochs, H.⁴, Nicholas, B.⁵, Park, M.⁵, Torgerson, T.⁴, Greene, M.², Piccirillo, C.^{1,6}*

¹McGill University, Microbiology and Immunology, Montreal, Canada, ²University of Pennsylvania, Pathology and Laboratory Medicine, Philadelphia, United States, ³McGill University, Pediatrics, Montreal, Canada, ⁴University of Washington, Pediatrics, Seattle, United States, ⁵McGill University, Medicine, Montreal, Canada, ⁶McGill University, Program in Infectious Diseases and Immunology in Global Health, Research Institute of the McGill University Health Centre, Montreal, Canada

CD4⁺FOXP3⁺ regulatory T cells are critical mediators of immune tolerance, and their deficiency due to mutations in the transcription factor *FOXP3* results in severe autoimmunity in IPEX patients. However, different *FOXP3* mutations result in a wide range of disease severity, highlighting the complexity of *FOXP3* interactions. Here, we used IPEX-derived *FOXP3*

mutations to identify specific molecular interactions through which *FOXP3* orchestrates the transcriptional and cellular profile of human Treg cells. Using a sensitive single-cell cloning strategy of primary cells derived from IPEX patients, as well as lentiviral overexpression of WT and mutated *FOXP3* in healthy naïve CD4⁺CD25⁻ cells, we analyzed the molecular and cellular defects caused by the most common IPEX mutation, pAla384Thr. We show that this mutation selectively impairs the suppressive capacity of Treg cells while sparing *FOXP3*'s ability to mediate repression of inflammatory cytokines such as IFN-γ, IL-2 and IL-17, and to induce Treg-associated surface markers such as CD25 and CTLA-4. Microarray and biochemical analyses revealed that *FOXP3*^{A384T} has a diminished ability to interact with TIP60, a histone acetyltransferase previously shown to bind to, and acetylate, *FOXP3* leading to an increased stability of the *FOXP3* protein. We were able to correct this specific defect using allosteric modifiers that enhance *FOXP3*/TIP60 interaction leading to a significant rescue in the suppressive capacity of *FOXP3*^{A384T}-transduced cells. These findings highlight the critical role of TIP60 in Treg biology and provide potential targets for therapeutic manipulation of Treg activity.

USP21 prevents the generation of T-helper-1-like exTreg cells*Li, B., Li, Y.**Instut Pasteur of Shanghai, Unit of Molecular Immunology, Shanghai, China*

FOXP3⁺ Regulatory T (Treg) cells harbor immune suppressive capacity and are crucial for the maintenance of immune homeostasis and control of dominant immune tolerance¹⁻³. Treg cells are considered to be heterogenic, where compromised *FOXP3* expression results in the generation of exTreg cells and acquisition of alternative effector or regulatory/effector hybrid fates⁴⁻¹⁰. However, direct tracing of *FOXP3* protein and its stability in exTreg cells in vivo remains unclear. Here we report that the E3 deubiquitinase USP21 prevents the depletion of *FOXP3* protein and restricts T-helper-1-like exTreg cell generation. Mice lacking USP21 in Treg cells display immune disorders characterized by spontaneous T cell activation and excessive T helper type 1 (Th1) skewing. USP21 stabilizes *FOXP3* protein by mediating its deubiquitination and therefore helps to maintain the expression of Treg signature genes. Moreover, at inflamed tissue loci, Treg-specific deletion of USP21 leads to potent induction of Th1-like exTreg cells. Our results demonstrate how USP21 prevents *FOXP3* protein depletion and controls Treg lineage stability under inflammation. These findings support the notion that instability or loss of *FOXP3* in Treg cells potentially induces exTreg cell generation in vivo.

Foxp3+ regulatory T cells (Treg) are thought to play a central role in maintaining tolerance against harmless antigens at mucosal sites. However, which antigens are actually recognized by Treg in particular in humans is so far unknown. We established a highly sensitive enrichment system based on antigen-induced CD154 (CD40L) versus CD137 (4-1BB) expression, to detect human antigen-specific conventional T cells (Tcon) and Treg directly *ex vivo* in peripheral blood. We show that the ubiquitous airborne fungal antigen *A. fumigatus* activates a dominant population of CD4+CD25+CD127-Foxp3+Helios+ Treg in peripheral blood of healthy donors, with demethylated TSDR and potent *in vitro* suppressive activity. In cystic fibrosis patients allergic to *A. fumigatus*, this Treg dominance is abrogated, due to a massive expansion of conventional Th2-type memory cells, despite the presence of functional Treg. Using a panel of 15 different *A. fumigatus* proteins we show, that in allergic donors, antigen-specific Treg surprisingly have non-overlapping target-specificities with Th2 cells, suggesting divergent target specificity of human Treg and Th2 effector cells as a potential risk for allergy development.

Our data identify innocuous airborne antigens as a target of human Treg and provide direct evidence that antigen-specific Treg are potent suppressors of allergy development. Furthermore we provide an explanation how allergen-specific Th2 responses can escape Treg control due to selective targeting of *A. fumigatus* proteins not protected by a specific Treg response.

Human regulatory T cells control TCR signaling and susceptibility to suppression in CD4+ T cells

Chelappa, S.^{1,2}, Lieske, N.V.^{1,2}, Hagness, M.^{1,2,3}, Line, P.D.³, Tasken, K.^{1,2}, Aandahl, E.M.^{1,2,3}

¹University of Oslo and Oslo University Hospital-Rikshospitalet, Centre for Molecular Medicine Norway, Nordic EMBL Partnership, Oslo, Norway, ²University of Oslo, Biotechnology Centre, KG Jebsen Centre for Inflammation Research and KG Jebsen Centre for Cancer Immunotherapy, Oslo, Norway, ³Oslo University Hospital-Rikshospitalet, Section for Transplantation Surgery, Oslo, Norway

Human CD4+CD25^{hi}FOXP3+ regulatory T cells maintain immunologic tolerance and prevent autoimmune and inflammatory immune responses. Regulatory T cells undergo a similar activation cycle as conventional CD4+ T cells upon antigen stimulation. Here, we demonstrate that T cell receptors

and costimulation are required to activate the regulatory T cell suppressive function. Regulatory T cells suppressed the T cell receptor signaling in effector T cells in a time-dependent manner that corresponded with inhibition of cytokine production and proliferation. Modulation of the activation level and thereby the suppressive capacity of regulatory T cells imposed distinct T cell receptor signaling signatures and hyporesponsiveness in suppressed and proliferating effector T cells and established a threshold for effector T cell proliferation. The immune suppression of effector T cells was completely reversible upon removal of regulatory T cells. However, the strength of prior immune suppression by regulatory T cells and corresponding T cell receptor signaling in effector T cells determined the susceptibility to suppression upon later reexposure to regulatory T cells. These findings demonstrate how the strength of the regulatory T cell suppressive function determines intracellular signaling, immune responsiveness, and the later susceptibility of effector T cells to immune suppression and contribute to unveiling the complex interactions between regulatory T cells and effector T cells.

Inflammatory monocytes contributes to the restriction of Legionella in a mouse model of Legionnaires' disease

Massis, L.M.^{1,2}, Lima-Junior, D.S.², Pereira, M.F.², Manin, G.¹, Zamboni, D.S.²

¹University of Sao Paulo, Biochemistry and Immunology, Ribeirao Preto, Brazil, ²University of Sao Paulo, Cell Biology, Ribeirao Preto, Brazil

Legionella species, in particular *Legionella pneumophila* and *Legionella longbeachae*, are mainly found in environmental sources like water reservoir and soil. *Legionella* can be an opportunistic pathogen of humans causing a severe pneumonia. The response to *Legionella* infection leads to a recruitment of immune cells to the lung that contributes to control of infection. CCR2 receptor and monocyte chemoattractant protein-1 (MCP-1) are critical for monocyte recruitment to the lungs in response to bacterial infection. In this context the aim of this study was to evaluate the importance of inflammatory monocytes in Legionnaires' disease. To address this question we infected *ccr2*^{-/-} mice and C57BL/6 mice with *L. pneumophila* flagellin deficient strain or with *L. longbeachae* strain. Our results demonstrated that MCP-1, IFN- γ and TNF are increased in the infection with both *Legionella* strains. Furthermore, *ccr2*^{-/-} mice are more susceptible to *L. pneumophila* and *L. longbeachae* infection compared to C57BL/6 mice. The infection also triggers a CCR2-dependent inflammatory monocyte migration to the lungs. To confirm the importance of inflammatory monocytes we adoptively transferred inflammatory monocytes to *ccr2*^{-/-} mice that rescue the restriction of the infection found in C57BL/6 mice. These results indicated that inflammatory monocytes participate in the control of *Legionella* infection. Therefore, CCR2-dependent inflammatory monocytes are important cells involved in inflammation and in the control

of the two most prevalent *Legionella* strains that cause pneumonia in humans.

***Mycobacterium tuberculosis* expresses noncoding RNAs to regulate mycobacterial and eukaryotic gene expression during infections**

Srivastava, S.¹, Raj, P.², Dozmorov, I.², Wakeland, E.², Gumbo, T.¹, van Oers, N.²

¹Baylor Scott & White Health, Baylor Institute for Immunology Research, Dallas, United States, ²UT Southwestern Medical Center, Immunology, Dallas, United States

Mycobacterium tuberculosis (*Mtb*) presently infects 1/3 of the World's population, causing active and latent pulmonary tuberculosis (TB). The pathogenic mechanisms used by *Mtb* remain poorly defined. We used a small RNA sequencing strategy on RNA extracted from *Mtb*-infected THP-1 macrophages to characterize the changes in eukaryotic microRNAs (miRs) and identify any mycobacterially-encoded small RNAs. A large number of mammalian microRNAs were differentially regulated during the infection course. Target prediction programs indicated that the mRNAs regulated by these miRs were involved in immune processes, metabolic pathways, cell communication, and developmental events. In addition, 35 *Mtb*-encoded small RNAs (18-30 nucleotides, *Mtb*-mRs) were uncovered. Several of these were also detected in lung tissue biopsies from TB infected monkeys. The 100-150 nucleotides surrounding the 35 *Mtb*-encoded small RNAs had extensive secondary RNA folding capabilities, including hairpins and antisense stretches more characteristic of eukaryotic pre-microRNAs. Two such small RNAs, *Mtb*-mR-1 and *Mtb*-R-6 were transcribed in *Mycobacterium avium* complex and *Mtb* strains in a hairpin loop and antisense sequence-dependent manner. These mRs were not expressed in *Mycobacterium smegmatis*, revealing a restricted expression to pathogenic strains. *Mtb*-encoded mR-1 and mR-6 modulated both prokaryotic and eukaryotic gene expression. Taken together, our findings reveal novel pathogenic processes deployed by *Mtb* to modulate infectivity.

703

Inflammatory properties and adjuvant potential of synthetic glycolipids homologous to mycolate esters of the cell wall of *Mycobacterium tuberculosis*

Tima, G.¹, Lehebel, P.¹, Denis, O.¹, Baird, M.², Huygen, K.¹, Romano, M.¹

¹Scientific Institute of Public Health, Immunology, Brussels, Belgium, ²Bangor University, School of Chemistry, Bangor, United Kingdom

The cell wall of mycobacteria is characterized by glycolipids composed of different classes of mycolic acids (MAs) (alpha-, keto- and methoxy-) and sugars (trehalose, glucose, and arabinose). Several studies using mutant strains have shown that the structure of MAs bound to trehalose influence the inflammatory potential of this glycolipid. Nevertheless, these studies were performed with mixtures of isolated glycolipids.

Here we were interested in dissecting the contribution of single class of mycolate esters in the inflammatory potential of *Mtb* cell wall using synthetic analogues. The synthetic compounds tested here vary in terms of their carbohydrates moiety (trehalose, glucose or arabinose) and in terms of the number, nature and class of mycolic acids bound to it. Our results showed that synthetic trehalose dimycolate (TDM), trehalose-, glucose- and arabinose-monomycolates (TMMs, GMMs and AraMMs) activate BMDCs in term of proinflammatory cytokines (IL-6 and TNF- α), ROS productions, upregulation of costimulatory molecules and activation of NLRP3 inflammasome by mechanism dependent on Mincle pathway. These results indicate that Mincle receptor can recognize pentose esters and contradict the hypothesis that the production of GMM is an escape mechanism used by pathogenic mycobacteria to avoid the recognition by the innate immune system. Finally, our data showed that TMM and GMM as well as TDM can induce Th1 and Th17 responses in mice in an OVA immunization model. Taken together, these data provide an interesting lead in the development of new adjuvant for subunit vaccine.

4002

Leptin and IL-17 mediated responses in vaccination against *Helicobacter pylori*

Becher, D.^{1,2}, Ortega, J.³, Raghavan, S.⁴, Sjökvist Ottsjö, L.⁴, Wijburg, O.¹, Strugnell, R.A.¹, Walduck, A.⁵

¹University of Melbourne, Microbiology and Immunology, Melbourne, Australia, ²Glaxo Smith Kline, Melbourne, Australia, ³MIT University, Melbourne, Australia, ⁴University of Gothenburg, Sahlgrenska Institute, Microbiology and Immunology, Gothenburg, Sweden, ⁵MIT University, School of Sciences, Health Innovations Research Institute, Melbourne, Australia

Infection with *Helicobacter pylori* is the greatest risk factor for gastric cancer. Candidate *H. pylori* vaccines tested in volunteers to date have generally been poorly effective and adverse effects are reported. Indeed there is evidence that "post immunisation gastritis" occurs because the tightly controlled inflammatory response in the gastric mucosa is unbalanced.

Vaccination is effective in animal models, and CD4⁺ T cells, and the adipokine leptin (Ob) and interleukin 17 (IL-17) have been show to be important for vaccine-induced protection against *H. pylori*. Leptin is pro-inflammatory, and impacts CD4⁺ T cell, regulatory CD4⁺ T cell (T_{reg}), and neutrophil function. IL-17 promotes neutrophil recruitment into tissues, and inflammatory cytokine production by macrophages.

Aims: To investigate the roles of leptin receptor (ObR) signalling and IL-17 in the vaccine- induced immune responses against *H. pylori*.

Methods: We studied responses in vaccinated wild-type C57BL/6 and ObR-signalling deficient C57BL/6 CgObR db/db mice (db/db).

Results: Vaccinated db/db mice are not protected from *H. pylori* challenge, gastric IL-17 production was also reduced in these mice. In the stomachs of wild-type mice, both leptin and ObR are expressed on epithelial, CD4⁺ T cells, CD4⁺ Treg, macrophages and neutrophils. Further, bone marrow chimaera studies revealed that functional ObR on BM-derived cells was

essential for vaccine-induced protection.

Conclusions: Our data support a link between leptin and Th-17 responses in gastric inflammation. We hypothesize that T-cell derived leptin impacts both Treg function and IL-17 production, regulating protective responses in the vaccinated stomach.

1935

NRAMP (Natural Resistance Associated Macrophage Protein, Slc11a1) plays a critical role in the resistance of mice to *Francisella tularensis*

Powell, D., Frelinger, J.

University of Arizona, Immunobiology, Tucson, United States

NRAMP (Natural Resistance Associated Macrophage Protein, Slc11a1) is a major mediator of resistance to *Salmonella*, *Listeria*, and *Mycobacterium*. Murine NRAMP has two known alleles, a functional NRAMP^{Gly169}, in DBA2/J, NOD, and 129p3/J related strains, and a non-functional NRAMP^{Asp169}, in C57BL/6 (B6) and BALB/c mice. B6 mice congenic for NRAMP^{Gly169} (B6-NRAMP^{G169}) show a marked resistance to intracellular pathogens. Here we examined the pathogenesis of *Francisella tularensis* Strain LVS in B6-NRAMP^{G169} mice. When intranasally (i.n.) challenged B6-NRAMP^{G169} mice showed no weight loss or signs of disease. In contrast B6 mice lost significant amounts (~15%) of weight upon challenge, as previously described. Organ burdens differed between B6-NRAMP^{G169} and B6 mice. Three days post infection all B6-NRAMP^{G169} mice had no detectable *Francisella* in the lung, liver or spleen. B6 mice had burdens approaching 1x10⁶ Colony Forming Units (CFU) in all three organs. To further examine the degree of resistance imparted by NRAMP^{Gly169} expression we further challenged mice deficient in TLR2, TLR4, and TLR9, expressing NRAMP^{Gly169} (B6-NRAMP^{G169} TLR2/4/9^{-/-}). While TLR4 has no effect on *Francisella* pathogenesis, TLR2 has been shown to be crucial in B6 mice surviving *Francisella* infection. Surprisingly, B6-NRAMP^{G169} TLR2/4/9^{-/-} mice showed no notable weight loss upon i.n. challenge. 80% of B6-NRAMP^{G169} TLR2/4/9^{-/-} mice showed no detectable *Francisella*. The mice that did show bacteria were still almost 100 fold less than B6 wild type mice. These data taken together serve to highlight that functional NRAMP^{Gly169} is a critical player in murine resistance to *Francisella* infection and interaction with the host immune response.

Commensal microbial modulation of immunity in the male urogenital tract

Murphy, S., Done, J., Schaeffer, A., Thumbikat, P.

Northwestern University, Urology, Chicago, United States

Staphylococcus epidermidis, a skin commensal, modulates local immune responses homeostatically and during inflammation. The human prostate harbors small numbers of bacteria that are considered to be clinically insignificant. These include gram-positive bacterial species such as *S. epidermidis* that are isolated from both patients and healthy men. Chronic pelvic pain syndrome (CPPS) in men has unknown etiology but is primarily associated with pain and alterations in prostate immunity. CPPS can be modeled using murine experimental prostatitis (EAP)

where we have shown that CD4+ve IL17A+ve T-cells play a critical role. Here we report that a specific *S. epidermidis* strain (designated NPI (non pain-inducing)) from a healthy human prostate ameliorates local immune activation and pain in the EAP model. The strain was isolated from the expressed prostatic secretion of a healthy human male and intra-urethally instilled into mice with EAP. Instillation reversed the influx of CD4+ve IL17A+ve T-cells associated with EAP by locally increasing the level of suppressive FoxP3+ve IL10 producing T-regs. In another murine model of CPPS, a human uropathogenic *E. coli* (UPEC) strain (designated CP1) induces chronic pain in mice that remains after bacterial clearance. Prophylactic instillation with NPI prevented CP1 colonization of the prostate and induction of pain, and therapeutic intervention with the commensal strain post-infection with CP1, ameliorated pain responses and reversed bacterial colonization. These results identify a new immunomodulatory niche for *S. epidermidis* and provide evidence for existence of a commensal flora of the prostate that interacts directly with the host immune response in health and disease.

Guanabenz protects against tuberculosis infection by targeting ESAT-6 of *Mycobacterium tuberculosis*

Samten, B., Jung, B.-G., Yi, N., Wang, X.

University of Texas Health Science Center at Tyler, Pulmonary Immunology, Tyler, United States

Tuberculosis remains as a major public health crisis due to lack of an effective vaccine and development of drug resistance by *Mycobacterium tuberculosis* (*Mtb*). Therefore, development of better vaccine and novel therapeutics are urgently needed for tuberculosis control. Early secreted antigenic target 6 kDa (ESAT-6) of *Mtb* is an essential virulence factor while it has been the focus of tuberculosis vaccine research. We have shown previously that ESAT-6 inhibits T-cell IFN- γ production via p38 mitogen activated protein kinase. Since ESAT-6 was shown to induce untranslated protein response (UPR) of lung epithelial cells and guanabenz, a centrally acting α 2-adrenergic antihypertensive drug, protects cells by suppressing UPR, we tested whether guanabenz protects from ESAT-6 inhibition of T cells and suppresses *Mtb* growth in human macrophages *in vitro* and in mouse infected through aerosol route. Our results show that guanabenz reversed ESAT-6 inhibition of T-cell IFN- γ production and proliferation dose dependently without the involvement of either α 2-adrenergic receptor or UPR-induced endoplasmic stress responses as determined by pathway specific inhibitors. Guanabenz also reduced *Mtb* growth in human monocyte-derived macrophages and inhibited *Mtb* growth and pathology of the lungs of *Mtb*-infected mice with no direct effect on *Mtb* growth in broth. Compared with controls, guanabenz also reduced inflammatory cytokines in the lungs of *Mtb*-infected mice and enhanced immune responses of T cells isolated from the spleens and the mediastinal lymph nodes of *Mtb*-infected mice. In conclusion, we demonstrated that guanabenz protects from tuberculosis infection probably by targeting ESAT-6, a major virulence factor of *Mtb*.

4205

Phosphoinositide-mediated oligomerization by defensins induces fungal and tumour cell lysis*Hulett, M., Poon, I., Lay, F., Baxter, A., Phan, T.K., Mills, G., Bleakley, M., Anderson, M., Kvangsakul, M.**La Trobe Institute for Molecular Science, La Trobe University, Department of Biochemistry and Genetics, Melbourne, Australia*

Cationic antimicrobial peptides (CAPs) such as defensins are ubiquitously found innate immune molecules that often exhibit broad activity against microbial pathogens and mammalian tumor cells. Many CAPs act at the plasma membrane of cells leading to membrane destabilization and permeabilization. Here we describe a novel cell lysis mechanism for fungal and tumor cells by plant and human defensins that act via direct binding to the plasma membrane phospholipid phosphatidylinositol 4,5-bisphosphate (PIP2). We determined the crystal structure of the plant defensin NaD1 in complex with PIP2, revealing a striking oligomeric arrangement comprising seven dimers of NaD1 that cooperatively bind the anionic head-groups of 14 PIP2 molecules through a unique "cationic grip" configuration. Site-directed mutagenesis of NaD1 confirms that PIP2 binding and oligomerization are important for fungal and tumor cell permeabilization. We have shown that human beta-defensin 3 also uses a similar mechanism for cell lysis. These observations identify a conserved innate recognition system by defensins for direct binding of PIP2 that permeabilizes cells via a novel membrane disrupting mechanism.

Neutrophil-producing IFN- γ eases tissue injury by driving macrophages to phagocytose apoptotic neutrophils during *Listeria monocytogenes* infection*Wang, G.¹, Lin, A.¹, Zhao, H.¹, Han, Q.¹, Zhang, C.¹, Tian, Z.^{1,2}, Zhang, J.¹*¹*Institute of Immunopharmaceutical Sciences, School of Pharmaceutical Sciences, Shandong University, Jinan, China,*²*University of Science and Technology of China, School of Life Sciences, Hefei, China*

IFN- γ plays a critical protective function against acute *Listeria monocytogenes* (Lm) infection, which was thought to be predominantly produced by NK cells in innate response. However, we found IFN- γ production was decreased mildly in Lm-infected Rag1^{-/-} and NK cell-depleted mice, while neutrophils were dominant IFN- γ -producing cells especially in blood and peritoneal cavity. IFN- γ was important in anti-*Listeria* immune response, which was indicated by poor survival, high bacteria loads in liver and spleen, severe tissue injury and the reduced number of splenic immune cells in GKO mice. IFN- γ was autocrinely released and effected on neutrophils during Lm infection, promoting bacteria clearance and inhibiting listeria toxin-induced neutrophil apoptosis. In addition, IFN- γ promoted the activation of macrophages and impaired *Listeria* replication. Importantly, IFN- γ could effectively drive macrophages to phagocytose apoptotic neutrophils, which would release tissue damage associated factors such as ROS and myeloperoxidase (MPO), and accompanied by TGF- β secretion. The uptake of

MPO by macrophages further promoted pathogen elimination. To sum up, we showed that neutrophil was an important source of early IFN- γ , which could promote bacteria clearance and ease tissue injury by driving macrophages to phagocytose apoptotic neutrophils.

Cellular sources of tumor necrosis factor in disease and cell type-restricted cytokine targeting*Nedospasov, S.^{1,2,3}*¹*Engelhardt Institute of Molecular Biology, Molecular Mechanisms of Immunity, Moscow, Russian Federation,* ²*Lobachevsky University, Experimental Immunology, Nizhni Novgorod, Russian Federation,*³*German Rheumatism Research Center (DRFZ), Leibniz Institute, Inflammation Biology, Berlin, Germany*

Proinflammatory cytokines are involved in pathogenesis of autoimmune diseases and cancer. As a result systemic inhibition of these cytokines may have a therapeutic effect. Our study in experimental arthritis suggests that TNF from one particular cellular source may play a protective, anti-inflammatory role. Another study suggests the importance of TNF from restricted cellular sources for resistance to infections that may be compromised during systemic TNF ablation. Finally, we and others have provided evidence that in several diseases pathogenic TNF is produced by myeloid cells. Thus, in the same disease the contribution of TNF may be opposite, depending on the source. Based on these findings we are developing bi-specific antibodies that would attach to the cell surface of a particular type of immune cells, and capture TNF released by these cells, preventing its dissemination and bioavailability. TNF from other sources should not be affected. Our constructs are based on single domain antibodies (V_HH) specific for human or mouse TNF and for cell type-specific markers, in particular, expressed by macrophages. We find that such antibodies, called MYSTI (myeloid-specific TNF inhibitors) can effectively attach to the macrophage cell surface, capture and retain the released TNF. Using mice humanized for the TNF system and macrophages isolated from such mice we assessed activity of these constructs *in vitro* and *in vivo*. Our findings may serve as a basis for bioengineering of a new type of cytokine inhibitors. Supported by Russian Ministry of Science and Education (14. Z50.31.0008), Russian Science Foundation (#14-50-00060) and Deutsche Forschungsgemeinschaft (NE 1466/2).

1884

Interleukin-27 inhibits synovial lymphoid neogenesis in inflammatory arthritis*Jones, G.W.¹, Bombardieri, M.², Greenhill, C.J.¹, McLeod, L.³, Nerviani, A.², Rocher-Ros, V.², Cardus, A.¹, Williams, A.S.¹, Pitzalis, C.², Jenkins, B.J.³, Jones, S.A.¹*¹*Cardiff University, Institute of Infection & Immunity, School of Medicine, Cardiff, United Kingdom,* ²*Queen Mary University of London, William Harvey Research Institute, London, United Kingdom,* ³*Hudson Institute of Medical Research, Clayton, Australia*

from early inflammatory arthritis patients has enabled disease classification based on local pathology. For example, synovitis can be classed as predominantly fibroblast- (pauci-immune), myeloid- or lymphoid-rich. Lymphoid histopathology can either comprise diffuse lymphocytic infiltrates or ectopic lymphoid-like structures (ELS) reminiscent of the follicular compartments of secondary lymphoid organs. ELS often develop at sites of chronic inflammation and autoimmunity where they contribute to immune-mediated pathology. However, mechanisms governing ectopic lymphoneogenesis are poorly defined. Evaluation of synovial tissue from rheumatoid arthritis (RA) patients revealed that reduced synovial interleukin-27 (IL-27) expression corresponded with the clinical presence of ELS and gene signatures associated with their development and activity. Induction of inflammatory arthritis in mice deficient in the IL-27 receptor (IL-27R) promoted synovial ELS formation, which was associated with increased synovial expression of pro-inflammatory cytokines (*Il17a*, *Il21*) homeostatic chemokines (*Cxcl13*, *Ccl21*) and transcriptional regulators (*Bcl6*, *Prdm1*) linked with lymphoneogenesis. In both clinical and experimental RA, synovial ELS coincided with the heightened local expression of signature cytokines and transcription factors of the Th17 and T follicular helper (Tfh) cell lineages, and the presence of podoplanin-expressing T cells within lymphoid aggregates. IL-27 inhibited the differentiation of T helper cells into podoplanin-expressing Th17 cells, and an increased number of these cells were observed in the draining lymph nodes of IL-27R-deficient mice with inflammatory arthritis. Thus, IL-27 appears to negatively regulate ELS development in RA through control of effector T cell responses, which opens new opportunities for improved patient stratification and treatment.

Ongoing classical IL-6 signaling is required for Th17 maintenance and the pathogenesis of colitis

Harbour, S.¹, Maynard, C.¹, Zindl, C.¹, Jones, S.², Jones, G.², Weaver, C.¹

¹University of Alabama at Birmingham, Birmingham, United States, ²Cardiff University, Institute of Infection and Immunity, Cardiff, United Kingdom

Th17 cells reactive to the enteric microbiota are central to the pathogenesis of certain types of inflammatory bowel disease. Factors involved in early Th17 differentiation include IL-6, TGF- β and IL-1, however it is unknown to what extent factors other than IL-23 are important in the late development and maintenance of mature Th17 cells.

While early Th17 development is mediated by binding of IL-6 to membrane bound IL-6Ra (classical signaling), activated Th17 cells cleave surface IL-6Ra and are only responsive to soluble IL-6Ra complexed to IL-6 (trans signaling). Using two T-cell dependent models of colitis, we found that both naïve T cells and Th17 cells deficient in IL-6Ra, which cannot signal via classical IL-6, were unable to induce colitis in recipients. Lack of disease was associated with failure to induce and maintain a Th17 response respectively, with reduced numbers of recovered cells and inability to maintain an IL-17A+ phenotype. Further, co-transfer of IL-6Ra deficient Th17 cells into an inflammatory

environment driven by WT Th17 cells was unable to rescue the phenotype of these cells, despite the absence of defects in apoptosis, proliferation or trafficking, implying that the inability of IL-6Ra Th17 cells to drive disease is due to a Th17-intrinsic mechanism which cannot be compensated for by other Th17 factors including IL-23 and IL-21.

These results indicate that ongoing IL-6 signaling is required for the maintenance of Th17 cells, and this process is contingent on IL-6 classical signaling, as IL-6 trans signaling is not sufficient for development or induction of inflammation.

Understanding the role of pro-inflammatory cytokines in the development of gastric cancer

Low, J.T., Putoczki, T., Strasser, A., O'Reilly, L.A.

Walter & Eliza Hall Institute, Melbourne, Australia

NF κ B is an important transcriptional regulator of many genes involved in tumour-promoting inflammation, cell proliferation and survival. This pathway is frequently found to be over-activated in infiltrating immune cells in gastritis lesions and in gastric cancer (GC). Our laboratory has discovered that aging NF κ B1-deficient (*nfkb1^{-/-}*) mice develop GC mimicking the progression of human invasive intestinal-type GC (IGC). These mice develop chronic gastritis, gastric mucosal atrophy or dysplasia, with a high incidence of invasive gastric adenocarcinomas. We observed abnormally increased infiltration of F4/80-positive macrophages and other CD45-positive leukocytes in the gastric mucosa of young (pre-disease) *nfkb1^{-/-}* mice. Elevated levels of pro-inflammatory cytokines and chemokines were found in the serum of young *nfkb1^{-/-}* mice, and also in established tumours of these mice. This suggests that deregulated expression of pro-inflammatory cytokines or chemokines may contribute to IGC development in these animals.

Preliminary studies in *nfkb1^{-/-}* mice indicate that NF κ B1 loss results in abnormal STAT1/STAT3 stimulation, which contributes to deregulated cytokine production. To characterise the role of deregulated cytokines in IGC development in *nfkb1^{-/-}* mice, we crossed mice lacking functional alleles for IL-11Ra, IL-22 or IL-6 to *nfkb1^{-/-}* mice. IL-6, IL-22 and IL-11 are STAT3-activating pro-inflammatory cytokines implicated in GC development. Their levels are abnormally high in the serum and gastric tumour tissue of *nfkb1^{-/-}* mice. Early survival analysis indicates that loss of IL-6 may not improve survival of *nfkb1^{-/-}* mice. In contrast, loss of IL-11Ra or IL-22 prolongs survival of *nfkb1^{-/-}* mice, suggesting that these cytokines play an important role in IGC development.

Target organ-directed nanoparticles effectively deliver IL-27 for arthritis therapy

Meka, R.¹, Venkatesha, S.¹, Ruoslahti, E.², Moudgil, K.¹

¹University of Maryland School of Medicine, Microbiology and Immunology, Baltimore, United States, ²Sanford Burnham Prebys Medical Discovery Institute, La Jolla, United States

Rheumatoid arthritis (RA) is a debilitating autoimmune disease characterized by synovial inflammation, pain, and joint damage.

Many potent anti-arthritis drugs are available for arthritis therapy, but their prolonged use leads to severe adverse effects. These drugs are given orally or by injection, and thereby are distributed to multiple organs in the body besides the intended target, the inflamed joints, resulting in unwanted toxicity. Therefore, search continues not only for better therapeutic agents, but also for novel drug delivery approaches that preferentially target the inflamed joints. In this context, our previous studies in the rat adjuvant-induced arthritis (AA) model of RA revealed that IL-27, a new member of the IL-12 family, had immunomodulatory attributes (JBC, 2011), and that a phage encoding a 9-amino acid peptide denoted as "ADK" preferentially homed to inflamed joints following intravenous injection into arthritic rats (PNAS 2011). Peptide ADK was identified using a combination of *ex vivo* and *in vivo* screening of a phage peptide-display library in rats having AA. This peptide was distinct from the well-known RGD motif-bearing peptide in regard to its receptor-binding characteristics. Therefore, we employed peptide ADK to direct IL-27-entrapping liposomes to inflamed arthritic joints of rats. This nanoparticle-based therapy was effective in significantly reducing the severity of arthritis at a much lower dose than that of IL-27 in solution. Furthermore, the nanoparticles were tolerated well without any adverse effects. We believe that with appropriate modifications, a similar targeted therapeutic approach can be adapted for human RA therapy in the near future.

Regulators of inflammation and wound formation induced by trehalose 6,6'-dimycolate (TDM) from *Mycobacterium tuberculosis* *in vivo*

da Silva Domingues, J.F., Ducasse, L., Peixoto, A.

Institut de Pharmacologie et de Biologie Structurale - CNRS, Toulouse, France

Trehalose 6,6'-dimycolate (TDM) is a glycolipid found in the cell wall of *Mycobacterium tuberculosis* that alone can induce an inflammatory and granulomatous response *in vivo*, similar to a natural infection. These properties of TDM make it a potent adjuvant for subunit vaccine, yet excessive inflammation and wound formation are adverse side effects often observed upon immunization. So far the cellular and molecular mediators of the pathology associated with the response to TDM challenge remain poorly defined. Herein, we dissected the cellular dynamics of the inflammatory response to TDM challenge in the skin of mice and the cell-cell interactions occurring at the site of challenge by intravital multiphoton microscopy. In parallel, with the use of histology we established the cellular organization of the evolving wound upon challenge. In combination with the depletion of specific immune cells we provide evidence that TDM is not toxic by itself but induces significant immunopathology mediated by myeloid cells that are attracted to the site of challenge and promote wound formation. Altogether our results provide novel insights into the mechanisms behind the pathology induced by a potent adjuvant such as TDM that are important to guide the development of better adjuvants for vaccine research.

Haematopoietic cell kinase promotes myeloid endotypes underpinning the development of COPD and tumour progression in mice

O'Donoghue, R.^{1,2}, Jarnicki, A.³, Poh, A.^{1,4}, Masson, F.^{1,2}, Faux, M.⁵, Nowell, C.⁶, Bozinovski, S.⁷, Anderson, G.⁸, Ernst, M.^{1,2}

¹Olivia Newton-John Cancer Research Institute, Cancer and Inflammation Laboratory, Heidelberg, Australia, ²La Trobe University, Cancer Medicine, Bundoora, Australia, ³University of Melbourne, Pharmacology and Medicine, Melbourne, Australia, ⁴Walter & Eliza Hall Institute of Medical Research, Inflammation, Melbourne, Australia, ⁵Walter and Eliza Hall Institute of Medical Research, Structural Biology, Melbourne, Australia, ⁶Monash University, Monash Centre of Pharmaceutical Sciences, Melbourne, Australia, ⁷RMIT University, Health Innovations Research Institute, Bundoora, Australia, ⁸University of Melbourne, Pharmacology and Medicine, Melbourne, Australia

Chronic obstructive pulmonary disease (COPD) is the third leading cause of death in the world and is an independent risk factor for the development of lung cancer. Polymorphisms and mutations in haematopoietic cell kinase (Hck) have been observed in patients with COPD and lung cancer while aberrant activation of Hck ($Hck^{Up/Up}$) promotes the development of COPD hallmarks in the lungs of mice. Adult $Hck^{Up/Up}$ mice develop pulmonary inflammation compared to Wt mice, which is linked to emphysema from 12 weeks of age. This phenotype was independent of the adaptive immune system since lymphocyte deficient ($Hck^{Up/Up}; Rag1^{-/-}$) mice were similar to $Hck^{Up/Up}$ mice. Phenotypic analysis of inflammatory cells in the lungs of mutant mice showed enhanced numbers and enrichment of Cd11b+:Ly6g+:Csfr1+ myeloid-derived suppressor cells (MDSCs) and Cd11b+:F4/80+:Arg1+ alternatively activated macrophages (AAMs). These cells were implicated in promoting disease after adoptive bone marrow transfers of Wt bone marrow alleviated disease and reduced MDSCs and AAMs in $Hck^{Up/Up}$ host mice. Pulmonary inflammation was reduced in $Hck^{Up/Up}; Gcsf^{-/-}$ and $Hck^{Up/Up}; Il6^{-/-}$ mice consistent with the ability of these cytokines to promote MDSC and AAM differentiation respectively. The tumour enhancing properties of Hck was confirmed after lung tumour burden was significantly larger in $Hck^{Up/Up}; Kras^{LSL-G12D/+}$ mice than in $Kras^{LSL-G12D/+}$ and adenoma formation was promoted in $Hck^{Up/Up}; Scgb1a1-Cre; Kras^{LSL-G12D/+}$ mice compared to the bronchiolar hyperplasia observed in control mice. In summary, Hck activity within pulmonary macrophages promotes MDSC accumulation and AAM differentiation to drive a COPD-like inflammatory pulmonary disease and lung tumour progression in mice.

GM-CSF primes cardiac inflammation during Kawasaki disease

Stock, A., Wicks, I.

The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Kawasaki Disease (KD) is the leading cause of pediatric heart disease in developed countries. KD patients develop cardiac

inflammation, characterized by an early infiltrate of neutrophils and monocytes that precipitates coronary arteritis. While the early inflammatory processes are linked to cardiac pathology, the factors that regulate cardiac inflammation and immune cell recruitment to the heart remain obscure. Using a murine model of KD (induced by a water-soluble cell-wall fraction of *Candida albicans*, CAWS), we identified an essential role for GM-CSF in orchestrating these events. GM-CSF was rapidly produced by cardiac fibroblasts following CAWS challenge, precipitating cardiac inflammation. Mechanistically, GM-CSF acted upon the local myeloid compartment, driving the expression of inflammatory cytokines and chemokines that facilitated neutrophil and monocyte recruitment into the heart. Our findings describe a novel role for GM-CSF as an essential initiating cytokine in cardiac inflammation, and implicate GM-CSF as a potential target for therapeutic intervention in KD

1312

Regulation of CCL5 by Runx/CBF β is essential to maintain lung homeostasis

Seo, W., Taniuchi, I.

RIKEN IMS Center for Integrative Medical Sciences, Laboratory for Transcriptional Regulation, Yokohama, Japan

Recent findings suggest that Runx/CBF β transcription factors might directly control inflammation in addition to their roles during hematopoiesis. Indeed, we previously reported that mice with impaired Runx/CBF β function showed IL-4 dysregulation and airway inflammation with allergic characteristics. However, the spontaneous lung infiltration of Runx/CBF β -deficient mice was much more severe than that of the previously reported IL-4 transgenic mice, suggesting that there might exist other inflammatory molecules contributing to the observed lung pathology. The search for other dysregulated cytokines and chemokines from Runx/CBF β mutant mice revealed that CCL5, a potent inflammatory chemokine normally secreted from activated CD8⁺T cells, is over-expressed by activated CD4⁺T cells, indicating that Runx/CBF β not only represses CCL5 during the steady state but also control cell-type specific CCL5 expression. Elimination of CCR5, the major receptor for CCL5, rescued the lung pathology, confirming that CCL5-CCR5 axis is one of the main causes of the lung pathology. Our ChIP assays identified a conserved Runx/CBF β binding region located upstream of CCL5 promoter. Deletion of this Runx/CBF β binding region abrogated CCL5-GFP BAC reporter expression as well as endogenous CCL5 expression, indicating that this region contains a critical enhancer against which Runx/CBF β may counteract to regulate CCL5 expression in CD4⁺T cells. We propose that Runx/CBF β is involved in the intricate regulation of CCL5 by direct binding to an essential cis-regulatory region.

Protein kinase D1 links IRAK1 and TRAF6, but not TRAF3, in the MyD88-dependent Toll-like receptor signaling pathway

Yi, A.-K.¹, Park, J.-E.²

¹*University of Tennessee Health Science Center, Microbiology, Immunology and Biochemistry, Memphis, United States,*

²*University of Tennessee Health Science Center, Pediatrics, Memphis, United States*

The initial proinflammatory responses to *Saccharopolyspora rectivirgula* (SR), which causes farmers' lung disease, is dependent on Toll-like receptor 2 (TLR2) and MyD88, and MyD88 is absolutely required for SR-induced protein kinase D1 (PKD1) activation. We found that SR-mediated proinflammatory responses and neutrophil infiltration in the lungs are ablated in mice treated with PKD inhibitor or lacking the PKD1 gene. However, the mechanisms by which PKD1 is activated and functions to regulate TLR signaling are incompletely understood. In the present study, we found that upon TLR ligand stimulation, the receptor signaling complex composed of MyD88, IRAK4, IRAK1, TRAF6, and PKD1 is formed in membrane lipid rafts, and that IRAK4 and IRAK1, but not TRAF6, are required for recruitment of PKD1 to the receptor complex and for activation by TLR ligands. In addition, MyD88-dependent translocation of TRAF6 into lipid rafts, ubiquitination of TRAF6, degradation of IRAK1, activation of TAK1, NF- κ B and MAPKs, and subsequent expression of proinflammatory cytokines/chemokines are dependent on PKD1. However, PKD1 does not interact with TRAF3 and is dispensable for TLR-mediated type I interferon expression. Our findings indicate that PKD1 is a downstream effector of IRAK1, but an upstream modulator of TRAF6. Together with the known ability of PKD1 to shuttle between membrane lipid rafts and the cytosol, our results further support the hypothesis that PKD1 functions as a molecular shuttle that brings TRAF6 to IRAK1 in membrane lipid rafts and then aids in translocation of the IRAK1/TRAF6 complex to the cytosol, where TRAF6 interacts with its downstream effectors.

TLRs and FcRs acting together to eradicate infections

Bakema, J.¹, Tuk, K.², van Vliet, S.J.², Bruijns, S.C.², Vos, J.B.², Letsiou, S.³, Brenkman, A.B.³, van Egmond, M.²

¹*VUMC, Department of Otolaryngology/Head-Neck Surgery, Amsterdam, Netherlands,*

²*VUMC, Molecular Cell Biology and Immunology, Amsterdam, Netherlands,*

³*UMCU, Department of Metabolic Diseases and Netherlands Metabolomics Centre, Utrecht, Netherlands*

Cell-mediated mechanisms of the host defense are crucial for the control of infectious pathogens. Whereas pattern recognizing receptors, like Toll-like receptors (TLRs), play an essential role during primary responses, pathogen-specific antibodies play a key role during re-encounter with the same pathogen by inducing rapid Fc-receptor (FcR)- mediated uptake and clearance by immune effector cells. The individual importance

of these different classes of receptors is well studied. However, during binding and uptake of antibody-opsonized bacteria, ligands for both receptor systems are involved, and potential cross-talk between these two receptor classes received relatively little attention.

We therefore investigated whether antibody-opsonized bacteria could evoke simultaneous activation of FcRs and TLRs and demonstrated cross-talk between MyD88-signalling dependent TLRs and ITAM-bearing FcRs on various immune cells. Cross-talk between TLRs and FcRs on DCs, for instance, induced a profound altered secretory profile of inflammatory cytokines and eicosanoids. Moreover, this resulted in skewing of IFN γ producing TH-1-subset towards IL-17 and GM-CSF producing TH-cells. The observed altered cytokine profile, induced by cross-talk between the two receptors types, was regulated on both transcription and post-transcriptional levels.

In conclusion, our findings demonstrate functional cross-talk between pathogen recognizing TLRs and antibody binding FcRs. These observations generate novel insights in pathogen elimination during secondary infections which induce fundamentally different immune responses compared to non-antibody mediated primary immune responses. This knowledge could be helpful to develop and refine new therapies for inflammatory diseases as well as for induction of anti-tumor immune responses during antibody mediated treatment of cancer.

Cre-dependent DNA recombination activates cGAS-STING innate immune response

Pépin, G.¹, Ferrand, J.¹, Höning, K.², Gough, D.J.³, Williams, B.R.G.³, Hornung, V.⁴, Gantier, M.¹

¹Hudson Institute of Medical Research, Centre for Innate Immunity and Infectious Diseases, Clayton, Australia, ²University of Bonn, Institute of Molecular Medicine, Bonn, Germany, ³Hudson Institute of Medical Research, Centre for Cancer Research, Clayton, Australia, ⁴Ludwig-Maximilians University, Gene Center and Department of Biochemistry, Munich, Germany

Gene-recombinase technologies, such as Cre/*loxP*-mediated DNA recombination, are important tools in the study of gene function, but have potential side effects due to damaging activity on DNA. Here we show that DNA recombination by Cre instigates a robust antiviral response in mammalian cells, independent of legitimate *loxP* recombination. This is due to Cre-dependent DNA damage and the accumulation of cytoplasmic DNA, which recruits the cytosolic cyclic GMP-AMP (cGAMP) synthase (cGAS)-STING innate immune pathway. Importantly, we establish a direct interplay between this antiviral response and cell-cell interactions, indicating that low cell densities could be useful to help mitigate these effects of Cre *in vitro*. Taking into account the wide range of interferon stimulated genes that may be induced by the cGAS-STING pathway together with widespread use of the Cre/*loxP* based system, these results call for caution in the interpretation of data from Cre/*loxP*-based studies that do not include appropriate Cre-only controls.

2329

A mitochondrial target of imiquimod is involved in Nlrp3 inflammasome activation and cancer cell growth arrest

Gross, C.J.¹, Mishra, R.¹, Dittlein, D.C.², Wettmarshausen, J.³, Ruland, J.¹, Traidl-Hoffmann, C.², Perocchi, F.³, Gross, O.¹

¹Technische Universität München, Institut für Klinische Chemie und Pathobiochemie, Munich, Germany, ²Technische Universität München, Institut für Umweltmedizin, Munich, Germany, ³Ludwig-Maximilians-Universität, Genzentrum, Munich, Germany

Imiquimod is a topical immunomodulator that is used to treat genital warts and basal cell carcinoma. Its ability to activate Toll-like receptor 7 (TLR7) for the production of type I interferon and pro-inflammatory cytokines is presumed to underlie its efficacy. However, TLR7-independent effects of imiquimod, including growth arrest and apoptosis in cancer cells and NLRP3 inflammasome activation in myeloid cells, may contribute to its efficacy or adverse effects. We investigated the mechanism of NLRP3 inflammasome activation by imiquimod, including the involvement of endolysosomal leakage, ROS, and K⁺ efflux. Our results challenge the current model of Nlrp3 inflammasome activation. Further chemical proteomics and functional studies identified a direct mitochondrial target of imiquimod that is known to have an important metabolic role in immune cells and cancer cells. We present evidence that inhibition of this target by imiquimod is important for the ability of imiquimod to activate the Nlrp3 inflammasome in myeloid cells, and to trigger growth arrest in cancer cells.

1117

NOD/RIP2 signaling in response to non-peptidoglycan containing pathogen contribute to development of a TH1-biased response and resistance against *L. major* infection

Lima-Junior, D.S., Silva, J.S., Zamboni, D.S.

University of Sao Paulo, Ribeirão Preto, Brazil

The intracellular sensors Nod1 and Nod2 have key role in the host responses. During activation, these proteins signals via the adapter molecule Rip2, which is a protein kinase that leads to activation of NF- κ B and MAPK. Also, Nod1 and Nod2 participate in the detection/control of several pathogens as they sense PAMPs contained in the cell walls of Gram-negative and Gram-positive bacteria. However, the role of Nod1 and Nod2 during *Leishmania* infection is unknown. Here, we investigated the participation of Nod/Rip2 pathway in host response during *L. major* infection. Using *Nod1*^{-/-}, *Nod2*^{-/-} and *Rip2*^{-/-} BMDMs we observed an impaired induction of NF- κ B-dependent products in response to *L. major* infection. Moreover, IL-12p40 production and surface molecules expression were decreased in parasite infected-*Nod1*^{-/-}, *-Nod2*^{-/-}, *-Rip2*^{-/-} BMDCs. On the other hand, *Nod1*^{-/-}, *Nod2*^{-/-} and *Rip2*^{-/-} BMDCs presented an increased IL-4 production after infection with *L. major*. Nod1 and Nod2 activation was crucial for *in vivo* parasite replication control and resolved cutaneous lesions. Nod/Rip2-dependent response was required for dendritic cells activation and induction of effective Th1 response *in vivo*. Additionally, Rip2-dependent signaling in radio-sensitive compartments was required for the control of the infection and induction of Th1 response. These studies

indicate that Nod/Rip2-dependent responses account for host resistance against *L. major* infection by mechanisms dependent of Th1 cytokine. Importantly, this study shows that the Nod-Rip2 axis effectively participate of the induction of adaptive immune responses against a *Leishmania* parasite, thus providing a novel function for Nod-like receptors family or proteins in parasite-host interactions.

TLR13 signaling on cardiomyocytes and macrophages is critical to establish protective immunity to Coxsackievirus B3 infection

Qian, Q., Xu, W.

Soochow University, Institutes of Biology and Medical Sciences, Suzhou, China

Toll like receptor 13 (TLR13) is an unclarified TLR member responsible for the recognition of 23S bacteria rRNA. Little is known, however, of the impact of TLR3 on antiviral host defenses. Here we examined the role of TLR13 in the innate response to Coxsackievirus B3 (CVB3), a prevalent human pathogen associated with viral myocarditis and chronic dilated cardiomyopathy (DCM). We confirmed TLR13 as the most robustly up-regulated cardiac TLR in C57BL/6 mice following CVB3 infection. TLR13-deficient mice developed substantially higher viral load in the heart and spleen by day 3 following CVB3 infection thus had significantly increased mortality compared with their controls. However, survived mice had reduced heart inflammation and improved left ventricular dysfunction related with reduced cardiac T and CD11b+ leucocytes infiltration. TLR13 deficiency enhanced IFN γ +Th1 response but dramatically reduced T and neutrophil population in the spleen which may be related with the failure of viral elimination and increased mortality of mice. Cardiomyocyte deficient of TLR13 are highly susceptible to viral replication for reduced IFN- β production via IRF-7 activation; while CVB3 up-regulation of TLR13 in macrophages enhanced inflammatory cytokine production by promoting NF- κ B activation. Taken together, TLR13 innate response plays important role in host antiviral defense. TLR13 signaling in cardiomyocytes and splenocytes is critical for survival by promoting type I IFN production and neutrophil function; while macrophage TLR13 triggers local inflammatory mediators and promote immune infiltration into the heart. The protective versus pathogenic contribution of TLR13 in CVB3 infection may have profound impact on the development of viral myocarditis.

BAD-LAMP a novel actor of TLR9 trafficking in human plasmacytoid dendritic cells

Combes, A.¹, N'guessan Sari, P.¹, Arguello, R.¹, Camosseto, V.¹, Bendriss-Vermare, N.², Pierre, P.¹, Gatti, E.¹

¹Centre d'Immunologie de Marseille-Luminy, Marseille, France,

²Centre de Recherche en Cancérologie de Lyon, Lyon, France

The brain and DC associated LAMP-like molecule (BAD-LAMP/Lamp5) is a newly identified member of the family of lysosome-

associated membrane proteins (LAMPs). BAD-LAMP expression in most animals is confined to neurons. However, we could demonstrate that in humans, BAD-LAMP can specifically be found in the type I interferon-producing plasmacytoid DCs (pDCs). Human BAD-LAMP is localized in the endoplasmic reticulum-Golgi intermediate compartment (ERGIC) of freshly isolated CD123⁺ pDCs. Upon unmethylated cytosine-phosphate-guanine (CpG) oligonucleotides activation of pDCs, BAD-LAMP accumulates in endosomes with Toll Like Receptor 9 (TLR9) prior being strongly down-regulated. We further show that BAD-LAMP and the endosomal TLRs chaperone protein UNC93B1 co-localize and influence reciprocally their intracellular trafficking suggesting that BAD-LAMP could play a role in TLR trafficking in activated pDCs. The restricted pattern of BAD-LAMP expression allows for the rapid identification of normal and leukemic human pDCs in tissues and blood. We also could show that pDCs infiltrating human breast cancers have sustained BAD-LAMP expression, compared to their blood circulating equivalents. BAD-LAMP stands therefore as a potential accessory molecule contributing to the control of TLR signaling in pDCs both during exposure to nucleic acids and in pathological conditions like cancer.

3551

Molecular arrangement and activation of procaspases-1 and -8 at inflammasomes

Vajjhala, P.¹, Lu, A.^{2,3}, Brown, D.⁴, Sagulenko, V.¹, Schroder, K.⁴, Stow, J.⁴, Wu, H.^{2,3}, Stacey, K.^{1,4}

¹The University of Queensland, School of Chemistry and Molecular Bioscience, Brisbane, Australia, ²Harvard Medical School, Department of Biological Chemistry and Molecular Pharmacology, Boston, United States, ³Boston Children's Hospital, Program in Cellular and Molecular Medicine, Boston, United States, ⁴The University of Queensland, Institute for Molecular Bioscience, Brisbane, Australia

The inflammasome is a multi-protein complex that activates caspases-1 and -8 to mediate cell death and inflammatory responses to pathogens and cellular stress signals. Excessive activation of inflammasomes contributes to the pathology of many diseases thus a detailed understanding of inflammasome assembly and function may lead to the development of novel therapeutic agents. During inflammasome assembly, activated receptors of the NLR or PYHIN families, recruit the adaptor protein ASC and induce polymerization of its pyrin domain (PYD) into a filament. The caspase recruitment domains (CARD) of ASC are exposed on the ASC PYD filament and interact to condense the complex into a perinuclear speck. ASC CARD recruits procaspase-1 to the complex while ASC PYD recruits procaspase-8 via its death effector domains (DED). We show that ectopically expressed procaspase-8 DEDs form filaments that extend from an ASC cluster. However, full-length procaspase-8 localises within the centre of the ASC speck suggesting that catalytic domains from different filaments interact to condense procaspase-8. In contrast, procaspase-1 bundles ASC filaments into a tight ring, with which it co-localizes and also extends into the core of the ASC ring. Overexpression of ASC induces spontaneous specks that can recruit procaspases-1 and -8, but

caspase processing differs from that in ASC specks induced by the PYHIN protein AIM2. Our data suggest that filament formation is important for processing of procaspases into active forms at inflammasomes but additional interactions govern optimal processing and activation.

Therapeutic Antibodies

Monoclonal antibody against dengue virus nonstructural protein 1 wing domain protect mice from dengue virus infection

Lai, Y.-C.¹, Chuang, Y.-C.², Yeh, T.M.³

¹National Cheng Kung University, Institute of Basic Medical Sciences, Tainan, Taiwan, Republic of China, ²National Cheng Kung University, Medical Laboratory Science and Biotechnology, Tainan, Taiwan, Republic of China, ³National Cheng Kung University, Medical Laboratory Science and Biotechnology, Tainan, Taiwan, Republic of China

Dengue virus (DENV) infection is the most common mosquito-transmitted disease which may cause life-threatening dengue hemorrhagic fever (DHF) or dengue shock syndrome (DSS). Two main characteristic features of DHF/DSS are hemorrhage and vascular leakage. Previously, it has been shown that DENV nonstructural protein 1 (NS1) may play important roles in the pathogenesis of DHF/DSS by itself or by its antibodies which can cross-react with platelets and endothelial cells. Sequence homology analysis shows that C-terminal region amino acid 271-352 of DENV contains most of the cross-reactive epitope and passive immunization with antibodies against C-terminal deleted NS1 can protect mice from DENV infection. In this study, we further studied the mechanism and tested the possibility that whether monoclonal antibodies (mAb) against NS1 can be a potential therapy to protect mice against DENV infection. We first showed that NS1 is indispensable in the disease development in an established DENV-hemorrhagic mice model. Then we generated several anti-NS1 mAbs from NS1-immunized mice and screened for the ones that did not cross react to host proteins. Among them, we found mAb 33D2, which recognized all four serotypes of DENV NS1, could reduce viral load in both complement dependent and independent manner *in vitro*. Passive immunization of mAb 33D2 reduced all four serotypes of DENV-induced local skin hemorrhage and prolonged bleeding time in mice. Epitope mapping by phage-displayed random peptide library showed that mAb 33D2 recognized wing domain of NS1. These results suggest mAb 33D2 may represent a therapeutic antibody to prevent DHF/DSS.

Ultra-potent neutralization of GM-CSF by multispecific antibodies

Piccoli, L.¹, Corti, D.², Lanzavecchia, A.¹

¹Institute for Research in Biomedicine, Immune Regulation Laboratory, Bellinzona, Switzerland, ²Humabs Biomed SA, Bellinzona, Switzerland

Granulocyte-macrophage colony stimulating factor (GM-CSF) is a pro-inflammatory cytokine involved in the activation of monocytes, macrophages and granulocytes in several inflammatory and autoimmune diseases such as rheumatoid arthritis, multiple sclerosis, Crohn's disease, psoriasis, asthma and atopic dermatitis. GM-CSF is therefore a potential target for anti-inflammatory and autoimmune therapies.

We recently showed that autoantibodies to GM-CSF, causing autoimmune pulmonary alveolar proteinosis, potently neutralize the cytokine by synergistic action. In particular, a combination of three non-cross-competing antibodies completely neutralizes GM-CSF activity *in vitro* by sequestering the cytokine in high-molecular-weight complexes, and *in vivo* promotes the rapid degradation of GM-CSF-containing immune complexes in an Fc-dependent manner.

These findings prompted us to design a panel of anti-GM-CSF multispecific antibodies originated by different combinations of four non-cross-competing GM-CSF autoantibodies. Surprisingly, such multispecific antibodies have significantly higher neutralizing activity not only compared to single GM-CSF autoantibodies and to therapeutic antibodies MOR103 and Namilumab, but also compared to combinations of GM-CSF antibodies. These results suggest that multispecific antibodies chelate and sequester irreversibly GM-CSF from the interaction with its cognate receptor. These multispecific antibodies can be used at extremely low dosage to treat several GM-CSF-dependent inflammatory and autoimmune diseases.

Evaluation of a novel passive immunotherapy approach targeting HMGB1 in the treatment of sepsis

Stevens, N.¹, Fraser, C.², Chapman, M.³, Kuchel, T.², Diener, K.^{1,4}, Hayball, J.^{1,5}

¹University of South Australia, Experimental Therapeutics Laboratory, Adelaide, Australia, ²South Australian Health and Medical Research Institute, Preclinical, Imaging and Research Laboratories, Adelaide, Australia, ³Royal Adelaide Hospital, Department of Intensive Care Medicine, Adelaide, Australia, ⁴University of Adelaide, Robinson Research Institute, School of Medicine, Adelaide, Australia, ⁵University of Adelaide, School of Medicine, Adelaide, Australia

Sepsis is characterised by systemic inflammatory response syndrome (SIRS) triggered by infection from various pathogens which may benefit from passive immunotherapy during emergency care. Nuclear protein high-mobility group box 1 (HMGB1) has emerged as a key mediator in SIRS, where it acts as an alarmin signalling primarily through RAGE and TLR's. HMGB1 may also play a role in secondary immunosuppression and nosocomial infection which is a significant cause of mortality in septic patients. These contrary roles of HMGB1 have been linked to the redox status of two cysteine residues present on the A-box domain of the circulating protein.

From a clinical perspective, analysis of plasma samples taken from a cohort of adult septic patients revealed significantly higher levels of HMGB1 in non-survivors compared to survivors and healthy adults. To determine whether inhibition of HMGB1 could improve survival from sepsis, potent HMGB1-

neutralising ovine polyclonal antibodies were generated following similar methodology to currently available critical care therapies. Administration of anti-HMGB1 antibodies to mice in preclinical models of sepsis confers a survival advantage in a murine endotoxin model, reduces morbidity and circulating proinflammatory cytokines in a caecal ligation and puncture peritonitis model, and significantly increases survival following a secondary infection of survivors in a two-hit model. Further studies will assess HMGB1 redox status in sepsis patients, and determine the effect of anti-HMGB1 treatment in conjunction with clinically-relevant supportive interventions in an intensive care model of ovine sepsis. Together, these works will establish the validity of targeting HMGB1 by passive immunotherapy in sepsis.

Application of an ELISA based competitive binding assay to measure concentration of anti-TNF biologics and neutralising anti-drug antibodies in the clinical laboratory

Keating, P.¹, Hock, B.², Barclay, M.³, Stamp, L.⁴, Spellerberg, M.¹, O'Donnell, J.¹

¹Canterbury Health Laboratories, Immunology, Christchurch, New Zealand, ²Christchurch Hospital, Haematology Research Group, Christchurch, New Zealand, ³Christchurch Hospital, Department of Clinical Pharmacology, Christchurch, New Zealand, ⁴Christchurch Hospital, Department of Rheumatology, Immunology and Allergy, Christchurch, New Zealand

Introduction: There is increasing interest in measuring both drug and anti-drug antibody (ADA) levels in patients receiving anti-TNF treatment as part of algorithms for guiding therapeutic strategies.

Aim: Application of ELISA based methods to measure drug concentration and ADA in patients receiving either adalimumab or infliximab in the clinical laboratory to aid clinicians in their treatments.

Methods: An ELISA to specifically detect drug concentrations in patient sera with no evidence of interference by rheumatoid factor was developed. A subset of patients with low drug concentrations were tested for neutralising ADA by competitively inhibiting the in vitro binding of drug to solid phase TNF. The assays were made available to clinicians within New Zealand.

Results: In our experience, 62% of samples (n=182) had levels of drug less than 7mg/L, a suggested threshold for drug activity. Samples received were predominantly from those with Inflammatory Bowel Disease and disease activity was higher in those with drug concentrations < 7mg/L. Our method of neutralising ADA detection was more sensitive than commercially available bridging ELISA formats. Of the samples with drug concentration < 1mg/L, 40% of those taking adalimumab (n=15) and 30% of those taking infliximab (n=23) had developed ADA. Clinicians used the assay results to alter treatments.

Conclusion: Monitoring of anti-TNF biologic drug levels and ADA was well received by clinicians. The results confirm published data showing trough concentrations and presence of neutralising ADA are correlated with disease activity. The available assays have influenced the management of disease.

Novel ways of targeting PKCθ reveals new molecular clues about T cell signaling

Ozay, E.I.^{1,2,3}, Trombley, G.^{2,4}, Torres, J.^{1,2}, Chikkegowda, P.^{2,5}, Tew, G.N.^{1,3}, Minter, L.M.^{1,2,5}

¹UMass Amherst, Graduate Program in Molecular and Cellular Biology, Amherst, United States, ²UMass Amherst, Veterinary and Animal Sciences, Amherst, United States, ³UMass Amherst, Polymer Science and Engineering, Amherst, United States, ⁴UMass Amherst, Biochemistry and Molecular Biology, Amherst, United States, ⁵UMass Amherst, Graduate Program in Animal Biotechnology and Biomedical Sciences, Amherst, United States

Protein kinase C theta (PKCθ) activates several transcriptional programs in T cells responsible for the induction of normal immune responses. PKCθ can be phosphorylated on several residues and essentially, Threonine 538 (Thr538) phosphorylation leads to full T cell activation. There are studies showing PKCθ hyperphosphorylation leads to abnormal immune responses. For instance, patients with aplastic anemia, an immune-mediated bone marrow failure, express higher levels of Thr538 phosphorylation compared to healthy controls. Furthermore, Threonine 219 (Thr219) phosphorylation is necessary for PKCθ to translocate to immunological synapse (IS) strengthening T cell activation. PKCθ functions in the cytosol and in the nucleus; thus, its localization in T cells may result in differential responses. Here, our objective is to elucidate PKCθ-associated molecular signals and function by modulating its phosphorylation status and cellular localization. To achieve this, we delivered an intracellular antibody against Thr538 phosphorylation which blocked nuclear import, we used a small molecule inhibitor to prevent Thr538 phosphorylation, and we used a PKCθ-specific inhibitor to impair IS recruitment. Our results show that different means of targeting PKCθ reveal its distinct molecular mechanisms with regard to T cell signaling. Elucidating these mechanisms in detail may provide a greater understanding of specific PKCθ functions in order to modulate particular immune responses.

Preclinical development of a bispecific antibody that safely and effectively targets CD47 for the treatment of B cell cancers

Johnson, Z.¹, Papaioannou, A.¹, Cons, L.¹, Chatel, L.¹, Chauchet, X.¹, Hatterer, E.¹, Daubeuf, B.¹, Cosimo, E.², Shang, L.¹, Salgado-Pires, S.¹, Nelson, R.¹, Michie, A.², Fischer, N.¹, Kosco-Vilbois, M.¹, Masternak, K.¹, Ferlin, W.¹

¹Novimmune, Geneva, Switzerland, ²Glasgow University, Glasgow, United Kingdom

Immunotherapy represents the most promising new cancer treatment approach in decades and to date most novel immunotherapies rely on harnessing the killing power of T and NK cells to eliminate malignant cells. Exploiting patients' macrophages to kill tumor cells is gaining interest as an alternative, or complementary, approach that holds potential for the future. Many cancers up-regulate the expression of CD47 in order to evade immune surveillance and killing. This

'don't eat me' signal is a molecular means for healthy cells to limit their phagocytic elimination by macrophages and other innate immune cells and represents an interesting therapeutic target. However, the development of anti-CD47 monoclonal antibodies may be hindered due to the ubiquitous expression of CD47, leading to rapid drug elimination kinetics through target-mediated drug disposition, an unfavorable pharmacokinetic profile and target related toxicity including severe anemia. To address this, we have developed a bispecific antibody, NI-1701, that consists of a CD47 antibody arm with an affinity that affords rapid engagement/disengagement kinetics when binding CD47 in a monovalent setting. This arm is paired with a high affinity anti-CD19 arm in a fully human bispecific format resulting in an agent that selectively targets and kills CD19+ B cells. We demonstrate that this novel bispecific antibody is effective at inducing phagocytosis of a range of B cell cancer cell lines as well as patient derived cells, is effective at controlling human B cell tumour growth in mouse xenograft models, and circumvents the clinical pharmacology liabilities seen with a monoclonal antibody targeting CD47.

Anti-conformation monoclonal antibody effective in pre-clinical treatment of full Alzheimer's disease animal models by targeting pathological oligomeric forms of A β and modified Tau

Goni, F.¹, Marta-Ariza, M.¹, Herline, K.¹, Boutajangout, A.¹, Mehta, P.², Drummond, E.¹, Prelli, F.¹, Wisniewski, T.³

¹New York University Langone Medical Center, Neurology, New York, United States, ²NY State Institute for Basic Research in Developmental Disabilities, Immunology, New York, United States, ³New York University Langone Medical Center, Neurology, Pathology, Psychiatry, New York, United States

We have previously demonstrated that a non-self β -sheet oligomerized peptide could elicit an anti-conformational therapeutic response in Alzheimer's Disease (AD) animal models (Goni et al 2013, J Neuroinflammation) and serve as the basis for producing monoclonal antibodies that recognize pathological forms of A β and Tau in human AD brains and brains of AD animal models (Goni et al 2015 Alzheimer & Dementia pp485-6). We have now selected one of these monoclonals, mAb23B, with reactivity to both oligomeric Tau and A β , to treat 16 month old 3xTg AD mice with extensive preexisting A β and Tau pathology. Two groups of 10 animals, of comparable age, were inoculated i.p. biweekly for three weeks and weekly thereafter for 5 weeks with either 100 μ g of mAb23B in 100 μ L of sterile saline or vehicle control. Both groups were then tested for locomotor performance and radial arm maze cognitive analysis. The animals were then sacrificed and the brains harvested for histochemistry and biochemical analysis. No adverse reactions were observed during the infusion period or locomotor differences between groups. The mAb23B infused animals showed significant cognitive rescue compared to controls. This was associated with a non-significant decrease in A β plaques and intracellular PHF, but a significant decrease of the soluble oligomeric forms of A β and Tau. These results indicate that a humanized version of mAb23B would have potential as a treatment for AD.

Selective IL-2 immunotherapy

Boyman, O., Arenas-Ramirez, N., Woytschak, J.

University of Zurich, University Hospital Zurich, Department of Immunology, Zurich, Switzerland

At steady state, interleukin-2 (IL-2) is produced at low levels and serves to maintain CD4⁺ regulatory T (Treg) cell homeostasis. During immune responses, IL-2 levels acutely increase and also stimulate CD8⁺ T cells and natural killer cells. This notion has been translated to clinical use where low-dose recombinant IL-2 has been used for Treg cell-based immunosuppressive strategies in immune pathologies, while high-dose IL-2 has shown clinical efficacy in certain types of metastatic cancer. The detailed characterization, in the recent years, of functional, biophysical and structural properties of IL-2 has allowed the development of IL-2 formulations, including IL-2/anti-IL-2 monoclonal antibody complexes (briefly, IL-2 complexes) and IL-2 muteins. These IL-2 formulations selectively enhance IL-2's immune stimulatory versus inhibitory properties by acting preferentially on CD8⁺ T cells and natural killer cells versus Treg cells. I will discuss selective IL-2 immunotherapy by integrating these data into a framework and highlight recent developments in this field.

NK

The secret life of NK cells – the regulatory functions of NK cells are essential to balance immune responses and avoid immune pathology

Schuster, I.S., Coudert, J.D., Fleming, P., Andoniou, C.E., Degli-Esposti, M.A.

University of Western Australia and Lions Eye Institute

Key to effective immune responses is the ability to balance protective immunity with the risk of inappropriate, misdirected or dysregulated immune responses that can cause pathology. Effective immunity requires the coordinated activities of innate and adaptive immune responses. Natural killer (NK) cells are central players in innate immunity. The most acknowledged functions of NK cells are their cytotoxic potential and their ability to release pro-inflammatory cytokines early in the response and without prior activation. Recently however, it has become clear that NK cells are more than assassins. Indeed, NK cells appear capable of mediating a sophisticated series of activities that impact on the functions of both innate and adaptive immunity. Our studies have focused on defining the impact of NK cells on cytokine responses, virus-specific T cell responses and immunopathology. These studies have revealed important interactions between NK cells and macrophages and shown that these are essential for protecting tissues from immune-mediated pathology. We have also defined the impact of NK cell responses on T cell mediated immunity and how this affects the control of chronic viral infection. More recently we have extended this work to show that chronic cytomegalovirus infection is critical in the development of autoimmunity and have highlighted an unexpected regulatory role of NK cells in this process.

²The Walter and Eliza Hall Institute of Medical Research, VIC, Australia., ³The University of Melbourne, VIC, Australia., ³Hamilton Institute, Nat

Inflammatory diseases affect over 80 million people worldwide and accompany many diseases of industrialized countries, being the majority of them infection-free conditions. We now know that innate immunity is the main coordinator and driver of inflammation through the secretion of cytokines and other signaling proteins upon innate immune cell activation by

pathogen associated molecular patterns. The activation of purinergic P2X7 receptors in immune cells by extracellular ATP is a novel and increasingly validated “sterile” pathway to initiate inflammation. P2X7 receptor induces the activation of the NLRP3 inflammasome and caspase-1, leading to the release of IL-1beta via unconventional protein release. In the last years, we have gain substantial insights into the release of IL-1beta and other proteins that constitute the secretome of P2X7 receptor activation, being some of them dependent on caspase-1 driving pyroptotic cell death. Extracellular ATP, the physiological P2X7 receptor agonist, is a crucial danger signal released by stressed or injured cells, and one of the most important mediators of infection-free inflammation. We have recently translated this knowledge to human clinical pathology, where the development of selective P2X7 receptors with a suitable clinical profile, increase the therapeutic window to treat inflammatory, metabolic and degenerative diseases.

Innate Receptors

Molecular Mechanism controlling TLR7 responses in plasmacytoid dendritic cells

Miyake, K.

University of Tokyo

The Toll family of receptors have critical roles in microbial recognition and activation of defense responses. Nucleic acid (NA) is a major Toll-like receptor (TLR) ligand. TLR7/8 and 9 are localized in intracellular organelle and sense single strand (ss) RNA and ssDNA, respectively. TLR9 directly binds to short ssDNA fragment, which is generated by DNase II. The structure of TLR8 with ssRNA shows that TLR8 binds to Uridine and di-ribonucleotide UG instead of a ssRNA fragment. TLR7 and 8 are synergistically activated by ssRNA with Guanosine or Uridine, respectively. RNA sensing by TLR7/8 is distinct from DNA sensing by TLR9. Plasmacytoid dendritic cells (pDCs) sense viral infection by TLR7/9, and rapidly produce a large amount of type I interferon (IFN) upon viral infection. TLR9 is shown to traffic upon ligand stimulation and TLR9 trafficking is required for type I IFN. Much less is known about the molecular mechanism underlying TLR7 trafficking and type I IFN induction in pDCs. We here show the molecular mechanism specifically controlling ligand dependent TLR7 trafficking and TLR7-dependent type I IFN induction in pDCs. TLR7 ligand induced rapid cytoskeletal changes and anterograde TLR7 trafficking from the perinuclear region to the cell periphery. The molecules controlling TLR7 trafficking were required for type I IFN induction by TLR7 but dispensable for TLR9 responses. These results demonstrate that innate immune responses to DNA and RNA are differentially regulated in pDCs.

Identification of eomes-positive T helper cells as a pathogenic factor in chronic neuroinflammation

Raveney, B.¹, Oki, S.¹, Nakamura, M.², Lin, Y.^{1,2,3}, Sato, W.^{1,2}, Yamamura, T.^{1,2,3}

¹National Institute of Neuroscience, National Center of Neurology and Psychiatry, Department of Immunology, Kodaira, Japan,

²National Center Hospital, National Center of Neurology and Psychiatry, Multiple Sclerosis Center, Kodaira, Japan, ³National Center Hospital, National Center of Neurology and Psychiatry, Department of Neurology, Kodaira, Japan

Multiple sclerosis (MS), the autoimmune disease of the central nervous system (CNS), frequently manifests a relapsing/remitting course (RRMS), later shifting to a secondary progressive form (SPMS). Pathogenesis of SPMS is poorly understood and lacks effective therapies. We have previously reported that NR4A2 is upregulated by circulating T cells in RRMS patients and is NR4A2 is expressed by CNS-infiltrating Th17 cells during experimental autoimmune encephalomyelitis (EAE).

Mice with T cell-specific NR4A2 deficiency (NR4A2 cKO) did not develop early/acute clinical EAE symptoms, but instead developed an unexpected late/chronic EAE. Disease reduction was associated with reduced NR4A2-dependent Th17 cells, whereas in late disease, non-Th17 CNS-infiltrating T cells from NR4A2 cKO were pathogenic on transfer.

The absence of NR4A2-dependent T cell responses revealed a novel population of CD4⁺ T cells accumulating in CNS during late/chronic EAE that expressed the transcription factor eomes. Eomes RNAi treatment *in vivo* and CD4-specific eomes knockout suppressed the late/chronic symptoms in NR4A2 cKO. Such eomes⁺Th cells were implicated in granzyme B-mediated cytotoxicity potentially acting directly on PAR-1 receptors expressed by neurons; treatment with PAR-1 activating peptides restored late/chronic EAE in the absence of eomes. Strikingly, eomes⁺ Th cells were also remarkably increased in peripheral blood and further enriched in cerebrospinal fluid of SPMS patients.

Our findings raised the possibility that these previously unappreciated eomes⁺CD4⁺ T cells may be a novel therapeutic target for SPMS. NR4A2 cKO may also provide a useful animal model for investigating pathogenesis of late/chronic CNS autoimmunity.

General control non-derepressible 2 (GCN2) controls T_{reg}-mediated remission of acute neuroinflammation via chemokine signaling

Sonner, J.¹, Keil, M.¹, Lanz, T.^{1,2}, Oezen, I.¹, Bunse, T.¹, Bittner, S.³, Meyer, H.⁴, Meuth, S.⁵, Wick, W.^{2,6}, Platten, M.^{1,2}

¹German Cancer Research Center, DKTK CCU Neuroimmunology and Brain Tumor Immunology, Heidelberg, Germany, ²University

Hospital Heidelberg, Department of Neurology and National Center of Tumor Diseases, Heidelberg, Germany, ³University Medical Center of the Johannes Gutenberg-University Mainz, Department of Neurology, Mainz, Germany, ⁴European Molecular Biology Laboratory, European Bioinformatics Institute, Hinxton, United Kingdom, ⁵University of Muenster, Department of Neurology, Muenster, Germany, ⁶German Cancer Research Center, DKTK CCU Neurooncology, Heidelberg, Germany

Multiple sclerosis (MS) is an inflammatory disorder of the central nervous system (CNS) that is caused by an imbalanced immune response to self-antigens. Spontaneous remission from acute neuroinflammation is characterized by infiltration of regulatory T cells (T_{regs}). The tryptophan-degrading enzyme indoleamine 2,3-dioxygenase (IDO) has been implicated in restriction of autoreactive T cell responses as seen in neuroinflammation. Local depletion of tryptophan upon upregulation of IDO expression in response to inflammatory processes is thought to restrict T cell responses partly via activation of the stress kinase general control non-derepressible 2 (GCN2).

Our data show that GCN2 expression in T cells facilitates T_{reg} accumulation in the CNS to alleviate acute neuroinflammation. T cell-specific GCN2 knockout mice presented with a specific failure of spontaneous remission and impaired remission was associated with reduced T_{reg} frequencies in the inflamed CNS, while infiltration by T helper (T_H) 1 and T_H17 cells was not altered. This T_{reg}-specific defect was due to impaired migration towards a chemokine gradient.

In conclusion, these results identify GCN2 as a key player for T_{reg} infiltration into the CNS during acute neuroinflammation and point to a novel molecular mechanism that regulates chemokine signaling via GCN2 activation.

Assessment of vasoactive neuropeptide receptor expression in varying severities of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME)

Johnston, S.^{1,2}, El-Zahar, M.², Nguyen, T.^{1,2}, Knauth, E.¹, Staines, D.¹, Marshall-Gradisnik, S.^{1,2}

¹Menzies Health Institute Queensland, National Centre for Neuroimmunology and Emerging Diseases, Parklands, Australia,

²Griffith University, School of Medical Science, Parklands, Australia

Vasoactive neuropeptides (VN) are implicated in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) symptomatology due to their involvement in neurological-immunological communication as they are able to modulate the immune system. Preliminary research findings have reported significant changes in VN receptor numbers in T cells, however, the T cell phenotype(s) are yet to be investigated. The aim of this study was to investigate the level of VN receptor expression in T cells phenotypes, such as CD4 and CD8 cells among healthy individuals compared to CFS/ME patients with varying severities of this illness. Participants were classified as control (n=15, age 43.47±3.46), moderate CFS (n=15, age 39.47±2.82) or severe CFS (n=7 age 41.71±3.71). All CFS/ME participants meet the International Consensus Criteria (ICC) and were further classified as moderate or severe based on the Dr

Bell's CFS Disability scale. VN receptors VPAC1, VPAC2 and PAC1 expression on CD4 and CD8 T-cell subsets was investigated in stimulated and unstimulated conditions using flow cytometry. Severe CFS/ME patients showed a significant increase in VPAC2 expression on CD4+ T-cells when stimulated compared to healthy controls with trends being observed in expression of other receptors between groups. An increase in VPAC2 expression indicates dysregulation of the Th1/Th2 pathway. The dysregulation of the Th2 pathway may result from changes in VPAC2 expression in severe CFS/ME participants and their possible clinical presentation.

1979

CD8 T cell-mediated killing of orexin-producing neurons induces a narcolepsy-like phenotype in mice

Bernard-Valnet, R.^{1,2}, Yshii, L.¹, Queriaux, C.¹, Matthys, A.¹, Bauer, J.³, Pignolet, B.¹, Dauvilliers, Y.⁴, Peyron, C.⁵, Liblau, R.^{1,2}

Vienna, Center for Brain Research, Vienna, Austria, ⁴Gui-de-Chauliac Hospital, CHU de Montpellier, Department of Neurology,

Montpellier, France, ⁵Center for Research in Neuroscience of Lyon, Lyon, France

Narcolepsy with cataplexy is a rare and severe sleep disorder caused by destruction of orexinergic neurons. The disease is associated with genetic, environmental and biological factors pointing to an autoimmune origin. However, current animal models of narcolepsy, based on genetic disruption of the orexinergic neurotransmission or genetic destruction of the orexin⁺ neurons, do not allow studying its aetiology. Our goal was to generate a mouse model in order to decipher the immune mechanisms leading to orexin⁺ neurons loss and narcolepsy development. To this end, mice expressing influenza virus hemagglutinin (HA) in hypothalamic orexin⁺ neurons (called Orex-HA) were developed. The consequences of an autoimmune attack on these neurons were evaluated by adoptive transfer of effectors T lymphocytes specific for HA. Considering, the tight association of narcolepsy with the HLA-DQB1*06:02 allele, we first tested the pathogenic contribution of CD4 Th1 cells. However, although Th1 cells penetrated the hypothalamic and triggered local inflammation, they did not promote loss of orexin⁺ neurons or clinical manifestations of narcolepsy. In stark contrast, the transfer of cytotoxic CD8 T cells (CTLs) led to both T cells infiltration and specific destruction of orexin⁺ neurons. In situ, CTLs interacted directly with MHC class I-expressing orexin⁺ neurons, resulting in cytolytic granule polarization toward neurons. This neuronal loss caused manifestations mimicking human narcolepsy in the Orex-HA mice. The phenotype was further aggravated upon repeated injections of CTLs. This work demonstrates the potential role of CTLs as final effectors of the immunopathological process in narcolepsy.

EphA2 is necessary for the development of experimental cerebral malaria

King, T.¹, Mimche, P.¹, Bray, C.¹, Brady, L.¹, Meyer, E.², Galinski, M.², Lamb, T.¹

¹Emory University, Pediatrics Infectious Disease, Emory University School of Medicine, Atlanta, United States, ²Yerkes National Primate Research Center, Emory Vaccine Center, Atlanta, United States

Cerebral malaria (CM) is a leading cause of death from *Plasmodium falciparum* infection, yet the mechanisms of disease pathology are poorly understood. Eph receptors, the largest family of receptor tyrosine kinases in humans, have been linked to several neurological disorders although their roles in CM remain unknown. Experimental cerebral malaria (ECM) is a lethal condition resulting from *Plasmodium berghei* ANKA (PbANKA) infection of C57BL/6J mice that recapitulates key features of human CM including sequestration of leukocytes and parasitized red blood cells (pRBCs) in the brain along with blood-brain barrier (BBB) breakdown. Here we show that upregulation of EphA2 mRNA in brains of PbANKA-infected C57BL/6J mice is a feature of ECM absent in non-lethal *Plasmodium* infections including PbNK65. PbANKA-infected EphA2^{-/-} mice, unlike EphA2^{+/+} mice, have an intact BBB at ECM onset. This is likely because accumulation of CD8⁺ T cells, which mediate ECM development, is greatly reduced in brains of PbANKA-infected EphA2^{-/-} mice despite normal splenic expansion. Unlike EphA2^{+/+} mice, PbANKA-infected EphA2^{-/-} mice are protected from death even with peripheral and organ-sequestered parasite levels similar to EphA2^{+/+} mice suggesting BBB integrity, not parasite burden, is responsible for improved survival in EphA2^{-/-} mice. Therapeutically targeting EphA2 also leads to increased survival of PbANKA-infected C57BL/6J mice. Along with preliminary data showing *P. falciparum*-induced upregulation of ephrin-A mRNA in human PBMCs and EphA2 mRNA in human brain endothelial cells, our data suggests a novel, crucial role for EphA2 in ECM with potential translation to human CM.

Regulation of CD4 T cell-mediated inflammation by cognate interactions with B cells in experimental autoimmune encephalomyelitis

Parker Harp, C.R.¹, Archambault, A.S.², Sim, J.³, Russell, J.H.³, Wu, G.F.^{1,2}

¹Washington University School of Medicine, Pathology & Immunology, St. Louis, United States, ²Washington University

School of Medicine, Neurology, St. Louis, United States,

³Washington University School of Medicine, Developmental Biology, St. Louis, United States

The mechanisms by which B cells direct CD4 T cells in an antigen-specific, major histocompatibility complex II (MHCII)-dependent manner during inflammatory demyelination of the central nervous system (CNS) are unclear. Previously, we demonstrated that antigen presentation exclusively by B cells is sufficient to propagate CNS inflammatory demyelination in the animal model of multiple sclerosis, experimental autoimmune

encephalomyelitis (EAE). However, a delay in onset of disease is observed when B cells are the exclusive antigen presenting cell during EAE. These results raise questions regarding the timing and location of cognate interactions between B cells and CD4 T cells during secondary phases of autoimmune neuro-inflammation.

Passive EAE using encephalitogenic CD4 T cells from wild-type (WT) mice was induced by transfer into WT mice and mice with MHCII expression restricted to B cells that express a higher frequency of myelin oligodendrocyte glycoprotein (MOG)-specific receptor (termed IgH^{MOG}xB^{MHCII}). EAE was also induced in mice with temporal regulation of MHCII expression by antigen-specific B cells, (termed IgH^{MOG}xB^{Tam-MHCII}).

Tamoxifen administration rapidly induced maximal MHCII expression within three days. Disease was dependent on VLA4 expression by B cells. IgH^{MOG}xB^{Tam-MHCII} mice were resistant to passive EAE until tamoxifen administration 30 days post cell transfer, resulting in EAE onset within three days. Furthermore, decreasing the duration between cell transfer and tamoxifen administration increased the time to disease onset. Our findings indicate that B cells are capable of accessing CNS myelin targets and eliciting antigen-specific CD4 T cell-dependent neuro-inflammation to dictate the tempo of neuro-inflammation during EAE.

Inflammatory monocytes recruited from the bone marrow in West Nile virus or dengue encephalitis have distinctive differentiative fates in the CNS

Vu, L.D.¹, King, N.J.C.²

¹University of Sydney, Charles Perkins Centre, Pathology, Camperdown, Australia, ²University of Sydney, Pathology, Camperdown, Australia

West Nile (WNV) and Dengue viruses (DENV) are both flaviviruses associated with significant neurological disease. In WNV encephalitis we have shown that infiltrating Ly6C^{hi} monocytes directly correlate with disease development and mortality, but the differentiation and function of these cells remain contentious. Comparing lethal WNV and non-lethal DENV encephalitis in mice, we found two distinct differentiation patterns of bone marrow-derived monocytes (BMM) infiltrating the brain. During WNV encephalitis, BMM differentiated into Ly6C^{hi}CD11c^{low}MHCII^{int} inflammatory macrophages in an inoculation route-independent manner, while in DENV encephalitis, BMM gave rise to Ly6C^{hi}CD11c^{hi}MHCII^{hi} dendritic cells (DC). Intravenous adoptively transferred BMM from WNV-infected mice into DENV-infected mice and vice versa, differentiated in the brain into DC and inflammatory macrophages, respectively, indicating that the brain, not the bone-marrow milieu, drives the fate of infiltrating BMM. Intriguingly, however, in the DENV model, differentiation of BMM into DC was abrogated when WNV donor cells were injected intracranially, suggesting a requirement for 'priming' during leukocyte extravasation for subsequent downstream differentiation in the brain. Pathway analysis of gene transcription between DENV- and WNV-infected brains showed greater activation of the transforming growth factor-beta (TGF- β) -signalling pathway, including TGF- β , vasoactive

intestinal peptide and IL-16, in DENV- than WNV-infected brains. This pathway may modulate differentiation to favour generation of tolerogenic DC. We hypothesise that the local balance between pro- and anti-inflammatory responses, beginning at the endothelium, governs the subsequent differentiation of inflammatory monocytes infiltrating into the CNS. Understanding mechanisms underlying this differentiation may suggest potential therapeutic opportunities to control CNS inflammation.

Neuroinflammation drives the neuronal degenerative phenotype in a rat model of Ataxia-telangiectasia

Quek, H.¹, Luff, J.¹, Cheung, K.^{1,2}, Kozlov, S.¹, Gatei, M.¹, Lee, C.S.³, Bellingham, M.⁴, Noakes, P.⁴, Lim, Y.C.², Barnett, N.¹, Dingwall, S.⁵, Wolvetang, E.⁵, Mashimo, T.⁶, Roberts, T.^{1,3}, Lavin, M.¹

¹The University of Queensland, Centre for Clinical Research, Brisbane, Australia, ²QIMR Berghofer Medical Research Institute, Brisbane, Australia, ³Western Sydney University, Ingham Institute for Applied Medical Research, Liverpool, Australia, ⁴The University of Queensland, School of Biomedical Sciences, Brisbane, Australia, ⁵The University of Queensland, AIBN, Brisbane, Australia, ⁶Osaka University Graduate School of Medicine, Osaka, Japan

Neuroinflammation contributes to disease progression in neurodegenerative disorders including Alzheimer's disease and Amyotrophic Lateral Sclerosis. Ataxia-telangiectasia (A-T), an autosomal recessive disease caused by mutations in the ATM gene is characterised by progressive neurodegeneration which has been poorly recapitulated in *Atm* mutant mice. Consequently, pathways leading to neurodegeneration in A-T are poorly understood. Here we show that *Atm* knockout rats display a neuroinflammatory phenotype. Loss of *Atm* in neurons leads to accumulation of cytosolic DNA, increased cytokine production and constitutive activation of microglia. Rats lacking ATM had significant loss of motor neurons and microgliosis in the spinal cord, consistent with onset of paralysis. Betamethasone treatment extended *Atm* knockout rats' lifespan, prevented microglial activation and significantly decreased neuroinflammation and motor neuron loss. These findings provide a basis for neurodegeneration in A-T patients and rationale for anti-inflammatory drugs as treatment options for A-T patients and more generally in neurodegenerative diseases.

Protection against development of a mouse model of multiple sclerosis by a parasite-derived 68-mer peptide

Dixit, A.¹, Donnelly, S.², Lund, M.A.², Dalton, J.P.³, Greer, J.M.¹

¹The University of Queensland, UQ Centre for Clinical Research, Brisbane, Australia, ²University of Technology Sydney, The School of Life Sciences, Sydney, Australia, ³Queen's University Belfast, School of Biological Sciences, Belfast, United Kingdom

Helminths (parasitic worms) can exert protective effects on autoimmune diseases by modulating the type of immune response, and deliberate infection with helminths is being

explored as a potential therapeutic strategy for autoimmunity. However, the use of live helminths as therapeutic agents for autoimmune disease has a number of drawbacks, and it would be preferable to instead identify and use purified immunomodulatory components of the helminths. Previously it has been shown that the immunomodulatory activity of the liver fluke *Fasciola hepatica* resides in its excretory-secretory products (FhES), and further analysis of FhES has identified 3 major components: a 68 amino acid alpha helical cathelicidin-like peptide (FhHDM1), a cathepsin L-cysteine protease (FhCL1), and peroxiredoxin (FhPrx). In the current study, the ability of these three components to modify the course of a relapsing-remitting experimental autoimmune encephalomyelitis (EAE) model of multiple sclerosis (MS) was tested. FhHDM1 was the most effective, significantly ($p < 0.0001$) reducing the overall severity of the disease and the number of EAE relapses compared to mice treated with vehicle alone or mice treated with FhPrx. The effects were long-lasting, with mice continuing to show benefits for up to 70 days following a single course of FhHDM1 treatment. Preliminary investigation of the mechanism of action of FhHDM1 suggests that it does not affect the adaptive arm of the immune response, but instead exerts its effects by modulation of innate pro-inflammatory responses. The data suggest that this parasite-derived peptide has potential as a novel therapeutic agent for treatment of MS.

Protective roles for microglia in neuroinflammation

Włodarczyk, A.¹, Holtman, I.R.², Bruttger, J.³, Yogev, N.³, de Boer-Bergsma, J.J.², Nolling Jensen, K.¹, Martin, N.A.⁴, Karram, K.³, Boddeke, E.W.G.M.², Waisman, A.³, Eggen, B.J.L.², Owens, T.¹

¹Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark, ²University Medical Center Groningen, University of Groningen, Groningen, Netherlands, ³Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg University, Mainz, Germany, ⁴Institute of Clinical Research, Odense University Hospital, Odense, Denmark

Microglia are central nervous system (CNS)-resident immune cells. They are often referred to as brain macrophages and indeed share many phenotypic features with them. However, it is now recognized that they are of a separate lineage and are not replaced from blood-derived precursors, at least under normal circumstances. Microglia are implicated in neuroinflammatory and neurodegenerative diseases including multiple sclerosis (MS). We have shown that in a mouse model for MS-experimental autoimmune encephalomyelitis (EAE) numbers of microglia expressing CD11c significantly increase. These CD11c⁺ microglia are effective antigen presenting cells, but poor inducers of Th1 or Th17 responses. Interestingly, CD11c⁺ microglia express neuroprotective insulin-like growth factor 1 which suggests a neuroprotective rather than proinflammatory role. Here we show that CD11c⁺ microglia predominated in the neonatal brain and expressed genes governing neuronal and glial survival, migration and differentiation. These cells were localized in sites of primary myelination such as cerebellum and corpus callosum. They expanded rapidly after birth and then contracted to become almost undetectable in the adult CNS.

Neonatal and microglia from EAE CNS differed in their gene expression profiles, showing neurogenic and immune response gene signatures, respectively. Moreover, neonatal microglia showed a transient stem-cell like phenotype that was partially recapitulated by cells repopulating the adult CNS after microglia ablation. Interestingly, transplantation of neonatal microglia suppressed EAE. CD11c⁺ microglia therefore can deliver signals necessary for neurogenesis and myelination.

Impaired cellular metabolism and inhibitory receptor expression during chronic infection are linked by IRF4

Man, K.¹, Kallies, A.²

¹The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²The Walter and Eliza Hall Institute, Parkville, Australia

During chronic infection T cells acquire an exhausted phenotype that is characterized by high expression of inhibitory receptors and down-modulation of effector function. While this is required for the protection of the organism from excessive immunopathology, it also prevents successful immunity against persistent viruses or tumor cells. The molecular mechanisms that lead to T cell exhaustion are only incompletely understood. Here, we demonstrate that exhausted T cells exhibited impaired cellular metabolism, which was mediated by the TCR-dependent transcription factor IRF4. Blockade of inhibitory PDL1-PD1 interactions restored aspects of metabolic function, which was critical for improved population expansion and CD8 T cell function, thereby revealing a molecular circuit that links cellular metabolism and immune checkpoints. Thus, in addition to its critical role in promoting clonal population expansion and effector differentiation in the early phase of an immune response, IRF4 is required for the adoption of the exhausted T cell phenotype during chronic infection.

CD28 induces metabolic fitness in long-lived plasma cells through Slp76 for reactive oxygen species-dependent survival

Utle, A.¹, Carlson, L.², Peng, P.², Mahpour, A.¹, Maharaj, S.¹, Ventro, D.¹, Murray-Dupuis, M.³, Lee, K.¹

¹Roswell Park Cancer Institute, Immunology, Buffalo, United States, ²Roswell Park Cancer Institute, Buffalo, United States, ³Duke University Medical Center, Raleigh, United States

Sustained humoral immunity is dependent upon the continual production of antigen specific antibodies by plasma cells. Upon activation, B cells develop into short-lived plasma cells (SLPCs) which home to secondary lymphoid organs and live up to several weeks before undergoing apoptosis. In a second non-mutually exclusive model, plasma cells can home to the bone marrow where they reside in competitive survival niches and can exist the lifetime of an organism as long-lived plasma cells (LLPCs). We have shown that CD28, the canonical T cell co-stimulatory molecule, is required for LLPC survival

and antibody production; however, the mechanistic basis for this is unclear. Upon T cell activation, CD28 is known to induce glycolysis at the expense of mitochondrial respiration. To our great surprise, CD28 increases mitochondrial respiration and the spare respiratory capacity in LLPCs through the adaptor molecule Slp76. Furthermore, although CD28 does not directly affect glycolysis, the glycolytic capacity and glycolytic reserve are increased in LLPCs. Paradoxically, mitochondrial respiration derived reactive oxygen species (ROS) are required for CD28-mediated LLPC survival. CD28 activates NF κ B through ROS for Irf4 mediated upregulation of cMyc, which subsequently drives mitochondrial biogenesis. This leads to a self-reinforcing model wherein CD28 induces metabolic fitness in LLPCs through ROS-dependent signaling to NF κ B and subsequent Irf4-cMyc mediated mitochondrial biogenesis. Due to the highly biosynthetic nature of plasma cells and the limited nutrient availability in the bone marrow microenvironment, CD28 may govern the ability of LLPCs to compete in the survival niche for survival and continual antibody production.

1390

Chronically stimulated CD4 T cells exhibit a defective glycolytic metabolism yet produce rapid effector function after PD-1 blockade

Braun, M.¹, Bettonville, M.¹, D'Aria, S.¹, Porporato, P.², Sonveaux, P.²
¹Universite Libre de Bruxelles, Institute for Medical Immunology, Gosselies, Belgium, ²Universite Catholique de Louvain, Pole of Pharmacology and Therapeutics (FATH), Brussels, Belgium

Continuous exposure to antigen profoundly modifies T cell function and chronically-stimulated T cells develop a state of unresponsiveness characterized by a weakened capacity to proliferate and mount effector function. Unresponsiveness is maintained by engagement of cell-surface inhibitory receptors, such as PD-1, and immunotherapies targeting these receptors have proven to be effective in restoring T cell function. How persistent stimulation influences metabolic requirements for T cell function is unknown. We have developed a mouse model of chronic antigen exposure in which antigen-specific CD4 T cells are adoptively maintained in recipients expressing a systemic antigen. Proteomic analysis indicated that many enzymes involved in cellular metabolism were down-regulated in these cells. Consequently, the cells displayed low basal metabolism compared to naive or effector T cells. Moreover, they also exhibited reduced GLUT1 expression and mitochondrial mass. Consequently, upon activation, the cells carried out limited glucose uptake and ATP synthesis. Though blockade of PD-1/PD-L1 inhibitory pathway fully restored rapid effector function, such as IFN γ secretion, it did not switch metabolism towards aerobic glycolysis. Interestingly, PD-1 blockade also stimulated mitochondrial superoxide production in chronically-stimulated T cells and specific scavenging of superoxide, though promoting cell survival, inhibited IFN γ production. Thus, 1) chronically-stimulated CD4 T cells have a glycolysis-independent capacity to produce rapid IFN γ responses; 2) PD-1 blockade promotes mitochondrial dysfunction in these cells which stimulates IFN γ production. These observations should be considered when blocking PD-1/

PD-L1 for the treatment of chronic diseases.

SHIPi alters innate immunity in VAT to control obesity

Kerr, W.¹, Sudan, R.², Youngs, C.², Howard, K.³, Russo, C.³, Engelman, R.⁴, Chisholm, J.³, Srivastava, N.²

¹SUNY Upstate Medical University, Microbiology & Immunology and Pediatrics, Syracuse, United States, ²SUNY Upstate Medical University, Syracuse, United States, ³Syracuse University, Chemistry, Syracuse, United States, ⁴Moffitt Cancer Center, Comparative Medicine and Pathology, Tampa, United States

Low-grade chronic inflammation has been established as the key etiological phenomenon responsible for the initiation and perpetuation of obesity and its associated metabolic disorders. Novel therapeutic approaches that can specifically target inflammatory pathways are very much needed to avert this looming epidemic of obesity & diabetes. Genetic & chemical inhibition of SH2 domain containing inositol phosphatase (SHIP)1 has been associated with systemic expansion of immunoregulatory cells that promote a lean-body state however its function in immunometabolism has never been assessed. This led us to investigate the role of SHIP1 in metabolic disorders during excess caloric intake in mice. Using a small molecule inhibitor of SHIP (SHIPi), here we show that SHIPi treatment in mice significantly reduces body-weight and fat content and improves control of blood glucose and insulin sensitivity as well as increases energy expenditure, despite continued consumption of a HFD. Additionally, SHIPi reduces age-associated fat accumulation in mice. We find that SHIPi treatment reverses diet-associated obesity by attenuating inflammation in the visceral adipose tissue (VAT). SHIPi treatment increases IL4-producing eosinophils in VAT and consequently increases both AAM and MDSC. In addition, SHIPi decreases the number of γ -IFN producing T-cells and NK-cells in VAT. Thus, SHIPi represents a novel approach that permits control of obesity and diet-induced metabolic syndrome without apparent toxicity that could benefit the health of millions worldwide.

Lymphocyte activation gene 3 controls metabolic profile of naïve and activated CD4⁺ T cells

Piganelli, J.D.¹, Previte, D.M.², Menk, A.V.³, Delgoffe, G.M.³

¹University of Pittsburgh School of Medicine/Children's Hospital of Pittsburgh, Surgery, Immunology and Pathology, Pittsburgh, United States, ²University of Pittsburgh/Children's Hospital of Pittsburgh, Surgery, Pittsburgh, United States, ³University of Pittsburgh School of Medicine, Immunology, Pittsburgh, United States

LAG-3 is an inhibitory receptor surfaced expressed on CD4⁺ T cells that is upregulated upon MHCII/TCR engagement and eventually cleaved, for optimal CD4⁺ T cell activation. LAG-3 negatively regulates T cell homeostatic expansion, and LAG-3^{-/-} naïve T cells exhibit increased expansion in lymphopenic hosts as well as accelerated diabetes in NOD mice. Current interest in cellular metabolism has revealed that CD4⁺ T cell function is tightly coupled to its metabolic profile. Therefore, given that

LAG-3 is a regulator of CD4⁺ T cell proliferation and effector function, we hypothesized LAG-3 expression controls the metabolic profile of CD4⁺ T cells. Naïve T cells primarily rely on oxidative phosphorylation for basal metabolic needs. Naïve CD4⁺ T cells were isolated from wildtype (WT) and LAG-3^{-/-} animals, and oxygen consumption was measured. LAG-3^{-/-} CD4⁺ T cells showed enhanced basal respiration (OCR) and mitochondrial biogenesis measured by the ratio of mitochondrial to nuclear DNA ($p < 0.05$) and transcription factor TFAM levels ($p < 0.05$). The AMPK/Sirt-1 signaling pathway was also enhanced. Upon activation, CD4⁺ T cells alter their metabolic profile, becoming highly glycolytic. Activated LAG-3^{-/-} CD4⁺ T cells compared to WT demonstrated increased glucose uptake, lactate production ($p < 0.01$), and increased expression of glycolysis-associated genes. This heightened activation suggests that the metabolic phenotype exhibited in naïve LAG-3^{-/-} CD4⁺ T cells may be advantageous during activation. These results indicate LAG-3 as a potent regulator of cellular metabolism in naïve and activated CD4⁺ T cells, thus providing new avenues to exploit for targeted therapeutics to inhibit aberrant immune responses.

¹University of Rijeka, School of Medicine, Department of Histology and Embryology, Rijeka, Croatia, ²University of Rijeka, School of Medicine, Center for Proteomics, Rijeka, Croatia

Obesity and its complication Diabetes Mellitus type 2 (DM2) represent global health problems. It is well established that low-grade chronic inflammation, which originates in obese visceral adipose tissue (VAT), is an underlying cause of insulin resistance (IR) and DM2. It is characterized by accumulation of Th1-type immune cells in VAT and secretion of pro-inflammatory cytokines. Thus, obese VAT resembles immune response to a viral infection. Although obese people are very often exposed to viral infections, very little is known how a viral infection contributes to the progression of DM2. Cytomegaloviruses are species-specific beta-herpesviruses. Majority of humans are infected with HCMV and after acute infection they establish a life-long latency. Infection of mice with MCMV represents a well-accepted model for HCMV infection.

In this work we investigated how MCMV infection influences the development DM2 in well-established mouse model of diet induced obesity (DIO). The infection was associated with a rapid accumulation of activated NK cells, which was followed by a dramatic increase of M1 macrophages, CD4 and CD8 T cells. MCMV infection itself did not induce GI in mice fed with normal chawing diet. However, it induced fast progression of GI and IR after only 4 - 6 weeks of high fat diet treatment in comparison to the DIO mice. Depletion of NK cells reduced accumulation of M1 macrophages in VAT, suggesting that NK cells were mostly responsible for the induction. Altogether, our results show that MCMV infection can cause aggravation of VAT-inflammation and induce progression of DM2 in obesity.

Saturated fatty acids-induced metabolic stress leads to biased effector memory CD4⁺ T cell differentiation via mTOR-independent, PI3K p110d/Akt-mediated signals

Smith, J.¹, Mauro, C.¹, Cucchi, D.^{1,2}, Coe, D.¹, Fu, H.¹, Bonacina, F.³, Baragetti, A.³, Catapano, A.^{3,4}, Ammirati, E.⁵, Longhi, M.P.¹, Okkenhaug, K.⁶, Norata, G.D.³, Marelli-Berg, F.¹

¹Queen Mary University of London, William Harvey Research Institute, London, United Kingdom, ²Istituto Pasteur, Fondazione Cenci Bolognetti, Rome, Italy, ³Università degli Studi di Milano, Department of Pharmacological and Biomolecular Sciences, Milan, Italy, ⁴IRCCS Multimedica, Milan, Italy, ⁵Niguarda Hospital, Milan, Italy, ⁶Babraham Institute, Laboratory of Lymphocyte Signalling and Development, Cambridge, United Kingdom

Obesity is associated with low-grade systemic inflammation, which is believed to contribute to the development of its cardiovascular complications. Smouldering inflammation in obesity involves activation of adaptive immunity and infiltration of adipose and vascular tissue by T cells with an effector phenotype. However, the signals leading to T cell activation and targeted tissue infiltration during obesity are only beginning to be understood.

We have tested the hypothesis that high-fat diet (HFD)-induced metabolic stress directly affects the differentiation and trafficking of CD4⁺ T cells to non-lymphoid tissues. We found that memory CD4⁺

T cells primed in HFD-fed donors preferentially migrate in response to the pro-inflammatory chemokine CXCL10 *in vitro* and to non-lymphoid inflammatory sites *in vivo*. The existence of a differentiation bias during priming in HFD-fed animals was confirmed by experiments showing that CD4⁺ T lymphocytes priming during HFD regimen preferentially develop into CD44^{hi}-CD62L^{lo}-CCR7^{lo}-CXCR3⁺-LFA1⁺ effector-like memory T cells in mice. A similar CD4⁺ T cell phenotype was observed when a cohort of n=1,172 subjects selected from a large survey of free-living people was systematically analyzed.

Mechanistically, we show that this developmental bias is independent of any crosstalk of CD4⁺ T cells with dendritic cells but is mediated by direct exposure of CD4⁺ T cells to the saturated fatty acids, i.e. palmitate - enriched in HFD -, leading to increased activation of a PI3K p110d/Akt-dependent and -mTOR-independent pathway downstream of TCR engagement. The observed developmental bias of CD4⁺ T cells can be corrected by selective inactivation of the PI3K p110d/Akt pathway.

Precision immunometabolic checkpoint treatment of lethal murine sepsis: targeting the NAD⁺ and sirtuin 1-dependent homeostasis network

Liu, T.^{1,2}, Vachharajani, V.³, Zhang, X.¹, Xu, J.¹, McCall, C.²

¹Scientific Research Center, Shanghai Public Health Clinical Center, Fudan University, Shanghai, China, ²Wake Forest University School of Medicine, Molecular Medicine, Winston-Salem, United States, ³Wake Forest University School of Medicine, Anesthesiology, Winston-Salem, United States

Sepsis inflammation kills millions each year worldwide and all anti-inflammatory treatments have failed. Molecular-based precision medicine is urgently needed to reduce this global health care crisis. Toward meeting this goal, we developed a precise molecular-based treatment approach for improving sepsis outcome in mice by targeting an epigenetic immunometabolic checkpoint, which is controlled by NAD⁺ sensor nuclear sirtuin 1 (SIRT1). Mechanistically, nuclear SIRT1 couples with nuclear SIRT6 and mitochondrial SIRT3 to switch the glycolysis-dependent immune effector state (cytokine storm) to a fatty acid oxidation-dependent immune repressor state. In a successful sepsis response, the SIRT1 immunometabolic checkpoint and its network links resolve sepsis by restoring homeostasis. During lethal sepsis, the SIRT1 checkpoint becomes inflexible, resulting in sustained immune repression and failure of pyruvate to fuel the mitochondrial electron transport chain. This immunometabolic paralysis promotes infection and multiorgan failure. We previously reported that precisely inhibiting SIRT1 during immunometabolic failure retrieves checkpoint function, rebalances homeostasis and rescues septic mice from death. Here, we show that opening the pyruvate mitochondrial portal for glucose oxidation by inhibiting the repressor function of pyruvate dehydrogenase kinase—a downstream node in the nuclear SIRT1 and SIRT6 checkpoint network—also relieves immunometabolic paralysis, promotes bioenergy homeostasis and rescues septic mice from death. We conclude that precision medicine can improve sepsis outcomes by targeting immunometabolic checkpoints that impede homeostasis retrieval.

Pdcd4 inhibits macrophage lipoautophagy and promotes foam cell formation and atherosclerosis in mice

Wang, L., Jiang, Y., Zhang, L.

Shandong University, Immunology, Jinan, China

Macrophage foam cells, a major component of the atherosclerotic lesion, play vital roles in the development of atherosclerosis. Lipoautophagy, a type of autophagy characterized by selective delivery of lipid droplet for lysosomal degradation, may impact atherosclerosis by regulating macrophage foam cell formation. Previously, we reported that programmed cell death 4 (PDCD4), a tumor suppressor, negatively regulated autophagy in tumor cells. However, its roles in macrophage lipoautophagy, foam cell formation, and atherosclerosis remain to be established. Here, we found that Pdcd4 deficiency clearly improved oxidized low-density lipoproteins (ox-LDL)-impaired autophagy efflux, promoted autophagy-mediated lipid breakdown in murine macrophages, and thus prevented macrophage conversion into foam cells. Importantly, Pdcd4 deficiency in mice significantly upregulated macrophage autophagy in local plaques along with attenuated lipid accumulation and atherosclerotic lesions in high fat-fed Apolipoprotein E (ApoE) knockout mice. Bone marrow transplantation experiment demonstrated that Pdcd4-mediated autophagy in hematopoietic cells contributed to the development of atherosclerosis. These results indicate that endogenous PDCD4 promotes for macrophage foam cell formation atherosclerosis development via inhibiting autophagy

and provides new insights into atherogenesis, suggesting that promoting macrophage autophagy through down-regulating Pdcd4 expression may be beneficial for treating atherosclerosis.

Modulating lipopolysaccharide-induced cytokine secretion profiles of monocytes by manipulating metabolic pathways

Jones, N., Thornton, C.A.

Institute of Life Science, Swansea University Medical School,

Swansea, United Kingdom

Monocyte activation demands energy to fuel effector functions such as pro-inflammatory cytokine production with ATP. Glycolysis and oxidative phosphorylation are the two main energy-producing pathways within mammalian cells. Many types of human leukocytes undergo activation-induced metabolic rewiring preferentially toward aerobic glycolysis, a process initiated with a six-carbon monosaccharide precursor, typically glucose. This metabolic switch is known as the Warburg effect. However, little is known about whether monocytes possess this glycolytic switch.

Here we investigate the involvement of different respiratory pathways in IL-1 β , IL-6, IL-10 and TNF α production by lipopolysaccharide (LPS)-stimulated monocytes; respiratory pathways were inhibited with 2-deoxy-D-glucose (2-DG; glycolysis), oligomycin (oxidative phosphorylation), and etomoxir (fatty acid oxidation). The effect of different monosaccharide fuels (glucose, fructose, mannose and galactose) was also considered.

Inhibition of glycolysis and fatty acid oxidation reduced LPS-stimulated production of all cytokines but only IL-10 production was reduced with inhibition of oxidative phosphorylation. By measuring LPS-induced changes in extracellular acidification rates it was shown that monocytes do possess the glycolytic switch and utilise glucose as a primary energy source. Monocytes can also metabolise other monosaccharides especially mannose and to a much lesser extent, fructose and galactose. In contrast, LPS-stimulated cytokine outputs were increased with fructose and galactose compared to glucose and mannose.

Understanding the differential pathways and metabolic fuels contributing to monocyte function could have potential implications for understanding and treating inflammatory conditions.

Malaria is the most prevalent parasitic infection in the world and a major cause of mortality, with approximately 600,000 deaths in 2013. The liver stage of malaria represents a bottleneck for the parasite so we have focused on developing a vaccine targeting this phase in mice. Using a novel approach we have generated large numbers of tissue-resident memory cells (T_{RM}) in the liver that can protect against malaria. Briefly, PbT-I/uGFP cells (CD8⁺ transgenic T cells specific for malaria) are transferred into B6 mice and primed in lymphoid tissues by treating the recipient mice with an adjuvant and a malaria peptide conjugated to anti-Clec9A. A day later the mice are infected with adeno-associated virus expressing the same malaria epitope, allowing the PbT-I/uGFP cells to interact with antigen in the liver where they eliminate infected hepatocytes and form T_{RM} . These liver T_{RM} display a unique cell surface phenotype and express a gene signature associated with other resident memory populations. Intravital imaging of the liver one month post-vaccination revealed a mixed population of cells, one population patrolling the sinusoids and a second rapidly transiting the liver. Using PbT-I T cells expressing CX3CR1-GFP or CXCR6-GFP, we show that the rapidly transiting T cell population are those PbT-I cells that develop into circulating effector memory whereas the patrolling population are T_{RM} . Using CXCR3-specific antibodies, we specifically eliminate PbT-I T_{RM} which abrogates protection against sporozoite challenge. This suggests liver T_{RM} cells represent an effective weapon in the arsenal for malaria vaccine development.

Interleukin-6 and type I Interferon-signalling control ICOS-mediated humoral immunity to malaria

Sebina, L.¹, James, K.¹, Soon, M.¹, Best, S.¹, Hertzog, P.², Engwerda, C.¹, Haque, A.¹

¹QIMR Berghofer Medical Research Institute, Brisbane, Australia,

²Hudson Institute of Medical Research, Melbourne, Australia

Parasite-specific antibodies are effective at controlling blood-stage *Plasmodium* infections. However, generating these in humans has proven difficult, via natural exposure or vaccination. Explanations for this have focused on antigenic variation by the parasite, but have not considered whether host generation of antibody responses is sub-optimal. As a result, host immune factors that serve to control antibody responses remain poorly characterized. Using mouse models of blood-stage malaria, we explored roles for *Plasmodium*-induced innate cytokines, interleukin-6 (IL-6) and Type I Interferon (IFN-I), in controlling CD4⁺ T cell-dependent humoral immunity. Firstly, we demonstrated that CD4⁺ T cells and ICOS-signalling were crucial for germinal centre (GC) B cell and plasmablast responses. Next, we found that IL-6 was essential for optimal parasite control, and for production of parasite-specific, complement-fixing antibodies, IgM and IgG2b. Moreover, GC B cells, plasmablast responses, and ICOS expression by emerging and established

Tfh cells all required IL-6-signalling. In contrast, IFN-I signalling, which proceeded via conventional dendritic cells, but not T or B cells, suppressed parasite control, production of parasite-specific IgM and IgG, as well as GC B cell, plasmablast and Tfh cell responses. IFN-I-signalling acted early, by limiting ICOS expression on activated CD4⁺ T cells, and restricting their movement towards B cells that were required to cement the emerging Tfh phenotype. Finally, IFN-I blockade boosted early B cell responses in a manner partially dependent on IL-6. Thus, we reveal innate cytokine responses, long-established to occur during blood-stage *Plasmodium* infection, as possible targets for improved antibody-mediated immunity to malaria.

Immune-driven alterations in mucin glycosylation are essential for *Trichuris muris* worm expulsion

Hasnain, S.Z.¹, Lourie, R.¹, Hutson, P.G.², Dawson, P.³, Grencis, R.K.⁴, Thornton, D.J.⁵

¹Mater Research Institute-University of Queensland, Immunity, Infection and Inflammation Group, Brisbane, Australia, ²Mater Research Institute-University of Queensland, Mater Pathology, Brisbane, Australia, ³Mater Research Institute-University of Queensland, Developmental Disorders Group, Brisbane, Australia, ⁴University of Manchester, Manchester Immunology Group, Manchester, United Kingdom, ⁵University of Manchester, Wellcome Trust Centre for Cell-Matrix Research, Manchester, United Kingdom

Mucins are heavily glycosylated proteins that play an important role in rejection of the nematode, *Trichuris muris* (*T. muris*). The glycans decorating the mucin protein core can alter the protective properties of the mucus barrier. Therefore, we investigated changes in glycosylation during *T. muris* infection, using different infection doses and strains of mice that are resistant (high dose infection in BALBc/C57BL6 mice) or susceptible (high dose infection in AKR and low dose infection in BALBc mice) to *T. muris* infection. During chronicity, within the immediate vicinity of the *T. muris* nematode the goblet cell thecae contained mainly sialylated mucins. In contrast, maintained sulphation on the mucins was apparent in the goblet cells within the epithelial cell crypts in the resistant models. Examination of human appendices with chronic enterobiosis showed unglycosylated mucin accumulation within the endoplasmic reticulum compared to parasite free controls, consistent with a parasite-induced disruption of mucin processing. The maintained mucin sulphation (controlled by a T_H2 -immune response) contributed to the protective properties to the mucus layer, making it less vulnerable to degradation by *T. muris* exo-products. Interestingly, *T. muris* egg hatching was diminished in the sulphate anion transporter1^{-/-} mice, which were susceptible to a chronic infection despite strong T_H2 -immune response. This study highlights the complex process by which immune-driven alterations in glycosylation occur following *T. muris* infection, which contributes to resistance to chronic parasitic infection.

2454**HIF-1 α impairs monocyte's effector function and induces M2 macrophage polarization during chronic *Leishmania donovani* infection**

Hamami, A., Abidin, B.M., Charpentier, T., Fabié, A., Heinonen, K., Stäger, S. Institut Nationale de la Recherche Scientifique INRS, Institut Armand Frappier IAF, Laval, Canada

Leishmania donovani impairs the immune response by triggering a hypoxic micro-environment that facilitates the establishment of a chronic infection. Under this condition, HIF-1 α , the master regulator of the response to low oxygen tension, is stabilized in all cell populations. The effect of hypoxia on the immune response to *Leishmania* has not yet been investigated. Particularly, the role of HIF-1 α in macrophage and monocyte function during chronic visceral leishmaniasis remains unknown. Here, we investigate the role of HIF-1 α in inflammatory monocyte and dendritic cell functions, and in the modulation of macrophage polarization during chronic *L. donovani* infection. To this end, we generated CD11c-specific HIF-1 α knock-out mice that were then infected with *L. donovani*. Our data demonstrate that HIF-1 α limits inflammatory monocyte recruitment to the spleen and induces M2 macrophage polarization in response to extracellular lactate. The ablation of HIF-1 α in CD11c⁺ cells resulted in decreased intracellular lactate concentrations, lower expression of M2 macrophage markers, greater expansion and effector capacity of monocytes, and enhanced IFN γ production by CD4⁺ T cells. Moreover, mice with a targeted depletion of HIF-1 α in CD11c⁺ cells had a significantly lower splenic parasite burden, suggesting that induction of HIF-1 α in CD11c⁺ cells may represent a key factor adopted by *Leishmania* parasites to establish persistent infections.

3787**PD-L2 is crucial for establishing effective CD4⁺ Th1 immunity against malaria**

Wykes, M. QIMR Berghofer, Brisbane, Australia

Malaria is caused by *Plasmodium* parasites, which after introduction into the host by mosquitoes proceed to infect hepatocytes followed by red blood cells. It is the blood-stage infection that causes the symptoms and lethality associated with malaria. Many pathogens, including *Plasmodium* spp., exploit the programmed death-1 (PD-1)/PD-1 ligand-1 (PD-L1) pathway to 'deactivate' T cell functions but the role of PD-1/PD-L2 remains unclear. We studied malarial infections to understand the contribution of PD-L2 to immunity. Here we show that higher PD-L2 expression on blood dendritic cells (DC), from *Plasmodium falciparum*-infected individuals, correlated with lower parasitemia. Mechanistic studies in mice showed that PD-L2 was indispensable for establishing effective CD4⁺ Th1 immunity. Importantly, administration of soluble PD-L2 to mice with lethal malaria was sufficient to dramatically improve immunity and survival (92% vs 0%). These studies show a new function for PD-L2, which has potential to be translated into an effective treatment for malaria and other diseases where T cell immunity is ineffective or short-lived due to PD-1.

1742**Protein tyrosine phosphatase inhibition enhances the generation of protective Tr1 cells and attenuates the brain sequestration of pathogenic T cells during experimental cerebral malaria**

*Van Den Ham, K.^{1,2}, Richer, M.¹, Olivier, M.^{1,2}
¹Mc Gill University, Microbiology and Immunology, Montréal, Canada, ²Research Institute of the McGill University Health Centre, Montréal, Canada*

Neuropathology induced by *Plasmodium berghei* ANKA infection is dependent on the sequestration of cytotoxic CD8⁺ T cells within the brain microvasculature and augmentation of the inflammatory response. Inflammation is integral to controlling parasitemia, but can result in tissue damage if unregulated. IL-10 has the capacity to suppress inflammation and has also been implicated in limiting tissue parasite burden. Recently, IL-10-producing Foxp3⁺ CD4⁺ T cells were identified in *P. falciparum*-infected children and were determined to have a role in the regulation of pathogenic inflammation. Modulation of protein tyrosine phosphorylation has the capacity to alter the immune response and has previously been demonstrated to mitigate pathology in models of leishmaniasis, asthma and cancer. Here we determined that pharmacological inhibition of protein tyrosine phosphatase (PTP) activity markedly protected mice from developing experimental cerebral malaria (ECM). Protection was concomitant with an increase in IL-10⁺ Foxp3⁺ CD4⁺ T cells, which were shown to be largely comprised of LAG-3⁺CD49b⁺ type 1 regulatory cells. Moreover, the enhanced IL-10 production was established to be a major component of the protection afforded by PTP inhibition. Additionally, the decreased incidence of ECM was associated with significantly reduced sequestration of CD8⁺ T cells within the brain. And this attenuated accumulation correlated with decreased cell surface expression of CXCR3 on splenic CD8⁺ T cells. Overall, our study suggests that pharmacological modulation of host PTPs could provide a novel mechanism for the development of new immunotherapies to treat parasitic infections.

3324**The role of TREM-1 in the severity of human cutaneous leishmaniasis through a translational study**

*Ampuero, M.^{1,2}, Nunes, S.¹, Feijó, D.¹, Khouri, R.¹, Boaventura, V.^{1,2}, Barral, A.^{1,2}, Brodskyn, C.^{1,2}, Tavares, N.³
¹Fundação Oswaldo Cruz - FIOCRUZ, Centro de Pesquisas Gonçalo Moniz - CPqGM, Salvador, Brazil, ²Universidade Federal ba Bahia, Salvador, Brazil, ³Fundação Oswaldo Cruz - FIOCRUZ, Salvador, Brazil*

Leishmaniasis is a neglected disease caused by Leishmania. The immune response is critical for parasite killing, but it also accounts for inflammation and disease severity. The Triggering Receptors Expressed on Myeloid Cells (TREM) was recently identified as an amplifier of the innate immune response, which synergize with Toll-like receptors (TLRs) in the production of proinflammatory cytokines. TREM-1 is mainly expressed in neutrophils and its signaling depends on the adapter protein DAP12, resulting in cell degranulation, production of reactive oxygen species (ROS)

and activation of NFκB. We used bioinformatics tools to analyze public transcriptome data of lesions from patients infected with *Leishmania braziliensis*. The expression of all factors involved in TREM-1 pathway is increased. We validated these findings by Real-Time PCR with fresh samples of blood and biopsies. The expression of DAP12 and TLR4 messenger RNA (mRNA), but not of TREM-1 and TLR2, is significantly increased in biopsies. The expression of these mRNA is not altered in peripheral blood mononuclear cells (PBMC). However, there is a down regulation in TREM-1, DAP12, TLR2 and TLR4 expression in resting neutrophils. Moreover, TREM-2, that act as counterregulatory molecule, attenuating inflammation, was not detected in any of these samples. In conclusion, TREM-1 is differentially regulated between different compartments and its modulation depends on the presence of inflammatory stimulus. Preliminary data from flow cytometry suggests that TREM-1 expression is increased in infected macrophages. Further ongoing assays will be important to define the role of TREM-1 in the balance between inflammation and parasite killing.

Omics profiling of *Leishmania major*-infected human macrophages: a systems-level approach

Atri, C., Mkannez, G., Bali, A., Sghaier, M.R., Attia, H., Laouini, D., Ghouila, A., Guerfali, F.Z.

Institut Pasteur de Tunis, Immunology/Laboratory of Transmission, Control and Immunobiology of Infections, Tunis-Belvedere, Tunisia

Leishmania (L.) are intracellular protozoan parasites able to survive and replicate in the hostile phagolysosomal environment of infected macrophages in human host. To establish a successful infection and ensure their own survival, *Leishmania* have developed sophisticated strategies to subvert the host macrophage responses. As a result, a complex interplay takes place between the parasite and the macrophage, that subtends for a large part the clinical manifestations of leishmaniasis diseases.

Despite huge community efforts, only a small number of molecules are known to play a role during the infectious process. In order to provide the most complete profiling of invaded cells during this host-parasite conflict at different levels, we used transcriptomics (microarrays), regulomics (miRNAs) and proteomics profilings through a kinetic of infection during the first 24 hours of contact between monocyte-derived human macrophages and *L. major* metacyclic promastigotes. Using different available analyzing tools we identified molecules, networks, top functions and canonical pathways to be deregulated during the infection processes, tightly related to chemokine signaling, Toll Like receptor signaling or apoptotic pathways. This comprehensive approach is likely to allow the identification of new molecules and functional pathways that could be targeted by new treatments to this parasitic infection.

During infection, native *Trypanosoma cruzi* calreticulin mediates growth inhibition of a mammary tumor

Abello, P., Pizarro Bäuerle, J., Rosas, C., Maldonado, I., Sosoniuk Roche, E., Ferreira, A.

University of Chile, Faculty of Medicine, Immunology, Santiago, Chile

Decades ago, researchers from the former Soviet Union, detected that *Trypanosoma cruzi* (the agent of American Trypanosomiasis) infection inhibits tumor development. The molecular basis underlying this phenomenon has remained largely unknown. We propose that, in *T. cruzi* infected animals, native Calreticulin (nTcCRT), an endoplasmic reticulum (ER)-resident chaperone, translocated and externalized by the parasite, mediates, at least an important part of this anti tumor effect. Previously, we showed that, *in vitro*, TcCRT by virtue of its capacity to interact with Complement component C1 is a potent inhibitor of its classical pathway. Moreover, inactive C1q, still bound to TcCRT, acts as an 'eat me' signal, thus promoting infectivity (defined here as the capacity to contact and infect mammal host cells). This property is important for the parasite capacity to interact with both endothelial and a tumor cell line (the aggressive murine mammary adenocarcinoma TA3-MTXR). In agreement with this proposal, we have specifically neutralized the anti tumor properties of infection, with polyclonal anti-rTcCRT F(ab')₂ antibody fragments, devoid of their Fc-dependent capacity to recruit C1q. Moreover, these antibody fragments were used to specifically reverse the capacity of rTcCRT to inhibit EAhy926 endothelial cells proliferation. Thus, angiogenesis may be important in this tumor development. Moreover, anti-rTcCRT antibodies reversed the antitumor effect of epimastigotes (that express but do not translocate TcCRT) extracts. In synthesis, during *T. cruzi* infection, nTcCRT mediates important anti-tumor effects.

Eosinophil lineage commitment and IL-5-dependent expansion is regulated by IL-33 in mice

Johnston, L.¹, Hsu, C.-L.¹, Krier-Burris, R.¹, Chhiba, K.¹, Chien, K.¹, McKenzie, A.², Berdnikovs, S.¹, Bryce, P.¹

¹Northwestern University Feinberg School of Medicine, Department of Medicine, Division of Allergy-Immunology, Chicago, United States, ²MRC Laboratory of Molecular Biology, Cambridge, United Kingdom

Eosinophils are important in the pathogenesis of many diseases, including asthma, eosinophilic esophagitis and eczema. While IL-5 is necessary for the maturation of eosinophil progenitors (EoP) into mature eosinophils (EoM), the signals that promote commitment to the eosinophil lineage are unknown. The IL-33 receptor, ST2, is expressed on several inflammatory cells, including eosinophils, and is best characterized for its role during the initiation of allergic responses in the peripheral tissues. Recently, ST2 expression was described on

hematopoietic stem cells, where its function remains unclear. Here, we sought to determine whether IL-33 and ST2 contribute to hematopoietic lineage decisions. We found that both IL-33- and ST2-deficient mice exhibited diminished peripheral blood eosinophils at baseline. Correspondingly, IL-33 administration increased EoM as well as IL-5 in the blood and bone marrow in WT and IL-33-deficient but not ST2-deficient mice. Blocking IL-5 with a neutralizing antibody prevented IL-33-expanded EoP from maturing into EoM, while transgenic overexpression of IL-5 in ST2-deficient mice resulted in significantly lower hypereosinophilia than transgenic IL-5 mice. Finally, we observed that IL-33, but not IL-5, specifically expanded EoP and upregulated IL-5Ra on EoP as well as increased IL-5 after bone marrow was cultured for three days. Our findings identify a basal defect in eosinophilopoiesis in IL-33- and ST2-deficient mice. Furthermore, we establish unappreciated roles for IL-33 and ST2 in eosinophil development via progenitor regulation and define a mechanism whereby IL-33 licenses commitment into the eosinophil lineage by driving both responsiveness to IL-5 and IL-5 production.

Pulmonary NK cells prevent allergic airway sensitization: regulation by CB2-active eicosanoids

Roberts, K., Ferrini, M., Jaffar, Z.

University of Montana, Biomedical & Pharmaceutical Sciences, Missoula, United States

In allergic asthma, inhalation of airborne allergens such as house dust mite (HDM) effectively activates both innate and adaptive immunity in the lung mucosa. The contribution of pulmonary NK cells to the innate events preceding sensitization of the airways to the common house dust mite (HDM) allergen remains unclear. Cannabinoid CB2-active mediators are known to impact innate immunity including responses by monocytes and NK cells. To determine the role of the CB2-active eicosanoids during allergic sensitization, allergic airway inflammation was induced in mice by sensitization via the airways by intranasal HDM instillation, and responses in wild type (WT) and CB2-deficient (CB2^{-/-}) mice were compared. Mice lacking CB2 receptor exhibited elevated numbers of pulmonary CD3⁺CD19⁺NK1.1⁺ NK cells but were resistant to the induction of allergic airway inflammation and showed diminished airway hyperreactivity, pulmonary eosinophilia, T_H2 cytokine production and mucus secretion after HDM allergen inhalation. Cellular depletion and adoptive transfer studies were undertaken to dissect the mechanisms involved. Depletion of NK cells restored HDM responsiveness. Conversely, transfer of CB2^{-/-} NK cells into WT mice suppressed the allergic airway inflammation and was associated with a reduction in monocyte-derived dendritic cells but elevated CX3CL1 release and recruitment of Ly6C⁺CX3CR1⁺ monocytes. These studies demonstrate a hitherto unknown role for CB2 activation in allergic lung disease and reveal a role for NK cells in preventing allergic sensitization to HDM allergen.

In vivo optical imaging of skin allergy inflammation

Zhang, Z., Liu, Z., Luo, M., Luo, Q.

Huazhong University of Science and Technology, Wuhan National Laboratory for Optoelectronics, Wuhan, China

Optical molecular imaging is the most promising tools for investigating the function and motility of immune cells *in vivo*. Immuno-Optimaging as a new interdisciplinary research area has been developed for a decade. Here, we developed a multi-scale optical imaging approach to evaluate the spatio-temporal dynamic behavior and properties of immune cells from the whole field of organs to the cellular level at the inflammatory site: the recruitment of leucocytes was directly visualized using whole-field fluorescent imaging at the organ and tissue levels; the dynamic distribution of the leukocytes was directly visualized using large-scale scanning microscopy at the single-cell level; the motility and migration dynamics of leukocytes were visualized in real time and analyzed using time-lapse confocal imaging or two-photon excitation microscopy at the single-cell level with high temporal resolution. Meanwhile, some multi-color labeling mouse models based on the exogenous labeling with fluorescent protein and the endogenous labeling with fluorescent dye were established. The dynamic properties and function of immunocytes

(e.g. monocyte-macrophages and neutrophils) in the skin allergy inflammation (e.g., the delayed type hypersensitivity reaction or contact hypersensitivity) were visually investigated using multi-scale optical imaging techniques combined with the multi-color labeling mice model.

Intrinsic- and extrinsic- mediated CTLA-4-signals shape the T_H2 response: implications for allergic disorders

Pierau, M., Brunner-Weinzierl, M.C.

Otto-von-Guericke University, Children`s Hospital, Magdeburg, Germany

T helper (T_H) 2 lymphocytes play a crucial role in the initiation, progression and persistence of IgE-mediated allergic diseases. During the sensitization phase, the differentiation and clonal expansion of allergen-specific CD4⁺ T_H2-cells producing IL-4, IL-5, IL-10 and IL-13 is essential. During this step, a memory population of allergen-specific T-cells is also generated. Memory immune responses are long lived, antigen specific, and are characterized by a rapid and robust cytokine response to allergens. Cytotoxic T lymphocyte-associated antigen 4 (CTLA-4) is an inhibitory co-stimulatory molecule expressed by regulatory T-cells (Tregs) and activated T-cells. In this study, we will determine the role of intrinsic (CTLA-4 on CD4⁺ T_H2-cells) and extrinsic (CTLA-4 on Tregs) mediated CTLA-4-signals during the generation of effector and memory T_H2-subpopulations, with special emphasis on the role of Tregs.

For the characterisation of the T_H2-effector and -memory pool *in vitro* and *in vivo* we analysed multifunctional T-cells which synchronously produce several cytokines by boolean gating flow cytometry as well as expression of typically hallmark T_H2 molecules.

We found that intrinsic as well as extrinsic mediated CTLA-4-signals modulate the quality of T_H2-effector and -memory cells in vitro and in vivo.

Summarizing the different T_H2-cytokine-subpopulations in vitro revealed that CTLA-4^{-/-} T_H2-cells show an increased frequency of single-, double-, triple- and quadruple- producers. In vivo, quantity and quality of T_H2-effector cells in the memory pool was mainly dependent on extrinsic-mediated CTLA-4 signals triggered by Tregs during the priming phase.

Modulation of CTLA-4 signal transduction could be an option for therapeutic interventions of allergic diseases.

Unravelling modes of HLA-drug-TCR interaction in HLA-associated adverse drug reactions

Illing, P.¹, Mifsud, N.¹, Fettke, H.¹, Lai, J.¹, Ho, R.¹, Kwan, P.², Purcell, A.¹

¹Monash University, Infection and Immunity Program, Monash Biomedicine Discovery Institute, Biochemistry and Molecular Biology, Clayton, Australia, ²The Royal Melbourne Hospital, The University of Melbourne, Parkville, Australia

Adverse drug reactions (ADRs) impose a major economic burden on our health care system, and preclude certain individuals from utilising routine medications. A subset of ADRs are associated with specific alleles of the Human Leukocyte Antigen genes. The strongest associations reported are between HLA-B*57:01 and abacavir hypersensitivity syndrome, HLA-B*58:01 and allopurinol hypersensitivities, and HLA-B*15:02 and carbamazepine induced Stevens-Johnson Syndrome/Toxic Epidermal Necrolysis. A weaker association also exists between carbamazepine hypersensitivities and HLA-A*31:01. We have previously shown that abacavir causes a major alteration in the array of self-peptide ligands presented by HLA-B*57:01 via stable co-occupation of the antigen binding cleft, and stimulates robust, polyclonal CD8+ T cell responses. Here, we expanded this study to explore modes of interaction between allopurinol and carbamazepine (including structurally related drugs and metabolites) and ADR-associated HLA molecules. We found that carbamazepine and oxypurinol (the major metabolite of allopurinol) appear to interact in a more labile fashion with the ADR-associated HLA than abacavir and have a limited impact on peptide presentation. Paired analysis of T cell receptor (TCR) alpha and beta chains using a novel multiplex nested RT-PCR methodology at a single cell level, indicated that CD8+ T cell responses against carbamazepine were more restricted than those to abacavir. Responses to oxypurinol showed some diversity. Expression of identified TCRs in TCR-negative SKW3 T cell lines allowed confirmation of specificity and exploration of the mechanisms of drug presentation. These data suggest alternate modes of HLA-peptide-drug-TCR interaction that may cause a spectrum of diversity in the T cell response.

FIBCD1: a novel regulator of Th2 immune responses

Pilecki, B.¹, Fuchtbauer, D.¹, Thomsen, L.K.¹, Gotfred-Rasmussen, H.¹, Schlosser, A.¹, Sorensen, G.L.¹, Moeller, J.B.^{1,2}, Holmskov, U.¹

¹University of Southern Denmark, Institute of Molecular Medicine,

Odense, Denmark, ²Cornell University, Weill Cornell Medical College, New York, United States

FIBCD1 is a transmembrane protein highly expressed by intestinal and pulmonary epithelial cells. We have previously identified and characterized FIBCD1 as an endocytic receptor that binds acetylated structures including fungal and helminth-derived chitin, suggesting its involvement in host defence. Moreover, we have recently generated FIBCD1-deficient mice and shown their susceptibility to Th1/Th17-mediated intestinal inflammation induced by dextran sodium sulfate.

In the current study we aim to investigate FIBCD1 role in Th2-mediated intestinal and airway inflammation. B6N wild-type mice and FIBCD1-deficient littermates were subjected to

1) oxazolone-induced inflammatory bowel disease or

2) ovalbumin (OVA)-induced allergic asthma models.

We found that FIBCD1-deficient mice were protected from Th2-dominated gut and lung inflammation. Oxazolone-induced weight loss and decrease in colon length as well as histopathological signs of intestinal inflammation were all strongly attenuated in FIBCD1-deficient mice compared to wild-type littermates. Furthermore, we observed that FIBCD1-deficient mice were partially protected from ovalbumin-induced airway hyperresponsiveness and inflammation, major hallmarks of allergic asthma.

Obtained data suggest FIBCD1 involvement in Th2-like immune response. While the detailed mechanisms underlying FIBCD1 action are currently being investigated, our results indicate that FIBCD1 is a novel immune regulator and may be required for the optimal mobilization of a normal Th2 response.

3827

Exploring the IL7-IL7R pathway: a comparative approach confirms reduced gene expression in atopic dogs and a function in prenatal immune system development of chicks

Mazrier, H.¹, Vogelnest, L.J.¹, Kohl, A.², Taylor, R.M.¹, Sela-Donenfeld, D.², Wei, J.¹, Williamson, P.¹

¹School of Life and Environmental Sciences, Faculty of Veterinary Science, University of Sydney, Australia, ²Koret School of Veterinary Medicine, Robert H. Smith Faculty of Agriculture, Food and Environment, Hebrew University of Jerusalem, Rehovot, Israel

The signalling pathway of interleukin-7 (IL7) is known to regulate T-lymphocyte development. Accumulating evidence supports its involvement in inherited human immune-dysfunction diseases. Variants of the IL7-receptor alpha subunit gene (*IL7R*, or *CD127*) are associated with risk for human multiple sclerosis, diabetes, atopic dermatitis (AD), and some T-cell lymphomas. Considering the homology between dog and human gene sequences, complex-inherited canine immune diseases may serve as a useful animal model to study the role of this gene-pathway in human. Canine AD is a genetically-linked hypersensitivity which has early onset and shares similar clinical signs to human AD. Recent human studies suggest that the pathogenesis of AD involves immune dysregulation, orchestrated by cytokines associated with T-lymphocytes and skin barrier impairment. Our previous studies of canine AD revealed that IL7 was the most altered plasma cytokine

(elevated concentrations; 19 cytokine/chemokine multiplex bio-assay; $p=0.003$) while the IL7R gene showed the greatest differential expression (mRNA expression array of leukocytes; $p=0.001$) between affected and controls. The current study used a comparative approach to further explore the role of the IL7-IL7R pathway in canine AD and in-ovo. Several genes belonging to the IL7-IL7R pathway had decreased leukocyte expression patterns in atopic dogs, using quantitative real-time PCR (qRT-PCR). Immunofluorescence and qRT-PCR studies of normal chick embryos (E2.5 to E9) established expression of *IL7R* in early thymus development, suggesting a developmental function. Understanding the involvement of the IL7-IL7R pathway in canine AD, and its role in perinatal immune development may provide novel insights to its function in human immune-related diseases.

4189

IL-33 enhances IL-9-producing mucosal mast cell function in IgE-mediated food allergy

Wang, Y.-H., Liu, J., Shik, D., Smith, A.

Cincinnati Children's Hospital Medical Center, Cincinnati, United States

Food allergy affects approximately 2-4% of older children and adults and the prevalence of this disease is increasing significantly in developed nations. Little is known about the mechanisms that underlie the propensity to develop food allergy-induced, life-threatening anaphylaxis. We have identified a novel population of intestinal IL-9-producing mucosal mast cells (MMC9s) in mice that functions in promoting an anaphylactic response to ingested antigens. MMC9s are scarce in immunologically naïve mice, but accumulate in the gut of mice with TSLP-induced atopic dermatitis following ingestion of food antigens. Repeated intragastric antigen challenge induces significant accumulations of both MMC9 and CD4⁺T_{H2} cells, which correlates positively with symptoms and susceptibility to experimental food allergy. Mechanistically, following ingestion of food antigens, IL-33 expression is induced in mouse intestinal epithelium. MMC9s can produce high levels of IL-9, IL-13 in response to IL-33 and mast cell proteases 1 (chymase) and 6 (tryptase) in response to antigen/IgE complex crosslinking. By producing significant amounts of IL-9, MMC9s cause pronounced intestinal mastocytosis and the production of mast cells. Indeed, mice overexpressing intestinal IL-33 are more prone to develop gastrointestinal manifestations after repetitive intragastric OVA challenge; on the contrary, mice deficient of IL-33 or IL-1R1 (ST2) exhibit attenuated pathology of IgE-mediated intestinal anaphylaxis. Finally, atopic patients that develop food allergy display increased intestinal expression of *Il9* and MC-specific transcripts. These findings suggest that epidermal TSLP-initiated CD4⁺T_{H2} immune response drives MMC9 development in the gastrointestinal (GI) tract and that intestinal epithelial-derived IL-33 then amplifies MMC9 function to promote IgE-mediated food allergy.

The environment alters the immune response to ragweed pollen

Liu, S.-H.¹, Debiasi, M.¹, Anea, C.B.¹, Karrer, G.², Chaturvedi, P.³, Bellaire, A.⁴, Weckwerth, W.³, Epstein, M.M.¹

¹Medical University of Vienna, Department of Dermatology, DIAID, Vienna, Austria, ²University of Natural Resources and Applied Life Sciences, Vienna, Austria, ³University of Vienna, Department of Molecular Systems Biology, Vienna, Austria, ⁴University of Vienna, Department of Botany and Biodiversity Research, Vienna, Austria

Ambrosia artemisiifolia (ragweed) is a highly invasive plant with pollen that causes allergy. Using an experimental mouse model of ragweed pollen-induced allergic disease, we sought to determine whether environmental factors e.g., climate and pollution exacerbate pollen allergy. Ragweed pollen from several sources including some collected from urban and rural areas in Austria were repeatedly administered intranasally (i.n.) to female BALB/c mice. Pollen were either untreated or treated with low pH, high temperature and various pollutants including ozone to mimic acid rain, extreme heat and drought periods, and ground and air pollution. When treated or untreated ragweed pollen suspensions (10 µg) were administered i.n. 6 times over a 3-week period, mice developed lung and airway inflammation, mucus hypersecretion, and high serum ragweed-specific IgG1 titres in a dose-dependent fashion. Interestingly, disease was more severe with pollen from urban compared with rural areas. Similarly, *in vitro*-treated pollen generated differential *in vivo* responses. Taken together, these data demonstrate that the environment alters the allergenicity of ragweed pollen. These results have serious ramifications on environmental health and well-being and underscore the importance of addressing climate change and air quality issues by policy makers. Further studies are necessary to elucidate the mechanism underlying the environmental effect on pollen.

Sex-related differences in the interaction of CD4⁺ T cells with CD8⁺ T cells lead to female-dominant allergic airway inflammation

Miyasaka, T.¹, Ito, C.¹, Dobashi-Okuyama, K.¹, Masuda, C.¹, Kawano, T.¹, Ohkawara, Y.¹, Kikuchi, T.², Takayanagi, M.¹, Ohno, I.¹

¹Tohoku Pharmaceutical University, Department of Pathophysiology, Sendai, Japan, ²Niigata University Graduate School of Medical and Dental Sciences, Department of Respiratory Medicine and Infectious Diseases, Niigata, Japan

The severity of asthma, which is correlated positively with the intensity of type 2 T-helper (Th2)-driven airway inflammation, in adults are higher in women than men. The number of interleukin (IL)-13-producing T cells in peripheral blood lymphocytes is increased in female asthmatics compared with male asthmatics. However, it remains to be clarified how sex differences in Th2-oriented immune responses are generated in asthma. In the present study, we addressed sex-related regulation of Th2 immune responses by CD8⁺ T cells using a murine model of allergic asthma. Airway inflammation characterized by the accumulation of eosinophils and lymphocytes in the airways

and IL-4 contents in the lungs were significantly higher in female than male wild type (WT) mice, whereas no such sex differences were observed in CD8 knock-out (KO) mice. In WT mice, IL-4 production by CD4⁺ T cells prepared from bronchial lymph nodes were almost equivalent between male and female mice. Interestingly, IL-4 production by male CD4⁺ T cells was significantly reduced in the presence of male CD8⁺ T cells, but not female CD8⁺ T cells, while the production by female CD4⁺ T cells was not affected by the presence of either CD8⁺ T cells. Furthermore, the transfer of male CD8⁺ T cells, but not female CD8⁺ T cells, into male CD8KO mice significantly reduced the accumulation of inflammatory cells compared with saline transfer. These results suggest that the higher production of IL-4 in female mice may be attributable to sex-related difference in the suppressive activity of CD8⁺ T cells.

Out-manipulating the manipulator: development of a live attenuated human cytomegalovirus vaccine

Tomic, A.¹, Varanasi, P.R.², Borst, E.M.¹, Golemac, M.³, Malic, S.³, Mischak-Weisinger, E.M.², Riese, P.⁴, Guzman, C.⁴, Krmpotic, A.³, Jonjic, S.³, Messerle, M.¹

¹Hannover Medical School, Department of Virology, Hannover, Germany, ²Hannover Medical School, Department of Hematology, Hannover, Germany, ³Faculty of Medicine, University of Rijeka, Department of Histology and Embryology, Rijeka, Croatia, ⁴Helmholtz Centre for Infection Research, Department of Vaccinology, Braunschweig, Germany

Human cytomegalovirus (HCMV) is a major cause of morbidity in congenitally infected newborns and immunocompromised individuals. Thus, there is an utmost need to develop a HCMV vaccine to protect these vulnerable groups. CMVs have unique impact on the immune system and are therefore considered as promising vaccine candidates. In a mouse model expression of a host NKG2D ligand by CMV turned out to be a successful strategy to develop a live attenuated vaccine vector. Insertion of the NKG2D ligand not only contributed to the early control of the virus by NK cells, but also improved

T cell responses.

Results of this study show for the first time that a similar approach can be applied to HCMV. The expression of an NKG2D ligand in HCMV improved the safety profile and contributed to the preservation of immunogenicity of the virus as shown in *ex vivo* stimulation assays using primary human cells and *in vivo* in a humanized mouse model. Surprisingly, expression of the NKG2D ligand led to concomitant activation of innate and adaptive immunity, accomplished by distinct mechanisms. NK cell activation was only partially dependent on NKG2D, while activation of CD8⁺ T cells involved NKG2D. This mode of regulation was mediated by an unexpected influence of the NKG2D ligand on expression of MHC class I molecules.

These results indicate that a recombinant HCMV expressing NKG2D ligand can be used and further developed as a potent vaccine vector.

4223

Lipovaxin, a versatile chelating liposomal vaccine platform for surface-loading of recombinant antigens to generate self-adjuncting immune-stimulatory particles for improved immune responses

MacLennan, N., Price, J., Rusden, A., Gosling, K., Atmosukarto, I. Lipotek Pty Ltd, Canberra, Australia

Lipotek have developed a liposome platform that utilises chelating lipid-based immune-stimulatory nanoparticles for the co-delivery of recombinant antigens and immune potentiating agents. Antigens are attached to the surface of Lipovaxin liposomes by way of the commonly used poly-histidine tag engineered in the recombinant protein, which anchors the protein to a proprietary chelating lipid included in the liposome bilayer. As a result, antigens are all anchored in the same orientation and are displayed as highly ordered array on the surface of the liposomes, a conformation that mimics the display of surface antigens on viral particles. Chelating liposomes can be prepared with various immune-stimulatory properties, by including TLR ligands to achieve disease-relevant vaccine design.

This approach has been tested successfully with a number of antigens, including the model antigen OVA, a fusion of the tuberculosis antigen fusion ESAT6-Ag85C and the malaria antigen MSP2. In combination these studies have confirmed that particle delivered-surface anchored antigens are effectively drained to the lymph node resulting in greater antigen presentation. Furthermore we have demonstrated that the immune-stimulatory content of the particles increases internalisation by antigen presenting cells, the maturation of dendritic cells and the secretion of a range of cytokines. In mouse models humoral and CD4 and CD8 T cell responses have been induced successfully. The data presented will highlight the use of the Lipovaxin as a versatile vaccine platform.

Targeting dendritic cells with heterologous prime-boosting to enhance immunity

Li, J.^{1,2}, Lahoud, M.¹, Shortman, K.^{3,4}, Heath, W.^{2,5}, Caminschi, I.¹

¹Monash University, Infection and Immunity Program, Monash Biomedicine Discovery Institute, Melbourne, Australia, ²University of Melbourne, Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ³Macfarlane Burnet Institute for Medical Research & Public Health, Centre for Biomedical Research, Melbourne, Australia, ⁴Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ⁵ARC Centre of Excellence in Advanced Molecular Imaging, University of Melbourne, Melbourne, Australia

Vaccine regimens typically involve multiple immunisations to boost the immune response for more potent, long-lived immunity. However, many pathogens, such as malaria and HIV, have so far proven difficult to generate protective immunity against with conventional vaccines. In an effort to improve vaccine efficacy, we have delivered antigen directly to dendritic cells (DCs), the cells that initiate T cell responses. CD8⁺ DCs specialise in the activation of cytotoxic T cell responses, and

targeting antigen to these DCs greatly enhances primary cytotoxic T cell responses. However, targeting DCs also induces a potent humoral immune response, which was found to prevent boosting by neutralising the targeting construct within 1 hour after secondary immunisation. Indeed, the greater the primary anti-construct antibody response generated, the more difficult it proved to boost. To reduce the reactivity of the primary response to the boosting construct, we attempted heterologous prime-boosting with different forms of the targeting constructs. We compared combinations of different constructs recognising the same molecule, Clec9A, as well as constructs that recognise another CD8+ DC-restricted molecule, XCR1, for their ability to induce T cell responses. Our findings indicate that the most effective prime-boosting strategy requires changing the form of not just the targeting component, but also the antigen itself in the boosting construct. As new advances create more potent vaccines, strategies to minimise the interference from the primary response must be considered if effective boosting, and long-lasting memory, is to be achieved.

Dendritic cell responses to pneumococcal vaccines are impaired in HIV+ subjects

De La Rosa, I.¹, Rodriguez-Barradas, M.², Corry, D.¹, Mendoza, D.¹

¹Baylor College of Medicine, Medicine, Houston, United States,

²Center for Translational Research on Inflammatory Diseases, MEDVAMC, Houston, United States

Background: HIV+ subjects are more susceptible to invasive pneumococcal disease (IPD) than HIV- subjects in the antiretroviral (ART) era. Moreover, the pneumococcal polysaccharide (PPV) and conjugate (PCV) vaccines have reduced efficacy in HIV+ patients. Dendritic cells (DC) promote immune responses through cytokine production; however, their role in responses to PS is not very clear. We hypothesize that DC produce cytokines in response to pneumococcal vaccines and that HIV infection impairs this function.

Methods: We performed clustering analysis of 41 cytokines in supernatant of healthy PBMC exposed to PPV and PCV using Luminex technology. We exposed PBMC of HIV+ patients off ART, HIV+ patients on ART and age-matched HIV- controls to PCV and PPV ex vivo to measure specific cytokines production in DC by flow cytometry. We assessed if pre-vaccine DC production of cytokines ex vivo predicted post-vaccine serum opsonophagocytic killing activity (OPA) by linear regression. OPA is an in vitro correlate of protection against IPD.

Results: We found that DC produced IL-6 and IL-8 against both pneumococcal vaccines. IL-6 and IL-8 are known to induce chemotaxis, inflammation and B cell differentiation. Interestingly, the production of IL-6 and IL-8 after PCV and PPV was impaired in DC from HIV+ patients regardless of ART and predicted post-vaccine OPA. These results indicate a novel mechanism that could explain persistent poor vaccine responses and that could be exploited to improve vaccine efficacy in HIV+ subjects.

Vectorization in an oncolytic vaccinia virus of an antibody, a Fab and a scFv against PD-1 allow their intratumoral delivery and an improved tumor-growth inhibition

Fend, L.¹, Kleinpeter, P.¹, Thioudellet, C.¹, Geist, M.¹, Sfronato, N.¹, Koerper, V.¹, Brandely, R.¹, Villeval, D.¹, Rittner, K.¹, Silvestre, N.¹, Erbs, P.¹, Zitvogel, L.², Quemeneur, E.¹, Prévaille, X.¹, Marchand, J.-B.¹

¹TRANSGENE S.A., Illkirch Graffenstaden, France, ²Institut Gustave Roussy, Villejuif, France

We report here the successful vectorization of a hamster monoclonal IgG (namely J43) recognizing the murine Programmed cell death-1 (mPD-1) in Western Reserve (WR) oncolytic vaccinia virus. Three forms of mPD-1 binders have been inserted in the virus: whole antibody (mAb), Fragment antigen-binding (Fab) or single-chain variable fragment (scFv). mAb, Fab and scFv were produced and assembled with the expected patterns in supernatants of cells infected by the recombinant viruses. The 3 purified mPD-1 binders were able to block the binding of mPD-1 ligand to mPD-1 *in vitro*. Moreover, mAb was detected in tumor and in serum of C57BL/6 mice when the recombinant WR-mAb was injected intratumorally (IT) in B16F10 and MCA 205 tumors. The concentration of circulating mAb detected after IT injection was up to 1900-fold higher than the level obtained after a subcutaneous (SC) injection (*i.e.* without tumor) confirming the virus tropism for tumoral cells and/or that tumoral microenvironment allows virus escape from immune surveillance. Moreover, the overall tumoral accumulation of the mAb was higher and lasted longer after IT injection of WR-mPD-1, than after IT administration of 10 µg of J43. Interestingly, in the MCA 205 tumor model, WR-mPD-1 (both mAb and scFv) induced a therapeutic control of tumor growth similar to unarmed WR combined to systemically administered J43 and superior to that provided by an unarmed WR. These results pave the way for next generation of oncolytic vaccinia armed with immunomodulatory therapeutic proteins such as mAbs.

Vaccine encoding SIV accessory antigens protects against pathogenic challenge

Holst, P.J.

University of Copenhagen, Center for Medical Parasitology, Institute of Immunology and Microbiology, Copenhagen, Denmark

Conventional HIV vaccine strategies have not been successful. Here we immunized rhesus macaques intramuscularly and rectally with an SIV vaccine regimen based on a heterologous adenovirus prime-boost regimen and the use of the MHC class II associated invariant chain as a molecular adjuvant for the encoded antigens. The immunizations induced strong and broad T cell responses against the normally weakly immunogenic accessory antigens tat, vif, rev and vpr. Following repeated low dose intrarectal challenges, vaccinated animals demonstrated significantly reduced risk of acquisition ($P=0.04$, likelihood ratio test for leaky effect), and suppression of early viral replication in animals that became infected ($P=0.02$ combined effect on early replication). Infected vaccinees had better protection of the CD4+

T cell population in blood and mucosal tissues, maintenance of naïve CD4⁺ T cells, reduced T cell exhaustion and reduced T follicular helper cell expansion. Induction of potent T cell responses against weakly immunogenic accessory antigens is capable of preventing viral transmission, markedly diminishing early viral replication and reducing immune hyperactivation associated with disease progression. These results indicate that a vaccine that does not incorporate envelope proteins may be an effective strategy for protection against HIV infection and for reduction of infectiousness during early infection. Early results on the integration of accessory antigen vaccines into virus vectored gag and env based vaccines is expected.

The study was funded by the Danish Research Council, NIH grant R01 AI084793 (PI: R. Veazey) and the Danish AIDS-foundation

Pulmonary immunisation with recombinant influenza A viruses against *Mycobacterium tuberculosis*

Muflihah, H.¹, Flórido, M.¹, Triccas, J.², Xia, Y.³, Stambas, J.³, Britton, W.^{1,2}

¹Centenary Institute, Tuberculosis Research Program, Newtown, Australia, ²University of Sydney, Sydney Medical School, Sydney, Australia, ³Deakin University, School of Medicine, Geelong, Australia

The current *Mycobacterium bovis* BCG vaccine provides inconsistent protection against pulmonary infection with *Mycobacterium tuberculosis* (*Mtb*). Immunity induced by subcutaneous BCG wanes and does not promote early recruitment of T cell to the lungs after *Mtb* infection. Pulmonary immunisation may increase and prolong immunity at the site of *Mtb* infection. We have shown that intranasal (i/n) immunisation with a single dose of recombinant IAV (rIAV) expressing an *Mtb* CD4⁺ T cell epitope was immunogenic and protective against *Mtb* challenge. To enhance this effect, we constructed different strains of rIAVs, PR8 H1N1 and X31 H3N2, expressing the IA^b-restricted p25 CD4⁺ T cell epitope of *Mtb* Ag85B₂₄₀₋₂₅₄ (PR8-p25, X31-p25). Sequential i/n immunisation with these rIAVs significantly increased the frequency of IFN- γ secreting T cells specific to Ag85B₂₄₀₋₂₅₄ in the lungs and spleen, and resulted in protection against aerosol *Mtb* infection. To investigate whether the rIAVs could boost prior BCG immunisation, mice were immunised with BCG 12 weeks prior to the sequential rIAVs. This resulted in increased frequency of IFN- γ -secreting specific T cells and polyfunctional CD4⁺ T cells compared to the BCG alone ($p < 0.001$, $p < 0.05$). Using this approach, there was a consistent trend towards increased protection at 4 weeks after *Mtb* challenge, compared to BCG alone. Therefore, pulmonary immunisation with sequential rIAVs after BCG increases *Mtb*-specific T cell responses and may enhance protection at the site of *Mtb* infection. These results suggest the potential use of rIAVs for a new tuberculosis vaccine candidate.

1901

A cytolytic DNA vaccine to target cross-presentation of dendritic cells

Wijesundara, D.¹, Grubor-Bauk, B.¹, Gargett, T.², Yu, W.², Gowans, E.¹
¹The Basil Hetzel Institute, Surgery, Woodville, Australia, ²The Centre for Cancer Biology, Adelaide, Australia

The use of cost-effective vaccines capable of inducing robust CD8⁺ T cell immunity will contribute significantly to the development of prophylactic and therapeutic strategies aimed at eliminating persistent viral infections and cancers worldwide. Hence, DNA vaccines are ideal candidates for this purpose because they are inexpensive and easy to manufacture on a large scale even in low-income countries where many people suffer from absolute poverty. We have now generated published data to suggest that harnessing the cytolytic capacity of perforin (PRF) in a unique bi-cistronic cytolytic DNA vaccine system can significantly augment anti-viral T cell (including CD8⁺ T cell) immunity in mice as well as pigs which share a closer immune system to humans than mice. This highlights promising translational prospects especially for the Hepatitis C virus (HCV) therapeutic clinical trial that we plan to conduct soon using this vaccine. To further exploit this vaccine and expand its clinical applications, we decided to understand how this vaccine operates mechanistically to result in an immune adjuvant effect. In ICI 2016, I will discuss our progress in deciphering this mechanism and show exciting *in vivo* data to suggest that expression of our novel cytolytic DNA vaccine increases the capacity of dendritic cells (DCs) to mature and cross-present antigen to naïve CD8⁺ T cells compared to canonical DNA vaccines. Since DCs are crucial for initiating CD8⁺ T cell immunity, we anticipate that these findings will have important implications to effectively harness the immune system to target pathogens and cancers.

Understanding the molecular control of immune cell survival for the development of tailored immunotherapy

Carrington, E.^{1,2}, Zhan, Y.^{1,2}, Brady, J.^{1,2}, Sutherland, R.^{1,2}, Vikstrom, I.^{1,2}, Anstee, N.^{1,2}, Schenk, R.^{1,2}, Herold, M.^{1,2}, Lew, A.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research (WEHI), Parkville, Australia, ²University of Melbourne, Department of Medical Biology, Parkville, Australia

Apoptosis is critical for a normal functioning immune system, purging unwanted, harmful or superfluous cells from the repertoire. Too little apoptosis can lead to immunopathology and cancer, too much and immune system failure ensues. The Bcl-2 family of proteins are crucial regulators of immune cell apoptosis, with a balance between pro-apoptotic and anti-apoptotic members thought to determine survival outcome. Using mice over-expressing or genetically deficient in individual proteins, or treated in combination with mimetic inhibitors targeting selective Bcl-2 family members, we interrogated the survival requirements of various immune cell subsets. Interestingly, in contrast to the pro-apoptotic proteins,

manipulation of anti-apoptotic members (BCL-2, BCL-XL, BCL-W, A1, MCL-1) leads to differential survival of immune cell subsets. For example, plasmacytoid dendritic cells (pDC) were found to be dependent on BCL-2 for survival, whereas conventional dendritic cells (cDC) were not. We therefore advocate that these intrinsic survival requirements may be exploited in order to achieve cell-targeted immunosuppression for the tailored treatment of disease.

1877

Identification of a functional TGF-beta mimic secreted by the helminth *Heligmosomoides polygyrus*

Smyth, D.J.¹, Johnston, C.¹, McSorley, H.¹, Maizels, R.^{1,2}

¹University of Edinburgh, Edinburgh, United Kingdom, ²University of Glasgow, Glasgow, United Kingdom

The helminth parasite *Heligmosomoides polygyrus* can drive expansion of immunosuppressive regulatory T cells through its secretory/excretory products (HES), however the identity of the active molecule remained elusive. Data from an in vitro TGF-beta bioassay (cell line MFB-11) indicates that HES contains an orthologue or mimic which signals through the mammalian TGF-beta receptor. We have now identified a novel molecule, TGM, from the excretory secretory products of *H. polygyrus* that is a functional TGF-beta mimic. TGM shares no homology to mammalian TGF-beta (and is not a member of the TGF-beta superfamily), is acid stable (to pH 3) and remains fully active after 28 days at 37 degrees Celsius. TGM induces Foxp3 expression in murine T cells at similar concentrations (approx. 1 ng/ml) as mammalian TGF-beta, and induced Foxp3+ cells are functionally suppressive in vitro. An inhibitor of the TGF-beta receptor signalling kinase ALK5 (SB431542) completely ablates TGM activity, while neutralizing antibody against mammalian TGF-beta has no effect. Remarkably, TGM can induce FoxP3 expression of human peripheral blood CD4+ T cells at similar concentrations to mammalian TGF-beta, indicating that TGM could translate directly into human disease. We are now applying TGM to several mouse models of inflammation (asthma, colitis, autoimmunity and transplant tolerance) to assess its therapeutic potential and/or its involvement in immune modulation through the TGF-beta pathway.

Ultraviolet irradiation establishes an immune suppressive microenvironment within the skin-draining lymph nodes

Tse, B.¹, Marsh-Wakefield, F.¹, Kok, L.F.¹, Halliday, G.², Byrne, S.^{1,2}

¹University of Sydney, The Cellular Photoimmunology Group, Infectious Diseases and Immunology, Sydney, Australia, ²University of Sydney, Dermatology Research Laboratories, Sydney, Australia

The ultraviolet (UV) component of sunlight is a major contributor to skin carcinogenesis. However, multiple epidemiological and empirical studies support a role for UV in protection from diseases including metabolic syndrome, cardiovascular disease and a number of autoimmune diseases. While evidence of this protective effect is strongest for multiple sclerosis, the mechanism responsible for this protection is not well understood.

As UV is a strong modulator of adaptive immune responses, we hypothesised that UV-induced immune suppression is one way in which UV protects from CNS-targeted autoimmunity. In our previous work, exposure of mice to a dose of UV, which protected mice from experimental autoimmune encephalomyelitis (EAE), resulted in the preferential accumulation of leukocytes within the lymph nodes draining the site of UV irradiation. Furthermore, there was a concomitant decrease in the number of leukocytes in the CNS-draining lymph nodes. To determine the effect of UV on the skin-draining lymph nodes, UV-induced molecular changes were investigated. Using a combination of OpenArray and quantitative PCR, it was discovered that UV enhanced the expression of genes involved in immune suppression including CCR8 and GITR. Flow cytometry analysis confirmed this upregulation at the protein level, revealing that UV significantly increased the expression of these molecules on a CD4^{hi}CD8^{int} double positive T cell population. These results indicate that UV establishes an immunoregulatory environment within the skin-draining lymph nodes, which is likely to play an important role in UV-protection from autoimmunity.

Alarmin S100A8/A9 dependent accumulation of myeloid-derived suppressor cells (MDSC) and their relevance in rheumatoid arthritis

Kuhlencord, M., Zenker, S., Roth, J., Vogl, T.

University of Münster, Institute of Immunology, Münster, Germany

The differentiation and activation of MDSC in tumor conditions has been studied extensively over the last years. Various tumor-derived factors have been identified in promoting the accumulation of this suppressive cell population. Recent findings identified the two alarmins S100A8 and S100A9 as important factors in the differentiation of MDSC during tumor conditions. However, little is known about the expansion and activation, as well as the relevance of these cells in autoimmune diseases such as rheumatoid arthritis.

Our in vitro studies reveal that differentiation of myeloid progenitor cells in the presence of S100A8 promotes the accumulation of immature cells that phenotypically as well as functionally resemble monocytic MDSC (CD11b+ Ly6C+). These cells show strong suppressive effects on both, CD4 and CD8 positive T cells, mainly mediated via the production of nitric oxide (NO). The accumulation of MDSC by extracellular S100A8 was found to be mediated via the Toll-like receptor 4 (TLR4).

In addition, lack of intracellular S100A8/A9 results in a decreased number of MDSC indicating an intracellular role of this alarmin in MDSC development. In a mouse model of rheumatoid arthritis, first in vivo data indicate a correlation of high systemic S100A8/A9 level and the accumulation of MDSC, implying the importance of the two S100 proteins in facilitating MDSC expansion.

Our in vitro results clearly show a S100A8/A9 dependent accumulation of cells that phenotypically as well as functionally resemble monocytic MDSCs. Preliminary in vivo data strongly support the importance of these in vitro findings for the disease outcome in autoimmune diseases.

Resveratrol-induced myeloid-derived suppressor cells attenuate experimental autoimmune encephalomyelitis by regulating microRNA profile

Singh, N., Singh, U., Nagarkatti, P., Nagarkatti, M.
University of South Carolina School of Medicine, Pathology,
Microbiology and Immunology, Columbia, United States

Resveratrol (trans-3,5,4'-trihydroxystilbene; RES), is a plant-derived natural polyphenolic compound that possesses anti-inflammatory, antioxidant, and anticancer properties. Myeloid derived suppressor cells (MDSCs) constitute the recently discovered regulatory cells that possess potent immunosuppressive properties. In the current study, we investigated resveratrol-mediated epigenetic mechanisms leading to suppression of Experimental Autoimmune Encephalomyelitis (EAE) in mice. We observed that administration of RES into C57BL/6 mice immunized with MOG35-55 peptide to induce EAE, caused significant attenuation of the clinical symptoms and neuroinflammation, when used before or after the onset of EAE symptoms. Interestingly, we observed significant increases in MDSCs in the CNS of mice with EAE treated with RES, when compared to EAE mice treated with vehicle (VEH). Moreover, RES-induced MDSCs suppressed EAE, when adoptively transferred into mice. Also, RES-induced MDSCs showed suppressive effects on T cell proliferation *in vitro*. Upon analysis of microRNA (miR) profile in RES-induced MDSCs, we observed altered expression of a large number of miRs, when compared to MDSCs from VEH-treated mice with EAE. Upon analysis of these miRs, we observed their significant role in the regulation of MDSCs as well as various other molecular mechanisms and pathways including apoptosis, immunological pathways, cellular growth and proliferation. Data from the present study demonstrate for the first time the role of RES-induced MDSCs in the suppression of EAE through regulation of miRs. Thus, treatment with RES and/or RES-generated MDSCs may have potential in clinics to treat autoimmune diseases including, Multiple Sclerosis (NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20GM103641 and Veterans Affairs Merit Award BX001357).

A Non-hematopoietic erythropoietin analogue, ARA 290, prolonged allogeneic islet graft survival in a mouse model

*Watanabe, M.¹, Yao, M.H.¹, Cerami, A.², Brines, M.², Ericzon, B.-G.¹,
 Lundgren, T.¹, Kumagai-Braesch, M.¹*

¹Karolinska Institutet, Transplantation Surgery, Stockholm, Sweden, ²Araim Pharmaceuticals, Tarrytown, United States

Erythropoietin exerts anti-inflammatory, anti-apoptotic, and cyto-protective effects. We have recently shown that ARA 290, a non-hematopoietic erythropoietin analogue, protected isolated pancreatic islets from cytokine-induced damages and ameliorated inflammatory responses, resulting in engraftment of the even fewer transplanted islets in a syngeneic mouse model. In this study we further investigated the effect of ARA 290 on mouse allogeneic islet transplantation (PITx).

Methods: Immunomodulatory effects of ARA 290 were assessed by allogeneic mouse mixed lymphocyte culture (MLC) and bone marrow derived dendritic cells (DCs). Balb/c mice (H-2d) islets (3-400 islets) were transplanted of streptozotocin-induced diabetic C57BL/6N mice (H-2b) via the portal vein. Recipients were given ARA 290 (120 µg/kg) intraperitoneally just before and at 0, 6, and once per day during 14 days after PITx. Blood glucose level was monitored and graft survival was assessed. Immunological status was assessed at 5 days after PITx.

Results: The treatment with ARA 290 significantly prolonged graft survival time compared to non-treated control group (MGT; 15.0 days vs. 5 days, p=0.02, n=10 in each group). The frequency of allo-reactive IFN-γ producing precursors in the spleen was significantly lower in the ARA 290 treatment group animals. *In vitro* study, ARA 290 did not inhibit T cell proliferation nor IFN-γ production in allogeneic MLC. While, ARA 290 treated DCs showed less LPS driven CD86 up-regulations, and IL-6, TNF-α, and IFN-γ production.

Conclusion: ARA 290 significantly prolonged islet grafts survival following allogeneic PITx. With having anti-inflammatory and anti-apoptotic properties, ARA 290 may become a promising modality in clinical PITx.

Antigen-specific exosomes carrying miRNA-150 interact with ovalbumin-derived peptides to suppress the delayed-type hypersensitivity reaction in mice

*Bryniarski, K.¹, Nazimek, K.¹, Ptak, M.¹, Ptak, W.¹, Askenase, P.W.²,
¹Jagiellonian University Medical College, Department of Immunology, Krakow, Poland, ²Yale University School of Medicine, Department of Internal Medicine, New Haven, United States*

Introduction. T suppressor (Ts) cell-derived exosomes carrying miRNA-150 to suppress mouse contact and delayed-type hypersensitivity (DTH) responses are coated with specific antibody light chains (LC) from B1a cells [Bryniarski et al. J Allergy Clin Immunol 2013;132:170-181]. Current studies aim to investigate the exact role of LC ensuring antigen-specificity of exosome action in suppression of protein-induced DTH in mice. **Methodology.** CBA/J, Balb/c or pan-immunoglobulin deficient JH-KO mice were injected intravenously with ovalbumin-conjugated red blood cells (OVA-MRBC) to induce Ts cell production of exosomes and then were injected intradermally with OVA-saline solution to activate B1a cells to generate OVA-specific LC. Supernatant of lymph node and spleen cell culture was filtered and ultracentrifuged (100.000g) and pelleted exosomes were tested for their suppressive activity in active or adoptively transferred DTH induced by OVA or KLH antigens. In some instances, exosomes were pre-incubated with tryptic OVA-peptides, or JH-KO-derived exosomes were coated with LC separated on Sepharose column conjugated with tryptic OVA-peptides.

Results. OVA-specific exosomes administered intraperitoneally at 24-hour peak of DTH response alleviated subsequent ear swelling in CBA mice actively immunized with OVA but not with KLH. Pan-immunoglobulin-deficient JH-KO mice-derived exosomes were non-inhibitory unless they were pre-incubated with OVA-specific LC eluted from OVA-peptide column.

Incubation of OVA-specific exosomes with OVA-peptides prior to treatment of adoptively transferred DTH effector cells blocked their suppressive activity.

Conclusions. Above data proved that suppressive exosomes act antigen-specifically, likely due to the interaction of their surface LC with antigenic peptides complexed with MHC on antigen-presenting cells.

Coexpression of BTLA and PD-1 identifies a novel CD4⁺T-cell exhaustion phenotype in human hepatocellular carcinoma

Zhao, Q., Su, S., Zhang, M., Su, D., Wang, M.-L., Gao, Z.

Sun Yat-sen University, Guangzhou, China

Although immunotherapy targeting programmed cell death 1/programmed cell death ligand 1 (PD-1/PD-L1) pathway is being applied in clinic, the response outcomes are heterogeneous, suggesting existences of distinctive subsets within PD-1-expressing T cells that react differently to PD-1/PD-L1 blockade. However, markers to demarcate these subsets in human cancers remain unclear. Here, we found that both PD-1 and B and T lymphocyte attenuator (BTLA) were significantly up-regulated on CD4⁺ T cells from HCC tumor compared with those from paired nontumor liver. Interestingly, over 85% BTLA⁺ CD4⁺ T cells were PD-1-expressing cells and represented about 50% PD-1⁺ CD4⁺ T cells in tumors, and that level of BTLA⁺PD-1⁺ tumor CD4⁺ T cells were selectively associated with disease progression of patients. BTLA⁺ identified highly dysfunctional PD-1-expressing CD4⁺ T cell subset, whereas BTLA⁻ defined PD-1⁺ CD4⁺ T cells undergoing activation in HCC. Importantly, blockade of PD-L1 could restore the IFN- γ /TNF- α production in BTLA⁺PD-1⁺ tumor CD4⁺ T cells but partially suppressed the activation of BTLA⁻PD-1⁺ CD4⁺ T cells. Moreover, we provided evidence that interaction of BTLA and its ligand herpesvirus entry mediator (HVEM) also participated in suppressing CD4⁺ T cell function in HCC tumor. BTLA could identify distinct function of PD-1 expressing CD4⁺ T cells in human cancer, which might not only advance our understanding of inhibitory receptor blockade, but also provide new targets for clinical predictors of response to these immunotherapies.

Kinetics of the Foxp3⁺ cell response in kidney tissue of both autoimmune and non-autoimmune induced hyperglycemia in mice

Varli, S., Thorvaldson, L., Sandler, S., Singh, K., Stellan Sandler
Uppsala University, Uppsala, Sweden

Diabetes causes an elevation of the blood glucose level and a long-term hyperglycemia that contributes to kidney damage, i.e. diabetic nephropathy (DN). DN exhibits signs of inflammation and infiltration of mononuclear cells. Foxp3⁺ T cells maintain the homeostasis of immune system. Herein, we determined the numbers of Foxp3⁺ Treg cells in the kidneys of multiple low dose streptozotocin (MLDSTZ) treated male mice, NOD female mice

and single dose STZ (SDSTZ) treated mice. MLDSTZ and NOD mice were used as models for autoimmune T1D and the SDSTZ model was studied as a model for non-autoimmune induced hyperglycemia. Surprisingly, we found an increase in the numbers of Foxp3⁺ Treg cells and an infiltration of mononuclear cells in the kidneys of SDSTZ, MLDSTZ, and NOD mice. Thus, our data reveal that Treg cells are increased in kidneys of mouse models of both hyperglycemia and T1D. However, the upregulation of Treg cells did not protect against both hyperglycemia and infiltration of mononuclear cells in kidneys. In addition, administration of the novel anti-inflammatory cytokine IL-35 prevented the mononuclear cell infiltration in kidneys of MLDSTZ and NOD diabetic mice, suggesting that IL-35 could be investigated to prevent mononuclear cell infiltration in kidneys and perhaps DN.

PM2.5 induces oxidative stress in splenic CD11b⁺ cells in mouse

He, C.¹, Ichinose, T.², Song, Y.¹, Wang, D.¹, Morita, K.¹, Kanazawa, T.¹, Yoshida, Y.¹

¹University of Occupational and Environmental Health, Department of Immunology and Parasitology, Kitakyushu, Japan,

²Oita University of Nursing and Health Sciences, Department of Health Sciences, Oita, Japan

Epidemiological studies demonstrated that ambient PM2.5 (particulate matter, PM with aerodynamic diameter less than and equal to 2.5 μ m) exposure was associated with mobility of respiratory diseases, cardiovascular disease, diabetes, and mortality. Evidences indicate PM2.5 contributes to systemic influence rather than respiratory restricted dysfunction. Immune system plays essential roles in PM exposure related adverse health outcomes; however effects of PM2.5 on immune system and established mechanisms remain to be elucidated. In the present study, we investigated the splenic response in PM2.5-exposed mice. PM2.5 used in the present study was collected from the atmosphere at Shenyang in China. BALB/c mice were intratracheally administered of PM2.5 or saline four times at 2-week intervals, and sacrificed at 24 hours after the last administration. Cell viability and mitogen-induced proliferation in splenocytes were decreased in PM2.5-exposed mice compared to control mice. Additionally, ConA-induced IL-2 and LPS-induced TNF- α production in splenocytes from PM2.5-exposed mice were lower than that of control mice. Immunoblotting demonstrated increased expression of Heme Oxygenase-1 (HO-1) in the splenocytes after PM2.5 exposure. Activation of ERK was also identified in splenocytes from PM2.5-exposed mice. Particularly, increased HO-1 expression and ERK activation were detected in CD11b⁺ cells from PM2.5-exposed mice, but not in CD4⁺ or CD8⁺ or B220⁺ cells. Furthermore, antioxidant N-acetylcystein partially rescued suppression effects on splenocytes from PM2.5-exposed mice. Taken together, these results suggest that administration of PM2.5 induces suppression of splenocytes with oxidative stress, and CD11b⁺ cells work as responder cells.

Down-regulating E protein function augments ILC2 production in the thymus

Sun, X.-H.¹, Wang, H.¹, Qian, M.L.¹, Zhao, Y.¹, Zhuang, Y.², Urban Jr, J.³, Fung, K.-M.⁴

¹Oklahoma Medical Research Foundation, Oklahoma City, United States, ²Duke University Medical Center, Durham, United States,

³U.S. Department of Agriculture, Agriculture Research Service, Beltsville Human Nutrition Center, Beltsville, United States, ⁴University of Oklahoma Health Sciences Center, Pathology, Oklahoma City, United States

Innate lymphoid cells (ILCs) have gained recognition as important regulators in various immune responses. How these cells are generated is just beginning to be understood. Current paradigm states that all ILCs originate from common lymphoid progenitors (CLP) in the bone marrow through an array of downstream ILC progenitors. *Id2*, a member of the *Id* family that inhibits E protein transcription factors, is expressed in these ILC progenitors and is indispensable for ILC differentiation. Unexpectedly, we found that down-regulating E protein function in the thymus by *Id1* expression or conditional deletion of two E protein genes resulted in massive expansion of ILC2s in the thymus as well as other organs where ILC2 normally reside. Consequently, the mutant mice exhibit augmented spontaneous infiltration of eosinophils and heightened responses to allergen, papain, in the lung. Furthermore, these mice also display increased ability in the expulsion of helminth parasites, *N. Brasiliensis*. These results raise an interesting question as to whether the thymus is a natural site for ILC2 production and the phenotypes of our mutant mice simply highlight such capacity. Indeed, lineage tracing experiments using *lck-Cre/ROSA26-stop-tdTomato* mice demonstrate that *tdTomato* specifically marks a fraction of ILC2s in the thymus as well as in the lung, suggesting that thymus-derived ILC2s preferentially home to the lung. We also found that thymic progenitors were able to differentiate into ILC2 cells *in vitro*. Together, our data reveal a new ILC2 differentiation program occurring in the thymus, which enriches our knowledge about ILC2 ontogeny and has potential biological significance.

Differential roles of T helper 2 cells and group 2 innate lymphoid cells in allergic airway inflammation

Hendriks, R.W.¹, Li, B.¹, Stadhouders, R.², Rao, T.N.³, Beerens, D.¹, Brem, M.¹, De Bruijn, M.¹, Lukkes, M.¹, Bergen, I.¹, Hoogsteden, H.¹, Kool, M.¹, Fehling, H.J.³

¹Erasmus MC, Pulmonary Medicine, Rotterdam, Netherlands,

²Center for Genomic Regulation, Laboratory of Hematopoietic Stem Cells, Transdifferentiation and Reprogramming, Barcelona, Spain, ³University Clinics, Ulm, Germany

Both T helper-2 (Th2) cells and group 2 innate lymphoid cells (ILC2) are major producers of IL-5 and IL-13 in house dust mite (HDM)-driven allergic airway inflammation. We found that in HDM-challenged mice the induction of ILC2s required prior

sensitization with HDM allergen. ILC2 induction was dependent on T cells, whereby activation of ILC2s and Th2 cells was concomitant. Here, we present the characterization of a GATA3-YFP knock-in mouse model that allows direct *in situ* visualization of GATA3⁺ ILC2s and Th2 cells. In these animals, the expression level and function of the transcription factor GATA3 are unperturbed, which is critically important since we previously demonstrated an essential and dose-dependent role for GATA3 in ILC2s. Confocal microscopy revealed that ILC2s and T cells occupied distinct locations in lungs from mice with HDM-driven allergic airway inflammation: ILC2s were scattered underneath the mucosa and Th2 cells were present within clusters of lymphocytes. In addition, we generated epigenome maps of FACS-sorted GATA3⁺ ILC2s and Th2 cells isolated from mediastinal lymph nodes and broncho-alveolar lavage of GATA3-YFP mice with allergic airway inflammation. Chromatin immunoprecipitation and deep-sequencing (ChIP-Seq) experiments revealed remarkably similar genome-wide histone-3 lysine-4 dimethylation (H3K4Me2) active chromatin signatures among *in vivo* activated ILC2s and Th2 cells. However, specific loci showed striking differences between the two cell types, including loci implicated in allergic inflammation, such as *Alox5* (encoding 5-lipoxygenase), *Csf2* (GM-CSF), *Tnfrsf4* (Ox40), and several chemokine (*Cxcl*) genes. Taken together, these findings indicate novel biological roles for ILC2s in asthma - distinct from Th2 cells.

Deciphering the innate lymphoid cell developmental program reveals transient requirement of the transcription factor Nfil3

Seillet, C.¹, Mielke, L.¹, Zalcenstein, D.¹, Su, S.¹, Gao, J.¹, Almeida, F.¹, Shi, W.¹, Ritchie, M.¹, Naik, S.¹, Huntington, N.¹, Carotta, S.², Belz, G.¹

¹Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ²Boehringer-Ingelheim, Vienna, Austria

Innate lymphoid cells (ILCs) are enriched at mucosal surfaces where they provide immune surveillance. Several groups have described ILC progenitor populations, however, their potential to generate all ILC lineages remains unclear. Here we describe the *c-kit*⁺ CILP that generated all ILC subsets, including NK cells, and the CD25⁻ ILC2-restricted *Sca-1*⁺ precursor. Using CEL-seq to determine the global transcriptional changes that occur during ILC development we identified several novel pathways in the differentiation process and established the hierarchical interactions amongst *Id2*, *Nfil3* and *Tcf7* utilized by progenitor cells for generation of ILC populations. Importantly, we showed that only transient expression of *Nfil3* was required for commitment to the ILC lineage prior to induction of *Id2* and *Tcf-1* expression that are key downstream regulators of the *c-kit*⁺ CILP. Collectively, our computational and functional mapping of transcription factor activity at the earliest stages of ILC differentiation revealed the molecular complexity underlying ILC commitment.

3162**Flt3L controls the number of innate lymphoid cells in fetal and adult mice**

Bärenwaldt, A.¹, von Burg, N.¹, Kreuzaler, M.², Sitte, S.³, Horvath, E.¹, Peter, A.¹, Vöhringer, D.³, Rolink, A.², Finke, D.¹

¹University Children's Hospital Basel, University of Basel, Department of Biomedicine, Basel, Switzerland, ²University of Basel, Department of Biomedicine, Basel, Switzerland, ³University Clinic of Erlangen, Friedrich Alexander University Erlangen-Nuremberg, Department of Infection Biology, Erlangen, Germany

Fms-like tyrosine kinase 3 ligand (Flt3L) is an important cytokine for hematopoietic progenitors in the bone marrow (BM) and differentiation of dendritic cells (DCs) in the periphery. While the effect of Flt3L on B cells, T cells and myeloid cells is well studied, the role of Flt3L for the different groups of innate lymphoid cells (ILCs) is not clear.

To investigate the effect of Flt3L on ILC development we analyzed ILC numbers in *flt3l*^{-/-}, *flt3l*-tg and Flt3L-treated mice. Deletion of Flt3L led to reduced numbers of fetal intestinal ILC3s, resulting in impaired Peyer's patch development. In the adult intestine, loss of Flt3L reduced the number of all groups of ILCs. For ILC3s, this reduction was even more pronounced as in *IL7*^{-/-} mice. Conversely, Flt3L transgenic mice showed increased numbers of ILCs. Furthermore, administration of recombinant Flt3L could increase all ILCs in WT mice and ILC1s and ILC3s in *IL7*^{-/-} mice, but was unable to rescue ILC numbers in *Flt3L*^{-/-} mice. To test whether ILC numbers were indirectly affected by Flt3L-dependent DCs, we analyzed DC-deficient mice. These animals had normal or even elevated ILC numbers under steady state conditions arguing against a role for DCs in regulating ILC numbers. Finally, we could show that Flt3L influenced ILC numbers by regulating the precursor pool of ILCs in the fetal liver and the bone marrow and, in contrast to IL-7, acts mainly on early stages of ILC differentiation.

224**Differential ID2 in the group 3 innate lymphoid cells control the development of different gut associated lymphoid tissues**

Wang, W.¹, Li, Y.¹, Fu, Y.-X.², Guo, X.¹

¹Tsinghua University, School of Medicine, Beijing, China, ²University of Texas Southwestern Medical Center, Department of Pathology, Dallas, United States

Gut associated lymphoid tissues (GALTs), including the mesentery lymph nodes (mLNs), Peyer's patches (PPs), and isolated lymphoid follicles (ILFs), are important locations for the initiation of adaptive immune responses in the intestine. Group 3 Innate lymphoid cells (ILC3s) are defined by ROR γ t expression and include lymphoid tissue inducer (LTi) cells, which play a critical role in the development of GALTs. However, the function of ID2 in these well-differentiated ILCs is still unclear.

In our study, *Rorc*^{cre}/*Id2*^{fl/fl} mice showed normal mLNs, but completely lacked PPs and ILFs compared with WT mice. Furthermore, ILC3s were significantly reduced in the gut of *Rorc*^{cre}/*Id2*^{fl/fl} mice compared with WT mice, but were actually increased in mLNs, indicating that the development or maintenance of ILC3s in the

gut, but not mLNs, requires ID2 regulation.

Moreover, ID2 deficient ILC3s exhibited significantly reduction of the lymphotoxin expression in the gut, which is important for the formation of GALTs. Furthermore, we found IL-7 stimulation could induce lymphotoxin expression in WT ILC3s, while the IL-7Ra expression was dramatically reduced in ID2 deficient ILC3s, suggesting that ID2 may regulate the lymphotoxin expression through IL-7 signaling. On the other hand, we found that the expression of Rank was upregulated in ID2 deficient ILC3s from the gut and mLNs, which indicates that the elevated Rank may rescue ILC3s' survival and lymphotoxin expression through NF- κ B pathway. Taken together, our results suggest that ID2 could regulate the function and maintenance of ILC3s through IL-7 and Rank signaling to further determine the differential development of GALTs.

954**Tissue-microenvironment dictates the fate and tumor-suppressive activity of type 3 ILCs**

Nussbaum, K.¹, Burkhard, S.H.¹, Klose, C.S.², Arnold, S.J.³, Diefenbach, A.^{2,4}, Becher, B.¹

¹University of Zurich, Institute of Experimental Immunology, Zurich, Switzerland, ²University of Freiburg Medical Center, Institute of Medical Microbiology and Hygiene, Freiburg, Germany, ³University of Freiburg Medical Center, Department of Internal Medicine IV, Freiburg, Germany, ⁴University of Mainz Medical Center, Institute of Medical Microbiology and Hygiene, Mainz, Germany

ROR γ t-dependent innate lymphoid cells (ILC3s) have been implicated in the control and suppression of solid tumors. While intestinal ILC3s promote tumor progression in the presence of IL-23, we showed that lymphoid IL-12-activated *RORc*^{fate map(fm)+} ILCs significantly inhibit tumor growth. The IL-12/IL-23 axis, hence, influences the tissue-specialization that ILCs acquire to gain tumor-suppressive or -promoting capacities. Thus far, the impact of the tissue-microenvironment on their phenotype and function remains largely elusive. We show clearly demarcated tissue specification across lymphoid and non-lymphoid organs. While the intestinal *RORc*^{fm+} ILCs retain their ILC3 phenotype, lymphoid-derived *RORc*^{fm+} ILCs acquire an NK cell/ILC1-like phenotype. Strikingly, adoptively transferred *RORc*^{fm+} ILCs distributed among various organs and phenotypically adapted to their new tissue-environment.

However, only the lymphoid *RORc*^{fm+} ILCs were tumor-protective while intestinal *RORc*^{fm+} ILCs failed to suppress tumor growth. Yet, despite their lymphoid origin and phenotypic similarities, *bona fide* type 1 ILCs (*RORc*^{fm} ILC1s/NK cells) also failed to suppress tumor growth, indicating that the ontogeny of the cells supersedes the phenotypic variations.

We thus propose that the tissue-microenvironment combined with ontogeny provides the specific function, whereas the phenotype provides merely a snapshot of some ILC properties with only a small predictive value to translate into functional properties.

1497**Redefining human ILC using high dimensional single cell analysis***Simoni, Y.¹, Fehlings, M.², Ginhoux, F.¹, Newell, E.²**¹A*STAR, SgN, Singapore, Singapore, ²A*STAR, Singapore, Singapore*

Animal models highlight the importance of innate lymphoid cells (ILC) in many immune responses. However, technical limitations have hampered adequate characterization of ILCs in humans. Here, we used mass-cytometry including a broad range of surface makers and transcription factors to accurately identify and profile these cells across twelve different healthy and inflamed tissue types. High dimensional analysis with t-Distributed Stochastic Neighbor Embedding (t-SNE) allowed for clear phenotypic delineation of ILC2 and ILC3 subsets. In the same analysis, ILC1 cells were not detected in any tissue, but we did identify iILC1-like cells that appear to be representative of a broader category of NK cells present in mucosal and non-mucosal inflamed tissues. In addition, our analysis shows that human ILC are highly heterogeneous between individuals and between tissues. This is the first study giving a global, comprehensive and detailed description of ILC heterogeneity in humans across patients, tissues at steady state and in inflammation.

4103**Cross-talk between pancreas resident innate lymphoid cells and T cells in autoimmune diabetes***Heuts, F.¹, Wardzinski, L.¹, Wang, C.J.¹, Ono, M.², Ovcinnikovs, V.¹, Kenefeck, R.¹, Kogimtzis, A.¹, Ryan, G.³, Withers, D.³, Walker, L.¹**¹University College London, Institute of Immunity & Transplantation, London, United Kingdom, ²Imperial College London, Department of Life Sciences, London, United Kingdom, ³University of Birmingham, College of Medical & Dental Sciences, Birmingham, United Kingdom*

During the initiation of autoimmune diabetes T cells enter the pancreas and orchestrate the destruction of insulin-producing beta cells. While staining for CD25+ regulatory T cells in the pancreas of diabetic mice we identified a lineage-negative CD25+ population. These cells express the phenotypic markers of ILC2 cells including CD127, ST2, ICOS, Thy1, klrp1, IL-13, IL-5, IL-6 and the transcription factor GATA3. The ILC population was present independent of disease as it could be detected in the pancreas of normal non-diabetic animals and rag gene deficient animals. Co-culture of T cells with pancreas-derived ILC altered the pattern of CD4 T cell cytokine production. Conversely, exposure of the ILC2 population to T cells during the development of diabetes modulated gene expression and phenotype of pancreas resident ILCs whilst lung ILC2s in the same animal did not show such changes. Collectively these data support a model of bidirectional communication between innate lymphoid cells and T cells in the pancreas which may have implications for the development of autoimmune diabetes.

1168**GATA3 regulates the development and functions of innate lymphoid cell subsets at multiple stages***Zhong, C.¹, Yagi, R.¹, Northrup, D.², Cui, K.², Wilhelm, C.³, Bouladoux, N.³, Hu, G.², Mao, K.³, Belkaid, Y.³, Zhao, K.², Zhu, J.¹**¹NIAID, NIH, Laboratory of Immunology, Molecular and Cellular Immunoregulation Unit, Bethesda, United States, ²NHLBI, NIH, Bethesda, United States, ³NIAID, NIH, Bethesda, United States*

Both IL-7R α -expressing innate lymphoid cells (ILCs) and CD4 T helper (Th) cells are critically involved in immune responses to pathogens by producing a similar set of cytokines. Similar to its essential function in CD4 T cell development in the thymus, GATA3 is indispensable for the development of IL-7R α -expressing ILC subsets. Residue ILCs found in the conditionally *Gata3*-deficient mice are exclusively lymphoid tissue inducers (LTis), consistent with a selective loss of PLZF-expressing ILC progenitors in the bone marrow of these mice. Nevertheless, *Gata3*-deficient mice do not develop lymph node structure suggesting that GATA3 also regulates the functions of LTis. After the ILCs had fully developed, GATA3 remains essential for the maintenance and functions of ILC2s. Genome-wide anti-GATA3 ChIP-Seq and gene expression (RNA-Seq) analyses indicate that GATA3 directly regulates a similar set of cytokines and receptors in Th2 cells and ILC2s. Furthermore, despite of its low expression, GATA3 plays a critical role in modulating the homeostasis, further maturation, and functions of the ILC3 subsets by directly regulating the expression of several important genes including *Il7r*, *Rorc* and *Il22*. Thus, GATA3 regulates the development and functions of innate lymphoid cell subsets at multiple stages. The work was supported by the Intramural Research Program of NIH, NIAID and NHLBI.

2270**Balance of environmental factors modulates cell fate decision of adaptive lymphocytes and innate lymphoid cells***Koga, S.^{1,2,3}, Hozumi, K.⁴, Hirano, K.-I.⁴, Yazawa, M.^{4,5}, Koyasu, S.^{2,6}, Moro, K.^{1,2,7,8}**¹RIKEN Center for Integrative Medical Sciences (IMS), Laboratory for Innate Immune Systems, Kanagawa, Japan, ²RIKEN Center for Integrative Medical Sciences (IMS), Laboratory for Immune Cell Systems, Kanagawa, Japan, ³Yokohama City University, Department of Supramolecular Biology, Kanagawa, Japan, ⁴Tokai University School of Medicine, Department of Immunology, Kanagawa, Japan, ⁵Tokai University, Department of Biochemistry, Kanagawa, Japan, ⁶Keio University School of Medicine, Department of Microbiology and Immunology, Tokyo, Japan, ⁷Yokohama City University Graduate School of Medicine, Department of Medical Life Science, Kanagawa, Japan, ⁸Precursory Research for Embryonic Science and Technology (PRESTO), Japan Science and Technology Agency, Tokyo, Japan*

Group 2 innate lymphoid cells (ILC2 cells) derive from CLP and the progenitors and transcription factors involved in their development are well reported. However, the microenvironment that regulates the expression of transcription factors and promotes specific differentiation of ILC2 cells remains unclear. To identify the external factor that induces specific differentiation

of lymphocytes, we isolated CLP and co-cultured with TSt4-DLL1 stromal cells under different concentrations of IL-7. We found that the concentration of IL-7 differentially regulates T cell and ILC2 differentiation. Next, we established TSt4 Tet-off DLL stromal cells in which DLL expression levels can be regulated by changing the concentration of Doxycycline (Dox). The strength and duration of Notch signaling divided commitment to T cell, B cell and ILC2 lineages in CLP co-cultured under different concentrations and exposure times of Dox. Furthermore, to clarify the specific environment that supports ILC2 development *in vivo*, we focused on the mesentery, the most abundant source of ILC2 cells. We identified ILC progenitor cells in the fetal mesentery that had potential to differentiate into all ILC subset but not T cells and B cells under the TSt4 co-culture system. We also observed in fetal mesentery KLRG1⁻ immature ILC2 cells, which have not acquired the ability to produce IL-5 and IL-13 under IL-33 stimulation in the absence of STAT5 activators. Our findings demonstrate that concentration of IL-7, and strength and duration of Notch signaling regulate lymphocyte lineage determination and the mesentery plays an important role in the differentiation and maturation of ILC2 cells.

PRMT5 regulates B cell development and germinal center homeostasis

Litzler, L.C.^{1,2}, Zahn, A.¹, Methot, S.P.^{1,3}, Bois, T.¹, Richard, S.⁴, Di Noia, J.M.^{1,2,3}

¹Institut de Recherche Clinique de Montréal, Montréal, Canada,

²Université de Montréal, Biochimie, Montréal, Canada, ³McGill University, Experimental Medicine, Montréal, Canada, ⁴Lady Davis Institute, Montréal, Canada

B cells develop in the bone marrow, where the rearrangement of immunoglobulin genes leads to the expression of a functional B cell receptor. Mature B cells then populate the periphery, where their activation by cognate antigen prompts the formation of germinal centers (GC). GC B cells undergo somatic hypermutation, underpinning the production of high affinity antibodies, and isotype switching. Arginine methylation is a post-translational modification, still understudied in B cells, which is involved in many cellular processes. Here, we investigate the role of protein arginine methyl transferase 5 (PRMT5) in B cell development and antibody diversification.

We found that, *in vivo*, PRMT5 expression is induced during early B cell development. Indeed, PRMT5 ablation in pro-B cells causes a total block in development at that stage. PRMT5 is induced *in vivo* in GC from immunized mice, as well as *ex vivo* in activated mouse primary B cells, compared to resting follicular B cells. In immunized mice, conditional ablation of PRMT5 in activated B cells results in a three-fold decrease in GC B cells and drastically impairs antigen-specific antibody production. *Ex vivo*, depletion of PRMT5 in activated mouse primary B cells reduces class switch recombination, cell proliferation and viability.

Overall, PRMT5 is necessary for B cell development and antibody diversification. We are investigating the mechanism

of action behind these phenotypes. Since PRMT5 is overexpressed in B cell lymphomas, our research will lead to a better understanding of PRMT5's role in both normal and malignant B cells.

Single molecular force sensitivity and threshold for the activation of B cell receptors

Wan, Z., Liu, W.

Tsinghua University, Beijing, China

B lymphocytes show remarkable mechanosensing capability by utilizing B cell receptors (BCRs) to sense antigens. However, the sensitivity and threshold for the activation of BCRs resulting from the stimulation by mechanical forces are unknown. Here we systemically addressed this question using a ds-DNA based tension gauge tether (TGT) system serving as a predefined single molecular force gauge ranging from 12 to 56 pN to restrict BCR and antigen tension. Utilizing total internal reflection fluorescence microscopy, we observed that IgM-BCR activation is sensitive to single molecular forces. We observed an obvious multi-threshold effect with a low-end 12-16 pN force which triggered a weak activation, whereas a 23-43 pN force initiated a medium-level activation, and a high-end 50-56 pN force produced a strong activation. Such patterned dependence on mechanical forces with multi-threshold effects did not strictly rely on myosin IIA, dynein and integrin. However, the break-through of the high-end but not the medium- or low-end mechanical force threshold in IgM-BCR activation required myosin IIA and the inside-out activation of integrin. Surprisingly, we found that the activation of the isotype-switched IgG-BCR or IgE-BCR only requires an extremely low threshold of less than 12 pN, providing an explanation for their rapid activation in response to antigen stimulation. Mechanistically, we found that the cytoplasmic tail of the IgG-BCR heavy chain is both required and sufficient for the low mechanical force threshold to activate the IgG-BCR. These results defined the single molecular force sensitivity and threshold that are required to activate different isotypic BCRs.

3757

Transcriptional and epigenetic regulation of germinal centre and plasma cell differentiation

Good-Jacobson, K.^{1,2}, Di Pietro, A.¹, Pupovac, A.¹

¹Biomedicine Discovery Institute, Monash University, Infection and Immunity Program and Biochemistry and Molecular Biology, Clayton, Australia, ²Walter and Eliza Hall Institute, Parkville, Australia

The production of high-quality antibody is central to adaptive immunity. Affinity is increased through iterative rounds of mutation, selection and expansion of selected clones. These functions are physically segregated in the dark zone (mutation) or light zone (selection) of the germinal centre (GC). Crucially, differentiation into plasma cells is repressed until properly selected clones exit the GC. It is critical to understand activation and repression mechanisms that allow these germinal processes

to occur. Deletion of the transcription factor c-Myb in mature B cells led to altered affinity maturation and aberrant up-regulation of plasma cell transcription factors within the GC after immunisation with NP-KLH in alum. Indeed, a subset of cycling cells within the GC secreted antibody and were CD138⁺Blimp-1-GFP⁺. The transcription factor T-bet, normally suppressed in our Th2-biased model, was also upregulated. Deletion of T-bet in c-Myb-deficient mice suppressed the formation of aberrant plasma cells within the GC, thus identifying c-Myb and T-bet as crucial regulators of differentiation. Chromatin accessibility studies of the T-bet promoter revealed that there was a significant increase in chromatin accessibility in flu-infected c-Myb-deficient GC B cells compared to wild-type. Therefore, we hypothesise that histone modifications are critical in GC function and repression of differentiation. Indeed, deletion of the histone acetyltransferase MOZ results in a significantly impaired dark zone. We are currently investigating polycomb group proteins that are expressed in different zones of the GC, and in particular EED, the binding partner of EZH2 which is critical for GC formation.

G1-phase nucleotide paucity causes AID-induced mismatch repair to be mutagenic in germinal centre B cells

Thientosapol, E.^{1,2}, Boznjak, D.^{1,2}, Durack, T.¹, Stevanovski, I.¹, Jolly, C.^{1,2}

¹Centenary Institute, Sydney, Australia, ²University of Sydney, Faculty of Medicine, Sydney, Australia

Somatic hypermutation of Ig genes in activated B cells requires the generation of "founder" U:G mismatches via deamination of genomic C by Activation-Induced cytidine Deaminase (AID). Founder mutations can be further processed by uracil base excision repair (BER), or by mismatch repair (MMR). Both processes result in a mix of faithful repair, and further mutagenesis - of the founder base pair, and/or of nearby base pairs. Processing by MMR results in downstream mutations introduced by DNA polymerase η , largely at A:T base pairs, but also at G:C base pairs. Since pol η is not involved in canonical S/G2-phase MMR, the basis of its recruitment during antibody hypermutation has been a mystery. We recently showed that BER excises AID-induced dU predominantly in G1-phase (Sharbeen et al. 2012 J. Exp. Med. 209:965-74). Here we present data suggesting that AID-induced MMR also occurs in G1-phase. Using genetic tools, we enhanced G1-phase synthesis of dNTPs, inhibited G1-phase dNTP degradation, or both, in activated B cells in mice, and substantially reduced the incidence of MMR-dependent Ig mutations, while having no obvious effect on the incidence of AID-induced founder mutations, or upon AID-induced class switching. Our data suggest that both BER- and MMR-induced mutagenesis downstream of AID is the result of DNA repair recruitment in "non-canonical" cell cycle phases. We propose that MMR-induced Ig mutagenesis results from attempting DNA repair under conditions of severe nucleotide paucity.

3172

The impact of Arginine methylation on BCR signaling

Infantino, S.^{1,2}, Light, A.¹, O'donnell, K.^{1,2}, Belz, G.³, Richard, S.⁴, Tarlinton, D.^{1,2}

¹WEHI, Immunology, Parkville, Australia, ²Monash University, Immunology, Melbourne, Australia, ³WEHI, Molecular Immunology, Parkville, Australia, ⁴Lady Davis Institute for Medical Research, McGill University, Montreal, Canada

Signals through the B cell receptor (BCR) are transmitted by a multitude of molecules, many of which undergo post-translational modification. In BCR signaling, arginine methylation, a characterized post-translational modification, has been suggested to control B cell development. Specifically, Protein Arginine Methyl-Transferase 1 (PRMT1) has been shown to methylate Ig- α and consequently to modulate BCR signal. We have examined the consequence of a conditional deletion of the *prmt1* gene in B cells. We find that PRMT1 regulates B cell maturation by shaping the pre-B cell compartment and modulating the subsequent transition to the immature B cell stage. By deleting PRMT1 at the CD23⁺ stage of B cell development, we find that both follicular and marginal zone B cells were not affected. When activated, PRMT1-deficient B cells displayed an altered proliferation and survival capacity. Arginine methylation mediated by PRMT1 is required in B cells for humoral immunity. Indeed, in response to protein antigen, B cells lacking PRMT1 failed to form germinal centre. Moreover, the T-independent immune response against a polysaccharide antigen was also severely impaired in mice lacking PRMT1 in B cells. Thus PRMT1 plays a critical, B-cell intrinsic role in specifying the outcome of humoral immune responses and in fine-tuning B cell development.

What determines B cell fate during infection?

Sutton, H., Cai, Y., Singh, M., Enders, A., Cockburn, I.

John Curtin School of Medical Research, Canberra, Australia

When naïve B cells are activated by antigen, they undergo clonal expansion and can adopt 3 main cell "fates": plasmablasts, germinal center B cells and early memory B cells. However, how B cell fate is determined is poorly understood, especially during infection. To address this question we characterized the B cell response against the central repeat region ((NANP)_n) of the circumsporozoite protein (CSP), a major *Plasmodium* surface antigen. We used B cell tetramers to sort different (NANP)_n-specific B cell populations and then used next generation sequencing to gain a snapshot of the entire (NANP)_n-specific BCR repertoire after *Plasmodium* immunization. We determined that, the immune response was highly restricted, utilizing just 1-3 different Vh regions. Utilizing this restricted repertoire, it was possible to identify B cell clones based on their shared CDR3s. We were able to detect B cell clones that could differentiate into multiple cell fates, suggesting that differentiation is somewhat stochastic. To test the impact of BCR affinity on B cell fate, we used a novel knock-in mouse expressing the heavy chain of an anti-(NANP)_n antibody. This mouse had a highly expanded number of (NANP)_n specific cells, which, crucially had different

affinities for the antigen based on pairing with different light chains. We found that strong BCR-antigen interactions lead to differentiation into the plasmablast pathway. As a result a model is proposed which states that strong or weak BCR-antigen interactions trigger differentiation into particular cell fate while intermediate interactions lead to stochastic fate determination.

1835

Distinct germinal center selection at local sites shapes cross-protective memory B cell response to viral escape

Adachi, Y., Ato, M., Takahashi, Y.

National Institute of Infectious Diseases, Department of Immunology, Tokyo, Japan

Respiratory influenza virus infection induces cross-reactive memory B cells targeting invariant hemagglutinin (HA) regions of viral escape mutants. However, cellular events dictating the cross-reactive memory B cell responses remain to be fully defined. Here we dissected the development of cross-reactive germinal center (GC) / memory B cells following influenza virus infection using two types of HA probes. Somatic mutated GC B cells developed in several organs, but lung GCs were superior to those in secondary lymphoid organs for persistence, proliferation rate, and cross-reactivity. Moreover, the persistent lung GCs selected preferentially cross-reactive B cells into lung memory compartment.

To gain further insight into the lung GCs, we detected the persistent GCs by immunohistochemistry using GL7 as the marker of GCs. GL7⁺ B cell clusters were readily detectable in the MLN and spleen. In contrast, iBALT-like structures containing both less dense GL7⁺ B cell clusters and CD4⁺ T cells, but lacking defined T cell area, were observed in the lungs. Furthermore, viral RNA was detectable in the infected lung for up to 30 days after infection, implying viral persistence may lead to distinctive feature of GCs in the lungs.

Taken together, our data illustrate the unique features of the persistent local GCs to select cross-reactive B cells, which likely contribute to broad protection against antigenically evolving pathogens like influenza virus.

1522

TAPP adaptors control Akt-dependent metabolic activation of germinal center B cells and suppress autoimmunity via binding to the SHIP product PI(3,4)P2

Jayachandran, N.¹, Landego, I.¹, Hou, S.¹, Meija, E.², Sheikholeslami, K.¹, Hatch, G.², Alessi, D.³, Marshall, A.¹

¹*University of Manitoba, Immunology, Winnipeg, Canada,*

²*University of Manitoba, Pharmacology and Therapeutics, Winnipeg, Canada,* ³*University of Dundee, Dundee, United Kingdom*

The phosphoinositide phosphatase SHIP regulates B cell activation by converting the PI 3-kinase product PI(3,4,5)P3 to PI(3,4)P2. While this activity of SHIP appears critical for generation of effective adaptive immunity while avoiding autoimmunity, the function of PI(3,4)P2 in B cells remains relatively unexplored. Tandem PH domain containing proteins

(TAPPs) are adaptor proteins that specifically bind to PI(3,4)P2 via their C-terminal PH domains, targeting them to the plasma membrane. Mice bearing inactivating mutations in the PH domains of both TAPP1 and TAPP2, uncoupling them from PI(3,4)P2, exhibit hypergammaglobulinemia and develop lupus-like characteristics including anti-DNA antibodies and deposition of immune complexes in kidneys. Here we find that TAPP KI mice develop chronic germinal centres (GCs) and age-associated increases in B cell expression of activation, exhaustion and memory markers, all of which are B cell intrinsic and dependent on the co-stimulatory molecule ICOS. TAPP KI B cells exhibit elevated phosphorylation of Akt and its target GSK3, and increased survival. Strikingly, TAPP KI B cells exhibit increased metabolic activity associated with elevated oxygen consumption rate, increased extracellular acidification rate, increased expression of glucose transporter Glut1 and increased glucose transport rate. Together our findings suggest that TAPP-PI(3,4)P2 interaction is important for regulating signalling via Akt, B cell metabolism and development of autoimmunity.

1973

T-helper signals restore B-cell receptor signaling in autoreactive anergic B-cells by upregulating CD45 phosphatase activity

Szodoray, P.¹, Stanford, S.M.², Bottini, N.², Nakken, B.¹

¹*University of Oslo and Oslo University Hospital-Rikshospitalet, Department of Immunology, Oslo, Norway,* ²*La Jolla Institute for Allergy and Immunology (LIAI), Division of Cellular Biology, La Jolla, United States*

Background: We recently identified a human B-cell population that is naturally autoreactive and tolerized by functional anergy, termed BND-cells.

Objective: To identify the molecular mechanism how anergic, autoreactive BND-cells escape functional anergy and whether this process is altered in lupus patients.

Methods: Isolated peripheral blood naïve and BND-cells were cultured with various stimuli and their activation status was determined by intracellular Ca²⁺-mobilization assay. Lyn and Syk kinase activity were assessed by phospho-flow analysis. CD45 phosphatase activity was determined with a novel flow-based assay, which takes advantage of the fluorogenic properties of phosphorylated coumaryl amino propionic acid, an analog of phosphotyrosine, which can be incorporated into peptides. Real-time qPCR was utilized to quantitate LYN, SYK and CD45 mRNA.

Results: T-helper signals reversed the state of anergy allowing BND-cells to fully respond to antigenic stimulation by restoring signaling through the B-cell receptor. The mechanism was dependent on increased activity of the tyrosine phosphatase CD45, and CD45-dependent activation of Lyn and Syk kinases. CD45 phosphatase activity was increased by T-cell help both in BND and naïve B-cells. Furthermore, we found that BND-cells obtained from SLE patients exhibited increased CD45 activity and B-cell receptor signaling capacity, thus being less tolerized, than BND-cells from healthy controls.

Conclusion: Our findings suggest that CD45 is a key regulator of B-cell receptor signaling thresholds mediated

by T-cell help. This raises the possibility that BND-cells could represent precursors of autoantibody-secreting plasma cells and suggests a role for these autoreactive B-cells in contributing to autoimmunity if not properly controlled.

Human B cell memory defined by tyrosine phosphatase CD45 activity

Nakken, B.¹, Stanford, S.M.², Bottini, N.², Szodoray, P.¹

¹University of Oslo and Oslo University Hospital-Rikshospitalet, Department of Immunology, Oslo, Norway, ²La Jolla Institute for Allergy and Immunology (LIAI), Division of Cellular Biology, La Jolla, United States

We previously discovered that CD45 phosphatase activity was upregulated upon T cell help in naïve human B cells, enhancing B cell receptor signaling in naïve B cells and restoring antigen-signaling in anergic B cells through activation of early B cell receptor signaling kinases. This novel connection between T cell help and upregulation of CD45 phosphatase activity suggested that CD45 phosphatase activity may be important for B cell memory, allowing heightened responses upon re-exposure to antigen.

We report herein that B cell subsets expressing the classical memory B cell marker CD27 exhibited a robust increase in CD45 phosphatase activity compared to their naïve counterparts. Moreover, this finding also included the CD27-IgG⁺ memory subset in addition to the CD27-IgM⁺ memory subset, showing that increased CD45 phosphatase activity encompass memory B cell subsets not included by conventional memory marker. The highest level of CD45 phosphatase activity was found within the IgG class-switched memory B cells, which have undergone most somatic hypermutation, express the highest-affinity B cell receptors and are postulated to have received the most efficient T cell help.

Functional analyses revealed that increased CD45 phosphatase activity in memory B cells translated into increased B cell receptor signaling capacity and ability to differentiate into plasma cells. These results explain in part the heightened recall responses of memory B cell subsets and emphasize the role of CD45 phosphatase activity in the B cell memory phenotype. Understanding the mechanisms resulting CD45 phosphatase activity may prove important in understanding immunity to infection and development of vaccines.

The contribution of interferon lambda to systemic lupus erythematosus

Macri, C.¹, Pang, E.S.¹, Pooley, J.¹, Fancke, B.², O'Keefe, M.¹

¹Monash University, Biomedicine Discovery Unit, Clayton, Australia,

²Burnet Institute, Centre for Biomedical Research, Melbourne, Australia

Systemic lupus erythematosus (also called SLE, or lupus) is an autoimmune disease that is characterised the production of autoantibodies, resulting in a broad range of symptoms that can affect any organ in the body. Recent studies have identified an "interferon (IFN) signature" that is carried by many SLE patients. This was evidenced by the expression of IFN-stimulated genes (ISGs) that are typically induced by type I IFN (encompassing IFN- α and IFN- β). Interferon lambda (IFN- λ) is a recently identified cytokine that is secreted by dendritic cells (DCs). IFN- λ shares functional similarities with type I IFN by activating a STAT-dependent signaling pathway that leads to ISGs expression. Plasmacytoid DCs are a major source of IFN- λ in response to Toll-Like receptor (TLR)-7 and TLR-9 stimulation. Mouse CD8+ DCs and their human equivalents, CD141+ DCs, also produce large amounts of IFN- λ in response to TLR-3 ligand. We have observed that IFN- λ plays a crucial role in DC innate immune response. We have also investigated the role of IFN- λ in the development of autoimmunity. High levels of IFN- λ were detected in the serum from different lupus-prone mice and in the serum from some lupus patients. Furthermore, DCs from lupus-prone mice over-express IFN- λ in response to different stimuli. Altogether, these data suggest that IFN- λ is a potential harmful cytokine during lupus that may represent a target of interest for the design of new treatments.

Targeting infectious disease related antigen to Clec9A enhances antibody responses

Park, H.Y.^{1,2}, Tan, P.S.^{1,2}, Caminschi, I.^{1,2}, Alonso, S.³, Shortman, K.^{2,4}, Lahoud, M.H.^{1,2}

¹Monash University, Biochemistry and Molecular Biology, Melbourne, Australia, ²Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ³National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, ⁴Walter & Eliza Hall Institute of Medical Research, Immunology, Melbourne, Australia

Targeting antigen (Ag) to dendritic cells (DCs), by injecting Ag coupled to a monoclonal antibody (mAb) specific for a DC surface molecule, is an established experimental strategy for enhancing immune responses and has the potential for improving the efficiency of vaccines. We have focused on emerging infectious

diseases, Influenza and Hand foot and mouth disease (HFMD) where potent Ab responses are required for protection. We have generated targeting constructs consisting of anti-Clec9A Ab genetically fused to key pathogen derived Ags; (1) anti-Clec9A-Influenza M2e and (2) anti-Clec9A-HFMD Enterovirus 71 SP70. To determine whether the candidate Ag targeted to Clec9A could induce immune responses, mice were injected with the targeting Ab or a control Ab, then production of anti-specific Ag Ab response was measured. Our results indicate small amount of the anti-Clec9A-Influenza M2e mAb produces enhanced and prolonged Ab responses in the absence of adjuvants or additional signals for DC activations whereas the anti-Clec9A-HFMD Enterovirus 71 SP70 mAb which presents Ag to only B cell epitope produced moderate Ab responses. In addition, we have utilized SP70 to know whether the B cell epitopes, as well as the T cell epitopes, must be targeted to the Clec9A-bearing DC. For maximal Ab response, both B and T cell epitopes need to be targeted to Clec9A bearing DC, suggesting the DC presents Ag to B cells as well as T cells. Our current focus is to develop Clec9A-targeting strategy for the enhancement of vaccine effectiveness, because protection against many infectious diseases depends on Ab production.

3343

Role of dendritic cells in the induction of immune response by lentiviral vector

Cousin, C.¹, Felix, T.¹, Cara, A.², Negri, D.², Fabrega, S.³, Dadaglio, G.¹, Leclerc, C.¹

¹Institut Pasteur, Unité de Régulation Immunitaire et Vaccinologie, Inserm U 1041, Paris, France, ²Istituto Superiore di Sanita di Roma, Roma, Italy, ³Plateforme Vecteurs Viraux et Transfert de Gènes, SFR Necker, US 24, UMS 3633, Paris, France

Non-replicating integrase deficient lentiviral vector (IDLV) can transduce dendritic cells (DC) leading to their activation, cytokine production and strong cytotoxic T lymphocyte (CTL) activity. However, the role of the different DC subsets in the *in vivo* induction of immune responses by IDLV is not established. Thus, we aim to determine the mechanisms by which IDLV induce strong and persistent CTL responses.

First, we showed that IDLV induced a strong *in vivo* activation of both conventional and plasmacytoid DCs (cDCs and pDCs respectively) and the production of a large panel of seric inflammatory cytokines and chemokines. To assess the role of DC subsets in the induction of immune responses, we used mouse strains deficient in pDCs or cDCs. We first established that cDC activation is not affected in pDC-deficient mice. In contrast, in cDC-deficient mice, we showed that pDC activation induced by IDLV vaccination is fully abolished. In addition, we demonstrated that the induction of specific CTL responses is abrogated in the absence of cDCs, but is not affected by pDCs depletion.

IDLV has a ssRNA genome which could be detected by various intracellular receptors (TLR, RIG-I and DNA sensors). We have established that IDLV signaling is independent of all TLR potentially involved in the activation of innate responses, as well as of RIG-I and DNA sensors.

In conclusion, we showed that cDCs are mandatory for the

induction of both innate and adaptive responses by IDLV. The pathways involved in the induction of immune responses by IDLV are under analysis.

High mobility group box 1 protein contributes to the enhancement of co-stimulatory molecule-expression and cross-presentation by mucosal DCs through oral administration of cholera toxin

Wakabayashi, A., Yonekawa, M., Ishii, K., Kuroki, K., Shinya, E., Takahashi, H.

Nippon Medical School, Department of Microbiology and Immunology, Tokyo, Japan

We have already reported that oral administration of an antigen plus cholera toxin (CT) induced antigen-specific CTLs in the mucosal tissues. In this study, we examined if activation and cross-presentation by DCs are achieved by high mobility group box 1 protein (HMGB1), a damage associated molecular pattern molecule (DAMP) released from the damaged mucosal tissues by CT. We found that expression of CD80 and CD86 was enhanced on CD11c⁺ DCs of the mesenteric lymph nodes (MLNs) when C57BL/6 (B6) mice are orally administered with CT. In these mice, HMGB1 was increased in both fecal extracts and plasma. MLN cells were cultured with HMGB1 or CT and the expression of CD80 and CD86 on DCs was analyzed by flow cytometry. Then their expression was enhanced by the addition of HMGB1 but not CT and such *in vitro* DC activation using HMGB1 was inhibited by the addition of glycyrrhizin (GL), an inhibitor of HMGB1. Thus, we orally administered OVA plus CT to B6 mice treated with either intravenous (i.v.) injection or oral administration of GL. Subsequently, both i.v. and oral treatment with GL effectively suppressed the mucosal DC activation and proliferation of OVA-specific OT-I T cells. These results suggest that both i.v. or oral treatment of GL can efficiently act as an inhibitor of HMGB1 released from the damaged mucosal sites through CT stimulation. In conclusion, we show here that HMGB1 released from the damaged mucosal tissues by CT seems to contribute to DC activation and cross-priming of CTLs in the mucosa.

The role of dendritic cells in sexual transmission of HIV

Harman, A.N., Bertram, K.M., Botting, R.A., Baharlou, H., Sandgren, K.J., Cunningham, A.

The Westmead Institute, Centre for Virus Research, Westmead, Australia

Human anogenital mucosae contain various tissue types, which represent unique opportunities and barriers for transmission of viruses, and each of these tissues should be considered separately in terms of how transmission occurs. Dendritic cells (DCs) and macrophages present in these tissues are two of the first cell types to encounter viruses during sexual intercourse. Furthermore, these cells play a direct role in the transmission of some viruses such as HIV where they transfer the virus to T cells in which explosive replication occurs.

Different anogenital tissues are likely to contain unique

combinations of DC and macrophage subsets however very little human data is available concerning these differences. Therefore, we have gained access to all the anogenital tissues that HIV encounters during transmission (labia, vagina, cervix, glans penis, foreskin, anus and rectum). Using flow cytometry and fluorescence microscopy we have thoroughly characterised the immune populations found in these tissues. Critically, we have identified key differences in specific immune cell subsets present in different anogenital sites and in the viral binding receptors they express.

Understanding the differences in composition of immune cells that interact with viruses in anogenital tissues is critical in the development of strategies to block transmission and in mucosal vaccine development. This is particularly the case for anorectal tissue as there is little knowledge available on its immune cell composition. This represents a key gap in our understanding as transmission across this tissue is hundreds of times more efficient in the case of HIV.

2481

Dendritic cell activity is dependent on circadian rhythmicity and mitochondrial dynamics

Cervantes-Silva, M.P., Sánchez-García, F.J.

Escuela Nacional de Ciencias Biológicas-Instituto Politécnico Nacional, Immunology, Mexico City, Mexico

Dendritic cells (DCs) capture, process and present antigens, thus initiating primary immune responses, all of which take place in a timely-ordered fashion. It has been recognized that immune responses such as T cell activation and cytokine production are dependent on the time of the day (i.e., circadian rhythm-dependent). Strikingly, mice mortality rate in LPS-induced endotoxic shock depends on whether LPS is applied during daylight or at night.

There is increasing evidence of a close relationship between immune response and cell metabolism, including a role for mitochondria in processes such as immune synapse, and antigen processing and presentation.

Mitochondrial activity correlates with circadian rhythmicity, and crosstalk between circadian rhythmicity, mitochondrial dynamics and macrophage bactericidal activity has been observed.

Here, we analysed *in vitro* DCs function in the context of both circadian rhythmicity and mitochondrial dynamics. Murine (balb/c) bone marrow-derived dendritic cells (GM-CSF-differentiated) were synchronized with dexamethasone; antigen uptake, antigen processing, mitochondrial dynamics, expression of clock proteins, and mitochondrial fusion- and fission-related proteins, were determined at different time points spanning at least a whole circadian cycle (24 h). At critical time points of DCs activity (antigen processing), DCs were stimulated with LPS for 12 h, fixed, and used for allogeneic T cell (from C57 mice) proliferation (antigen presentation assays).

Results showed that DCs function is regulated by both circadian rhythmicity and mitochondrial dynamics, contributing to the understanding of the fine-tune balance between immunity, cell metabolism, and circadian rhythmicity.

1176

Induction of tolerogenic dendritic cells by nasopharyngeal carcinoma-derived exosomes

Renaud, S.¹, Aboussemdai, H.¹, Mustapha, R.¹, Mrizak, D.¹, Ingelaere, C.¹, Mason, J.², Fitzpatrick, Z.³, Moralès, O.¹, Delhem, N.¹
¹CNRS, Lille, France, ²University of Notre Dame, Elkhart, United States, ³Harvard Medical Sciences University, Boston, United States

Background: A characteristic of the nasopharyngeal carcinoma (NPC) micro-environment is the presence of immunosuppressive exosomes released by tumor cells. Our team has recently shown that NPC-derived exosomes, which carry Galectine-9, favor the recruitment and suppressive activity of human regulatory T cells (Treg), thus contributing to NPC immune escape (Mrizak et al, JNCI, 2015). In this study, our objective is now to evaluate whether these NPC-derived exosomes could promote the emergence of tolerogenic immature dendritic cells (tolDC) able to induce regulatory T cells from naïve CD4⁺ T cells ultimately contributing to the tolerance of tumor cells.

Methods and results: We performed a complete phenotypical and functional study comparing the effect of NPC and healthy donor-derived exosomes on DC maturation. This study includes (i) cell morphological analysis by photonic microscopy, (ii) transcriptomic study by RTqPCR, (iii) flow cytometric analysis of the expression of specific markers (phenotypic DC and co-stimulatory markers), (iv) a preliminary DC functional study by western blotting (IDO) and finally (v) a secretome analysis by ELISA (IL-10; TGF- β , TNF- α). Taken together our results strongly suggest that the presence of NPC-derived exosomes favors the emergence of semi-mature DCs seemingly tolerogenic.

Conclusion: Despite the importance of immature DCs as mediators of cancer immune escape, no other studies have shown the impact of tumor exosomes on the maturation of human DCs. Thus, these promising results should open new prospects for antitumor immunotherapies based on the inhibition of factors involved in the emergence and activation of Treg.

TGF- β -induced regulatory T cells directly suppress B cell responses through a non-cytotoxic mechanism

Zheng, S.G., Wang, J., Olsen, N.
 Penn State University College of Medicine, Hershey, United States

Foxp3⁺ regulatory T cells (Treg) playing a crucial role in the maintenance of immune tolerance and prevention of autoimmune diseases consist of thymus-derived naturally-occurring CD4⁺Foxp3⁺ Treg cells (nTreg) and those that can be induced *ex vivo* with TGF- β (iTreg). Although both Treg subsets share similar phenotypes and functional characteristics, they also have potential biologic differences on their biology. The role of iTreg in regulating B cells remains unclear so far. The suppression assays of Treg subsets on activation, proliferation and antibodies production of B cells were measured using a Treg and B cell co-culture system *in vitro*. Transwell and antibody blockade experiments were performed to assess the

roles of cell contact and soluble cytokines. Treg were adoptively transferred to lupus mice to assess *in vivo* effects on B cells. Like nTreg, iTreg subset also directly suppressed activation and proliferation of B cells isolated from C57BL/6. nTreg subset suppressed B cell responses through cytotoxic manner related to expression of Granzyme A, Granzyme B and Perforin; while the role of iTreg subset on B cells did not involve in cytotoxic action, but depending on TGF- β signaling. Furthermore, iTreg subset can significantly suppress antibody produced by lupus B cells *in vitro*. Comparison experiments using microarray assay on autoantibodies demonstrated that adoptive transfer of iTreg had a superior effect than nTreg subset on suppressing lupus B cell responses *in vivo*. Our data implicate a role and advantage of iTreg subset in treating B cell-mediated autoimmune diseases, boosting the translational potential of these findings.

Deregulation of PAX5 causes abnormal B cell lymphopoiesis and spontaneous precursor B cell lymphoma development in mice

Boast, B.¹, Reed, J.², Bergmann, H.¹, Yabas, M.^{1,3}, Roots, C.¹, Young, C.^{1,2}, Nutt, S.⁴, Goodnow, C.^{1,2}, Enders, A.¹

¹The Australian National University, The John Curtin School of Medical Research, Department of Immunology, Canberra, Australia, ²The Garvan Institute of Medical Research, Department of Immunology, Sydney, Australia, ³Trakya University, Department of Genetics and Bioengineering, Edirne, Turkey, ⁴Walter and Eliza Hall Institute of Medical Research, Molecular Immunology Division, Melbourne, Australia

Pax5 knock out mice have a complete block in early B cell development and die at approximately 3 weeks of age due to neurological complications. Through ENU mutagenesis, we have discovered a strain of mice with a mutation in *Pax5* that impairs protein function and B cell development but allows enough PAX5 expression for mice to survive into adulthood. Mutations in PAX5 are also implicated in approximately 30% of paediatric B cell acute lymphoblastic leukaemia (B-ALL). Our ENU-induced *Pax5* mutant mice spontaneously develop precursor B cell lymphomas. In agreement with published data about cooperation between activation of STAT5 and PAX5 in tumour development, we find that STAT5 is highly phosphorylated in tumour cells from the PAX5 mutant mice. The incorrect function of the mutant PAX5 protein results in deregulation of target proteins and abnormal B cell lymphopoiesis before tumour development. Mutant mice have an abnormal population of CD19⁺B220⁻ precursor B cells in the bone marrow that have not previously been described. These abnormal cells are highly proliferative and are partially able to rearrange the *Igh* locus. The phenotype of these cells appears to be very similar to that of tumour cells that develop later on. We therefore hypothesise a relationship between these abnormal cells, and subsequent tumour development in mutant mice. In summary, we present a mouse strain with abnormal PAX5 function, highlighting the crucial role of the affected protein domain. Mutant mice spontaneously develop precursor B cell lymphomas that might eventually be used as a model for human B-ALL.

381

IL-4-treated mast cells activate regulatory B cells in a cross-talk involving microvesicles*Marsh-Wakefield, F.^{1,2}, O'Sullivan, C.², Leighton, S.², Gillis, C.^{1,2}, Halliday, G.², Byrne, S.^{1,2}*¹University of Sydney, Cellular Photoimmunology Group, Infectious Diseases and Immunology, Sydney, Australia, ²University of Sydney, Dermatology Research Laboratories, Sydney, Australia

The ultraviolet (UV) component of sunlight is most well known for its contribution to the development of skin cancers. This is in part due to its capability of suppressing the adaptive immune response, although the exact mechanism by which UV achieves this is not fully understood. Mast cells as well as a subset of regulatory B cells have been found to be essential for UV-induced immune suppression. To investigate the potential role of mast cells in regulatory B cell activation our laboratory developed a co-culture system whereby IL4-treated bone marrow-derived mast cells are mixed with B cells. The activated B cells were in turn found to be functionally suppressive against a murine model of allergic contact dermatitis. It was also discovered that mast cell-derived microvesicles could activate regulatory B cells. The molecular mechanism involves an upregulation of IL10, IL13 and subunits of IL35 (EBI3 and p35). However the mast cells but not the B cells were the primary cells responsible for producing these cytokines. As the microvesicle-activated B cells could in turn promote mast cell production of IL13, an important cross-talk is suggested to induce immune suppression. Revelation of the nature of mast cell-B cell interactions following UV exposure could lead to novel therapeutic targets aimed at either enhancing the therapeutic benefits of phototherapy for skin diseases, or preventing UV-induced immune suppression to mitigate the risks of photocarcinogenesis.

2020

A disintegrin and metalloprotease 10 (ADAM10) regulates inducible costimulatory ligand (ICOS-L) levels on B-cells*Lownik, J.^{1,2}, Cooley, L.^{1,2}, Damle, S.¹, Conrad, D.¹*¹Virginia Commonwealth University, Department of Microbiology and Immunology, Richmond, United States, ²Virginia Commonwealth University, Center for Clinical and Translational Research, Richmond, United States

Up to 40% of the population of developed countries suffer from atopic disease and that number is expected to rise over the coming years. Recently, we have shown the importance of ADAM10 in allergic disease, with conditional deletion of ADAM10 in B-cells (ADAM10^{B-/-}) in mice leading to a decreased asthmatic phenotype. In addition, B-cells from asthmatic patients had increased protein and mRNA levels of ADAM10. Here we report that ADAM10 regulates ICOS-L on B-cells. ADAM10^{B-/-} mice exhibit approximately 10-fold increase in ICOS-L surface levels on naïve B-cells compared to wildtype mice, which persists after stimulation with anti-CD40, whereas ICOS-L mRNA message levels are 10-fold reduced in ADAM10^{B-/-} B-cells. Similar increases in ICOS-L expression are seen when WT mouse or human B-cells are cultured in the presence of ADAM10 inhibitors. Flow analysis indicates that T-cell ICOS levels in ADAM10^{B-/-} mice is essentially

equivalent to the isotype control staining levels, indicating that the high ICOS-L expression causes strong downregulation of T-cell ICOS. ICOS-L-ICOS engagement has an important role in T-cell responses, particularly for T_{FH} cells. Consistent with the negligible ICOS expression on T-cells from ADAM10^{B-/-} mice, they also have reduced numbers of T_{FH} cells and impaired antibody production. Given the importance of ICOS-L/ICOS in the induction of asthmatic disease and our results demonstrating alterations in this pathway in ADAM10^{B-/-} mice, we hypothesize that abnormal regulation of ICOS-L by ADAM10 explains the decreased allergic phenotype seen in ADAM10^{B-/-} mice and that ADAM10 inhibitors may provide new way to modulate T_{FH} and Th2 responses.

2973

Myosin 1g participates in CD44-recycling in B-lymphocytes*López-Ortega, O.^{1,2}, Santos-Argumedo, L.¹*¹Centro de Investigación y de Estudios Avanzados del IPN, Biomedicina Molecular, Ciudad de Mexico, Mexico, ²Facultad de Medicina Universidad Nacional Autónoma de México, Ciudad de Mexico, Mexico

Recycling of adhesion molecules is an important process for cell adhesion and cell migration. This phenomenon is actin-cholesterol- and sphingolipid-enriched lipid rafts-dependent, involving several proteins such as actin, tubulin, GTPases, kinesins and dyneins; however, the motor proteins associated in these processes are unknown. Class I myosins are proteins with a conserved structure that consists of three regions: head, neck and tail. There are 8 class I myosins in mammals, ranging from myosin 1a to 1h, which are molecular motors that interact both with actin fibers and plasma membrane phosphoinositides. Myosin 1g (Myo1g) binds primarily to PIP2 and PIP3; these phosphoinositides are significantly present in several types of vesicles. In this work, we identified Myo1g as the important motor protein that drives the recycling of CD44 in B lymphocytes. We demonstrated that the lack of Myo1g decreases the levels of CD44 and GM1 at the surface of the cell. In cells lacking Myo1g, the recycling of adhesion molecules is delayed at the initial step of the recycling pathway. Defects in the lipid-raft-recycling in Myo1g-deficient cells have a significant impact in cell capping and cell migration. Both processes require the transport of lipid rafts to the surface of cell, to deliver the signaling components and the extra membrane essential for the expansion of the cell surface. Thus, Myo1g is important for the recycling of the lipid rafts in the membrane, affecting the associated proteins that regulate adhesion and migration of B lymphocytes.

IL-27 directly influences germinal center B cell development via STAT1*Vijayan, D.^{1,2,3}, Mohd. Redzwan, N.², Avery, D.², Wirasinha, R.², Brink, R.¹, Walters, G.^{4,5,6}, Adelstein, S.⁷, Kobayashi, M.⁸, Gray, P.⁹, Elliott, M.¹⁰, King, C.^{2,3}, Vinuesa, C.⁴, Ghilardi, N.¹¹, Ma, C.^{2,3}, Tangye, S.^{2,3}, Batten, M.^{2,3}*¹QIMR Berghofer Medical Research Institute, Immunology,

Brisbane, Australia, ²Garvan Institute of Medical Research, Immunology, Sydney, Australia, ³University of New South Wales, St Vincents Medical School, Sydney, Australia, ⁴John Curtin School of Medical Research, Australian National University, Department of Immunology and Infectious Disease, Canberra, Australia, ⁵Canberra Hospital, Department of Renal Medicine, Canberra, Australia, ⁶Australian National University, Australian National University Medical School, Canberra, Australia, ⁷Royal Prince Alfred Hospital, Clinical Immunology, Sydney, Australia, ⁸Hiroshima University, Department of Pediatrics, Hiroshima, Japan, ⁹University of New South Wales School of Women's and Children's Health, Sydney, Australia, ¹⁰University of Sydney, Sydney Medical School, Sydney, Australia, ¹¹Genentech, Department of Immunology, San Francisco, United States

Dysregulated germinal center (GC) activity can result in antibody driven autoimmune disease, such as lupus. IL-27 has a pro-inflammatory role in germinal center (GC) responses. We previously demonstrated that IL-27 effects on T follicular helper cells (T_{FH}) are essential for supporting GC. The present study provides the first demonstration that IL-27 signals also directly enhance the differentiation of human B cells towards a CD20⁺CD38⁺CD27^{low}CD95⁺CD10⁺ phenotype, consistent with that of GC B cells. Loss-of-function mutations in STAT1, but not STAT3, prevented IL-27 mediated differentiation of human GC-like B cells. The GC-driven *Roquin*^{san/san} lupus mouse model was used to determine the importance of IL-27 signals to B cells *in vivo*. *Il27ra*^{-/-}.*Roquin*^{san/san} mice exhibited amelioration of lupus pathology. Significantly reduced GC B cells and anti-DNA IgG2a(c)+ switched B cells were observed and mixed bone marrow chimeras confirmed that IL-27 signaling promotes GC activity through both B and CD4⁺ T cell-intrinsic mechanisms. Together, our data provides the first evidence of a direct role for IL-27 in GC B cell differentiation. The amelioration of lupus pathology in *Il27ra*^{-/-}.*Roquin*^{san/san} mice suggests that modulating IL-27 functions in GC responses could be an attractive therapeutic strategy in the treatment of some lupus patients.

2788

CD21^{low}- age-associated B cells are memory B cells in autoimmunity

Höök, N.¹, Aranburu, A.¹, Grimsholm, O.^{1,2}, Gerasimcik, N.¹, Mårtensson, I.-L.¹

¹University of Gothenburg, Gothenburg, Sweden, ²Bambino Gesù Children Hospital, Rome, Italy

A B cell subset (CD21^{-low}) expressing low levels of complement receptor 2 (CR2, CD21) has been described in conditions of chronic immune stimulation in humans, e.g. autoimmune diseases. A CD21^{-low} B-cell subset has also been described in mice where it accumulates with age, and a similar subset is enriched under autoimmune conditions, e.g. in lupus prone mice and in those that lack a pre-BCR (*SLC*^{-/-}). However, it is unclear what type of cells they are. Here we demonstrate that in autoimmunity, in *SLC*^{-/-} mice, a majority of the splenic CD21^{-low} subset are memory B cells that express IgM and have undergone somatic hypermutation. About half of these CD21^{-low} cells express CD11c. Hybridomas established from these

cells produce autoantibodies that recognize DNA and nuclear antigens. Thus, under autoimmune conditions, the CD21^{-low} B cells are memory B cells.

Inflammasome function in autoimmunity

Thygesen, S.J., Sester, D.P., Sagulenko, V., Stacey, K.J.

The University of Queensland, School of Chemistry and Molecular Biosciences, St Lucia, Australia

Inflammasomes are molecular complexes activated by infection and cell stress, responsible for activating caspase-1 that subsequently facilitates IL-1 β processing and cell death. We have discovered inflammasome deficiencies in the autoimmune NZB mouse strain. NZB has a point mutation leading to loss of expression of inflammasome initiator NLRP3, and is also deficient in AIM2 inflammasome function. NZB mice develop anti-erythrocyte antibodies and haemolytic anaemia, and also anti-nuclear antibodies typical of lupus. We hypothesise that the inflammasome deficiencies in NZB alter the interaction of the host with both microflora and pathogens, promoting prolonged production of cytokines such as type I IFN, which contribute to loss of tolerance. The progeny of NZB and NZW mice (NZB/W F1) have a more severe lupus-like phenotype, developing anti-nuclear antibodies and immune complex-mediated glomerulonephritis at around 5-6 months of age, dying around 10-12 months from kidney failure. We have found that NZW has normal inflammasome function, and macrophages from NZB/W F1 mice have an intermediate inflammasome response compared to the parental strains, although there is no sign of deficiency when the stimulus strength is high. NLRP3 may have contrasting roles at different stages of disease. The partial NLRP3 deficiency in NZB/W F1 mice could contribute to the initiation of autoimmunity. However, with abundant self danger molecules as triggering stimuli later in disease, NLRP3 inflammasome may exacerbate kidney damage.

The role of SSc5D in pathogen recognition and inflammation

Santos, R.F.^{1,2}, Mendes, S.¹, Bessa-Pereira, C.^{1,2}, Oliveira, L.¹, Carmo, A.M.¹

¹IBMC/i3S, Porto, Portugal, ²University of Porto/ICBAS, Porto, Portugal

Scavenger receptor cysteine-rich (SRCR) receptors are a group of membrane-attached or secreted proteins that contain one or more domains structurally similar to the membrane distal domain of the type I macrophage scavenger receptor. These receptors are thought to mediate protein-protein interactions within the immune system and/or to serve as pathogen pattern recognition receptors. However, the overall function of the SRCR family is still poorly understood. Soluble scavenger receptor with 5 domains (SSc5D) is a secreted SRCR glycoprotein that we found to be abundant in the human serum and whose expression was

detected in cells of myeloblastic, monocytic and lymphocytic origin. By immunohistochemical staining of sections of different organs, we additionally identified the presence of SSc5D in epithelial cells of the gastrointestinal and genitourinary tracts. Furthermore, SSc5D was strongly detected in human placenta, most noticeably in syncytiotrophoblast cells, but interestingly it was almost undetectable in tissue samples displaying signs of infection, thus suggesting a possible role in fetal immunity. While we describe that SSc5D is able to bind to pathogenic bacteria and that bacterial challenges induce SSc5D secretion from certain cell types, several inflammatory mediators also induce significant changes in SSc5D protein levels in human cell models, suggesting also a role for SSc5D on inflammation. Overall, our results indicate that SSc5D is involved in fighting infectious agents as well as in inflammatory responses.

3961

Fungal immunomodulatory proteins LZ-8 and GMI activate the NLRP3 inflammasome via stimulating ROS generation

Hsu, S.-Y., Lu, C.-Y., Chen, C.-J.

National Taiwan University, Department of Biochemical Science and Technology, Taipei, Taiwan, Republic of China

The inflammasome is a multiprotein complex which mediates the processing and production of proinflammatory cytokines IL-1 β and IL-18. The NLRP3 inflammasome complex is composed of NLRP3, ASC, and procaspase-1, in which caspase-1 is autoactivated and processes pro-IL-1 β and pro-IL-18 into mature cytokines. LZ-8 and GMI are fungal immunomodulatory proteins (FIPs) derived from *Ganoderma lucidum* and *Ganoderma microsporum*, respectively. FIPs are known to stimulate the activation of dendritic cells and T lymphocytes, and in animals, FIPs exhibit adjuvant and antitumor functions. In this study, we investigated the immunostimulatory mechanisms of FIPs and found that LZ-8 and GMI can stimulate inflammasome activation and IL-1 β production in murine macrophages. LZ-8 and GMI stimulated caspase-1 activation and IL-1 β production in peritoneal macrophages and BMDMs, which was strongly enhanced when cells were co-stimulated with LPS. FIP-stimulated IL-1 β production in LPS-primed BMDMs was markedly attenuated when cells lacked the expression of NLRP3, ASC, or caspase-1, indicating that FIPs activate the NLRP3 inflammasome. FIP-induced IL-1 β production was inhibited in the presence of high extracellular KCl or inhibitors targeting the membrane pores P2X7 and pannexin-1, indicating the requirement of potassium efflux through ion channels. FIPs stimulated ROS generation in BMDMs, and blocking ROS production by N-acetylcysteine significantly inhibited FIP-induced IL-1 β production. Overall our findings provide evidence that FIPs are new type of protein ligands that activate the NLRP3 inflammasome via stimulating ROS generation, and this activity may contribute to the immunomodulatory functions of FIPs.

Inhibition of TLR3 signalling by single stranded oligonucleotides

Järver, P.¹, Dondalska, A.¹, Lennox, K.², Behlke, M.², EL-Andaloussi, S.³, Spetz, A.-L.¹

¹Stockholm University, Department of Molecular Biosciences, Wenner-Gren Institute, Stockholm, Sweden, ²Integrated DNA Technologies Inc, Coralville, United States, ³Karolinska Institutet, Department of Laboratory Medicine, Stockholm, Sweden

TLR3 is a pattern recognition receptor found in cellular endosomes and it recognizes dsRNA, which can be found in some viral genomes, produced during viral replication cycles, or released by dying cells. TLR3 activation is engaged in defences against viral infections. However, TLR3 hyperresponsiveness has been implicated in certain pathologic and inflammatory conditions. To address TLR3-induced inflammation, we have previously used single stranded oligonucleotides (ssONs) and showed that they can inhibit TLR3-mediated activation of human monocyte-derived DCs (MoDCs), as well as decrease cytokine production in the airways of cynomolgus macaques. We have now further investigated the mechanism(s) behind this inhibition in human MoDCs. We provide data showing that ssONs might be direct inhibitors of TLR3 signalling as they interact directly with TLR3, as well as compete for the same binding site as the dsRNA analogue, Poly I:C. Furthermore, the binding of ssONs is pH and length dependent and the observed inhibition appears to be sequence independent. Stability modifications are not essential for inhibition of TLR3 signalling, but seem necessary for retained activity. The biokinetics of the ssON-mediated inhibition appear to follow that of clathrin-mediated endocytosis and certain structural features are required for ssONs's inhibitory activity. Finally, we propose that the observed inhibitory effect could be a negative feedback-loop preventing over-activation of TLR3 from endogenous dsRNA. Our data provide the basis for elucidating the molecular mechanism(s) involved in the inhibition of TLR3 signalling which, could give further insight into therapeutic methods for TLR3-mediated immunopathogenesis.

Bacterial DNA sensed by STING activates guanylate-binding proteins via type I IFN signaling pathway enhancing host cell defense

Costa, M.¹, Marim, F.¹, Marinho, F.¹, Harms, J.², Splitter, G.², Smith, J.³, Kanneganti, T.⁴, Barber, G.⁵, Oliveira, S.¹

¹Federal University of Minas Gerais / Institute of Biological Sciences, Biochemistry and Immunology, Belo Horizonte, Brazil, ²University of Wisconsin-Madison, Pathobiological Sciences, Madison, United States, ³University of Wisconsin-Madison, Pediatrics, Madison, United States, ⁴St Jude Children's Research Hospital, Immunology, Memphis, United States, ⁵University of Miami Miller School of Medicine, Cell Biology, Miami, United States

Immunity against invading microbes depends on the recognition of pathogen-associated molecular patterns by innate receptors. Signaling pathways triggered by *Brucella abortus* DNA involves TLR9, AIM2 and STING. Previously, our research group showed

that *Brucella* DNA-induced IFN- β is dependent on STING. In this study, we observed by microarray analysis that several type I IFN associated genes are down-regulated in STING KO macrophages infected with *Brucella* or transfected with bacterial DNA compared to C57BL/6 cells. Among these genes are guanylate-binding proteins (GBPs), CXCL10, CXCL11, Mx1. We confirmed that expression of GBP2, GBP3 and GBP5 is dependent on type I IFN signaling using IFNAR KO mice. Further, we determined whether GBPs affect intracellular survival of *Brucella* using BMDM from GbpChr3 and Gbp5 KO mice. Luminometry of lux expressing *Brucella* indicated that BMDM of GbpChr3 and Gbp5 KO mice did not control bacterial replication as well as the wild-type BMDM. Further, macrophages derived from STING KO mice showed reduction in IL-1 β secretion and caspase-1 activation when infected with *Brucella* or stimulated with bacterial DNA. These findings demonstrate that STING mediated type I IFN pathway is critical for engagement of GBP-mediated killing of *Brucella* which may result in the release of bacterial DNA for the activation of AIM2. Finally, STING and AIM2 KO mice are more susceptible to *Brucella* infection suggesting these DNA sensors are critical to induce an effective innate immune response. Funding: This study was supported by funding agencies CNPq, FAPEMIG and CAPES.

Myeloid immunoreceptor tyrosine-based activation motif (ITAM)-coupled receptors (ITAMRs) activate innate immunity against fungi or bacteria through the recognition of pathogen-associated molecular patterns (PAMPs). Recent studies have reported that several FcR γ -associated receptors recognize PAMPs of mycobacteria. For instance, Mincle and MCL recognize trehalose-dimycolate (TDM).

Mycobacterial cell wall contains various type of MA-containing lipids, which include non-glycosylated MAs, such as free MA itself and glycerol monomycolate (GroMM), and glycosylated MAs, such as TDM and glucose monomycolate (GMM). These cell-wall lipid constituents dynamically change depending on mycobacterial conditions, such as proliferating or dormant status, and regulate host immune responses. However, how host recognize and respond to MA-containing lipids other than TDM, remains obscure.

Recently, we have identified a DAP12-associated ITAMR named IgSFR2 as a novel receptor recognizing MA-containing lipids. We found that macrophage stimulation with the non-glycosylated MAs produced the chemokine MCP-1 but only few or no inflammatory cytokines such as TNF and IL-6, while the glycosylated MAs induced both of them. The non-glycosylated

MA-induced chemokine production was abolished by IgSFR2 deficiency, while the glycosylated MA-induced cytokine and chemokine production was abolished by Mincle deficiency, indicating that IgSFR2 and Mincle are innate receptors for non-glycosylated and glycosylated MAs, respectively. Interestingly, IgSFR2 also could bind to glycosylated MAs but its binding inhibited cytokine response through Mincle. These results suggest that IgSFR2 and Mincle distinctively recognize MA-related lipids for the induction of different immune responses and hence their balance may regulate immune response to different conditions of mycobacteria.

Cross-regulation between the inflammasome and linear ubiquitination machinery

*Douglas, T.*¹, *Champagne, C.*², *Lapointe, J.-M.*³, *Saleh, M.*⁴

¹McGill University, Microbiology and Immunology, Montreal, Canada, ²McGill University, Medicine, Montreal, Canada, ³McGill University, Comparative Medicine and Animal Resources Centre, Montreal, Canada, ⁴McGill University, Biochemistry, Montreal, Canada

The linear ubiquitin assembly complex (LUBAC) is a tripartite E3 ubiquitin ligase complex which plays key roles in mediating cellular life or death decisions downstream of various innate receptors. Mice that lack the adaptor of LUBAC, Sharpin, develop a severe multi-organ inflammatory disease termed chronic proliferative dermatitis in mice (*cpdm*) which shares pathological hallmarks with atopic dermatitis in humans. While skin inflammation in this context has been shown to be driven by TNF α , the relative contribution of additional inflammatory pathways remains poorly characterized. We have recently identified the Nlrp3 inflammasome to be critical for driving dermatitis in *cpdm* mice by mediating the production of inflammatory cytokines and through the induction of apoptosis and necroptosis. Given these findings we hypothesized that there may exist a cell-intrinsic interaction between LUBAC and the inflammasome. Here, we identify LUBAC to be a novel negative regulator of inflammasome activity in keratinocytes by mediating the linear ubiquitination of caspase-1. Furthermore, the central E3 ligase of LUBAC, HOIP, is cleaved by caspase-1 during apoptosis, impeding substrate linear ubiquitination. These findings provide further insight into the complex interplay between the inflammasome and cell death machinery and add to our understanding of inflammasome regulation.

Analysis of the binding specificity of antibody to dopamine-2 receptor in paediatric autoimmune movement and psychiatric disorders

Sinmaz, N., Pilli, D., Merheb, V., Amatoury, M., Pathmanandavel, K., Ramanathan, S., Dale, R., Brilot, F.

Brain Autoimmunity Group, Institute for Neuroscience and Muscle Research, The Kids Research Institute, Children's Hospital at Westmead, Discipline of Paediatrics and Child Health, University of Sydney, Sydney, Australia

Autoantibodies to neuronal surface antigens have been associated with brain disorders. The identification of these autoantibodies is important as they can be used as biomarkers for diagnostic purposes. We recently identified dopamine-2 receptor (D2R) autoantibodies in children with autoimmune movement and psychiatric disorders, however the target epitope(s) remain unknown. To assess anti-D2R antibody specificity, we subcloned D2R mutants modified in their extracellular domains and expressed them in human embryonic kidney cells. Confocal microscopy and flow cytometry were used to assess cell-surface expression levels of mutant D2R. Using a flow cytometry live cell-based assay, we found 0/35 (0%) D2R antibody-positive patient sera bound to N^{TermD1R}cD2R, suggesting the autoantibody epitope was within D2R N-terminus. Next, we examined autoantibody immunoreactivity to D2-22 D2R and found 25/35 (71%) patients recognised an epitope in this region. As this extracellular D2R domain also included an N-glycosylation site at position 23, we next assessed autoantibody to the D2R N-glycosylation. Out of the 25 patients positive for D2-22 D2R binding, 22/25 (88%) recognised N23Q with a 40% reduced immunoreactivity. Furthermore, D26E/A29P was subcloned to emulate mouse D2R, and 15/25 (60%) patients recognised this construct with a 45% decreased immunoreactivity. In order to abolish epitope binding, we subcloned R20K/P21G/F22W/N23Q/D26E/A29P mutant; 11/25 (44%) did not recognise this construct and the rest of the patients (14/25, 56%) bound the mutant, but with a substantial 79% decrease in immunoreactivity compared to D2-22 D2R. Defining the D2R antigenic region is important to elucidate functional effects of antibodies and provide precise testing for patients.

Role of the cholinergic system in experimental pulmonary tuberculosis

Islas-Weinstein, L.^{1,2}, Barrios-Payán, J.¹, Mata-Espinosa, D.³, Marquina-Castillo, B.³, Hernández-Pando, R.¹

¹National Institute of Medical Sciences and Nutrition, Experimental Pathology, Mexico City, Mexico, ²National Autonomous University of Mexico, Mexico City, Mexico, ³National Institute of Medical Sciences and Nutrition, Mexico City, Mexico

Acetylcholine is an endogenous nicotinic and muscarinic receptor agonist that is secreted in the lungs of BALB/c mice under pathological conditions. Specific interactions of

acetylcholine with cholinergic receptors have been associated with macrophage deactivation, increased Th2 activity and decreased Th1 and Th17 responses in mouse models of pulmonary inflammation. Using high performance liquid chromatography (HPLC), lungs of BALB/c mice infected with *Mycobacterium tuberculosis* strain H37Rv revealed specific lung acetylcholine elevations particularly during late active disease that may contribute to protective immune decay and disease progression. Lung and brain tissue were also analyzed to determine the kinetics of specific acetylcholine receptors during the course of the disease. In order to study the contribution of the cholinergic system to the disease evolution, mice received either: saline solution (control group) or nicotinic selective antagonists coinciding with periods of acetylcholine exacerbation. Mice lungs were obtained after treatment and parameters of disease progression such as: granuloma formation, bacilli loads (colony-forming units) and pneumonia were measured. Our results showed that the administration of specific nicotinic receptor antagonists resulted in improved immune protection permitting better control of bacterial growth when compared to the control group. Thus, the cholinergic system contributes to decreased inflammation during late stages of disease through the partial suppression of cell-mediated immunity, permitting bacilli growth. Its pharmacological manipulation using anticholinergic agents may hence emerge as a novel therapeutic approach in the treatment of this significant infectious disease.

Viruses such as Epstein-Barr virus (EBV) and Human herpesvirus 6 (HHV-6) have recently considered as potential causes of multiple sclerosis (MS). CD8+ T cells are the essential mechanism to handle with viral diseases. T CD8+ lymphocytes can be subdivided in to different subtypes; naïve, early-, intermediate- and late-differentiated, according to the expression of CD27, CD28, CD45 and CD57, the phenomena may induced by viruses. Our aim was to determine the EBV and HHV-6 load and their relation with CD8+ T cells composition change in RRMS patients. In this study we performed quantitative detection of

EBV and HHV-6 DNA in plasma in RRMS patients, in active phase (n=23) and healthy age- and gender-matched controls (n=19) using Real-time PCR. CD8+ subset frequency with Anti-CD27, CD28, CD45 and CD57 monoclonal antibodies were measured using flowcytometry. Although higher EBV viral load was found in MS patients compared to controls (250.95 copies/ml and 4.15 copies/ml respectively), it was not significant (P=0.1). There was no difference between patients and controls in HHV-6 copy numbers (P=0.9). Notably, we demonstrated higher frequency of early-differentiated CD8+ cells (CD8+ CD27+ CD28+ CD45RO+ CD57-) in RRMS patients (P=0.03). We also identified higher proportion of CD27+ CD28- CD8+ T cells in HHV-6 positive compared to HHV-6 negative patients (P=0.01). In addition, CD27+ CD28+ CD45RO- CD57- CD8+ frequency in RRMS patients was positively correlated with HHV-6 viral load (P=0.009). The present study indicates further evidence for changes in CD8+ T cells subsets composition that may be associated with persistent antigenic stimulation.

Innate receptor signaling and Type I interferons in glial response in the central nervous system

Khoroshi, R.M.H.¹, Zaucha Sørensen, M.¹, Wais, V.¹, Dieu, R.¹, Thorsen Mørch, M.¹, Nistal-Villán, E.², González-Aseguinolaza, G.², Webster, G.³, Lienenklaus, S.⁴, Owens, T.¹

¹Institute of Molecular Medicine, University of Southern Denmark, Neurobiology Research, Odense, Denmark, ²Centro de Investigación Médica Aplicada (CIMA), Gene Therapy and Regulation of Gene Expression Program, University of Navarra, Pamplona, Spain, ³Innate Immunotherapeutics, Auckland, New Zealand, ⁴Institute for Laboratory Animal Science, Hannover Medical School, Hannover, Germany

Type I interferons (IFN), including IFN- β , play a central role in regulation of inflammation. IFN- β is used as a therapeutic for multiple sclerosis (MS), an inflammatory demyelinating disease in central nervous system (CNS). IFN- β is induced by ligation of innate receptors, including Toll-like receptors (TLRs). Microglia and astrocytes express innate receptors and are known to be involved in the regulation of inflammation. Previous studies identified microglia as a major source of endogenous Type I IFN in the CNS, and induction of microglial type I IFN by a TLR3 agonist administered directly into the cerebrospinal fluid protected against experimental autoimmune encephalomyelitis, a mouse model of MS. To further study glial responses and induction of type I IFN we have administered a range of innate receptor agonists directly to the CNS of mice. These include agonists to TLR2, 3, 4, 7, 9, a construct (MIS416) composed of ligands to NOD2-TLR9, as well as an AAV-vector encoding 2CARD-MAVS200. We present results from reporter mice showing in vivo expression of IFN- β , as well as cellular source and glial response. Administration of a TLR3 ligand transiently induced strong up-regulation of IFN- β , within hours, whereas a TLR2 ligand was ineffective. TLR3 ligation did not induce IFN- β in astrocytes. IFN response factors and IFN-inducible chemokines were upregulated in astrocytes and microglia. Our studies support a general hypothesis that microglia initiate a regulatory response via type I IFN that acts on astrocytes.

Insight into regulatory mechanisms induced by a novel immunospecific therapy with synthetic multi-epitope targeting agent modulate MS-like disease

Kaushansky, N., Kaminitz, A., Allouche-Arnon, H., Ben-Nun, A. The Weizmann Institute of Science, Rehovot, Israel

Specific neutralization of the pathogenic autoimmune cells is the ultimate goal in therapy of autoimmune diseases. Among all approaches proposed for MS therapy, an approach that neutralizes only the pathogenic T cells, while leaving the innocent immune cells intact, is the ultimate goal in the immune-specific therapy for MS. We recently showed that a concomitant "multi-epitope-targeting" approach, using a specifically designed artificial multi-epitope protein (Y-MSPc) is required for effective antigen-based immune-specific therapy of EAE. Strikingly, Y-MSPc was consistently more effective than treatment with the single peptide or with the peptide cocktail, both in suppressing the development of "classical" or "complex" EAE and in ameliorating ongoing disease. Overall, the modulation of EAE by Y-MSPc was associated with anergizing the autoreactive T-cells, downregulation of Th1/Th17 cytokine secretion and upregulation of TGF- β secretion. Moreover, administration of Y-MSPc is associated also with a remarkable increase in a unique subset of myeloid-derived dendritic-cells (DCs), CD11c+CD11b+Gr1+ in both spleen and CNS of treated mice. These DCs, are functional in down-modulation of MS-like-disease displayed increased production of IL-4, IL-10 and TGF- β and low IL-12. Functionally, these DCs suppress the in-vitro proliferation of T-cells and were functional in-vivo, as their adoptive transfer into EAE induced mice resulted in suppression of the disease, associated with a remarkable induction of CD4+FoxP3+ regulatory cells.

These results, which highlight the efficacy of "multi-epitope-targeting" agent in induction of functional regulatory CD11c+CD11b+Gr1+myeloid DCs, further indicate the potential role of these DCs in maintaining peripheral tolerance and their involvement in downregulation of MS-like-disease.

Cytokine production of CD4⁺ responder and regulatory T cells and the effect of IL-21 in co-culture in myasthenia gravis patients

Alahgholi-Hajibehzad, M.¹, Durmus, H.², Aysal, F.³, Gulsen-Parman, Y.², Oflazer, P.², Deymeer, F.², Saruhan Direskeneli, G.⁴

¹Istanbul University, Istanbul, Turkey, ²Istanbul University, Istanbul Medical Faculty Department of Neurology, Istanbul, Turkey, ³Bakirkoy Research and Training Hospital for Psychiatric and Neurological Diseases, Istanbul, Turkey, ⁴Istanbul University, Istanbul Medical Faculty Department of Physiology, Istanbul, Turkey

Impairment in the suppressive function of regulatory T cells (Treg) was reported in myasthenia gravis (MG). In this study, mechanisms that underlie the defect of Treg were investigated in patients with anti-acetylcholine receptor antibody positive MG (AChR-MG). The proliferation and cytokine production were measured in a suppression assay system performed with

polyclonal activation of responder T cells (Tresp). Restoring effect of IL-21 on suppression was evaluated in vitro in co-culture.

Tresp from MG patients secreted significantly lower levels of IL-2, whereas the proliferation did not differ from the controls. In Tresp/Treg co-cultures, IL-4, IL-6, IL-10 and IL-17 levels were increased in the presence of Treg, whereas IFN- γ was decreased in both patient and control groups. In MG patients, IL-2 levels did not change with the addition of Tregs to cultures, whereas it decreased significantly in controls. The addition of IL-21 to co-cultures increased the proliferation of Tresp and decreased the secretion of IL-4 and IL-17 in MG and controls. However IL-21 did restore the proliferation of Tresp from MG patients as in the controls and the production of cytokines was not effected by IL-21 in vitro differentially in the co-cultures.

This study is supported by TUBITAK (Grant #: 110S297), and Istanbul University Research Fund (BYP).

The transcription factor T-bet negatively regulates germinal centre responses and humoral immunity to malaria

Ly, A.^{1,2}, Ryg-Cornejo, V.^{1,2}, Chiu, C.Y.^{1,2}, Ioannidis, L.J.^{1,2}, Jacobson, K.³, Kallies, A.^{1,2}, Hansen, D.S.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, ²The University of Melbourne, Department of Medical Biology, Parkville, Australia, ³Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia

Malaria, the infectious disease caused by the *Plasmodium* parasites, claims the lives of almost half a million people annually. A large body of evidence suggests that naturally acquired immunity to malaria develops after many years of repeated infections. This form of protection is not sterilizing, and only prevents the development of symptomatic disease by substantially reducing blood-stage parasite densities. Immunological studies suggest that antibodies to *Plasmodium* antigens are inefficiently generated and responses wane rapidly in the absence of on-going parasite exposure. Moreover, individuals residing in areas of high malaria transmission have been found to exhibit a delayed development of parasite-specific memory B cells. These findings lend support to the notion that acute malaria may impede the generation and maintenance of malaria-specific B cell responses. However, this hypothesis has not been extensively investigated. Using the *P. berghei* ANKA rodent malaria model, we found that severe malaria infection impairs germinal centre responses and inhibits T follicular helper (Tfh) cell differentiation in the spleen. Our findings revealed that infection induces a high frequency of Tfh cell precursors that displayed low levels of PD-1 and CXCR5 and co-expressed T helper 1 associated molecules, including the transcription factor T-bet and chemokine receptor CXCR3. Moreover, genetic deletion of T-bet significantly restored Tfh cell differentiation and resulted in efficient germinal centre formation, as well as improved parasite-specific antibody responses to infection. Together, these results demonstrate that the same pro-inflammatory pathways that drive severe

symptomatic malaria have detrimental effects on the induction of protective humoral immunity.

Inflammatory monocyte- and neutrophil-derived CXCL10 impairs efficient control of blood-stage malaria infection and promotes severe disease

Ioannidis, L.J.^{1,2}, Nie, C.Q.³, Ly, A.^{1,2}, Ryg-Cornejo, V.^{1,2}, Chiu, C.Y.^{1,2}, Hansen, D.S.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research, Infection and Immunity Division, Victoria, Australia, ²The University of Melbourne, The Department of Medical Biology, Victoria, Australia, ³The University of Melbourne, Office for Research Ethics and Integrity, Victoria, Australia

Cerebral malaria (CM) is a severe and often fatal complication of *Plasmodium falciparum* infection. This syndrome results from the sequestration of parasitized red blood cells in the brain microvasculature and strong inflammatory responses to infection. Among the inflammatory factors produced in response to infection, the chemokine CXCL10 has been identified as a biomarker of CM. Consistent with this, we have previously shown that CXCL10 blockade alleviates brain intravascular inflammation and protects malaria-infected mice from CM. In addition to organ-specific effects, here we found that a lack of CXCL10 during infection also reduces parasite biomass. To identify the cellular sources of CXCL10 involved in these processes, wild-type and CXCL10^{-/-} mice were irradiated and reconstituted with bone marrow from either wild-type or CXCL10^{-/-} mice. Chimeric mice were then infected and brain parasite and leukocyte sequestration, as well as parasite biomass was assessed. This revealed that hematopoietic cell-derived CXCL10 impairs efficient control of parasite biomass, regulates leukocyte recruitment to the brain and is responsible for the development of CM. Inflammatory monocytes and neutrophils were identified as the main cellular sources of CXCL10 responsible for the induction of these processes. Moreover, the improved control of infection observed in the absence of CXCL10-mediated trafficking was associated with a preferential accumulation of CXCR3⁺CD4⁺ T follicular helper cells in the spleen and enhanced antibody responses to infection. These findings indicate that some inflammatory responses elicited during malaria infection contribute to the development of high parasite densities involved in the induction of severe disease in target organs.

Evaluation of immunomodulatory activities of lentinan in combination with miltefosine in Balb/c mice against visceral leishmaniasis

Shivhare, R.¹, Ali, W.¹, Singh, U.S.¹, Khattri, S.², Puri, S.K.³, Gupta, S.³

¹King George's Medical University, Department of Pathology, Lucknow, India, ²King George's Medical University, Department of Pharmacology and Therapeutics, Lucknow, India, ³CSIR-Central Drug Research Institute, Division of Parasitology, Lucknow, India

Visceral leishmaniasis (VL), a vector-borne infection, caused by protozoan parasite *Leishmania* is the second largest parasitic

killer after malaria. VL is potentially fatal disease in which parasite distorts the normal immune function of the host. Single-drug therapy against VL is far from satisfaction since existing antileishmanials have several limitations. Miltefosine, only oral drug, is the mainstay of the VL elimination program but its teratogenic effect, narrow therapeutic window and resistance issue raise the concern. Thus, combinations of existing drugs and/or immunomodulators are the options for the successful treatment of VL. In our study in *Leishmania donovani*/mouse model of VL, we have assessed the optimum dose (2.5 mg/kg×5 days, intraperitoneal route) of lentinan, a biological defense modifier and tested in combination with short dose (2.5 mg/kg×5 days, oral) of miltefosine and detailed immunological parameters (Th1/Th2 cytokines, IgG antibody, nitric oxide, splenocyte proliferation and phagocytic activity) were investigated at days 7 and 14 post treatment. Animals that received combination therapy showed sterile cure (~100% inhibition of parasite) of VL in both liver and splenic cells. Combination group displayed ($p < 0.001$) increased level of Th1 cytokines, IFN- γ , IL-12 and TNF- α along with nitric oxide and significantly suppressed level of Th2 cytokines, IL-10, IL-4 and TGF- β . Furthermore, maximum IgG2 antibody level, splenocyte proliferation and induced phagocytic ability of macrophages were recorded during combination therapy when compared with other treated groups. Collectively, lentinan has synergistic effect on miltefosine efficacy and its protective effect against VL is host-mediated and involves potentiation of Th1 mediated immune responses.

834

Combining immunoproteomics and *in silico* MHC-II epitopes prediction for the identification of potential protective antigens against *Echinococcus granulosus* infection in mice

Miles, S., Navatta, M., Dematteis, S., Mourglia-Ettlin, G.

Universidad de la República, Faculty of Chemistry - Department of Biosciences - Laboratory of Immunology, Montevideo, Uruguay

Echinococcus granulosus is the parasite responsible for cystic echinococcosis. In intermediate hosts, induction of specific antibodies play important roles in susceptibility/resistance phenomena. Identification of the targets of such antibodies is extremely important for the assignment of protective antigens. Therefore, we have analyzed the differential recognition of tegumental antigens from *E. granulosus* protoscoleces (termed PSEx) by antibodies from early-infected mice belonging to high (Balb/c) and low (C57Bl/6) susceptible strains. Through 2DE and immunoblots we described remarkable differences in the recognition patterns by IgM, IgA and IgG subclasses. Then, by means of mass spectrometry we identified 10 proteins from PSEx which were solely recognized by antibodies from the most resistant mouse strain. Gene ontology term enrichment classified most of them as cytoplasmatic proteins involved in metabolic processes with catalytic activity. On the other hand, since T-dependent antibody responses depends on the collaboration between B and T cells via antigens presented in MHC class II molecules, we further analyzed MHC class II epitopes in the set of proteins identified. Through the online prediction software NetMHCII, we discriminated such epitopes

between C57Bl/6 and Balb/c alleles (H2-IAb and H2-IAd, respectively), and our results predicted that 9 out of 10 proteins have a larger number of epitopes with higher binding affinity towards the allele in C57Bl/6. In summary, our results suggest that the genetic predisposition to generate better T-dependent antibody responses against particular (and thus potentially protective) antigens might be a key factor influencing the susceptibility of the host to the infection by *E. granulosus*.

Perforin is required for edema and blood-brain barrier disruption in vital regions of the brain in experimental cerebral malaria

Johnson, A.¹, Huggins, M.², Jin, F.²

¹Mayo Clinic, Immunology and Neurology, Rochester, United States, ²Mayo Clinic, Immunology, Rochester, United States

Human cerebral malaria (HCM) is a serious complication of *Plasmodium falciparum* infection, resulting in coma, neurological deficit, and death. Recently, the first large-scale MRI study in humans identified brain swelling/edema as the most prominent biomarker of fatal HCM. We therefore investigated the mechanism by which edema and blood-brain barrier (BBB) disruption occurs in the *Plasmodium berghei* ANKA (PbA) infection model of HCM. We developed T2-weighted and gadolinium-enhanced T1-weighted small animal magnetic resonance imaging (MRI) platforms to study edema and CNS vascular permeability, respectively. T2-weighted MRI analysis of symptomatic PBA infected C57Bl/6 mice revealed significant edema. In addition, gadolinium enhanced T1-weighted MRI analysis of these animals revealed punctate CNS vascular permeability in vital regions of the brain and brain stem. Confocal microscopy confirmed CNS vascular permeability in these brain regions, with FITC albumin leakage from vasculature co-localizing with disrupted BBB tight junction proteins, occludin and claudin 5. Importantly, perforin deficient C57Bl/6 mice, despite having identical levels of PbA infected erythrocytes and brain infiltrating CD8 T cells, are completely resistant to edema and BBB disruption in these studies. We conclude the onset of brain edema in experimental cerebral malaria is mediated by perforin, providing a mechanism for how a significant biomarker of fatal HCM occurs in this deadly neurological disease.

***Echinococcus granulosus* infection ameliorates airway inflammation in ovalbumin-induced mouse allergic asthma model**

Zhang, W., Wang, H., Li, J., Wen, H.

The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China

Background: Cystic echinococcosis (CE) is a near cosmopolitan zoonosis caused by the larval stage of the dog tapeworm *Echinococcus granulosus*. The infection induces a polarized T-helper type 2 (Th2) systematic immune response in its intermediate hosts. However, it is not known whether the

infection modulates lung inflammation by regulating local immune response. In this study, we examined the effects of *E. granulosus* infection on mouse ovalbumin (OVA)-induced asthma model.

Methods: BALB/c mice were intraperitoneally transplanted with 50 small *E. granulosus* cysts cultured in vitro. At 3 months post-inoculation, the mice were sensitized and challenged with ovalbumin (OVA). For histopathological studies, hematoxylin eosin and periodic acid schiff staining was used to examine the inflammatory cells infiltration and goblet cells hyperplasia, respectively. Cytokine levels were measured by mouse cytometric bead array (CBA) Kit and quantitative qPCR and other molecular biological approaches.

Results: *E. granulosus* infection significantly increased Th2 and Treg cytokine levels in serum and lung tissues, but down-regulated the expression of IL-5 in the lungs and IL-17A in serum and lung tissues of asthmatic mice sensitized and challenged with OVA. Histological staining of lung tissues showed that *E. granulosus* infection significantly reduced the severity of OVA-induced airway inflammation including reduction of eosinophil cell infiltration and mucus production. The infection also reduced eosinophil accumulation induced by OVA in bronchoalveolar lavage fluid and also ameliorated airway hyperresponsiveness, a hallmark symptom of asthma.

Conclusions: *E. granulosus* infection remarkably reduces the severity of OVA-induced airway inflammation likely through enhancing IL-10 and down-regulation of IL-5 and IL-17A.

Costimulatory signals derived from myeloid leukemia cells contribute to functional exhaustion in CD4⁺ T cells

Ozkazanc, D.¹, Buyukasik, Y.², Esendagli, G.¹

¹Hacettepe University Cancer Institute, Ankara, Turkey, ²Hacettepe University Medical Faculty, Ankara, Turkey

Expression of costimulatory molecules on myeloid leukemia cells has been associated with disease severity and bad prognosis. Since the effector T cell responses under chronic stimuli are shadowed by exhaustion, a state of hypo-responsiveness, this study explores the contribution of myeloid leukemia-derived costimulatory signals to Th cell exhaustion as an indirect immune escape mechanism. Found on leukemia cells, CD86 and ICOS-LG costimulatory molecules supported Th activities however, under prolonged stimulation, T cells were directed into an exhaustion-related state. Alternatively, Th cells co-cultured with peripheral blood monocytes preserved their functional responsiveness. The in vitro-generated exhausted Th cells were characterized by the upregulation of PD-1, CTLA-4, LAG3 and TIM-3 surface molecules. These TIM-3⁺ Th cells were reluctant to proliferate upon restimulation and displayed attenuation in IL-2, TNF- α and IFN- γ production. IL-2 supplementation restored the proliferation capacity of exhausted Th cells. When the costimulatory signals were blocked with CTLA-4-Fc and ICOS-Fc recombinant proteins or CD86⁺ leukemia cells were depleted, the percentage of exhausted Th cells was significantly decreased. Moreover, in the bone marrow samples of acute

myeloid leukemia (AML) or myelodysplastic syndrome (MDS) patients, PD-1⁺/TIM-3⁺/LAG3⁺ Th cells were identified together with myeloid blasts expressing CD86 and/or ICOS-LG, in vivo. Collectively, the constitutive costimulation provided by myeloid leukemia cells contributes to T cell exhaustion as a novel immunogenic escape mechanism.

Seromic profiling of melanoma patients using a custom protein microarray platform

Duarte, J.^{1,2,3}, Woods, K.^{1,2}, Tsao, S.C.-H.^{1,2}, Cebon, J.^{1,2}, Blackburn, J.³

¹Olivia Newton-John Cancer Research Institute, Cancer Immunobiology Laboratory, Heidelberg, Australia, ²La Trobe University, School of Cancer Medicine, Heidelberg, Australia, ³University of Cape Town/Institute of Infectious Disease and Molecular Medicine, Blackburn Laboratory, Cape Town, South Africa

There is increasing evidence that the aberrant expression of cancer-testis (CT) antigens - a family that are auto-immunogenic and mainly restricted to tumours in various types of human cancers - makes them attractive immunotherapy targets, as well as possible cancer diagnostic markers. Therefore, we aimed to measure differences in CT antigen-specific antibody repertoires between melanoma patient samples, and assess whether these could identify novel diagnostic or prognostic biomarkers, which could aid in the detection and management of cancer.

We carried out a retrospective serological study of antibody titres across a large cohort of eighty-eight malignant melanoma patients undergoing a variety of distinct cancer treatments (surgery, chemotherapy, radiotherapy, immunotherapy or none), using our recently developed and validated novel CT antigen microarray platform.

We successfully identified abundant antibody titres towards two antigens, NY-ESO-1 and CTAG2 - a highly homologous pair - expressed across 48% (n = 42/88) and 45% (n = 40/88) of all patients, respectively, with reported diagnostic and clinical efficacy predictive biomarker potential. Additionally, when considering treatment specific antibody patterns, the highest antibody levels were observed for treatment naïve patients. Furthermore, the overlap in antibody titres of this pair validated our array platform, showing consistency among our obtained results across patients.

In conclusion, we showed that our novel protein microarray platform represents a sensitive, high-throughput and customizable means to detect and quantify the presence of large panels of cancer-specific human antibodies in serum, obtaining consistently robust, high quality and reproducible data, and demonstrating its potential feasibility and inferred biological significance.

Differential expression of the inhibitory receptors PD-1, CTLA-4 and BTLA on effector T cells is a requirement for the development of intestinal type gastric cancer

Morales-Alvarez, A.¹, Gómez, M.², Burgos, R.³, Parra-López, C.¹

¹Universidad Nacional de Colombia, Medical School, Bogota,

Colombia, ²Hospital el Tunal E.S.E Nivel III, Gastroenterology Service, Bogotá, Colombia, ³Hospital el Tunal E.S.E Nivel III, Pathology Service, Bogotá, Colombia

Gastric cancer is a multistep process influenced by chronic inflammation, where initial states such as severe atrophic gastritis or intestinal metaplasia are associated to high risk of adenocarcinoma development. It has also been shown that gastric cancer patients have an immunosuppressive status; however, the timeframe of how this status evolved remains unclear. Using multi-color flow cytometry here we developed a strategy to screen the antigen presenting-cells (APC) and T cell compartments in PBMC from individuals in different stages of the carcinogenesis process (healthy donors (n=12), gastritis (n=20), metaplasia (n=18), early cancer (n=15) and advanced cancer (n=22)). The levels of Tregs, MDSCs, myeloid and plasmacytoid dendritic cells (DCs) *ex vivo* and the immune-phenotype of DCs and T cells (including the induction of effector Th17 vs Tregs) after *in vitro* stimulation were measured. In some individuals the findings in PBMC were compared to the contexture of immune-cell infiltrate in biopsies by immunohistochemistry. Our results show that patients with cancer and metaplasia compared with gastritis patients and healthy donors, have a marked immune-suppression phenotype evidenced by an increase in Treg and MDSCs *ex vivo*, DCs refractoriness to pro-inflammatory stimuli and poor T cell response to TCR stimulation accompanied by a differential expression of PD1, BTLA and CTLA-4 inhibitory receptors. This study support that the transition from metaplasia to intestinal type of gastric cancer might be in part explained by differential expression of inhibitory receptors in effector T cells.

The role of CD169 in tumour metastasis

Muhsin-Sharafaldine, M.-R., Saunderson, S.C., Dunn, A.C., D. McLellan, A.

University of Otago, Microbiology & Immunology, Dunedin, New Zealand

Tumour spread (metastasis) is the leading cause of death in cancer patients. Tumour soluble factors including extracellular vesicles may condition host organs for metastatic tumour spread. The CD169 (sialoadhesin) molecule expressed in lymph node is an important uptake and immune-modulator system for sialic acid-rich extracellular vesicles. In order to study the role of CD169 in melanoma metastasis, we first developed a model for metastatic melanoma spread from the skin to the lymph nodes. Subcutaneous implantation of 10⁶ B16 (F1 or F10) into the ventral carpal aspect of forelimb resulted in melanoma infiltration into the axillary and brachial lymph node within 12 days. Models using intradermal and subcutaneous implantation in the flank or ear pinnae either did not yield consistent metastasis or resulted in a higher welfare cost to the animals. Metastasis was quantified by Image-J analysis of frozen sections of lymph nodes and tumour infiltrated areas were confirmed by exclusion of the majority of CD45 labelled leukocytes. Although CD169^{-/-} mice displayed a lower levels of metastatic lymph node lesions over the course of the two studies, this failed to reach statistical significance in one experiment. CD169^{-/-}

displayed higher immune responses to tumour extracellular vesicles, and protection against subcutaneous melanoma was enhanced beyond that observed with control C57BL/6 mice. Together, these findings suggest that capture of tumour extracellular vesicles by CD169 may participate in tumour escape mechanisms.

The cold shock protein YB-1 (Y-box binding protein 1) regulates resistance against apoptosis in T-lymphocytes

Meltendorf, S.¹, Gieseler-Halbach, S.¹, Handschuh, J.², Pierau, M.¹, Mertens, P.R.³, Thomas, U.², Brunner-Weinzierl, M.C.¹

¹Universitätskinderklinik Magdeburg, Experimentelle Paediatric, Magdeburg, Germany, ²Leibniz Institute for Neurobiology, Department of Neurochemistry and Molecular Biology, Magdeburg, Germany, ³Otto-von-Guericke University Magdeburg, Department of Nephrology and Hypertension, Diabetes and Endocrinology, Magdeburg, Germany

The cold shock protein YB-1 is highly expressed in tumours, such as breast cancer, and associated with hyperproliferation and resistance against apoptosis. Enhanced YB-1 expression at the transcript and nuclear protein levels have been shown to correlate with poor prognosis for tumour patients and resistance to chemotherapy. Its role in T-lymphocytes is not understood so far.

Human CD4⁺ T-lymphocytes isolated from PBMCs were stimulated with anti-CD3/anti-CD28 coupled beads. YB-1-signaling was manipulated by overexpression of YB-1^{wt} and various mutations using lentiviral transduction of FuGW-GFP-constructs or reduction of YB-1 using specific YB-1shRNA. Localisation within T-lymphocytes was determined by microscopy. Apoptosis was induced by anti-CD95 cross-linking and analyses carried out six to eight days after initial stimulation. Expression of pro- and anti-apoptotic molecules was monitored by FACS, Western blot, and real-time PCR.

Transduction of GFP-YB-1^{wt} constructs and mutant variants thereof into primary human CD4⁺ T-cells yielded around 40% GFP positive cells. Various YB-1 mutant proteins exhibited distinct subcellular localisations. We observed that GFP-YB-1 overexpression reduced apoptosis by 60% compared to the control. Additionally, the percentage of apoptotic cells was decreased with specific inhibitors (QVD) for apoptosis in empty vector-transduced cells but not in YB-1^{wt} overexpressing cells. Furthermore, we observed substantial differences in the expression of the pro- and anti-apoptotic molecules Bax and Bcl2. The reduction of YB-1 with YB-1shRNA leads to elevated apoptosis in T-Lymphocytes. Thus, YB-1 tightly controls and inhibits apoptosis in T-cells and could therefore serve as a major player to induce apoptosis resistance in various types of cancers, such as T-ALL.

3375

B7-H1 (PD-L1) is expressed in the Tasmanian devil facial tumor microenvironment and is strongly upregulated in response to IFN- γ *Flies, A.^{1,2}, Woods, G.¹, Lyons, A.B.³, Hayball, J.²**¹Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, ²University of South Australia, Adelaide, Australia, ³School of Medicine, University of Tasmania, Hobart, Australia*

In 1996 a clonal, transmissible tumour was discovered in wild Tasmanian devils and this devil facial tumour disease (DFTD) has been a primary cause of a greater than 85% decline in the wild devil population. In 2015 a second transmissible tumour was discovered in wild Tasmanian devils, further threatening the survival of the species. Although the second transmissible tumour (DFT2) has not been fully characterized, in the nearly 20 years of ongoing transmission the first transmissible tumour (DFT1) has accumulated greater than 17,000 somatic mutations. Evidence from human clinical trials and mouse models suggests that blocking PD-1:B7-H1 interactions is an effective treatment against a wide range of cancers and that blocking the PD-1:B7-H1 pathway is most effective in cancers with a high number of mutations. We hypothesized that the DFTD cells use the PD-1:B7-H1 pathway to evade the anti-DFT responses. We developed a panel of devil specific monoclonal antibodies against PD-1 and B7-H1, some capable of blocking PD-1 binding to B7-H1. Immunohistochemistry of devil tissues revealed that B7-H1 was not normally expressed on primary tumours, but was present in the microenvironment of metastatic tumours. *In vitro* stimulation of several DFTD cell lines with IFN- γ resulted in upregulation of B7-H1 on the cell surface. Altogether our results suggest that B7-H1 is transiently upregulated by IFN γ and that abrogating the effects of B7-H1 in the tumour microenvironment and lymphoid organs might be critical to ongoing development of the vaccine to treat DFTD cancers.

Characterising T-cell responses against mutated tumour neo-antigens*Chee, J.¹, Ma, S.¹, Creaney, J.^{1,2}, Robinson, B.^{1,2,3}**¹University of Western Australia, National Centre of Asbestos Related Diseases, School of Medicine and Pharmacology, Nedlands, Australia, ²Sir Charles Gairdner Hospital, Australia Mesothelioma Tumour Bank, Nedlands, Australia, ³Sir Charles Gairdner Hospital, Department of Respiratory Medicine, Nedlands, Australia*

A feature of carcinogen-induced cancers is the accumulation of mutations in the cancer cell. Cytotoxic T lymphocytes (CTLs) recognise mutated proteins (neo-antigens), and in some cases, boosting CTL responses specifically against neo-antigens causes tumour regression. We have previously interrogated mutations in asbestos induced mesothelioma with RNA and exome sequencing. By applying MHC-binding algorithms on the sequencing data, we described mutated predicted CTL neo-antigens. We detected immune responses against one of the predicted neo-antigens: mutated *Uqrc2* (Uq2) in mesothelioma

bearing animals. It is unclear if Uq2-specific CTL responses are important for immunosurveillance, or if boosting them will be effective for tumour regression. To understand the role neo-antigen-specific T cells play in tumour immunity, we tracked the development of Uq2-specific CTLs during tumour growth, and how they changed after immunotherapy.

The frequencies of neo-antigen specific T cells are low and restricted to only one or a few mutated neo-antigens. Uq2-specific CTLs were < 0.1% of total CD8⁺. Conventional flow cytometry techniques were not sensitive enough to detect them. Using an ELISPOT assay, we demonstrated that the frequencies of Uq2-specific responses varied between tumour bearing mice, and generally increased after different therapies (e.g. checkpoint-blockade immunotherapy, chemotherapy or Treg depletion). For effective translation, e.g. using neo-antigen vaccines, assays with increased sensitivities, or an additional T cell expansion step must be used to detect and phenotype neo-antigen specific T cells. To that extent, we have optimised sensitive pMHC tetramer enrichment assays, and *in vitro* T cell expansion protocols to further analyse neo-antigen specific cells.

Oxidative stress and age related impairments in the maintenance of immunological memory*Pangrazzi, L.¹, Meryk, A.¹, Trieb, K.², Grubeck-Loebenstien, B.¹**¹University Innsbruck, Research Institute for Biomedical Aging Research, Innsbruck, Austria, ²Klinikum Wels-Grieskirchen, Wels, Austria*

Aging induces a basal level of inflammation throughout the body, a condition known as inflammaging, which contributes to immunosenescence. New strategies to counteract immunosenescence in the elderly are needed, in particular by improving the maintenance of immunological memory. It has been demonstrated that memory T cells and long-lived plasma cells home to bone marrow niches, well organized structures which promote the survival of these cells through homeostatic proliferation. CD4⁺ and CD8⁺ effector memory T cell survival is promoted by IL-7 and IL-15. IL-7 is believed to be important for long-lived memory T cells while IL-15 is mostly important for short-lived CD28⁻ senescent T cells, of which accumulation is associated with mortality in old age. The expression of effector memory T cells and proinflammatory factors were investigated in bone marrow mononuclear cells (BMMC) using qPCR and FACS, finding that, with age, IL-7 decreases while IL-15, IL-6, TNF α , IFN γ and IL1 β increase. Stimulation of peripheral blood mononuclear cells (PBMC) with IFN γ and TNF α lead to increased IL-15 expression in CD11c^{hi} cells and monocytes, well-known producers of this cytokine. A correlation was found between ROS levels and IL-15 expression in the same cell populations. Incubation of stimulated PBMCs with ROS scavengers N-acetylcysteine and vitamin C completely neutralized the effects of proinflammatory molecules in CD11c^{hi} cells and monocytes. This indicates that oxidative stress may contribute to the age-related impairments in the maintenance of immunological memory. Antioxidant treatment may be an

important strategy to counteract immunosenescence, reducing the level of proinflammatory cytokines in old age.

The role of IL-1 and IL-23 signaling in tumor elicited inflammation in colon cancer

Grivennikov, S., Dmitrieva, O., Hou, V.

Fox Chase Cancer Center, Cancer Prevention and Control, Philadelphia, United States

Many solid tumors are characterized by the presence of immune infiltrates and are able to enhance the expression of inflammatory cytokines - a process referred to as tumor elicited inflammation (TEI). In colorectal cancer (CRC), early oncogenic events lead to deterioration of the integrity of epithelial barriers, allowing translocation of the microbial products and induction of pro-inflammatory cytokine expression, particularly of IL-23 and IL-17A. The intricate mechanistic details of TEI remain to be worked out, however we and others showed that microbial-driven expression of IL-23 stimulates the production of its downstream pro-inflammatory and pro-tumorigenic effector cytokines (e.g. IL-17A, IL-17F and IL-22). We hypothesized that members of IL-1 family (IL1a, b) cooperate with IL-23 in induction of TEI and colorectal cancer progression. Using conditional IL-1R, IL-23R and ligand knockout mice, we demonstrated that IL-1 and IL-23 responsive T cells and Innate lymphoid cells (ILC) type 3 are required to integrate upstream microbiota and stressed tissues released signals to enhance pro-tumorigenic IL-17 production. By multiphoton imaging we have demonstrated the dynamics of IL-17 producing cells in tumor and normal tissue. We also determined that strongly adhesive bacteria, capable only of colonizing tumor tissue are sensed by monocytes and macrophages to induce IL-1 and IL-23 production. Altogether, we established the role of microbiota and IL-1/IL-23 signaling in induction of Tumor elicited inflammation and immunity in CRC tumors.

OPG may protect bleomycin-induced pulmonary fibrosis by inhibiting SMAD2/3 dependent TGF- β 1 activation

Weng, D.¹, Li, H.¹, Ge, B.²

¹Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Respiratory Medicine, Shanghai, China, ²Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Clinical and Translational Research Center, Shanghai, China

Rationale: Idiopathic pulmonary fibrosis (IPF) is a highly heterogeneous and lethal pathological process with limited therapeutic options. The pathogenesis of IPF is a complex process with continual injury, chronic inflammation and wound healing response. We found OPG (osteoprotegerin) were significantly increased in IPF patients than that in healthy controls.

Methods: To investigate the role of OPG in the pathogenesis of IPF, we used WT and OPG^{-/-} mouse to establish the model of pulmonary fibrosis by bleomycin. We analyzed the histopathology and evaluated expression of various key

cytokines. We also investigate the adaptive immune response by flow cytometry. Finally, important signaling pathway was determined by western blotting.

Results: We found that OPG-deficiency led to exacerbation of inflammation and fibrosis during fibrosis. OPG^{-/-} mice showed increased Th1, Th17, Th2 and decreased Tregs at early stage of BLM-induced fibrosis. OPG^{-/-} mice showed increased inflammatory cytokines at early stage of BLM-induced fibrosis. OPG^{-/-} mice have decreased Th1, Th17 and Bregs at late stage of BLM-induced fibrosis. OPG^{-/-} KO mice showed increased inflammatory cytokines, TGF- β and decreased IL-17A at late stage of BLM-induced fibrosis. OPG may inhibit TGF- β 1-dependent activation of SMAD2/3 signaling in pulmonary fibrosis.

Conclusions: Our data provided clear evidences that OPG might play a critical role in the pathogenesis of idiopathic pulmonary fibrosis. OPG may protect mice from bleomycin-induced pulmonary fibrosis by inhibiting SMAD2/3 dependent TGF- β 1 activation.

Keywords: OPG, pulmonary fibrosis, SMAD2/3, TGF- β 1

Socs1 and Socs3 degrades Traf6 via polyubiquitination in LPS induced acute necrotizing pancreatitis

Zhou, X.¹, Liu, Z.², He, Y.³

¹Affiliated Hospital of Sichuan Medical University, Department of Vascular and Thyroid, Luzhou, China, ²University of Texas MD Anderson Cancer Center, Houston, United States, ³Affiliated Hospital of Sichuan Medical University, Luzhou, China

Mechanisms involved in inflammatory development during acute pancreatitis (AP) are largely vague, especially in the transformation of acute edematous pancreatitis (AEP) into acute necrotizing pancreatitis (ANP). This current study aims to investigate the functions of Traf6 in different acute pancreatitis models in vitro and in vivo, and to identify the possible regulatory mechanism in the progression of inflammation from mild to severe. Our data revealed that the level of Traf6 expression was significantly increased in the mild AP induced by caerulein, and the up-regulation of Traf6 played a protective role in acinar cells against caerulein-induced apoptosis. In contrast, only Traf6 protein but not mRNA was downregulated in the severe ANP induced by combination treatment of caerulein and LPS. Mechanistic studies showed that LPS upregulated the levels of Socs1 and Socs3 expressions in acinar cells, Socs1 and Socs3 interacted Traf6 directly and degraded Traf6 protein via polyubiquitination, thereby counteracted the protective function of Traf6. In vivo study further showed that combination treatment of caerulein and LPS failed to induce an ANP model in the TLR4 knockout mice, and the level of Traf6 expression in the pancreatic tissues remained the same as that from the AEP mouse. Taken together, our study reveals that Traf6 functioned as a protective factor in the progression of AP, and LPS induced Socs1 and Socs3 exacerbate mild AP to severe AP, which provides evidence for developing a new therapeutic target to combat AP.

2974**ATF3 is a key regulator of macrophage interferon-responses**

Labzin, L.I.¹, Schmidt, S.V.², Masters, S.L.^{3,4}, Beyer, M.², Krebs, W.², Klee, K.², Stahl, R.¹, Lütjohann, D.⁵, Schultze, J.L.², Latz, E.^{1,6,7}, De Nardo, D.^{3,4}

Cytokines and IFNs downstream of innate immune pathways are critical for mounting an appropriate immune response to microbial infection. However, the expression of these inflammatory mediators is tightly regulated, as uncontrolled production can result in tissue damage and lead to chronic inflammatory conditions and autoimmune diseases. Activating Transcription Factor 3 (ATF3) is an important transcriptional modulator that limits the inflammatory response by controlling the expression of a number of cytokines and chemokines. However, its role in modulating IFN responses remains poorly defined. Here, we demonstrate that ATF3 expression in macrophages is necessary for governing basal IFN β expression, as well as the magnitude of IFN β cytokine production following activation of innate immune receptors. We found that ATF3 acted as a transcriptional repressor, and regulated IFN β via direct binding to a previously unidentified specific regulatory site distal to the *Irfn1* promoter. Additionally, we observed that ATF3 itself is a type I IFN-inducible gene, and that ATF3 further modulates the expression of a subset of inflammatory genes downstream of IFN signaling, suggesting it constitutes a key component of an IFN negative feedback loop. Consistent with this, macrophages deficient in *Atf3* showed enhanced viral clearance in LCMV and VSV infection models. Our study therefore demonstrates an important role for ATF3 in modulating IFN responses in macrophages by controlling basal and inducible levels of IFN β , as well as the expression of genes downstream of IFN signaling.

3944**Constitutive AHR signaling-mediated modulation of antiviral IFN response**

Yamada, T.¹, Kameyama, T.^{1,2}, Watts, T.H.³, Matthews, J.^{4,5}, Takaoka, A.^{1,2}

¹Division of Signaling in Cancer and Immunology, Institute for Genetic Medicine, Hokkaido University, Sapporo, Japan, ²Molecular Medical Biochemistry Unit, Graduate School of Chemical Sciences and Engineering, Hokkaido University, Sapporo, Japan,

³Department of Immunology, University of Toronto, Toronto, Canada, ⁴Department of Pharmacology and Toxicology, University of Toronto, Toronto, Canada, ⁵Department of Nutrition, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway

The aryl hydrocarbon receptor (AHR) is a ligand-activated transcription factor that mediates the toxicity of many environmental xenobiotics including dioxins, and also has important biophysiological roles. However, its role in innate immune responses during viral infection is not fully understood. Type I interferons (IFNs) are produced in response to viral infection and are crucial cytokines for the activation of antiviral immune responses. The induction of type I IFNs is triggered by the detection of the viral nucleic acids through pattern recognition receptors. In this study, we show that constitutive AHR signaling in the steady state modulates type I IFN response during infection with various types of virus. The type I IFN response was markedly enhanced in AHR-deficient mouse embryonic fibroblasts (MEFs) during infection with various types of virus. Such an excessive response was also observed upon pharmacological inhibition with an AHR antagonist or a TDO inhibitor. Furthermore, we identified TIPARP as an AHR target gene that is essential for AHR-mediated regulation of type I IFN production. Mechanistic studies revealed that TIPARP interacts and post-translationally ADP-ribosylates TBK1, resulting in the inhibition of its kinase activity. Thus, our findings demonstrate a novel link between AHR signaling and innate signaling for the modulation of IFN-mediated antiviral response during viral infection, suggesting a physiological role of constitutive activation of the AHR-TIPARP axis mediated by endogenous ligands such as tryptophan metabolites, in restraining the IFN-dependent host antiviral defense system.

3389**Potent antitumor effect of two self-limiting adeno-associated viruses**

Vásquez, M., Aranda, F., Paredes, V., Fioravanti, J., Gomar, C., Ardaiz, N., Berraondo, P.

Center for Applied Medical Research (CIMA), University of Navarra, Division of Immunology and Immunotherapy, Pamplona, Spain

Interferon alpha (IFN α) is a cytokine approved for the treatment of several malignancies but the serious adverse effects induced by the high doses of the cytokine limit its clinical utility. We have developed a murine model of colon cancer liver metastases that reproduce the clinical outcome of the IFN α therapy: high doses of IFN α encoded by an adeno-associated virus (AAV-IFN) induce a potent antitumor effect associated with lethal toxicity. Low doses of AAV-IFN are well tolerated but do not induce an antitumor effect and mice die due to the colon cancer liver metastases. Co-administering an adeno-associated virus that encodes for an anaphylactic peptide that activates several danger signals, we were able to trigger a potent antiviral response that partially eliminated the AAV genomes once the tumor was eradicated. Thus, liver metastases of colon cancer could be eradicated without the toxicity associated to long-term interferon alpha expression.

Salmonella porins are a multivalent vaccine candidate against typhoid, paratyphoid, and non-typhoidal salmonellosis

Pérez-Toledo, M.^{1,2}, Valero-Pacheco, N.^{1,2}, Aguilar-Salvador, D.I.¹, Leonardo-Reza, M.¹, Dionicio-Martínez, N.¹, Pastelin-Palacios, R.³, Cunningham, A.F.⁴, Isibasi, A.¹, López-Macías, C.^{1,5}

¹Mexican Social Security Institute, Medical Research Unit on Immunochemistry, Mexico City, Mexico, ²Instituto Politécnico Nacional, National School of Biological Sciences, Mexico City, Mexico, ³Universidad Nacional Autónoma de México, Faculty of Chemistry, Mexico City, Mexico, ⁴University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom, ⁵University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom

Salmonella-related diseases account for approximately 1 million deaths around the world. *S. Typhi* and *S. Paratyphi* cause typhoid and paratyphoid fever, respectively, while *S. Typhimurium* and *S. Enteritidis* are associated to non-typhoidal salmonellosis. Although different vaccines are employed to combat *S. enterica* infections, nowadays there is no vaccine that targets typhoidal and non-typhoidal serovars. Porins are outer membrane proteins that have shown to be safe and immunogenic. They have also shown to be a protective target for antibody responses during *Salmonella* infection. Since porins are well conserved among Gram-negative bacteria, we asked whether these proteins could be used as a potential vaccine candidate against typhoid, paratyphoid, and non-typhoidal salmonellosis. Through an *in silico* analysis, we confirmed that OmpC, OmpF, and OmpD porins share a high degree of amino acid identity amongst Typhi, Typhimurium, Enteritidis, and Paratyphi A serovars. The co-immunisation of *S. Typhi* and *S. Typhimurium* porins in mice elicited long-lasting IgG and IgM antibody responses that bound to whole inactivated bacteria. In primed and challenged mice, we found significantly lower bacterial numbers in spleen and liver for all serovars compared to the naïve controls. We also found that opsonisation of bacteria with anti-porins serum lowered bacterial burden in organs when compared to naïve mice. Overall, these results suggest that the mixture of porins is a potential vaccine candidate against typhoid, paratyphoid, and non-typhoidal salmonellosis.

Exceptionally long CDR3H of bovine scFv antigenized with BoHV-1 B-epitope generates specific immune response against the targeted epitope

Pasman, Y., Kaushik, A.

University of Guelph, Molecular and Cellular Biology, Guelph, Canada

Earlier, our laboratory discovered that some bovine antibodies are among the largest known to exist in a species with an exceptionally long CDR3H (>48 amino acids) with multiple cysteine amino acids. Such CDR3H generates a unique antigen-binding site with a "stalk-knob" structure capable of providing configurational diversity via variable intra-CDR3H

disulfide bridging. Given the large CDR3H size, unlike mouse and human immunoglobulins where CDR3H is relatively shorter, these provide suitable platform for antigenization with large configurational B-epitopes. We first identified a B-epitope on gC envelope protein of bovine herpes virus type-1 (BoHV-1) recognized by a neutralizing bovine IgG1 antibody. A 156 amino acid long gC fragment (gC156) (UL44; NCBI Genome NC_001847 position 16,818-17,285) was expressed as a recombinant protein in *P. pastoris*. Subsequently, an scFv fragment with a 61 amino-acid long CDR3H (scFv1H12) was constructed where gC156 was grafted into the CDR3H with short flanking flexible linkers (gC156scFv1H12). The gC156scFv1H12 was successfully expressed in *P. pastoris*. The grafting of BoHV-1 B-epitope in bovine scFv with an exceptionally long CDR3H sustained configuration similar to native glycoprotein on BoHV-1 envelope as these could be recognized by BoHV-1 neutralizing scFv3-18L in solid phase. Free recombinant gC156 and its antigenized form, gC156scFv1H12, were characterized and used to immunize bovine calves. The antigenized scFv, gC156scFv1H12, induced higher antibody response as compared to free recombinant gC156 fragment in the calves.

Epithelial ovarian cancer stem cells: a potential vaccine for ovarian cancer

Wu, D.¹, Wang, J.², Zhang, Y.², Cai, Y.², Ren, M.², Dou, J.¹

¹School of Medicine, Southeast University, Department of Pathogenic Biology and Immunology, Nanjing, China, ²Zhongda Hospital, School of Medicine, Southeast University, Department of Gynecology & Obstetrics, Nanjing, China

Epithelial ovarian cancer (EOC) is the most malignant type of gynecological tumor due to its high recurrence rate following initial treatment in the China. Though EOC is a highly chemosensitive disease, it is a difficultly cured owing to the presence of drug-resistant cancer stem cells (CSCs) that are responsible for EOC initiation, metastasis, chemo-resistance, and recurrence. The aim of this work was to investigate the effects on the inhibition of EOC growth by vaccination of CSC vaccine. The CD117+CD44+CSCs were isolated from human EOC SKOV3 and HO8910 cell lines by using a magnetic-activated cell sorting system, respectively. The nude mice were subcutaneously inoculated with the inactivated SKOV3 or HO8910 CD117+CD44+CSC vaccine three times before the mice were challenged subcutaneously with SKOV3 or HO8910 cells. The inhibition tumor efficacy of CSC vaccine was assessed by the tumorigenicity, immune efficient analysis by flow cytometer, and enzyme-linked immunosorbent assays, respectively. The results showed that, compared to the non-CSC vaccine, the inhibition tumor efficacy of SKOV3 or HO8910 CD117+CD44+CSC vaccine was significantly increased in the xenograft mice. Vaccination of SKOV3 CD117+ CD44+CSCs resulted in increasing cytotoxic activity of natural killer cells, enhancing serum IFN- γ , and decreasing TGF- β levels in the mice. The SKOV3 CD117+CD44+CSC vaccine significantly reduced the CSC and the aldehyde dehydrogenase 1 positive cell populations in the ovarian cancer tissues. The data provided the first evidence that the human SKOV3 or HO8910 CD117+CD44+CSC-based

vaccine may be an attractive therapeutic approach to excitation of anti-tumor immunity for treatment of ovarian cancer.

Development of a BCG challenge model for the testing of vaccine candidates against bovine tuberculosis

Villarreal-Ramos, B.¹, Berg, S.¹, Blunt, L.¹, McShane, H.², Muller, J.², Ramasamy, A.², Spiropoulos, J.¹, Hicks, D.¹, Clifford, D.¹, Hewinson, R.G.¹, Vordermeier, H.M.¹

¹Animal and Plant Health Agency, Bacteriology/Bovine TB Research, Addlestone, United Kingdom, ²Jenner Institute, Oxford, United Kingdom

Despite the application of the test and slaughter policy, the incidence of bovine tuberculosis (BTB) in the UK has been increasing; this is thought to be due to the existence of a wildlife reservoir. Vaccination is being considered as part of a sustainable strategy for the control of BTB. The live attenuated *Mycobacterium bovis* bacillus Calmette-Guerin (BCG) has been used experimentally to vaccinate cattle against BTB. However, BCG only confers partial protection against BTB and therefore, there is a need to develop improved vaccines. BTB vaccine efficacy experiments require BSL3 facilities which are expensive to maintain, generally oversubscribed and represent a bottle neck for the testing of vaccine candidates. It is reasonable to propose that if a vaccine is to be successful in conferring protection against *M. bovis* it should also confer protection against BCG. In this work we have evaluated intranodal BCG challenge as a model for the selection of vaccine candidates. Intranodally injected BCG was detected in vivo for at least 21 days after injection. As a group, cattle vaccinated with BCG presented lower BCG cfu counts at 21 days after intranodal BCG challenge than non-vaccinated cattle. Importantly, within the BCG vaccinated group, cattle could be divided into protected and non-protected according to their bacterial load. This model could be used to prioritize between competing vaccine candidates; furthermore this model could be used to explore the nature of the mycobacteriocidal immune responses elicited by BCG, which could help understand why BCG sometimes protects and sometimes does not.

Differential expression of the IL17 cytokines and receptors in cells isolated from the female reproductive tract of mice during and after a genital *Chlamydia* infection

Carey, A., Trim, L., Armitage, C., Beagley, K.

Institute of Health & Biomedical Innovation, School of Biomedical Sciences, QUT, Kelvin Grove, Australia

Chlamydia trachomatis is often referred to as a silent infection, due to its asymptomatic nature and the devastating consequences of infection on reproductive health. *Chlamydia* infection can cause pelvic inflammatory disease, tubal obstruction and infertility in women. The mechanism of pathology development in the female reproductive tract is not fully understood. The production of IL17A in the oviducts of mice has proven to be a double edged sword, both enhancing

chlamydial vaccine induced immunity and being involved in oviduct pathology development. The cellular source of IL17 and associated receptor expression throughout chlamydial infection is unknown. We used our female mouse model of immunization (chlamydial major outer membrane protein/Iscomatrix) and genital infection to examine the cellular sources of the IL17 group of cytokines (IL17A-F) and corresponding receptors (IL17RA-E) at two, six and 35 days post infection, with or without immunization. Cells (CD4⁺, CD8⁺, NKT, $\gamma\delta$ TCR⁺, Ly6G⁺, F4/80⁺, NK and epithelial) were isolated from cervix/vaginal tissues and oviducts and collected via flow cytometry sorting at each time point. The mRNA expression of each IL17 cytokine and receptor was examined at each time point using digital droplet PCR. This highlighted that the cellular source and levels of the IL17 group of cytokines and receptors changed throughout infection and that immunization altered this expression. This greater understanding of the role of IL17 will underpin the development of vaccines that protect, without collateral tissue damage and provide a basis for trials of experimental IL17 inhibitors as a potential treatment for chlamydial disease.

The pig as a large preclinical model for therapeutic human anti-cancer vaccine development

Overgaard, N.H.¹, Frøsig, T.M.¹, Welner, S.¹, Rasmussen, M.², Ilsøe, M.¹, Sørensen, M.R.¹, Andersen, M.H.³, Buus, S.², Jungersen, G.¹

¹Technical University of Denmark, National Veterinary Institute, Frederiksberg C, Denmark, ²University of Copenhagen, Department of International Health, Immunology and Microbiology, Copenhagen N, Denmark, ³Copenhagen University Hospital, Herlev, Center for Cancer Immune Therapy, Department of Hematology, Herlev, Denmark

Immunotherapy has increased overall survival of metastatic cancer patients, but appropriate tailoring of vaccine formulations to mount cytotoxic T cell (CTL) responses towards co-delivered antigens is crucial. Development of therapeutic cancer vaccines has largely been based on rodent models and the majority failed to establish therapeutic responses in clinical trials. Since the porcine immunome is closely related to the human counterpart, we introduce pigs as a large animal model for human cancer vaccine development via the use of our unique technology for swine leukocyte antigen (SLA) production. 20-mer overlapping peptides covering the porcine IDO protein sequence, a cancer antigen important in human disease, was administered to pigs formulated in CTL-inducing adjuvants. 136 candidate IDO-derived 9-11 mer peptides were identified in silico and peptide-SLA class I complex stability measurements revealed 89 stable ($t_{1/2} \geq 0.5$ hour) complexes. We showed that using our immunization strategy it was possible to break the peripheral tolerance and induce a cell mediated response to an endogenous antigen. The body size and metabolism of the pig allow dose translation to humans; therefore we designed a titration study with pigs receiving either 1 μ g, 10 μ g or 100 μ g of each peptide covering the majority of IDO-derived potential CTL epitopes formulated in CAF09 adjuvant and delivered by the intra-peritoneal route. Immune responses were tracked by IFN- γ ELISpot and peptide-MHC tetramers. Determining the

optimal dose is crucial to mount a proper Th₁ response, and we believe pigs will be a highly beneficial model for the subsequent design of clinical trials.

The influence of vitamin D and cotinine on the T regulatory cells in children with asthma

Wawrzyniak, A.¹, Lipińska-Opałka, A.¹, Kalicki, B.¹, Zdanowski, R.², Lewicki, S.², Murawski, P.³

¹Military Institute of Medicine, Department of Pediatrics, Nephrology and Allergology, Warsaw, Poland, ²Military Institute of Hygiene and Epidemiology, Warsaw, Poland, ³Military Institute of Medicine, ICT, Warsaw, Poland

Background: Asthma is one of the most common chronic respiratory disease in children. It is claimed that vitamin D inhibits immunological reactions with Th1 and Th17 lymphocytes. The influence of vitamin D on T-regulatory cells (Treg) is not clear. Literature data evaluating the effect of cotinine on the immune system in children with asthma are poor.

Aim of the study: The aim of this study was to analyze the effect of vitamin D and cotinine on Treg Foxp3 and other immune parameters (phenotype CD3, CD4, CD8, CD19, CD16/56, anti-CD3 HLA -DR3) in patients with asthma. It was also investigated the correlation between the concentration of vitamin D and cotinine and severity of asthma.

Material and methods: The study involved 25 children diagnosed with asthma. The evaluation of severity was carried out using the Asthma Control Test and spirometry. The control group consisted of 15 healthy children. The study was performed using flow cytometry with monoclonal antibodies.

Results: It was found significantly lower levels of vitamin D in children with asthma compared to healthy children ($p < 0.005$). In children with asthma has been found significantly lower number of regulatory T cells in serum compared with the control group ($p < 0.002$). There were no significant differences in other immunological parameters. The study showed no significant correlation between vitamin D3, cotinine and the course of asthma and Treg.

Conclusions: These results do not confirm the influence of vitamin D and cotinine on Treg and clinical course of allergic diseases.

1078

The influence of vitamin D and cotinine on the selected immune parameters in children with atopic dermatitis.

Preliminary reports

Lipińska-Opałka, A.¹, Wawrzyniak, A.¹, Kalicki, B.¹, Zdanowski, R.², Lewicki, S.², Murawski, P.³

¹Military Institute of Medicine, Department of Pediatrics, Nephrology and Allergology, Warsaw, Poland, ²Military Institute of Hygiene and Epidemiology, Warsaw, Poland, ³Military Institute of Medicine, ICT Department, Warsaw, Poland

Background: Atopic dermatitis is a chronic inflammatory skin disease, with the key role of immune system disorders. Decreasing number of regulatory T cells (Foxp3) seems to be the major abnormality. Numerous reports pointed the role of vitamin D in modulation of the immune system function. However there are a small number of data regarding the effects of cotinine on the immune system.

Aim of the study: The aim of the study was to analyze the percentage of lymphocytes (CD3+, CD4+, CD8+, CD4/CD8 ratio, CD19+, CD16+/56+, CD3 +anti HLA -DR+) and natural regulatory T lymphocytes in patients with atopic dermatitis. Additionally the correlation between immune parameters and vitamin D levels and cotinine was performed.

Material and methods: The study involved 28 children with a diagnosis of atopic dermatitis. The control group consisted of 15 healthy children. The phenotype of lymphocytes was evaluated by flow cytometry.

Results: In children with atopic dermatitis significantly lower number of regulatory T cells in serum compared with the control group ($p < 0.002$) has been found. There were no differences in the other studied parameters between examined groups. The study revealed a negative correlation between serum vitamin D levels and the percentage of NKT cells ($p < 0.04$). Moreover, there was no significant correlation between vitamin D, cotinine levels and the severity of the disease.

Conclusions: The results confirmed the role of regulatory T cells in the pathogenesis of atopic dermatitis. Effects of vitamin D and cotinine on the severity of the disease has not been proven.

1079

IL-18 has a critical role in the maturation of pathogenic eosinophils in disease state

Mishra, A., Venkateshaiah, S.U., Manohar, M., Verma, A.K., Mishra, A., Allergy

Tulane University School of Medicine, Medicine/Pulmonary, New Orleans, United States

Eosinophils are multifunctional leukocytes that are critically involved in host defense, promoting allergic inflammation and allograft rejection. These diverse functions of eosinophils indicate that they may generate and mature differently in allergic condition. Herein, we show that both *in vivo* and *in vitro* eosinophil also be generated independent to endogenous IL-5 by IL-18. IL-18 is reported induced in all allergic diseases and a number of reports indicate that overexpression promotes tissue eosinophilia. We first time demonstrate that both rIL-5 and rIL-18 differentiate distinct subsets that have different structural and morphological characteristics, including size, shape and granular content levels. The microarray analysis detected highly induced CD274 transcripts in rIL-18 differentiated eosinophils compared to rIL-5 differentiated eosinophils. The CD274 expression was furthest validated and two distinct CD274+ and CD274- eosinophil subsets identified in the blood of healthy mice and humans. Notably, no CD274+ eosinophil develops *in vivo* or *in vitro* in the absence of endogenous IL-18. Most importantly, we observed that the CD274+ subset exclusively increases in the blood of various allergic patients including asthma. In addition, we report that all tissue eosinophils (CCR3+/Siglec-F+) in the

airway of asthmatic mice and most eosinophils (CCR3+/Siglec-8+) in the nasal lavages of asthma/rhinitis patients and esophageal biopsies of eosinophilic esophagitis patients are solely express CD274+ subset. Taken together, we report CD274+ and CD274- eosinophil in health and disease and provide evidence that IL-18 is critical the maturation of pathogenic CD274+ eosinophils. These investigations provide novel diagnostic and therapeutic target strategies for eosinophil-associated allergic disorders.

Sensitization to inhaled allergens and risk factors for allergic diseases (including asthma) in Brunei Darussalam

Chieng, C.¹, Sharif, H.^{2,3}, Taib, R.⁴, Taib, S.⁵, Cunningham, A.C.²

¹RIPAS Hospital, Immunology Laboratory Services, Bandar Seri Begawan, Brunei Darussalam, ²Universiti Brunei Darussalam, PAPRSB Institute of Health Sciences, Gadong, Brunei Darussalam, ³Imperial College London, Allergy & Clinical Immunology, NHLI, London, United Kingdom, ⁴RIPAS Hospital, Dept of Paediatrics and Neonatology, Bandar Seri Begawan, Brunei Darussalam, ⁵RIPAS Hospital, Department of Laboratory Services, Bandar Seri Begawan, Brunei Darussalam

Allergic diseases to inhaled allergens are on the rise in the ASEAN region (Lai, Beasley *et al.* 2009). Studies in Western countries indicate that *Dermatophagoides pteronyssinus* (DerP) is the major allergen in 50% of patients, however this seems to be higher in urban tropical settings (ranging from 70-98%). A number of studies in SE Asia have demonstrated that children with respiratory and allergic symptoms (including allergic rhinitis, asthma, and atopic dermatitis) are predominantly sensitized to house dust mite (HDM) in Hong Kong (Leung *et al.* 1997), Indonesia (Baratawidjaja *et al.* 1999), Thailand (Daengsuwan *et al.* 2003), and Korea (Kim *et al.* 2015). Interestingly, in Singapore there appears to be a mono-specific IgE response to DerP which is associated with increased prevalence of allergic airway diseases (Andiappan *et al.* 2014). There are no published studies on IgE sensitization to inhaled allergens in Brunei.

Specific IgE levels to a panel of defined inhaled allergens were measured in patient serum by fluoroenzymeimmunoassay using the Phadia 100 platform. Laboratory data will be compared to electronic clinical records. 503 positive results were seen in 1740 samples in 1 calendar year (Jan - Dec 2015). The highest levels of sensitisation observed was to HDM (d1, d2, d3; 61%-81%), the storage mite *Blomia tropicalis* (75%) followed by cockroach, bermuda grass and acacia.

The significance of this study is the identification of risk factors for potential morbidities (eg asthma) with the aim of improving patient management (allergen identification and avoidance) plus raising awareness on allergy in Brunei Darussalam.

1097**cDNA cloning and in silico characterisation of ML domain protein-homolog allergen from the house dust mite *Suidasia pontifica****Bajao, J.E.¹, Ramos, J.D.²*¹University of Santo Tomas, Graduate School, Manila, Philippines,²University of Santo Tomas, College of Science, Manila, Philippines

Suidasia pontifica (Sp) is a house dust mite (HDM) that was proven to cause sensitization of up to 75% of tropical allergic patients. Characterization of specific allergens from Sp is a significant step in elucidating the clinical importance of this HDM. Here, we describe the cDNA cloning of a gene from Sp with significant homology to ML lipid binding domain protein, or the HDM group 2 allergen. The cDNA was synthesized from the isolated total RNA of pure Sp culture. The gene encoding for the ML domain protein from Sp (Sui p 2) was amplified and sequenced from the cDNA using gene-specific primers. Sequence and structural characterization of Sui p 2 gene was done in silico. Three clones were produced and all of them contains a 405 bp open reading frame. Among the other HDM group 2 allergen, sui p 2 gene exhibits highest percent identity to *Tyrophagus putrescentiae* (65.84%) while *Dermatophagoides farinae* (50.26%) exhibits the lowest. Deduced amino acid sequence showed that Sui p 2 exhibits 47.62% sequence homology to *Dermatophagoides farinae*. Predicted tertiary structure showed an immunoglobulin fold, consisting of two anti parallel β strands, three conserved disulfide bridges, and a lipid binding cavity, which is distinctive to the ML protein family. Ten possible epitope forming amino acid has also been seen. Thus, Sui p 2 might have a role in HDM induced allergy and innate immunity exacerbation. Characterization of Sui p 2 is important to properly evaluate its use for allergy component resolved diagnosis and allergen specific immunotherapy.

1098**Mast cell-eosinophil crosstalk reveals potential therapeutic strategy for atopic dermatitis***Naidoo, K.^{1,2}, Jones, A.¹, van den Elsen, L.¹, Lee, J.³, Le Gros, G.¹, Forbes-Blom, E.¹*¹Malaghan Institute of Medical Research, Wellington, New Zealand,²Victoria University of Wellington, Wellington, New Zealand,³Mayo Clinic, Scottsdale, United States

Atopic dermatitis (AD), an inflammatory skin disease, has become a significant health concern worldwide. It impacts their quality of life and imposes a life long burden, particularly amongst children. Treating this disease remains a challenge, as current management strategies for AD are nonspecific. Therefore there is a vital need for pharmacotherapy that calms the immunological storm associated with AD. Previous investigations demonstrate that mast cells and eosinophils are key effector cells driving allergic inflammation. We sought to elucidate mast cell - eosinophil interactions during AD to identify putative targets for treatment. Our aim was to suppress these key cell types or block the mediators released such as eosinophil peroxidase (EPO) and interleukin 9 (IL-9). To address this we established a model of chronic allergic skin

inflammation, with the use of MC903. This murine model of allergic skin inflammation was characterized by significant skin thickening, pronounced inflammatory cell infiltrate and elevated cytokine production that resembles AD in humans. The effects of blocking IL-9 and EPO were examined by the use of anti-IL-9 and resorcinol respectively. Our data revealed IL-9 blockade as well as the use of resorcinol significantly ameliorated disease. These results suggest MC903-induced AD is IL-9 dependent and the contribution of mast cells and eosinophils is strongly associated with disease severity. Thus, these effector cells are attractive targets for the treatment of AD.

1099**The effect of ORMDL3 overexpression in mast cells***Ogi, K., Takabayashi, T., Yamada, T., Sakashita, M., Narita, N., Fujieda, S.*

Fukui University, Division of Otorhinolaryngology Head and Neck Surgery, Faculty of Medical Science, Fukui, Japan

Purpose: In recent years, the patients with allergic rhinitis (AR) have been increasing on a worldwide level. Single-nucleotide polymorphism studies have linked the chromosome 17q12-q21 region, where human Orosomucoid like 3 (ORMDL3) gene is localized, to the risk of asthma. We have reported that genetic variants in the 17q21 are significantly associated with AR in the Japanese population. Although mast cells are involved in development of AR, the contribution of ORMDL3 to mast cell physiology is unknown. The purpose of this study is to reveal the function of ORMDL3 in mast cells.

Method: To examine the function of ORMDL3 in mast cells, we transfected the cDNA of ORMDL3 into RBL-2H3 cells. We generated stable clones overexpressing ORMDL3 from these transfected cells. Using these stable clones, we analyzed IgE-mediated degranulation by β -hexosaminidase assay and cytokine production by real-time quantitative PCR. We stimulated the cells by optimal or low concentrated antigen, IgE only without antigen (monomeric IgE). Moreover, we investigated intracellular signal transduction by immunoblotting.

Result: Our data showed that overexpression of ORMDL3 had no effect on degranulation induced by antigen in optimal concentration, but enhanced degranulation by low concentrated antigen. Moreover, we found that overexpression of ORMDL3 enhanced inflammatory cytokine production induced by not only optimal concentrated antigen stimulation but also low concentrated antigen stimulation and monomeric IgE stimulation. Immunoblotting analysis revealed that phosphorylation of extracellular signal regulated kinase is enhanced in stable cell lines overexpressing ORMDL3.

Conclusion: ORMDL3 acts as an enhancer of inflammatory cytokine production in mast cells.

1100**Identification of nasal resident bacteria as causative allergens in eosinophilic chronic rhinosinusitis**

Takeda, K.^{1,2}, *Sakakibara, S.*^{1,3}, *Motooka, D.*⁴, *Nakamura, S.*⁴, *Yamashita, K.*³, *Standley, D.M.*^{3,5}, *Hayama, M.*², *Shikina, T.*², *Inohara, H.*², *Kikutani, H.*^{1,3}

¹Research Institute for Microbial Diseases, Osaka University, Suita, Japan, ²Osaka University Graduate School of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery, Suita, Japan, ³WPI-Immunology Frontier Research Center, Osaka University, Suita, Japan, ⁴Genome Information Research Center, Research Institute for Microbial Diseases, Osaka University, Suita, Japan, ⁵Institute for Virus Research, Kyoto University, Kyoto, Japan

Eosinophilic chronic rhinosinusitis (ECRS) is a refractory allergic disease and associated with nasal polyps (NPs) characterized by intensive eosinophilic infiltration. High levels of IgE are detected in NPs of ECRS patients, nonetheless, causative allergens have been unidentified. By using NP tissues and lymphocytes from patients, we have attempted to identify causative allergens. In the immunohistochemical analysis, clusters of IgE⁺ cells were observed in NPs. A fraction of IgE⁺ cells displayed the plasmablastic morphology and expressed activated-induced cytidine deaminase (AID), a key factor for somatic hypermutation (SHM) and class-switch recombination (CSR), indicating that these IgE plasmablasts were differentiated within NP tissues. Immunoglobulin cloning from sorted plasmablasts of NPs revealed that in most cases, the variable region of IgE contained a relatively large number of mutations, implying multiple rounds of germinal center reaction. We next generated monoclonal antibodies from IgE⁺ plasmablasts of NP. In the reactivity tests, we found that ~20% of expressed antibodies reacted with nasal resident bacteria such as *S. pyogenes* and *S. aureus*, while no clone was reactive to known inhalants including pollen and mites. As Th2 cells supposed to trigger not only IgE production but also local eosinophil infiltration and inflammation in ECRS, we examined T cell responses of patients against residential bacteria. Among the bacteria we tested, *S. pyogenes* induced activation of patient-derived blood CD4⁺ T cells with Th2 cytokine production, which was not observed in T cells from healthy donors. Collectively, we propose that nasal resident bacteria are one of the causative allergens of ECRS.

1101**Novel compounds that induce specifically class switching to IgA**

*Yamamoto, K.*¹, *Yonesu, K.*², *Kojima, H.*², *Okabe, T.*², *Shinkura, R.*¹

¹Nagahama Institute of Bio-Science and Technology, Immunology, Shiga, Japan, ²University of Tokyo, Drug Discovery Initiative, Tokyo, Japan

Allergic disorders, such as hay fever and asthma, afflict many people in developed countries. Allergies are thought to be a detrimental outcome of excessive immune response that acts against an innocuous antigen, allergen. IgE antibody is a central mediator of allergic responses. Therefore most of the current treatments for allergy target to inhibit IgE responses. However they are still palliative and not curative.

To suppress IgE production, we thought a new strategy that forced B cells to class-switch towards IgA instead of IgE. Upon antigen stimulation, IgM⁺ B cells can class switch to other isotypes such as IgG, IgE and IgA. However, the mechanism how B cells switch specifically to each isotype is not completely understood. Therefore we performed screening of chemical compounds which induced specifically class switching to IgA in mouse B cells. The chemical compounds (3,337 compounds) were provided by Drug Discovery Initiative of the University of Tokyo. As a result, we finally selected three candidate compounds which were structurally related. They induced IgA, but neither IgG1 nor IgE, production in mouse B cells in vitro.

1102**Plasmacytoid dendritic cell numbers predict individual interferon- α production more accurately than TLR7 expression**

*Murray, L.*¹, *Ferreira, M.*², *Upham, J.*^{1,3}

¹University of Queensland, Translational Research Institute, Woolloongabba, Australia, ²QIMR Berghofer Medical Research Institute, Herston, Australia, ³Princess Alexandra Hospital, Woolloongabba, Australia

People with asthma are more prone to have respiratory infections that spread to lower respiratory tract, which has been found to be due to impaired antiviral immune response, especially type I interferon. Plasmacytoid dendritic cells (pDC) and TLR7 are closely associated with interferon- α production. As TLR7 along with TLR8 have been associated with asthma, it is important to understand how TLR7/8 gene expression and gene variations affect cytokine production in response to viral activation.

Therefore, we stimulated PBMC from 150 people with and without asthma with rhinovirus-16 for 24h. RT-PCR from whole blood showed that the expression of pDC marker CD303 was the most significant predictor of interferon- α production ($r=0.559$, $p<.001$) ahead of TLR7 expression. TLR8 expression showed a negative effect on interferon- α production ($r=-0.328$, $p<.001$), which reflects its postulated role as a negative regulator of TLR7 function. No significant differences between asthma group and controls were observed, however women produced more interferon- α than men ($p>.05$).

Baseline TLR7 expression had seemingly no effect on interferon- α production, though study numbers are still small at this stage. Most of the variability in interferon- α production arose from variations in pDC numbers as demonstrated by CD303 expression. These results also highlight TLR8 involvement in interferon- α production, and we are currently examining genetic variations in TLR7/8. The future aim is to recruit a total of 300 people for genotyping TLR7/8 and to include more people with more severe asthma to distinguish whether type I interferon impairment is associated with disease severity.

1103**Dietary olive oil enhanced oral tolerance to attenuate allergic asthma responses***Chen, M.-L.¹, Yu, C.-J.¹, Yu, C.-H.²*¹*Chang Jung Christian University, Department of Nutrition and Health Sciences, Tainan, Taiwan, Republic of China, ²Chang Jung Christian University, Innovative Research Center of Medicine, Tainan, Taiwan, Republic of China*

It has been known that fatty acids modulate the responses of cells of the immune system. The monounsaturated fatty acid (MUFA)-rich diet has been shown to attenuate many chronic diseases, such as cardiovascular disease, diabetes, obesity, and asthma. However, the effects of dietary olive oil on T cell responses of allergic asthma are still unclear. Our previous study, the MUFA-rich diet increased the TGF- β 1 production by ConA-stimulated splenocytes from BALB/c mice. In this study, we like to study the effects of dietary MUFA on the regulatory T (Treg) cells and allergic immune responses. BALB/c mice were orally administered ovalbumin (OVA) in the initial of experiment process, then sensitized and challenged with OVA to induce allergic asthma. The mice were fed with AIN-76 diet that contains 5 or 20% olive oil during the experiment, individually. The results indicated that oral antigen significantly decreased bronchial airway hyper-responsiveness (AHR), which was increased in high fat diet group and olive oil treatment tends to attenuate the hyper-responsiveness. Furthermore, dietary olive oil was also significantly decreased Th2 cytokines and serum IgE levels. Furthermore, olive oil increased Foxp3 expression. These data suggested that the MUFA-rich diet did attenuate Th2 and AHR in allergic asthma and improved regulatory T cell expression, which associated with oral tolerance.

1104**Phenotyping of allergen-reactive CD8⁺T cells in IgE-mediated allergy***Samadi, N.¹, Kitzmüller, C.¹, Geyeregger, R.², Bohle, B.¹, Beatrice Jahn-Schmid, B.¹*¹*Medical University of Vienna, Department of Pathophysiology and Allergy Research, Vienna, Austria, ²Department of Clinical Cell Biology and FACS Core Unit, CCR, Vienna, Austria*

T cells play a main role in the induction and maintenance of IgE-mediated allergy. The function of CD4⁺ T cells in the pathophysiology of allergic disorders has been extensively investigated while the role of CD8⁺ T cells is still poorly understood and controversial. The aim of this project is to characterize allergen-specific CD8⁺ T cells in patients with different allergic manifestations (rhinoconjunctivitis, atopic dermatitis and atopic bronchial asthma). Different seasonal (birch pollen and grass pollen) and perennial allergens (cat dander and house dust mite) were included. PBMCs from allergic patients were stained with the proliferation dye eFluor 670 and incubated with allergen. Proliferating CD3⁺CD8⁺ cells were then assessed for the expression of differentiation markers (CD27, CD28, CD45RO, CXCR3, CRTh2, PD-1), homing markers (CCR4, CD62L, CD29b), intracellular cytokines (IL-4, IL-5, IL-13, IL-17, IL-22 and IFN- γ , TNF- α), and cytotoxic proteins (granzyme B and

perforin) by flow cytometry and compared to non-proliferating CD8⁺ cells. We found allergen-reactive CD8⁺ T cells in all allergic manifestations. Moreover, largest numbers were detected upon stimulation with house dust mite and grass pollen extracts. Proliferating cells contained higher numbers of cells producing IL-4, granzyme B and perforin than non-proliferating CD8⁺ T cells. In addition, a significantly higher expression of CD27, CD45RO, CD62L, and CD29b was detected in allergen-reactive CD8⁺ T cells indicating central memory T cells of mucosal origin. Thus, we could demonstrate allergen-reactive IL-4⁺ CD8⁺ T cells in different allergic manifestations which produce cytotoxic proteins. Their functional activity will be investigated in future experiments.

1105**Differential gene network analysis to identify asthma-associated therapeutic targets in house dust mite-specific T-helper memory responses***Troy, N.M.¹, Hollams, E.², Holt, P.G.², Bosco, A.²*¹*Telethon Kids Institute, The University of Western Australia, Perth, Australia, ²Telethon Kids Institute, Perth, Australia*

Background: Asthma is a heterogeneous disease characterized by airways inflammation, airways remodeling, and reversible airflow obstruction. The atopic form is thought to be driven in part, by allergen-induced Th2-associated inflammation. However, the vast majority of atopics do not develop asthma, suggesting underlying complexities in atopy pathogenesis, which cannot be fully explained via the classical Th1/Th2 paradigm.

Aim: The first aim was to test the hypothesis that variations in allergen-driven CD4 T-cell responses are associated with susceptibility to express an asthma phenotype. And secondly, to pinpoint novel therapeutic opportunities by mining gene expression data from HDM-stimulated CD4 T-cells.

Methods: The study population consisted of; House dust mite (HDM) sensitized atopics with asthma (n=22); HDM sensitized atopics without asthma (n=26); and HDM nonsensitized controls (n=24). PBMC were cultured in the presence or absence of HDM for 24 hours. CD4 T-cells were isolated and gene expression patterns profiled on microarrays.

Results: Differential network analysis identified a collection of asthma-associated genes in HDM-driven CD4 T-cell responses of sensitized atopics with asthma. The asthmatic response was characterized by upregulation of a Th2-associated gene network and was predicted to be driven by IL-2, IL-4, and TNF. This network was reconstructed to reveal a series of hub genes (highly connected) involved in inflammation. Finally, we identified putative negative regulators of asthmatic CD4 T-cell responses to HDM including genes, drugs and metabolites, which represent logical candidates for therapeutic intervention.

Conclusion: Differential network analysis of HDM-induced CD4 T-cell responses can reveal covert disease-associated genes and predict novel therapeutic targets.

1106**Immunological mechanisms of short-term pre-seasonal sublingual allergen immunotherapy tablet treatment for seasonal allergic rhinitis**

Varese, N.^{1,2}, Rolland, J.^{1,2}, Phan, T.^{1,2}, Deckert, K.², Hew, M.², O'Hehir, R.^{1,2}

¹Monash University, Immunology & Pathology, Melbourne, Australia, ²The Alfred Hospital and Monash University, Allergy, Immunology and Respiratory Medicine, Melbourne, Australia

Background: Oral sublingual tablets, Oralair[®], have been shown recently to be effective in treating allergic rhinitis. They provide a better tolerated option than conventional subcutaneous injection therapy. Oralair[®] tablets contain pollen extracts from 5 of the most common allergy-causing European grasses but include ryegrass, the major seasonal pollen for allergy in south-eastern Australia. A 7-month regimen is typical but patient adherence can be problematic. We performed a longitudinal study to investigate immunological changes after a 4-month pre-grass pollen season course of Oralair[®].

Study design: Patients with moderate to severe seasonal allergic rhinitis with or without mild stable asthma and with positive ryegrass pollen (RGP)-specific IgE were recruited. Oralair[®] treatment was used daily for 4 months prior to the grass pollen season. A cohort of clinically-matched patients was used as controls.

Results: Oralair[®]-treated patients showed clinical improvement based on visual analogue and symptom scores. Compared with baseline, serum RGP-specific IgG4 levels were increased after treatment. In vitro stimulation of peripheral blood mononuclear cells with RGP extract induced increased proportions of CD4+CD25+Foxp3+ and CD4+CD45RA-Foxp3+ Tregs after treatment, and CD4+CD45RA-CD27-CD25+ cell proportions were also increased. Higher levels of IFN- γ were present in RGP-stimulated culture supernatants after treatment. Control subjects showed no significant change in clinical symptoms or immunological parameters during the same time period.

Conclusions: Immunological and clinical benefits were observed following a shortened Oralair[®] treatment course, consistent with those for traditional sub-cutaneous allergen immunotherapy. Continuation of this short-course pre-seasonal regimen for another two years should provide patients with long lasting efficacy.

1107**Impact of hydrocarbon adsorbed on nanoparticles in house dust mite induced chronic asthma mouse model**

de Nadai, P., Ait-Yahia, S., Everaere, L., Balsamelli, J., Marquillies, P., Duez, C., Tsicopoulos, A.

Univ. Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, U 1019 - UMR 8204 - CIL - Centre d'Infection et d'Immunité de Lille, CIL Team 13 Pulmonary Immunity, Lille cedex, France

Nanoparticles are a promising technology in many areas, however, little is known about the long-term impact of exposure to such materials, in particular in patients suffering from pulmonary diseases such as asthma. These particles are able to adsorb environmental pollutants such as polycyclic aromatic

hydrocarbons (PAH). The cytokine IL-22 is involved in skin repair and remodeling but also in epithelial-mesenchymal transition, a prerequisite for bronchial remodeling in chronic asthma. The Aryl hydrocarbon Receptor (AhR), a transcription factor binding PAHs, and involved in the production of IL-22, might represent a link between pollutants and airway remodeling in asthma.

We assessed the impact of nanoparticles adsorbed with the PAH Benzo(a)pyrene (B(a)P), on the production of IL-22 in a murine model of house dust mite (HDM) induced chronic asthma. We demonstrate that in WT mice, co-administration of a suboptimal dose of HDM and B(a)P-nanoparticles induced increase in IgE production, in broncho-alveolar lavage eosinophils and in Th2 type cytokines. Moreover, IL-22 was overexpressed whereas IL-17 was decreased. We observed an increase in mucus secretion but no difference in collagen deposition in lung sections. IL-22 KO mice were used to investigate the role of this cytokine, and showed a decrease in all parameters except for IgE production and a large increase in IL-17 expression.

In conclusion, in HDM chronic model, PAH nanoparticles are able to increase lung inflammation with low dose of allergen partially depending on IL-22 production.

1108**The house dust mite allergen Der p 13 is a fatty acid binding protein able to activate TLR2 signaling**

Satitsuksanoa, P., Jacquet, A.

Chulalongkorn University, Medicine, Bangkok, Thailand

Background: The House dust mite (HDM) allergen Der p 13 is a fatty acid binding protein which could participate to the initiation of allergic response through activation of innate immunity. We previously demonstrated that Der p 13 triggered IL-8 release by cultured airway epithelial cells. The goal of the present study was to characterize the signaling pathways activated by Der p 13 leading to such proinflammatory cytokine production.

Methods: Cultured human airway epithelial cells (BEAS_2B) were directly stimulated with different concentrations of rDer p 13 (1-20 μ g/ml) or Pam3Cys, a TLR2 ligand positive control under serum-free conditions. To investigate the activation of TLR2 signaling, the cells were pretreated with anti-hTLR2 blocking antibody or transfected with plasmid encoding dominant negative MyD88. The contribution of MAPK and NF- κ B in the Der p 13-induced cell activation was evaluated by cell pretreatment with specific MAPK or NF- κ B inhibitors.

Results: Preincubation of cells with blocking anti-human TLR2 mAb drastically reduced the Der p 13-induced IL-8 secretion from BEAS-2B cells. This TLR2-dependent cell activation was shown also to engage the MyD88 adaptor protein. The blockade of MAPK pathways through cell pretreatments with U0126, SB203580 or SP600125 (MEK1/2, p38, JNK MAPK inhibitors respectively reduced the IL-8 up-regulation caused by rDer p 13. Similar reduction of IL-8 release was observed with I κ B- α phosphorylation BAY-11-7082 and proteasome MG132 inhibitors.

Conclusions: Der p 13, through its ability to trigger TLR2-dependent innate immune signaling, must be considered as a potential contributor to the induction of the HDM allergic response.

1109**What data is sufficient and useful to define a protein as a cause of IgE mediated allergy?**

*Goodman, R., WHO/IUIS Allergen Nomenclature Subcommittee and the AllergenOnline.org expert panel
University of Nebraska--Lincoln, Food Allergy Research and Resource Program, Lincoln, United States*

Background: Identification of allergens in publications and sequence annotations are rapidly increasing, but often based on inadequate data. The route of exposure, types of proteins, abundance and complexity of the source materials present many challenges. Predicting proteins from DNA sequences may be incorrect. Identification and characterization of allergens are important for developing diagnostic and therapeutic reagents and for risk assessment of foods made from genetically modified organisms or novel ingredients. The WHO/IUIS Allergen Nomenclature Subcommittee (www.Allergen.org) and experts of AllergenOnline (www.allergenonline.org) suggestions:

Allergen characterization: Taxonomic source, tissue/organ; Amino acid sequence (N-terminal, LC-MS/MS or translated DNA with confirmation of a partial amino acid sequence); Post-translational modifications, glycosylation, disulfide-bridges; Abundance in the allergenic source; Test protein purity and source (purified natural or recombinant-source).

Demonstrated IgE binding: Sera from multiple relevant allergic human donors with history of exposure and reactions and from non-allergic donors; IgE binding tests (reducing, non-reducing or native immunoblot, ELISA), inhibition methods to demonstrate specificity, and characteristics of IgE detection reagents; Test IgE binding to pure protein and extract of source. Biological reactivity: In vivo challenges with pure protein are rarely performed (foods or inhalation), but skin prick tests are useful. Basophil activation or mediator release with surrogate or autologous cells, using a dose-response comparison of source and pure protein.

Allergen databases: Submit unpublished summary data to WHO/IUIS for an allergen name (e.g. Ara h 2) prior to publication. Publish a well described, controlled study and update WHO/IUIS. Publications are screened by AllergenOnline to update a risk assessment database.

1110**Implication of NOD-1 receptor in an experimental house dust mite-induced asthma model**

Ait Yahia, S.¹, Vorng, H.¹, Marquillies, P.¹, Duez, C.¹, Delacre, M.¹, Wallaert, B.^{1,2}, Chamaillard, M.¹, Tsiopoulos, A.^{1,2}

¹CILL - Center for Infection and Immunity of Lille INSERM U 1019 - CNRS UMR 8204, Lille, France, ²Clinique des Maladies Respiratoires, CHRU de Lille, Lille, France

Introduction: Allergic asthma is characterized by a Th2 adaptive immune response. Receptors of innate immunity, pattern-recognition receptor (PRR), have an important role in the induction and orientation of the immune response. Among these PRR, Nucleotid-binding oligomerization domain 1 (NOD1) is one of the receptors involved. NOD1, a sensor of Gram-negative peptidoglycan, has been shown to play a key role in

the induction of the systemic adaptive response by favoring a Th2 profile. Furthermore, polymorphisms of NOD1, have been associated to asthma. We demonstrated that NOD1 agonist displayed a pro Th2 adjuvant activity and contributed to the exacerbation of asthma in vivo. Moreover some allergens have been described as direct PRR activators. The aim of this study was to assess whether allergens can directly activate NOD1 receptor and may contribute to the development of increased immune response.

Methods: The role of NOD1 was investigated in the house dust mite (HDM)-induced asthma model, using Wild-Type and NOD1 deficient mice. Lung inflammation was assessed by determining total and differential cell counts in bronchoalveolar lavage (BAL), and by measuring Th2 cytokines and chemokines by ELISA in lung protein extracts. Total IgE levels were quantified in the serum.

Results: Our results show that HDM-sensitized/challenged NOD1 deficient mice exhibited less pulmonary inflammation when compared to the wild-type mice. Indeed eosinophilia and pulmonary Th2 cytokines were decreased in NOD1 deficient mice. Finally, the levels of total serum IgE were diminished in NOD1 deficient mice.

Conclusion: The preliminary results suggest that the allergen may directly activate NOD1 receptor.

1111**IgE sensitization to crab allergens due to inhalational exposure: identification of novel allergens**

Kamath, S.^{1,2}, Thomassen, M.³, Koeberl, M.², Nugraha, R.², Aasmoe, L.³, Bang, B.³, Lopata, A.^{1,2}

¹James Cook University, Australian Institute of Tropical Health and Medicine, Townsville, Australia, ²James Cook University, Centre for Biodiscovery and Molecular Development of Therapeutics, Townsville, Australia, ³University Hospital of North Norway, Tromsø, Norway

Occupational exposure and sensitization to food proteins and allergens is a serious health concern, and affects 4-36% of the workforce in the seafood industry. Although there have been previous attempts to identify and characterize air-borne food allergens, there is still a poor correlation between the inhalational allergen exposure on molecular level and clinical reactivity among the seafood processing workers. The aim of this study was to implement a combined proteomic- and allergenomic-based strategy to identify the major IgE-reactive proteins in crab processing factory among asthmatic or allergic crab workers and investigate the inhalational allergen load for major crab allergens.

Twenty crab-processing workers were recruited for this study with clinical asthma and/or positive skin prick test to crab extract. Air-borne allergen load was measured by sampling air from the personal breathing zones of the workers. IgE antibody reactivity to king and edible crab allergens were analysed using serum from worker by immunoblotting and mass spectrometric characterization of allergens.

90% of the tested crab workers showed strong IgE binding and recognition to crab proteins. Strong IgE reactivity was observed to crab tropomyosin and arginine kinase. In addition, IgE

binding to novel putative allergens were observed. The current study provides an insight into the role of major crab allergens, which maybe be the primary sensitizer in the development of allergy and asthma in the crab industry. The outcome of this study assists in better work safety for workers at risk of developing ingestion-induced food allergy and future development of immunotherapeutic strategies.

1112

Heterogeneity in IgE sensitization as well as T cell immunogenicity and cross-reactivity to major and minor grass pollen allergens

Gupta, S., Koed, G.K., Skovsgaard, J., Grauert, G., Lundegaard, C., Ipsen, H., Wurtzen, P.A.

ALK, Global Research-Immunology, Hørsholm, Denmark

Background: IgE mediated allergy to grass pollen has a high prevalence worldwide and various grass species are recognized by grass allergic patients in different geographical regions. The current study aimed to determine the frequency of T cell responses to individual allergens (group 1-5) from *Phleum pratense* (Phl p) and homologous allergens from other grass species and relate the T-cell responses to IgE reactivity.

Methods: Grass allergen-specific T-cell lines were established through stimulation of peripheral blood mononuclear cells (PBMC) from 51 Danish grass pollen allergic donors with natural purified grass allergens (group 1-5) in-vitro. T-cell responses were studied by fluorospot and proliferation assays. In parallel, serum IgE specific to the individual allergens was measured by ImmunoCAP and ISAC measurements. Cross-reactivity to related temperate and subtropical grasses was investigated for selected T-cell epitopes.

Results: T-cells from the majority of the donors reacted to Phl p 4 and 5, whereas responses to Phl p1, 2 and 3 were less frequent. This suggests that Phl p4 is a strong T cell immunogen and Phl p1 is less important for T-cell activation. In contrast, Phl p1 and 5 were recognized by IgE from more than 80% of the patients whereas less than 50% were IgE sensitized towards Phl p2 and 4. T-cell cross-reactivity differed considerably between allergens and epitopes but strong cross-reactive T-cell epitopes were found for most grass allergens.

Conclusion: IgE, T cell reactivity and cross-reactivity data will help us to understand the Immunogenicity of grass allergens towards developing novel vaccines for Allergen Immunotherapy.

1113

Expression of microRNA in mouse model of asthma treated by Jade-Screen Powder objective

Shen, C.-B.^{1,2}, Yu, L.¹, Ding, X.-Y.¹, Wang, S.¹

¹Shanghai TCM-Integrated Hospital, Pediatrics, Shanghai, China,

²Shanghai University of TCM, Shanghai, China

In order to investigate the effect of Jade-Screen Powder (JSP, Chinese traditional prescription) against asthma in mice by detect microRNA associated with modulated effects on helper T cells. Methods 40 Balb/c mice were randomized into control group, asthma model group, JSP treated group and

dexamethasone treated group. The mice model of allergic inflammation was established on both upper and lower airways by ovalbumin. The estimation of IL-13 (interleukin-13) and IL-17 in lung tissue homogenate was detected by ELISA and conventional pathological examination in lung was performed. The expressions of miR-146a, miR-146b, miR-210, miR-21a and miR126 in spleen tissue was analyzed by quantitative real time PCR. Results The expressions levels of IL-13 and IL-17 in JSP treated group were significantly lower than in asthma model group ($t=3.785$, $P=0.005$; $t=9.891$, $P=0.000$), and the expressions levels of IL-13 as well as IL-17 decreased in dexamethasone treated group than in asthma model group ($t=2.779$, $P=0.024$; $t=6.225$, $P=0.000$). The expression of miR-210 in JSP treated group was higher than in asthma model group (3.95 fold, $t=2.718$, $P=0.026$) and dexamethasone treated group (3.07 fold, $t=-3.962$, $P=0.012$). The expression of miR-126 in JSP treated group was higher than in asthma model group (2.15 fold, $t=2.405$, $P=0.043$), and dexamethasone upregulated the expression of miR-126 relative to asthma model group (4.48 fold, $t=-3.069$, $P=0.015$).

Conclusions: Th2 cells and Th17 cells participate in the pathogenesis of asthma and can be depressed by JSP. JSP is able to affect the helper T cells by regulate miR-210 and miR-126 to treat asthma.

1114

The effect of omega-3 on serum levels of Th1/Th2/Th9/Th17 and Th22 cytokines in patients with childhood asthma

Farjadian, S.¹, Moghtaderi, M.²

¹Shiraz University of Medical Sciences, Department of Immunology, Shiraz, Iran, Islamic Republic of, ²Shiraz University of Medical Sciences, Allergy Research Center, Shiraz, Iran, Islamic Republic of

There has been a considerable interest in the potential therapeutic value of dietary supplementation with omega-3 fatty acids in patients with asthma. To identify the effect of omega-3 fatty acids on pulmonary function and cytokines serum levels in asthma, 50 children with persistent asthma were scheduled to take a soft gel capsule including 180 mg EPA and 120 mg DHA daily for consecutive three months. Pulmonary function was evaluated by spirometry and serum levels of Th1, Th2, Th9, Th17 and Th22 cytokines were measured by flow cytometry using multiplex bead-based assay before and after the treatment. After treatment with omega-3, IL-17A and TNF- α levels decreased significantly. Peak expiratory flow (PEF) was also extensively improved in 32% of the patients. Omega-3 can be helpful in governing of inflammation in alternative therapy of asthma.

1115

IgE and non-IgE mediated reaction following anti-IgE therapy for severe asthma: a therapeutic dilemma

Ali, S.B.¹, Jodie, T.¹, Lucas, A.^{2,3}, Hollingsworth, P.N.¹, Lucas, M.^{1,4,5,6}

¹Sir Charles Gairdner Hospital, Immunology, Perth, Australia,

²Centre for Cell Therapy and Regenerative Medicine, University of Western Australia, School of Pathology and Laboratory Medicine,

Perth, Australia, ³Murdoch University, Institute of Immunology and Infectious Disease, Perth, Australia, ⁴University of Western

Australia, School of Medicine and Pharmacology, Perth, Australia, ⁵University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia, ⁶Murdoch University, Institute of Immunology and Infectious Disease, Perth, Australia

Omalizumab (Xolair®) is a humanised monoclonal antibody against immunoglobulin E (IgE) for the treatment of allergic asthma and chronic urticaria. Xolair® contains polysorbates to enhance solubility (1) and can induce severe allergic reaction (anaphylaxis) in 0.1% of subjects (2).

We describe a 40-year old patient with severe asthma and frequent anaphylactic reactions in the community who commenced Xolair®. Thirty minutes after the first dose, she developed injection site ulceration, an urticarial rash and wheeze requiring adrenaline. Subsequent therapy (300mg subcutaneous; fortnightly) was given in intensive care unit with corticosteroid and anti-histamine premedication. Four months later, Xolair® treatment was ceased. Following this, she had 28 episodes of anaphylaxis in 16 months and multiple hospital admissions. Xolair® was reintroduced, each time accompanied with an anaphylactic reaction. Xolair® desensitisation was unsuccessful. The decrease in frequency of anaphylaxis in the community, hospital admissions and total serum IgE with satisfactory asthma control justifies current Xolair® continuation. Investigation of her anaphylactic episodes, demonstrated an acute (within 15 minutes) rise in platelets, lymphocytes, neutrophils and monocytes. Skin-prick testing (SPT) to Xolair® was initially negative but became positive later in the treatment, indicating an IgE-mediated reaction. SPT and injection site biopsy after 24-hours demonstrated a perivascular T-cell infiltrate. IFN γ ELISpot testing with Xolair® (10 μ g/mL) was also positive (>200 SFU/Million PMBC), indicating the presence of Xolair® specific T-cells.

This case points towards a pathophysiology involving both IgE and T-cell mediated immune responses. Further investigation to identify the cause and culprit (omalizumab or polysorbates in Xolair®) is underway.

1116

Mast cell-derived PGD₂ attenuates anaphylaxis via DP receptor

Nakamura, T.¹, Yamada, R.¹, Fujiwara, Y.¹, Fujii, W.², Hamabata, T.¹, Aritake, K.³, Urade, Y.³, Murata, T.¹

¹University of Tokyo, Graduate School of Agriculture and Life Science, Animal Radiology, Tokyo, Japan, ²University of Tokyo, Graduate School of Agriculture and Life Science, Applied Genetics, Tokyo, Japan, ³University of Tsukuba, International Institute for Integrative Sleep Medicine, Tsukuba, Japan

Objective: Activated mast cell releases several vaso-active mediators such as histamine and induce life threatening allergic reactions; anaphylaxis. Although mast cells strongly express hematopoietic-prostaglandin D synthase (H-PGDS), the role of prostaglandin D₂ (PGD₂) in anaphylaxis remains unknown.

Results: Mast cell activation by Compound 48/80 (C48/80) caused anaphylactic responses; vascular hyper-permeability and hypothermia in wild-type (WT) mice. Systemic H-PGDS deficiency exacerbated all of the C48/80-induced anaphylactic

responses. Serum histamine level and the effectiveness of the blockade of histamine H1 receptor were comparable in both lines of mice. Immunohistochemistry showed that mast cells strongly expressed H-PGDS in WT ear. Mast cell-specific H-PGDS deficiency (MCPT5Cre H-PGDS^{fl/fl}) exacerbated the C48/80-induced vascular hyper-permeability. Systemic PGD₂ receptor DP but not CRTH2 deficiency also exacerbates C48/80-induced hyper-permeability. Finally, DP receptor agonist abolished the C48/80-induced hyper-permeability and hypothermia in both WT and H-PGDS^{-/-}.

Conclusion: Mast cell-derived PGD₂ attenuated anaphylaxis by inhibiting vascular hyper-permeability through DP receptor activation.

1117

Dectin-1 plays an important role in HDM-induced allergic airway inflammation through the activation of CD11b⁺ dendritic cells

Ito, T.¹, Hirose, K.¹, Norimoto, A.¹, Tamachi, T.¹, Yokota, M.¹, Saku, A.¹, Takatori, H.¹, Saijo, S.², Iwakura, Y.³, Nakajima, H.¹

¹Chiba University, Department of Allergy and Clinical Immunology, Graduate School of Medicine, Chiba, Japan, ²Chiba University, Department of Molecular Immunology, Medical Mycology Research Center, Chiba, Japan, ³Tokyo University of Science, Research Institute for Biomedical Sciences, Chiba, Japan

It is well known that sensitization against fungi is closely associated with severity of asthma. Dectin-1 (gene symbol *Clec7a*), a C-type lectin receptor, recognizes not only a fungal cell wall component β -glucan but also some component(s) in house dust mite (HDM) extract. However, the roles of Dectin-1 in HDM-induced allergic airway inflammation remain unclear. In this study, by using Dectin-1-deficient (*Clec7a*^{-/-}) mice, we examined whether Dectin-1 is involved in HDM-induced allergic airway inflammation. We found that HDM-induced eosinophil and neutrophil recruitment into the airways was significantly attenuated in *Clec7a*^{-/-} mice as compared with that in wild-type (WT) mice. In addition, HDM-induced IL-5, IL-13, and IL-17 production from mediastinum lymph node (MLN) cells was reduced in HDM-sensitized *Clec7a*^{-/-} mice. Dectin-1 was expressed on CD11b⁺ dendritic cells (DCs), an essential DC subset for the development of allergic inflammation, but not on CD103⁺ DCs, plasmacytoid DCs, or lung epithelial cells. Transcriptome analysis revealed that the expression of chemokine/chemokine receptors including CCR7, which is indispensable for DC migration to draining lymph nodes, was decreased in *Clec7a*^{-/-} DCs. In accordance with these results, the number of HDM-labeled DCs in MLNs was significantly reduced in *Clec7a*^{-/-} mice as compared with that in WT mice. Taken together, these results suggest that Dectin-1 expressed on CD11b⁺ DCs senses some molecule(s) in HDM extract and plays a critical role in the induction of HDM-induced allergic airway inflammation by inducing the expression of chemokine/chemokine receptors in DCs.

1118

Annexin A1 (ANXA-1)-mimetic peptide controls the inflammatory and fibrotic effects induced by house dust mite (HDM) in mice*Ferreira, T.¹, Trentin, P.¹, Arantes, A.C.¹, Silva, T.¹, Castro, G.¹, Flower, R.², Perreti, M.², Martins, M.A.¹, Silva, P.¹*¹Oswaldo Cruz Foundation, Laboratory of Inflammation, Rio de Janeiro, Brazil, ²William Harvey Research Institute, Biochemical Pharmacology Department, London, United Kingdom

Endogenous glucocorticoid are critical on their potent anti-inflammatory activity, a response partially dependent on the release of pro-resolving mediators such as AnxA1. In many inflammatory and cellular settings, the anti-inflammatory activity of AnxA1 is reproduced by peptides derived from the N-terminal region of the protein, including the peptide Ac2-26. We investigated the therapeutic properties of peptide Ac2-26 on experimental asthma induced by HDM in mice. AnxA1 null and Balb/c mice were sensitized with intranasal instillation of HDM, every other day, during 3 weeks. In another experiments, Balb/c mice were treated with peptide Ac2-26 or budesonide, 1 h before antigen starting, on the week 2 of sensitization. 24h after the last challenge, lung function, inflammatory and fibrotic markers were measured. All the experimental procedures were approved by the Ethics Committee of Animal Use of FIOCRUZ (license LW57/14). HDM led to increased airways hyper-reactivity (AHR) to methacholine, eosinophil accumulation in lung tissue as well as an excessive deposition of extracellular matrix. Increased tissue generation of inflammatory cytokines was also detected. A clear exacerbation of these pathological changes was observed in AnxA1 null mice as compared to the controls. Ac2-26 peptide inhibited all the inflammatory parameters. Budesonide was less effective than the peptide. Taken together, we observed that AnxA1 null mice show an exacerbation of several aspects of asthma, indicating that AnxA1 plays a pivotal role in the features of severe asthma. In addition, peptide Ac2-26 protects against several pathological changes associated with asthma, suggesting a possible a therapeutic agent for severe asthma.

1119

New strategies of atopic dermatitis treatment in children*Slavyanskaya, T.¹, Derkach, V.²*¹'People' Friendship University of Russia, Allergology and Immunology, Moscow, Russian Federation, ²Pacific State Medical University, Vladivostok, Russian Federation

Targeted therapies in the management of atopic dermatitis in children is a topical issue. The determination of the immunopathogenic phenotype (IPF) in 300 children (Ch) 5-17 years with moderately severe AD during exacerbation has made it possible to discover an allergic form of AD with sensitization to HDMA in 94 Ch (SCORAD 44.2±2.46). It has been noted the prevalence of Th2-cells, phagocytic index/number falls down to 25.5±1.02% and 2.14±0.4 of microbial bodies respectively. Ch have received 3 different complex therapy program (CTP): 1CTP basic therapy (BT); 2CTP BT and subcutaneous immunotherapy (SCIT); 3CTP combined immunotherapy - CIT (BT+SCIT+

immunomodulator (IM), aimed at activation of phagocytes). Application of CIT contributed to IFN γ synthesis activation and reduction of level of IL-4 and IL-13 cytokines, stimulating specific IgE. The CIT has made it possible to conduct SCIT according to an accelerated schedule, increasing clinical effectiveness as compared 1CTP and 2CTP. In the 3CTP during 3 years, we have recorded a considerable decrease of the SCORAD, reduction of flare-ups, BT in the absence of AD manifestations and hospital care, improvement of quality of life, long-term treatment effect. Scientific research study confirms CIT clinical efficiency for children with AD. This study shows prospects for the use of CIT, indicated unmet needs. Inclusion of SCIT is reasonable only if AD is of allergic form. This study shows prospects for the use of CIT which joins SCIT and IM. A future strategy of treating Ch with AD should be based on application the individual targeted therapy.

1120

VISTA/PD-1H negatively regulates generation of Th2-mediated allergic responses*Ohno, T., Kondo, Y., Azuma, M.**Tokyo Medical and Dental University, Department of Molecular Immunology, Tokyo, Japan*

Objective: VISTA/PD-1H is an immune-checkpoint molecule of the CD28-B7 family. Unlike CTLA-4 and PD-1, VISTA is broadly and constitutively expressed on most of immune cells except for B cells and seems to function as a receptor on T cells and a ligand on APCs. Its counter receptor has not been identified yet. To investigate the roles of VISTA in Th2-mediated immune responses, we examined the effects of anti-VISTA mAb treatment in an OVA-induced allergic airway inflammation mouse model.

Methods and results: Anti-VISTA mAb (MIH63) was administered i.p. at the sensitization and airway hypersensitivity (AH) was assessed by methacholine-induced airway resistance after the continuous three day challenge. The anti-VISTA mAb treatment did not clearly affect AH responses. However, total cell numbers in BAL and spleens were significantly increased by the anti-VISTA mAb treatment. The proportion of macrophages, but not of eosinophils, in BAL was also increased. In addition, serum IgE and OVA-specific IgG1 and IgG2a were dramatically increased by the anti-VISTA mAb treatment. Production of IL-4 and IL-13 by OVA-stimulated CD4+ T cells from draining lymph nodes was also increased.

Discussion: Our results suggest that VISTA greatly contributes to inhibition of Th2 cell generation and Th2-mediated antibody production, but does not protect local airway tissue inflammation. We will further investigate the effects of anti-VISTA treatment at the challenge.

1121

Coronin-1 regulates the Fc ϵ RI-mediated mast cell functions*Oku, T., Ando, Y., Tsuji, T.**Hoshi University, Microbiology, Tokyo, Japan*

Coronin-1, a hematopoietic cell-specific actin-binding protein, is thought to be involved in immunological functions through

its interaction with actin filaments. We previously reported that 1) Coronin-1 is phosphorylated by protein kinase C (PKC) and that

2) Coronin-1 has two phosphorylation sites, Ser-2 and Ser/Thr-412 (Ser in mouse and rat, Thr in human).

In this study, we investigated roles of Coronin-1 in mast cell functions. First, we generated Coronin-1-knockdown RBL-2H3 cells by using lentiviral vectors. The stable knockdown of Coronin-1 rendered these cells less responsive to antigen cross-linking of FcεRI, resulting in decreased degranulation (β-hexosaminidase) and cytokine production (TNF-α). Next, we established hybridomas secreting antibodies specific for phospho-Ser-2 and phospho-Ser-412 of Coronin-1 to assess the phosphorylation of Coronin-1 during FcεRI-mediated activation of RBL-2H3 cells. Coronin-1 was found to be transiently phosphorylated at Ser-412 but not at Ser-2. The Ser-412 phosphorylation was inhibited by the pan-PKC inhibitor, chelerythrine, and by the PKCα/β-specific inhibitor, Gö6976. The treatment of RBL-2H3 cells with Gö6976 suppressed the β-hexosaminidase secretion and the TNF-α production. These results strongly suggest that Coronin-1 plays an important role in mast cell functions, and that the functions were regulated by its phosphorylation at Ser-412.

1122

TSLP mediated airway hyperresponsiveness via regulating the expression of epithelial NGF

Chen, Y.-L.

Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan, Republic of China

Airway epithelium defends the invasion from microorganisms and regulates immune responses in allergic asthma. The nerve growth factor (NGF) and thymic stromal lymphopoietin (TSLP) would be produced from airway epithelium after the stimulations of allergens or proinflammatory mediators. They were highly expressed in bronchoalveolar lavage (BAL) fluid of asthmatics and have been suggested that these two cytokines are involved in allergic immune responses and probably in AHR. However, the correlation between these two cytokines was still unclear. In this study, we used RNA interference (RNAi), which can particularly silence target gene, in OVA-induced asthma model to reveal the functional roles of the specific cytokine in airway inflammation and AHR. The aim of this study was whether TSLP mediated AHR via NGF- neural pathway. Results were showed that the primary lung cells expressed TSLP receptors and was induced the expression of NGF by TSLP stimulation *in vitro*. In asthmatic model treated with lentivirus containing targeted shRNA, the degrees of AHR and airway inflammation were significantly reduced. The level of NGF in BAL fluids was significantly decreased. Furthermore, TSLP could regulate the expression of epithelial NGF. To compare the efficacy of two cytokines in airway inflammation, TSLP was a major cytokine in the recruitment of inflammatory cells and CD11c⁺ CD11b⁺ cells in airway. The finding showed a new role of TSLP in airway inflammation, and provided the consequence to TSLP therapy in allergic asthma.

1123

Study on fatty acids composition in breast milk and association with the occurrence of infant atopic dermatitis

Shen, Y.-J., Lin, B.-F.

National Taiwan University, Department of Biochemical Science and Technology, Taipei, Taiwan, Republic of China

Introduction: Atopic dermatitis (AD) is a pruritic skin inflammation disease that usually starts in early infancy. Recently, breast-feeding is considered to be good to infants. However, it is noted that some AD infants get better after stop breast feeding. We suspected that some nutrients in breast milk may be changed and affect AD. Because fatty acids are directly related to immune responses and easily affected by the diet, our aim is to investigate the association between fatty acids and infant AD.

Materials and methods: We collected breast milk samples and AD infants' condition from National Taiwan University Hospital. Breast samples were divided into control and AD group that from mothers who give birth to normal and AD infants. The fatty acid composition was expressed as percentage of total fatty acids detected with C8-C24 chain length and short chain fatty acids concentration by gas chromatography.

Results: The result shows that the percentage of docosahexaenoic acid (DHA) in breast milk samples from control group is greater than that from AD group (percentage of DHA 0.08±0.03% and 0.13±0.07% for control and AD group respectively; P< 0.1). We will report the complete analysis of fatty acid composition and allergic immune responses between control and AD group.

Conclusion: Our finding suggests that fatty acids composition in breast milk might affect infant allergic disease. These results may be used as a reference for mothers to adjust the diet with more beneficial fatty acids when breast-feeding to reduce the risk of infants suffering from allergic diseases.

Subcutaneous allergen specific immunotherapy in patients with allergic rhinitis: efficacy, safety and predictors for clinical response

Ye, Y.-M.¹, Hur, G.-Y.², Kim, H.-A.¹, Shin, Y.-S.¹, Nahm, D.-H.¹, Park, H.-S.¹

¹Ajou University School of Medicine, Suwon, Korea, Republic of, ²Korea University College of Medicine, Seoul, Korea, Republic of

Background: Allergen specific immunotherapy is the only disease modifying treatment for allergic disease. We sought to evaluate the efficacy and safety of allergen specific subcutaneous immunotherapy (SCIT) in patients with allergic rhinitis (AR).

Methods: We reviewed medical records of 1,064 adult patients who were sensitized to HDM and/or pollens and have taken SCIT with Allergoid® from 2000 to 2012. Remission was defined as patients needed no medication for at least 1 year and without rhinitis symptoms.

Results: Of 1,064 patients with AR (mean age 33.8±13.5, 49.5% male, 48.9% severe AR, 49.1% HDM, 29.7% Rush), 374 (35.2%) achieved the remission of AR. Mean duration for achieving AR

remission was 7.56 ± 0.17 years. Cox regression analysis showed that old age (0.99, 0.98-0.99, $P=0.001$), severe AR (0.68, 0.54-0.85, $P=0.001$), and accompanied AA (0.74, 0.60-0.91, $P=0.005$) were significant determinants of poor response to SCIT. In total 232 (21.8%) patients had experienced adverse event (AE)s during their buildup phase, and particularly in patients starting SCIT with rush mode compared to those with conventional mode (39.2% vs 14.4%, $P < 0.001$). Cutaneous reactions (218 cases) including urticaria, angioedema and injection site swelling were the most frequent AE followed by respiratory symptoms (35 cases) and anaphylaxis (35 cases).

Conclusions: A retrospective cohort study covering 12 years of follow-up demonstrated that 35.2% of AR patients arrived at the remission with low occurrence of severe AEs with SCIT. Initial severity, age and accompanied asthma can impact on the clinical response to SCIT in patients with AR.

Asthmatic airway inflammation is alleviated by adeno-associated viral vectors carrying CD39 in OVA-sensitized mice model

Huang, Y.-A., Wu, C.-J., Kuo, M.-L.

Chang Gung University / Graduate Institute of Biomedical Sciences, Taoyuan, Taiwan, Republic of China

Asthma is a chronic respiratory disease characterized by recurrently attacks of breathlessness and wheezing. Th2 response plays a crucial role in pathogenesis of asthma, resulting in eosinophilia and airway hyper-responsiveness (AHR). Extracellular ATP has been revealed as an important mediator and danger signal responding to cellular stress or tissue damage in acute and chronic inflammation. Accumulation of ATP in bronchoalveolar lavage fluid (BALF) of asthmatic subjects suggests that extracellular ATP and the downstream responses are involved in the pathogenesis of asthmatic airway inflammation. The concentration of extracellular ATP is regulated by CD39, an ecto-ATP/ADPase encoded by *entpd1*. Elevated ATP level in BALF of OVA-sensitized mice was compounded by the increased AHR, eosinophilia and IL-5 production as well as reduced expression of CD39. To lessen the level of extracellular ATP by increasing the expression of CD39, recombinant adeno-associated virus based CD39 expression vector (rAAV-CD39) was generated. rAAV-CD39 was administrated into the lungs of OVA-sensitized mice, and several cardinal features were analyzed. In rAAV-CD39 treated mice, expression level of CD39 was rescued, and ATP upregulation in BALF was restricted. AHR, eosinophilia and IL-5 produced by the draining lymph node cells were decreased by the administration of rAAV-CD39. These data indicated that the treatment of rAAV-CD39 attenuated the asthmatic airway inflammation and AHR. We considered that CD39 mediated reduction of extracellular ATP could be a potential approach for gene therapy on asthma.

1126

Adverse effects of prenatal wood smoke exposure on house dust mite-induced asthma

Jaffar, Z., Ferrini, M., Carvalho, S., Roberts, K.

University of Montana, Biomedical & Pharmaceutical Sciences, Missoula, United States

Globally, biomass burning (from woodstoves, wildfires and agricultural burns) contributes significantly to both indoor and outdoor wood smoke (WS) particulate matter ($PM_{2.5}$) exposures and associated adverse health effects. Although such exposures are associated with acute respiratory tract infections and are linked to childhood asthma, the adverse effects of prenatal WS exposure have not been adequately studied. Airborne allergens, including those of the house dust mite (HDM), are the most common trigger of asthma, particularly in children. Allergic asthma is a chronic bronchial inflammatory condition characterized by eosinophilic inflammation, airway hyperreactivity, mucus production and remodeling. To investigate possible linkage between WS exposure and asthma incidence, C57BL/6 offspring were exposed in utero to either WS (3 mg/m³ $PM_{2.5}$) or filtered air and the lung inflammatory response elicited by HDM allergen inhalation was compared. Prenatal WS exposure caused a pronounced increase in HDM allergen-induced airway inflammation, AHR and Th2 cytokine levels in the offspring compared to clean air. Moreover, in utero WS exposure resulted in a marked increase in peribronchial and perivascular inflammation and mucus production. Flow cytometric analysis revealed a marked elevation in the number of pulmonary dendritic cells and Siglec-F+ eosinophils in the offspring. The enhanced responsiveness was associated with airway cysteinyl leukotriene production. Collectively, these results demonstrate that prenatal WS exposure leads to exacerbation of allergic airway inflammation in the offspring and may identify future targets for prevention.

B Cells

1127

IL-10 producing B cells in breast cancer draining lymph nodes

Mehdipour, F., Talei, A., Razmkhah, M., Bagheri, M., Ghaderi, A.

Shiraz University of Medical Sciences, Shiraz Institute for Cancer Research, Shiraz, Iran, Islamic Republic of

Introduction: IL-10 producing (B10) B cells are mostly studied and characterized in autoimmune diseases while their phenotype and roles in solid malignancies are largely unknown. In the current study the frequency and phenotype of B10 cells in tumor draining lymph nodes (TDLNs) of breast cancer patients and its association with lymph node involvement were investigated.

Materials and methods: Mononuclear cells were isolated from 17 metastatic lymph nodes (MLNs) and 25 non metastatic lymph nodes (nMLNs). Lymphocytes and enriched B cells were stimulated in vitro and after surface and intracellular staining subjected to flow cytometry.

Results: The percentage of B10 cells did not show significant

changes in MLNs compared to nMLNs. However, the frequency of B10 cells significantly decreased in nMLNs of node positive compared to node negative patients ($P=0.001$). There were no significant correlations between the frequency of B10 cells and the percentages of IL-10+ or CD25+FoxP3+ regulatory T cells in TDLNs of breast cancer patients. Phenotypical characterization of B10 cells in TDLNs revealed that they were mostly enriched within CD24hiCD27+ memory pool and could have both switched (CD27+IgM-) and unswitched (CD27+IgM+) memory phenotype. Also most of B10 cells were CD5-, CD11c-, CD23- and CD43-.

Conclusion: IL-10 producing B cells could be detected in TDLNs of breast cancer patients mostly within the B cell memory pool. Also our study proposed a possible association between lymphatic involvement and the decrease in B10 cell frequency in nMLNs.

1128

Cytokine profile of B cells in breast cancer draining lymph nodes

Ghaderi, A., Mehdipour, F.

Shiraz University of Medical Sciences, Shiraz Institute for Cancer Research, Shiraz, Iran, Islamic Republic of

Introduction: B cells are generally considered as antibody producing cells and their role as cytokine producing cells is not well elucidated in solid malignancies. In this study, cytokine profile of B cells in tumor draining lymph nodes (TDLNs) of patients with breast cancer and its association with lymph node involvement were investigated.

Materials and methods: Mononuclear cells were isolated from 17 metastatic lymph nodes (MLNs) and 25 non metastatic lymph nodes (nMLNs). Enriched B cells were stimulated in vitro and after surface and intracellular staining subjected to flow cytometry.

Results: The percentages of IL-2, IFN- γ and TGF- β producing B cells were not significantly different in MLNs and nMLNs of breast cancer patients. The percentage of TNF- α producing B cells showed a non significant decrease in MLNs in comparison with nMLNs ($P=0.065$). However, the frequency of B cells with intermediate to high expression of TNF- α (TNFint/hi B cells) was significantly decreased in MLNs in comparison with nMLNs ($P=0.026$). The percentage of TNFint/hi B cells was also decreased in nMLNs of node positive compared to node negative patients ($P=0.034$). We also found a significant reverse correlation between the frequency of TNFint/hi B cells and the frequency of CD25+FoxP3+CD4+T cells in nMLNs ($R=-0.6$, $P=0.004$).

Conclusion: Our investigation revealed that invasion of the breast tumor to draining axillary lymph nodes had a negative impact on the B cell production of pro-inflammatory cytokine TNF- α even in nMLNs.

1129

Natural IgE production intrinsically requires CD1d expression on B cells

Kitoh, A.¹, Shibuya, R.¹, Kabashima, K.^{1,2,3}

¹*Kyoto University Graduate School of Medicine, Department of*

*Dermatology, Kyoto, Japan, ²Singapore Immunology Network (SIn), A*STAR, Biopolis, Singapore, ³PRESTO, Saitama, Japan*

Several studies have revealed antigen-independent effects of IgE antibodies on various mast cell functions in vitro. In addition, hapten-irrelevant IgE normally present in mice is required for sensitizing mice to contact hypersensitivity through mast cell modulation of dendritic cell migration and function, suggesting that naturally produced IgE plays an essential role in the maintenance of mast cell function in vivo. However, the mechanism by which IgE is naturally produced in vivo is unclear. We found that serum IgE levels were markedly decreased in CD1d-deficient mice compared to control wild-type BALB/c mice. In addition, amounts of IgE bound on skin and peritoneal mast cells were significantly lower in CD1d-deficient mice than in wild-type mice, suggesting that the defect of natural IgE production observed in CD1d-deficient mice was of physiological significance. Wild-type mice transplanted with bone marrow cells from CD1d-deficient mice showed significantly lower levels of serum IgE, compared to wild-type bone marrow cell-transplanted mice, suggesting that CD1d expression on hematopoietic cells is required for natural IgE production. To investigate the requirement of CD1d on B cells for their natural IgE production, we generated mixed bone marrow chimeric mice where wild-type B- or CD1d-deficient B-derived IgE could be distinguished and found that the IgE produced in these mice was largely produced from wild-type B cells. Taken together, our results suggest that CD1d expression on B cells is intrinsically required for natural IgE production in vivo.

1130

Memory B cell subset formation in acute and chronic viral disease

Pupovac, A., Good-Jacobson, K.

Infection and Immunity Program, Biomedicine Discovery Institute, Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia

Efficacious vaccine design is needed to tackle rapidly evolving pathogens. Memory B cell subsets provide the immune adaptability needed to challenge different pathogens. Human atypical memory B cells, originally characterised as "exhausted", are expanded in patients with chronic infectious disease. Currently, there is no animal model of atypical memory B cell formation. Therefore, little is known about the requirements for the formation of atypical memory in acute and chronic viral disease, and how the responses of atypical memory compare to that of classical memory in these disease states. To this end, we are utilising acute and chronic strains of lymphocytic choriomeningitis virus (LCMV) to understand memory B cell behaviour in vivo during chronic infections. Using an antigen-specific tetramer for LCMV to track antigen-specific B cells, our data indicates that while the chronic strain of the virus induced ongoing germinal centres (GC), very few of these cells were antigen-specific. In contrast to the GC B cell response after infection with the acute strain of the virus, the majority of B cells in chronic GCs were CXCR4+, suggesting an overrepresentation of dark zone B cells. Similar to human atypical memory B

cells, antigen-specific B cells *in vivo* had also modulated their expression of CXCR3, but only in the chronic strain was PD-1 upregulation evident. Identifying the requirements and functions of different memory B cell subsets in acute and chronic disease states will provide insight into the mechanisms driving B cell subset formation, which may allow for effective future vaccine development.

1131

A rare case of selective Ig-kappa light chain deficiency

Sadighi Akha, A.¹, Tschumper, R.², Mills, J.¹, Isham, C.¹, Viswanatha, D.¹, Snyder, M.¹, Murray, D.¹, Katzmann, J.¹, Jelinek, D.², Willrich, M.¹
¹Mayo Clinic, Laboratory Medicine and Pathology, Rochester, United States, ²Mayo Clinic, Immunology, Rochester, United States

Selective Ig-kappa and Ig-lambda deficiencies are extremely rare. So far, there have been 5 reported cases of Ig-kappa deficiency, 3 partial and 2 complete, the latter in two siblings also afflicted with cystic fibrosis. In 1985, sequencing the kappa constant region (*IGKC*) in one sibling identified a variant in each allele, p.Trp168Arg and p.Cys214Gly, that disrupted kappa chain folding.

Our case is a 73-year-old caucasian female suffering from peripheral neuropathy, but otherwise healthy and with no history of immunodeficiency. Immunofixation electrophoresis of her serum showed the total absence of Ig-kappa. Mass spectrometric analysis confirmed this finding and the polyclonal nature of the Ig-lambda repertoire. Flow-cytometric analysis showed no expression of Ig-kappa in the cytoplasm or surface of B cells. Other immunologic assessments only showed a mild decrease in her switched memory B cells; not atypical at her age. Sequencing *IGKC* showed she was homozygous for a missense mutation that interferes with kappa chain's folding.

The patient's 72-year-old brother, with no history of immunodeficiency, showed moderate B cell lymphopaenia, skewed kappa/lambda ratio in the serum, and decreased kappa/lambda expression in the cytoplasm and surface of B cells, but was otherwise normal. Sequencing *IGKC* demonstrated that he was heterozygous for the missense mutation identified in his sister.

These findings confirm that the complete absence of Ig-kappa is not incompatible with normal B cell development, and that it does not in itself manifest as an immunodeficiency. However, the presence of only one defective *IGKC* allele may have a quantitative effect on Ig-kappa expression.

1132

The functional response of B cells to antigenic stimulation during latent tuberculosis

Loxton, A.G., du Plessis, W., Chegou, N., Ronacher, K., Walzl, G.
 Stellenbosch University, Biomedical Sciences, Cape Town, South Africa

Mycobacterium tuberculosis (M.tb) remains a successful pathogen, causing tuberculosis disease numbers to constantly increase. Although great progress has been made in delineating the disease, the host-pathogen interaction is incompletely

described. B cells have shown to function as both effectors and regulators of immunity *via* non-humoral methods in both innate and adaptive immune settings. Here we assessed specific B cell functional interaction following stimulation with a broad range of antigens within the LTBI milieu. Our results indicate that B cells readily produce pro- and anti-inflammatory cytokines (including IL-1 β , IL-10, IL-17, IL-21 and TNF- α) in response to stimulation. TLR4 and TLR9 based stimulations achieved the greatest secreted cytokine-production response and BCG stimulation displayed a clear preference for inducing IL-1 β production. We also show that the cytokines produced by B cells are implicated strongly in cell-mediated communication and that plasma-memory B cells (CD19⁺CD27⁺CD138⁺) is the subset with the greatest contribution to cytokine production. Collectively our data provides insight into B cell responses, where they are implicated in and quantifies responses from specific B cell phenotypes. These findings warrant further functional B cell research with a focus on specific B cell phenotypes under conditions of active TB disease to further our knowledge about the contribution of various cell subsets which could have implications for future vaccine development or refined B cell orientated treatment in the health setting.

1133

The interplay between c-Myb and T-bet determines the fate of humoral response to influenza virus infection

Di Pietro, A.¹, Tempny, J.², Tarlinton, D.^{2,3,4}, Good-Jacobson, K.^{1,2,3}
¹Infection and Immunity Program, Biomedicine Discovery Institute, Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia, ²Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, ³University of Melbourne, Department of Medical Biology, Melbourne, Australia, ⁴Monash University, Alfred Hospital, Department of Immunology, Prahran, Australia

Humoral and cellular immune responses are generated upon influenza virus infection of the respiratory tract, creating transitory germinal centres (GC) in peripheral lymphoid organs. B cells within the GC undergo affinity maturation, clonal selection of high-affinity variants and subsequent differentiation into antigen-specific antibody-secreting plasma cells and memory B cells. These populations help in clearing the infection and provide long-term immunity, however, the transcriptional programs that determine the fate of B cells during influenza infection are not fully elucidated. Here, we explore the intrinsic *in-vivo* activity of the transcription factor c-Myb in regulating humoral responses.

Our preliminary results denoted that the deletion of c-Myb in mature B cells of mice immunised with the haptenated protein NP-KLH triggers the expression of other transcription factors, such as T-bet. As a direct consequence, T-bet downstream target genes, normally expressed after influenza infection and suppressed during the NP-KLH response, were up-regulated, resulting in aberrant plasma cell differentiation and class-switching to the IgG2c isotype. Conversely, the deletion of T-bet in mature B cells reverted the phenotype to wild-type. Surprisingly, the aberrant response also occurred in c-Myb-deficient mice infected with HKx31 virus (H3N2), in which T-bet

expression is a normal component of the humoral response. ATAC-seq experiments also supported these observations, revealing a greater chromatin accessibility in the T-Bet locus in c-Myb-deleted GC B cells from infected mice, compared to wild-type GC B cells.

According to these results, c-Myb is fundamental for inhibiting dysregulation of the humoral response via suppression of aberrant levels of expression of T-bet.

1134

Molecular signals involved in human B cell migration into the retina

Stempel, A.J.¹, Bharadwaj, A.S.², Olivas, A.², Franzese, S.E.², Ashander, L.M.^{1,2}, Ma, Y.¹, Lie, S.¹, Appukuttan, B.¹, Smith, J.R.^{1,2}

¹Flinders University, Adelaide, Australia, ²Oregon Health Sciences University, Portland, United States

Purpose: Posterior uveitis is a blinding inflammatory disease that involves the retina. B cells have been implicated in disease pathogenesis, but trafficking of B cells to the retina remains unstudied and may present targets for more effective therapies. We investigated involvement of 3 molecules in B cell migration to retina: CXCL13, ICAM-1, and VCAM-1.

Methods: Neural retina and retinal pigment epithelium were dissected from human cadaver eyes (n=8), and CXCL13 expression was examined by RT-PCR and immunohistochemistry. Human B cells, isolated by negative selection from peripheral blood of healthy adults (n=7-13), were migrated through Bowden transwells populated with endothelial cells isolated from human retina by selection on CD31. Anti-ICAM-1, anti-VCAM-1, or negative control antibody was applied to upper chambers, and CXCL13 or medium alone was applied to lower chambers. Integrity of endothelial monolayers was confirmed by measurement of Texas Red-conjugated 70 kDa dextran diffusion.

Results: CXCL13 transcript was detected in both neural retina and retinal pigment epithelium. Immunohistochemistry identified CXCL13 protein in ganglion cells, photoreceptors and some vascular endothelial cells; human retinal endothelial isolates did not contain CXCL13 transcript suggesting endothelial expression was by transcytosis. Anti-ICAM-1 antibody significantly reduced B cell migration in comparison to control, in the presence and absence of CXCL13 ($p \leq 0.002$). Anti-VCAM-1 antibody reduced migration less significantly, and only when CXCL13 was absent ($p=0.02$).

Conclusions: Our results suggest that targeting ICAM-1 may be an effective treatment for patients with posterior uveitis. Future studies will evaluate the impact of ICAM-1 blockade on B cell migration under flow conditions.

1135

Control of germinal center and early memory B cell homeostasis by BAFFR

Lau, A.^{1,2}, Chan, T.^{1,2}, Brink, R.^{1,2}

¹Garvan Institute of Medical Research, Immunology Research Program, Sydney, Australia, ²University of New South Wales, St. Vincent's Clinical School, Sydney, Australia

The signalling duo BAFFR and its ligand, BAFF are required for naïve B cell development and survival. During T-dependent responses, germinal center (GC) B cells express high levels of BAFFR. The immunisation of intact BAFFR-deficient or BAFF-deficient mice leads to initiation of GC responses that fail to be sustained past 7-14 days and an absence of memory B cells. However, since these deficient mice have structural abnormalities in their secondary lymphoid organs, it remains unclear to what extent GC and memory B cells depend on cell-intrinsic expression of BAFFR.

To investigate this question, we performed adoptive transfer studies to examine the response of BAFFR-deficient hen egg lysozyme-specific (SW_{HEL}) B cells in normal intact recipient mice.

Immature BAFFR-deficient and BAFF-deficient B cells formed GC responses that underwent normal Ig class-switching and affinity maturation. In addition, the absence of T cell-derived BAFF had no detectable impact on selecting high affinity GC B cells. However, BAFFR-deficient SW_{HEL} responses failed to be sustained indicating that BAFF-BAFFR signalling plays an important role in mature GC B cell survival. Interestingly, we found that 20-30% of normal GC B cells expressed low levels of BAFFR. BAFFR expression did not correlate with either antigen affinity or the GC light and dark zones. We are currently trying to determine what role this population may play in regulating GC homeostasis. Finally, early GC-independent memory B cell numbers were found to depend on BAFFR expression, suggesting their distinct survival requirement from the BAFF-independent memory B cells that develop from GC precursors.

1136

ASCIZ and dynein light chain-1 are essential for the development of innate B1 cells

King, A.^{1,2}, Wong, D.¹, Li, L.^{1,2}, Heierhorst, J.^{1,2}

¹St Vincent's Institute of Medical Research, Fitzroy, Australia, ²The University of Melbourne, Department of Medicine, St Vincent's Hospital, Fitzroy, Australia

B1 cells play crucial roles in innate immunity by producing "natural" antibodies as a first line of defence against newly encountered pathogens. Defects in the development of B1 cells can lead to autoimmune disorders and leukaemia. In contrast to conventional B cells, the mechanisms regulating B1 cell development and maturation remain poorly understood.

Here we show that B1 cell development is severely impaired in conditional KO mice that lack dynein light chain1 (DYNLL1) or the DYNLL1-transcription factor ASCIZ in the B cell lineage. We found that these mice exhibit a profound reduction in B1 cells in the peritoneal cavity at 4 weeks of age, that is partially compensated with time. ASCIZ and DYNLL1 are also required for normal B cell development, but we found that B1 and B2 cell numbers are differentially affected by other mutations. Whereas MYC over-expression was synthetic lethal with Asciz- or Dynll1-deletions in immature B2 cells, it partially rescued the B1 cell deficiency in these mice. Conversely, knockout of the pro-apoptotic protein BIM rescued the B2 cell defect but had no effect on the B1 compartment.

Our data demonstrate that ASCIZ and DYNLL1 are essential for the development of B1 cells and highlight differential roles for MYC and BIM in the regulation of B1 and B2 cell populations.

1137

Overexpression of TACI leads to reduced B cell but increased plasma cell numbers*Garcillan, B., Lim, E.X., Fabienne, M.**The University of Melbourne, Microbiology and Immunology, Melbourne, Australia*

Transmembrane activator and CAML interactor (TACI) is a receptor for the TNF-like cytokines BAFF and APRIL that modulates B-cell function. BAFF signalling through TACI is not required for B cell development and survival but appears to negatively regulate B cell and controls B cell homeostasis. TACI signalling is also essential for T-independent antibody responses, isotype class switching and differentiation into plasma cells. In humans, mutations in TACI have been associated with common variable immunodeficiency, demonstrating the important role of this receptor in regulating B-cell function. TACI^{-/-} mice show B cell hyperplasia, absent T-independent immune responses and reduced IgA levels. Here, we characterized a novel transgenic mouse model where human TACI and GFP are expressed under the control of the mouse TACI promoter (hTACI-Tg). Our results show that human TACI fully functions in mice. We found the highest level of TACI expression in plasma cells, B1 and MZ B cells. In contrast to previously published data, we didn't find TACI expression in activated T cells. Overexpression of TACI in our mouse model reduced the peripheral B-cell compartment while it increased plasma cell numbers. Consistent with the important role of TACI in isotype switching and antibody production, we observed increased levels of serum IgA. Results with this new animal model allows us to finely track the fate and function of TACI-expressing B cells and also is the first animal model enabling targeting of human TACI *in vivo*.

1138

RAG2 participated in controlling Igk loci DNA demethylation

Wu, C., Zhao, X., Zhang, P., Li, S., Yu, X., Jiao, J., Dong, Y., Ji, Y.
Xi'an Jiaotong University Health Science Center, Key Laboratory of Environment and Genes Related to Diseases (Xi'an Jiaotong University), Ministry of Education of China, PR China, Department of Pathogenic Biology and Immunology, Xi'an, China

Antigen receptor genes are assembled by V(D)J recombination during lymphocyte development. RAG endonuclease and loci specific "accessible", containing histone modifications, DNA methylation and displacement and removal of nucleosomes contribute to control the process. In this study, we chose D708A-R1^{-/-}H, R1^{-/-}H and R2^{-/-}H transgene mice. D708A-R1^{-/-}H mice is a *Rag1*^{-/-} background containing an Asp708/Ala active site mutant RAG1 protein that interacts with RAG2 and binds DNA normally but lacks catalytic activity and then bred with mice harboring a functionally rearranged B1-8i *Igh* allele transgene to generate and exhibit developmental arrests at the pre-B, equivalent to those observed in *Rag1*^{-/-}B1-8i (R1^{-/-}H) and *Rag2*^{-/-}B1-8i (R2^{-/-}H). We isolated CD19⁺ pre-B cells from these mice and analyzed Igk loci DNA methylation status. We found that when RAG2 alone or D708ARAG1 and RAG2 exist, Igk loci were demethylated. But RAG1 alone

exist, Igk loci were methylated. Wild type RAG2 recruited into R2^{-/-}B cells, VJk recombination could be detected and Igk loci were demethylated. Mutations in RAG2's non-core region could increase the RAG activity, however Igk loci kept in DNA methylation status. We found that expression of Gadd45a mRNA was reduced in RAG2's non-core region comparing to wild RAG2. We propose that RAG2 has the abilities of limiting the excessive RAG activity and regulating accessibility of Igk loci.

Keywords: V(D)J recombination, B cell, Igk, DNA methylation, RAG2, Gadd45a

Memory B cells develop from low-affinity clones in the germinal center light zone and are identified by CCR6 expression in mice and humans

Suan, D.^{1,2}, Krautler, N.¹, Maag, J.³, Butt, D.¹, Wood, K.¹, Hermes, J.¹, Priestley, D.¹, Statham, A.¹, Elliott, M.⁴, Marcel, D.³, Basten, A.¹, Tangye, S.¹, Brink, R.¹

¹Garvan Institute of Medical Research, Immunology, Darlinghurst, Australia, ²Westmead Hospital, Clinical Immunology and Allergy, Westmead, Australia, ³Garvan Institute of Medical Research, Genomics and Epigenetics Division, Darlinghurst, Australia, ⁴University of Sydney, Central Clinical School, Camperdown, Australia

Memory B cells (MBCs) and plasma cells (PCs) constitute the cellular output of germinal center (GC) responses that facilitate long-term humoral immunity and underpin vaccine efficacy. Whilst expression of the transcription factor BLIMP-1 is routinely used to identify cells undergoing PC differentiation, no such marker exists for the MBC lineage. It remains unclear, therefore, how MBC differentiation is integrated into the cyclic proliferation, somatic mutation and interzonal migration of GC B cells. Here we report that the chemokine receptor CCR6 uniquely marks MBC precursors in both mouse and human GCs. CCR6⁺ pre-MBCs are highly enriched within the GC light zone (LZ), are the most quiescent of all GC B cells and exhibit a gene expression signature indicative of MBC transition. Unlike PC precursors, pre-MBCs within the GC LZ possess low affinity for the immunising antigen, indicating a fundamental dichotomy in the processes that drive MBC and PC differentiation during GC B-cell responses.

1140

Selenoproteins regulate B cell receptor-mediated activation and development of B cells

Katkere, B., Markley, R., Shay, A., Prabhu, K.S., Kirimanjeshwara, G.
The Pennsylvania State University, Veterinary and Biomedical Sciences, University Park, United States

B cell development, activation and immunoglobulin affinity maturation are dependent on B cell receptor (BCR)-mediated signaling, which is sensitive to redox status of cells. Cellular redox status is regulated by several mechanisms including that

are controlled by selenoproteins, a class of proteins that contain amino acid selenocysteine at their catalytic sites. Although several selenoproteins are known to be expressed in developing and mature B cells, their precise role in B cell development and functions has not been explored. In order to bridge this gap in our understanding of B cell development and functions, we generated mice that lack expression of selenoproteins in B cells. BCR endocytosis, signaling, trafficking, and activation were significantly affected in selenoprotein-deficient B cells. Consistent with the role of BCR-mediated signaling in B cell development, mature B cell population was significantly (>40%) smaller in the absence of selenoproteins. Interestingly, BCR endocytosis was found to be regulated by selenoproteins with known redox regulatory functions (for example, Gpx1) while the downstream effects such as calcium signaling were regulated by selenoproteins that have redox-regulation independent functions (for example, Selk). These data suggest that several selenoproteins with overlapping and distinct functions may regulate BCR-mediated activation of B cells and their development. These studies provide the basis for discovery of potential targets for novel adjuvants and therapeutics.

1141

A lamprey monoclonal VLR antibody generated against multiple myeloma bone marrow aspirate specifically identifies plasma cells

Liu, Y.¹, Yu, C.², Chan, J.¹, Cooper, M.², Ehrhardt, G.¹

¹University of Toronto, Immunology, Toronto, Canada, ²Emory University School of Medicine, Atlanta, United States

Plasma cells are key effector cells to engage pathogenic challenges as well as contributors to autoimmune and malignant disorders. Only a limited number of plasma cell specific biomarkers have been identified thus far. The unique structural characteristics of the variable lymphocyte receptor (VLR) antibodies of the evolutionary distant sea lamprey prompted us to investigate whether VLR antibodies could be isolated that detect novel plasma cell antigens, which have not been recognized by conventional antibodies. Here we describe a monoclonal lamprey antibody, VLRB MM3, that was raised against primary multiple myeloma cells. VLRB MM3 recognizes a unique epitope of the CD38 ectoenzyme that is present on plasmablasts and plasma cells from healthy individuals and on most, but not all, multiple myelomas. Binding by the VLRB MM3 antibody coincides with CD38 dimerization and nicotinamide adenine dinucleotide (NAD) glycohydrolase activity. Our data demonstrate that the lamprey VLRB MM3 antibody is a unique reagent for the identification of plasmablasts and plasma cells with potential applications in the diagnosis and therapeutic intervention of plasma cell or autoimmune disorders. miR-338-5p regulates the biological function of B cells by targeting nuclear factor kappaB1

Xu, H., Ma, X., Song, D., Xue, D., He, X.

Third Affiliated Hospital of Soochow University, Urology Department, Changzhou, China

Objective: To investigate the effect of miR-338-5p on NF- κ B1 expression and the regulatory ability of IgG production by B cells.

Methods: Targeting verification assay of miR-338-5p on NF- κ B1 was conducted by dual-luciferase reporter assay. Purified CD20+ B cells were cultured with anti-IgM antibody, and/or recombinant human B cell activating factor (BAFF), after transfected with miR-338-5p agomiR, miR-338-5p antagomiR, NF- κ B1 siRNA (siNF- κ B1), and their corresponding negative control reagents. Real-time PCR and western blot assay were applied to determine NF- κ B1 (P105, P50) levels. Supernatant IgG concentration was detected by ELISA. Data were analyzed by SPSS 17.0 software, and $P < 0.05$ was considered to be significant.

Results: Compared with control groups, the hRluc/hLuc relative luciferase activity significantly increased in miR-338-5p mimic and NF- κ B1-3'-UTR Reporter co-transfection group; In the anti-IgM antibody and rhBAFF co-culture system, P105 and P50 levels in B cells, and IgG production by B cells transfected by miR-338-5p agomiR significantly increased, while those proteins' levels significantly decreased in miR-338-5p antagomiR transfection group. The effect of siNF- κ B1 was similar to those of miR-338-5p antagomiR. Correlation analysis results suggested that NF- κ B1 mRNA level was significantly positively correlated with IgG concentration.

Conclusions: miR-338-5p promoted IgG production by B cells through positively regulating NF- κ B1 expression, and indirectly regulating BAFF signal.

Immune suppressive doses of ultraviolet radiation activate a unique subset of B cells that are required for sunlight protection of mice from EAE

Marshall, J.¹, Kok, L.F.¹, Marsh-Wakefield, F.^{1,2}, Gillis, C.^{1,2}, Halliday, G.^{1,2}, Byrne, S.^{1,2}

¹University of Sydney, Cellular Photoimmunology Group, Infectious Diseases and Immunology, Sydney, Australia, ²University of Sydney, Dermatology Research Laboratories, Sydney, Australia

The ultraviolet (UV) radiation contained in sunlight is a powerful and broad spectrum immune suppressant. Activation of regulatory B cells is a major way in which UV suppresses adaptive immune responses. Small doses of UV, equivalent to 10 minutes of summer sun for humans, are all that are required to activate a unique population of B cells within the skin draining lymph node of C57BL/6 mice. As determined by flow cytometry, MHC II^{hi} B220^{hi} UV-activated B cells expressed significantly higher levels of CD19, CD21/35, CD25, CD210 and CD268 as well as the co-stimulatory molecules CD80, CD86, CD274 and CD275. There was no difference in the expression of CD276. UV-activated B cells were CD1d^{low}CD5⁻ meaning

that they are a different population to B10 cells. Mice exposed to UV and immunised with MOG/CFA to induce experimental autoimmune encephalomyelitis (EAE) displayed significantly less demyelination and reduced infiltration of inflammatory cells into the spinal cord. Consequently, UV-exposed groups showed delayed EAE onset, reduced peak EAE score and significantly suppressed overall disease incidence and burden. UV-protection from EAE was dependent on the successful activation of lymph node B cells because UV could not protect mice from EAE who were pharmacologically depleted of B cells. Thus, maintenance of a pool of regulatory B cells in peripheral lymph nodes appears to be essential to prevent the activation of encephalitogenic cells that cause CNS-autoimmunity. Exposure to UV is one way in which this pool of EAE-protecting cells can be maintained.

Does immunoglobulin class switching predominantly occur in germinal centers?

Roco, J.¹, Nefzger, C.², Mesin, L.³, Gonzalez, P.¹, Ellyard, J.¹, Polo, J.M.², Victoria, G.³, Toellner, K.⁴, Vinuesa, C.¹

¹John Curtin School of Medical Research, Australian National University, Department of Immunology and Infectious Disease, Canberra, Australia, ²Australian Regenerative Medicine Institute (ARMI), Monash University, Department of Anatomy and Developmental Biology, Melbourne, Australia, ³Whitehead Institute for Biomedical Research, Cambridge, United States, ⁴School of Immunity and Infection, Medical School IBR, University of Birmingham, Birmingham, United Kingdom

Class Switch Recombination (CSR) is an intrachromosomal DNA rearrangement by which mature B cells are able to express antibodies of different classes in response to antigen stimulation and co-stimulatory signals. Classical studies have identified germinal centers (GCs) as the main areas where CSR occurs. However one of the main caveats of these studies has been the inability to track rare antigen B-cell populations at early time points during the course of an immune response; therefore, most of the conclusions regarding CSR activation have been made after clonal expansion, when GCs are well formed. Thus, critical events that occur immediately after antigen-mediated B cell activation and prior to GC formation could have been missed. We have now taken advantage of mouse models in which we can track single antigen-specific B cells immediately after priming by T-cells, and prior to differentiation into GC or extrafollicular plasma cells, and then follow them during the course of GC reactions. To evaluate the timing and location of CSR *in vivo* we have analysed single antigen-specific B-cells at 12-24 hr intervals post-immunization. Without exception, $\gamma 1$ -, $\gamma 2b$ - and $\gamma 3$ -switch transcripts were expressed as early as 1.5 days after transfer but they were almost absent in GC B-cells. This rapid induction of switch transcripts reaches a peak between days 2.5 to 3.0 correlating with AID expression long before GC formation. Together, our data challenge the current dogma of isotype-switching occurring predominantly within GCs and suggest a model in which GCs play a regulatory role in this process.

1145

Systemic inflammation rapidly reorganizes mouse bone marrow B cells and their environment to alter repertoire development and drive early IgM responses

Moreau, J.^{1,2}, Paige, C.^{1,2}

¹University of Toronto, Immunology, Toronto, Canada, ²Princess Margaret Cancer Centre, Toronto, Canada

Maturation of B cells in the bone marrow is regulated by an organized tissue structure composed of local microenvironments, each providing a distinct cocktail of factors to the various stages of B cell development. As progenitors mature, they migrate between niches and towards the sinusoids. Systemic inflammation in mice disrupts B lymphopoiesis, however; it is unclear how B cell niches respond to these challenges and the impact on subsequent B cell fate remains unknown. In the current study, we report that injection of Freund's incomplete adjuvant induced a massive accumulation of mature B cells into the bone marrow. This response occurred rapidly (within hours) and was mediated by increased responsiveness to the chemokine CXCL12. B cell localization within the marrow itself was also altered with fewer cells in the sinusoids. Redistribution occurred concurrently with remodeling of supportive microenvironments, including a shift away from an early progenitor trophic environment in favour of more mature differentiation and antibody production. This was evidenced by reduced levels of IL-7, but increased expression of BAFF, MIF, IL-5, and IL-6, as well as, higher numbers of IgM secreting cells. Further, we observed expansion of a DX5⁺Thy1⁺ cell population previously shown to promote immature B cell survival and RAG expression. We identified these cells as basophils and noted reduced lambda light chain usage of immature B cells. These results demonstrate an exquisite sensitivity of the marrow to systemic inflammation and suggest that inflammatory signaling regulates B cell fate through control of B cell-niche interactions.

NFATc1 supports imiquimod-induced skin inflammation by suppressing regulatory B cells

Muhammad, K.¹, Alrefai, H.¹, Rudolf, R.¹, Pham, D.¹, Patra, A.¹, Klein-Hessling, S.¹, Avots, A.¹, Tenzer, S.², Goebeler, M.³, Kerstan, A.³, Serfling, E.¹

¹University of Würzburg, Molecular Pathology, Würzburg, Germany, ²Johannes-Gutenberg-University, University Medical Center, Mainz, Germany, ³University Hospital Wuerzburg, Department of Dermatology, Würzburg, Germany

The epicutaneous application of aldera[®], a cream containing the TLR7 agonist imiquimod (IMQ), to mice induces skin inflammation that exhibits many aspects of human psoriasis. Mice depleted of B cells or IL-10-deficient B cells show more fulminant inflammation upon IMQ exposure indicating that IL-10 synthesized by B cells controls skin inflammation. Inactivation of NFATc1 in B cells suppresses IMQ-induced skin inflammation. Upon *in vivo* application, aldera[®] cream strongly affects the murine immune system leading to immunoglobulin heavy chain switch, to an increase in IL-10-producing B cells and

a defect in NFATc1 induction in B cells. In vitro studies also show that IMQ induces the proliferation of IL-10 producing regulatory B cells. The induction of IL-10 RNA by IMQ can be blocked by BCR signals that induce NFATc1. NFATc1 binds to HDAC1 and suppresses IL-10 expression that dampens TNF α and IL-17 production by T cells. Our data indicates a close link between NFATc1 and IL-10 expression in B cells during IMQ-mediated skin inflammation and suggest that the suppression of NFATc1 activity might be of benefit to treat human psoriasis.

Prevalence, structure and putative mechanism for large genetic insertions in VDJ recombination

Koning, M.T.¹, van Bergen, C.A.M.¹, Trollmann, I.J.M.¹, Scherer, H.U.², van Attikum, H.³, Toes, R.E.M.², Kielbasa, S.M.⁴, Tijsterman, M.³, Veelken, H.¹

¹Leiden University Medical Center, Department of Hematology, Leiden, Netherlands, ²Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands, ³Leiden University Medical Center, Department of Human Genetics, Leiden, Netherlands, ⁴Leiden University Medical Center, Department of Medical Statistics and Bioinformatics, Leiden, Netherlands

Recently, large LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against *P. falciparum* RIFIN antigens (Tan *et al.*, Nature 2016). We investigated presence, prevalence, and structure of such VDJ insertions in healthy donors.

We obtained >32,000 unique full-length VDJ sequences from 6 healthy donors by an unbiased template-switching anchored PCR and full-length single molecule PacBio NGS sequencing. Abnormally long sequences and junctions were searched for gene homologies by BLAST.

5 VDJ of the same donor, representing all sequences with a CDR3 region >150 bp, carried insertions exclusively located at VDJ junctions ($E \leq 10^{-37}$). RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were insertions in unmutated IgM. The LAIR1 exon described by Tan *et al.* and an IGHV-IGHD intergenic region were inserted in IgG. Somatic hypermutation burden correlated strongly between the insertion and the IGHV segment ($r=0.9944$; $p < 0.001$). All insertions harboured cryptic RSS sites at both termini.

Insertions represent a rare but recurrent novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive positioning in VDJ junctions, and the universal presence of cryptic RSS suggest primary VDJ recombination as the generating event. Mechanistically, these insertions appear to represent transposons that are excised by the RAG complex at tandem cryptic RSS sites and are re-inserted in *trans* in analogy to immunoglobulin signal sequences during VDJ recombination. An AID-induced templated dsDNA break repair as suggested by Tan *et al.* appears unlikely. Certain loci (e.g. LAIR1) and certain individuals seem particularly prone to such insertions.

Blimp-1 cooperates with Aiolos to regulate the survival of multiple myeloma cells through modulating the expression of apoptosis-related genes

Hung, K.-H.¹, Su, S.-T.¹, Chen, C.-Y.², Hsu, P.-H.³, Huang, S.-Y.⁴, Wu, W.-J.¹, Chen, M.-J.M.⁵, Chen, H.-Y.¹, Wu, P.-C.⁶, Lin, F.-R.¹, Tsai, M.-D.⁷, Lin, K.-I.¹

¹Academia Sinica, Genomics Research Center, Taipei, Taiwan, Republic of China, ²National Taiwan University, Department of Bio-Industrial Mechatronics Engineering, Taipei, Taiwan, Republic of China, ³National Taiwan Ocean University, Department of Life Science, Keelung, Taiwan, Republic of China, ⁴National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Republic of China, ⁵National Taiwan University and Academia Sinica, Genome and Systems Biology Degree Program, Taipei, Taiwan, Republic of China, ⁶National Taiwan University, Graduate Institute of Biomedical Electronics and Bioinformatics, Taipei, Taiwan, Republic of China, ⁷Academia Sinica, Institute of Biological Chemistry, Taipei, Taiwan, Republic of China

Transcriptional repressor Blimp-1 plays a role in the control of plasma cell differentiation, establishment of long-lived plasma cells, and maintenance of the survival of multiple myeloma (MM) through modulating gene expression. Hence, to understand the interactome of Blimp-1 and its molecular network facilitates us to realize the pathogenesis of MM. Toward this goal, we identified Aiolos, an anti-apoptotic transcription factor of MM cells, as a Blimp-1-interacting protein by mass spectrometry. To realize their mode of action, our results from ChIP-chip assay indicated that they co-bind to large number of genes, including apoptosis-related genes. Particularly, Blimp-1 and Aiolos sustain the survival of MM cells as well as normal plasma cells via binding to and suppressing the apoptosis-related genes. Previous reports showed that the new therapeutic effect of MM, lenalidomide, lies in the induction of the apoptosis of MM cells through promoting the proteasomal degradation of Aiolos. However, the relationship between Blimp-1 and the action of lenalidomide is still elusive. Here, we found that MM cells treated with lenalidomide caused ubiquitination and proteasomal degradation of Blimp-1. We also identified a new Blimp-1 direct target, *CUL4A*, a core component of multiple cullin-RING-based E3 ubiquitin-protein ligase complexes and is known to be involved in degradation of Aiolos after lenalidomide treatment in MM cells. Furthermore, the lenalidomide-induced apoptosis in MM cells was partially rescued after reintroduction of Blimp-1 or knockdown of *CUL4A*. Taken together, our study demonstrated the mechanisms by which Aiolos and Blimp-1 maintains plasma cell survival.

1150

Effect of *Mycobacterium tuberculosis* on B cell development and differentiation in BALB/C mice

Liu, W.¹, Wang, C.², Lv, Y.², Wang, T.², Wu, L.², Wu, Y.², Liu, Q.², Guo, L.², Bai, L.¹

¹Dali University, Department of Medical Immunology and Microbiology, Dali, China, ²Dali University, Department of Medical Microbiology and Immunology, Dali, China

Tuberculosis is a severe infectious disease that is harmful to human in China. Some data indicate that anti-tuberculosis immunity is mainly innate immunity and cell-mediated immunity, but recent studies have shown a protective effect of B cell responses in tuberculosis. However, it is unclear that infection of *Mycobacterium tuberculosis* (Mtb) influences B cell development and differentiation. In this project, the BALB/c mice were infected successfully with the dominant genotype of Mtb isolated from Yunnan and H37Ra by tail intravenous injection with 10^6 CFU in per mouse. The infectious models were confirmed by isolated bacteria from the lungs, livers and kidneys of infected mice. We collected the cell suspensions of the bone marrow and spleen from the infectious mice both in the early stage (4w after infected) and later period of the infection (8w after infected). Then the ratio of pro-B, pre-B, immature B, transitional B, mature B, activated B and memory B cells population were investigated by flow cytometry. The results show that Mtb infection promoted B cell maturation. The early stage B cells, including pro-B (B220⁺CD43⁺), immature B (B220⁺IgM⁺IgD⁻) and T1 B (B220⁺IgM^{hi}IgD^{low}) cells decreased and mature B (B220⁺IgM^{low}IgD^{hi}) cell increased. It also promoted B cell activation (B220⁺CD69⁺) and memory B cell (B220⁺CD27⁺) increase. The above change is the benefit to anti-tuberculosis infection. The results also show that the Mtb isolate and H37Ra are similar to the influence of B cell development and differentiation.

This work is supported by a National Science Natural Foundation of China grant (No. 81241133).

Heat shock protein 70 is critically involved in CD19+CD24hiCD27+ B cells mediated suppression of Hashimoto thyroiditis

Wang, L.¹, Zha, B.², Chu, Y.³

¹Fudan University, Shanghai, China, ²Shanghai Fifth People's Hospital, Fudan University, Department of Endocrinology and Metabolism, Shanghai, China, ³Fudan University, Department of Immunology and Biotherapy Research Center, Shanghai, China

As we previously demonstrated, CD19+CD24hiCD27+ B Cells play a suppressive role in the peripheral blood of humans, with their numbers and function altered in autoimmune thyroid disease. Herein, we further reveal the mechanisms by which CD19+CD24hiCD27+ B Cells performed suppressive function in autoimmune thyroid disease. In this study, we show that the suppressive function of CD19+CD24hiCD27+ B Cells in human peripheral blood during Hashimoto thyroiditis (HT) is impaired, and the expression of intracellular heat Shock Protein 70 (Hsp70) which is highlighted by mRNA profiling decreased in CD19+CD24hiCD27+ B Cells. Moreover In vitro studies reveal that the induction of the expression of Hsp70 in HT patients' CD19+CD24hiCD27+ B Cells restored the suppressive function of this B cell subset, in contrast, inhibition of the expression of Hsp70 in healthy individuals' CD19+CD24hiCD27+ B Cells destroyed the suppressive function of this B cell subset. Furthermore, we show that the hsp70 related suppressive function of CD19+CD24hiCD27+ B Cells was interleukin(IL)-35 dependent and that silent the expression of IL-35 also

impaired the suppressive function of CD19+CD24hiCD27+ B Cells even when the intracellular hsp70 was highly expressed. These findings reveal a possible mechanism by which human regulatory B cells play suppressive role on autoimmune diseases.

1152

Exploring the role of c-Rel amplification and splicing in lymphomagenesis

Kober, M.^{1,2}, Kumar, D.^{2,3}, Schmidt-Suprian, M.^{1,2}

¹Technical University Munich, Hematology & Oncology, Munich, Germany, ²Max Planck Institute of Biochemistry, Molecular Medicine, Munich, Germany, ³Singapore Immunology Network (SigN), A*STAR, Singapore, Singapore

Constitutive activation of NF-κB transcription factors is a hallmark of various human lymphoid cancers. The vast majority of human lymphomas arise from B cells. This bias to the B cell lineage is thought to be due to DNA breaks, which occur during class-switch recombination and somatic hypermutation in germinal center B cells.

c-Rel is the only NF-κB family member which malignantly transforms lymphoid chicken cells in culture. Remarkably, the c-Rel gene locus is amplified in a high percentage of human B cell lymphomas, such as in Hodgkin lymphoma (HL), diffuse large B cell lymphoma (DLBCL) and primary mediastinal B cell lymphoma (PMBCL) (Barth et al., 2003; Gilmore et al., 2004; Weniger et al., 2007). In addition, a novel, notably active c-Rel splice variant has been detected in diffuse large B cell lymphoma patients, which was absent in healthy individuals (Leeman et al., 2008). Despite this evidence for an eminent involvement of c-Rel in human lymphomas, the role of c-Rel during lymphomagenesis remains unclear.

We generated novel mouse models to evaluate whether conditional c-Rel overexpression and aberrant splicing contribute to B cell lymphomagenesis *in vivo*. For this purpose, we used elaborate genetic tools based on BAC *cREL* gene locus modifications. We induced overexpression of c-Rel or GFP-c-Rel specifically in B cells (CD19Cre) or germinal center B cells (Cy1Cre). Initial results obtained from these mice will be discussed.

1153

Maintenance of IgG tetanus toxoid (TT) antibodies in humans is associated with TT-specific IgG⁺, but not IgD⁺IgM⁺, memory B cells

Tjiam, M.C.¹, Perera, R.², Fernandez, S.¹, French, M.A.^{1,3}

¹The University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia, ²Health Department of Western Australia, Tuberculosis Control Program, Perth, Australia, ³Royal Perth Hospital and PathWest Laboratory Medicine, Department of Clinical Immunology, Perth, Australia

Immunoglobulin (Ig) G antibodies play a central role in vaccine-induced immunity against pathogens. Circulating IgG antibodies are secreted by plasma cells, however long-term vaccine-induced memory is retained by memory B cells, of which IgG⁺ and IgD⁺IgM⁺ are the major subsets. The contribution of these memory B cell subsets to the maintenance

of plasma IgG antibody levels in humans is unclear. We adapted a flow cytometry-based method to enumerate antigen-specific memory B cell subsets using tetanus toxoid (TT) as a model antigen. Plasma TT-specific IgG antibodies and TT-specific memory B cells were assayed in 4 healthy adults before and at weeks 1, 2, 3 and 4 after a booster vaccination with TT and in 30 adults with latent or active tuberculosis (TB) and unknown TT vaccination histories. B cells were enriched from PBMC via negative bead selection, stained with CD3-PerCP-Cy5.5, IgG-FITC, IgM-APC, CD20-APC-H7, CD27-V450, IgD-BV510 and a multimeric TT-PE probe, and assessed by flow cytometry. Plasma TT-specific IgG antibody levels were measured via ELISA. Both plasma TT-specific IgG antibody levels and TT⁺IgG⁺ memory B cell proportions increased following booster vaccination and were strongly correlated ($p=0.81$, $p<0.0001$). Proportions of TT⁺IgD⁺IgM⁺ memory B cells exhibited no change following booster vaccination. Similarly, in the adults with TB and unknown TT vaccination history, plasma TT-specific IgG antibody levels correlated with the proportions of TT⁺IgG⁺ ($p=0.70$, $p<0.0001$), but not TT⁺IgD⁺IgM⁺, memory B cells. These results suggest that TT⁺IgG⁺, but not TT⁺IgD⁺IgM⁺, memory B cells contribute to the maintenance of circulating TT-specific IgG antibody levels.

1154

IL-34-dependent differentiation of monocytic cell with B cell stimulating activity

Magari, M., Ogawa, S., Toya, Y., Hieda, K., Yamane, F., Kanayama, N., Tokumitsu, H., Ohmori, H.

Okayama University, Department of Medical Bioengineering, Okayama, Japan

Follicular dendritic cells (FDCs) play a critical role for generating high-affinity antibody in germinal center (GC). We recently found a novel class of CD11b⁺ monocytic cells named as FDMC (CXCR4⁺ CD115⁺ CD11c⁻ I-Ad), whose differentiation was dependent on CSF-1R signaling triggered by IL-34 produced from FDC line, FL-Y (*J. Leukoc. Biol.* 2014). IL-34 is a recently identified cytokine, which share a common receptor, colony stimulating factor (CSF)-1 receptor, with CSF-1. FDMC was induced from c-kit⁺ CD11b⁻ splenocytes. Herein, we examined the specific action of IL-34 underlying FDMC differentiation and immunological functions of FDMC for activating B cells. 1) The number of FDMC induced on a strep tagged-IL-34 transduced FL-Y was significantly increased, compared with that on an original FL-Y line. However, conditioned medium from FL-Y cells could not reproduce FDMC induction activity of FL-Y cells. In accordance, FDMC could not be induced when precursor cells were separated from FL-Y line with transwell membrane. These results suggest that membrane-bound molecule on FL-Y is involved in FDMC induction activity of FL-Y, and may modulate CSF-1R signaling. 2) FDMC strongly promoted the cell division and the expression of GC-associated markers (GL7, Fas) of anti-CD40-stimulated B cells *in vitro*. FDMC also induced somatic hypermutation at Ig gene in cultured B cells stimulated with anti-CD40 mAb. The frequency of SHM was significantly increased by the addition of anti-IgM plus IL-4/IL-21 *in vitro*. In the condition, proportion of annexin V⁺ B cells was significantly increased, suggesting that FDMC might regulate the differentiation of GC-phenotype B cells.

1155

Mcl-1 is critical for Lyn deficient plasma cells despite altered signalling pathways

Low, M.^{1,2}, Tarlinton, D.^{1,3}, Infantino, S.^{1,3}

¹Walter and Eliza Hall Institute of Medical Research, Immunology, Parkville, Australia, ²Monash Health, Department of Clinical Haematology, Clayton, Australia, ³Monash University, Department of Immunology, Prahran, Australia

Plasma cells (PC) are the effector cells for the humoral immune system producing antibodies with the aim of eliminating foreign pathogens. Despite the importance of PC, relatively little is known about the signalling pathways that control PC function and survival. Lyn, a member of the Src family kinases is known to play a role in PC signalling with an absence of Lyn leading to splenic plasmacytosis and a disease phenotype similar to human systemic lupus erythematosus. In PC, Lyn has a predominant role in negative signalling with an absence of Lyn leading to increased phosphorylation STAT3 and STAT5 from IL6 and IL3 respectively. We have compared Lyn deficient versus Lyn intact PC and have identified differing gene expression profiles by both RNA and protein levels. Some of these genes have roles in PC that are incompletely understood and include CD200, Ly6C & CD272 with functional analysis ongoing. Analysis of Lyn deleted PC revealed no difference in Mcl-1 protein levels, a key regulator of PC survival. Additionally, deletion of Mcl-1 in Lyn deficient mice leads to a loss of PC in spleen and bone marrow similar to wild type animals. These results show that Mcl-1 is still a critical survival molecule in Lyn deficient PC suggesting that the splenic plasmacytosis in Lyn deficiency is due to, as yet, undefined pathways. Characterisation of these pathways using our identified list of genes could lead to improved understanding of PC survival pathways and lead to novel therapies for diseases modulated by PC.

1156

B cell-intrinsic role of DOCK2 in T cell-dependent humoral immunity

Ushijima, M., Fukui, Y.

Kyushu University, Division of Immunogenetics, Medical Institute of Bioregulation, Fukuoka, Japan

The small GTPase Rac has been implicated in various cellular functions by acting downstream of multiple receptors including B cell receptor (BCR). However, its role in humoral immunity and the upstream regulator are poorly understood. DOCK2 is an atypical Rac activator predominantly expressed in hematopoietic cells. We found that DOCK2 is essential for BCR-mediated Rac activation and critically regulates immunological synapse formation. This finding led us to examine B cell-intrinsic role of DOCK2 in humoral immunity. For this purpose, we took two distinct approaches: one is adoptive transfer of B cells expressing antigen-specific BCR in a class-switchable manner, and the other is conditional KO mice lacking DOCK2 expression in B-cell specific manner. By analyzing adoptively transferred B cells and conditional KO mice, we show here that DOCK2-Rac axis plays a key role in antigen-specific IgG responses.

1157**Involvement of CD40 on immune cells in response to immune complexes**

Atsumi, K., Matsushima, M., Ogiso, H., Ochi, H., Kusatsugu, Y., Oyabu, S., Ogasawara, N., Takemura, K., Kawabe, T.
Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan

Immune complex (IC), which is antibody-forming complex with its specific antigen, can cause immune responses by providing feedback. The immune responses against ICs by marginal zone B cells (MZBs), follicular dendritic cells (FDCs), and follicular B cells (FOBs) are seemed to be T cell-independent responses since GC formation and antibody production were induced in athymic nude mice by injection of ICs. CD40 is necessary for the generation of antibody responses to T cell-dependent antigens as well as for the development of GCs through the interaction with CD154 (CD40 ligand) on T cells. However, it is unclear whether immune responses against ICs are mediated by CD40-dependent mechanisms. In this study, we investigated the role of CD40 on immune responses against ICs, especially focused on the function of MZBs, FDCs, and FOBs.

CD40KO mice were not able to produce OVA-specific IgM and IgG as well as GC formation and B cell proliferation after IC immunization. IC localization in MZ and on FDCs after IC immunization were not affected even in the absence of CD40. However, the induction of FcγRIIB and VCAM-1 expression on FDCs were impaired in CD40KO mice after immunization with ICs even though ICs were trapped on FDCs. Although the expression of ICAM-1 seemed to be slightly increased by ICs in CD40KO mice, however, the extent of induction was quite low compared to that of WT mice.

These results suggested that CD40 would be important for activation of FDCs, but not for IC transporting, to provoke immune responses against ICs.

1158**Involvement of CD40 in the expression of Bcl6**

Ochi, H., Matsushima, M., Koderu, Y., Kusatsugu, Y., Atsumi, K., Oyabu, S., Ogasawara, N., Takemura, K., Kawabe, T.
Nagoya University Graduate School of Medicine, Department of Pathophysiological Laboratory Sciences, Nagoya, Japan

In immune response against T-dependent antigens, B cells are activated by the interaction with a cognate T cell and form germinal centers (GCs). Within GCs, B cells expressing high affinity antibodies are selected by the interaction with follicular dendritic cells and follicular helper T (Tfh) cells. Bcl6 is a transcriptional repressor required for GC formation. The expression of Bcl6 is restricted to the GC stage in mature B cells by transcriptional and posttranscriptional regulation. Moreover, Bcl6 expression in

T cells drives the formation of Tfh cells. CD40 is a molecule that belongs to the tumor necrosis factor-receptor family, and the engagement of CD40 and CD40 ligand plays an important role in T-dependent antibody responses. Our previous study reported that CD40 knock-out (KO) mice failed to form GCs by T-dependent antigens. In this study, we investigated the role

of CD40 on the expression of Bcl6 in GC-related lymphocytes, especially GC B cells and Tfh cells.

WT and CD40KO mice were immunized with 2×10^9 SRBC, and spleens were removed 3 or 6 days after immunization. We analyzed the expression of Bcl6 in B cells (B220⁺) and Tfh cells (CD4⁺CXCR5⁺PD-1⁺).

Although the expression levels of *Bcl6* mRNA in CD40KO B cells were comparable to WT B cells, the expression levels of Bcl6 protein was quite low in CD40KO mice. Moreover, Bcl6^{hi} cells in CD4⁺CXCR5⁺PD-1⁺ T cells were severely reduced in CD40KO mice. These results suggested that CD40 might contribute to the expression of Bcl6 in both B cells and Tfh cells.

1159**A new role for VpreB: an invariant surrogate antigen that selects Ig antigen binding sites**

Khass, M.¹, Blackburn, T.², Burrows, P.², Walter, M.², Capriotti, E.³, Schroeder, H.⁴

¹University of Alabama at Birmingham, Clinical Immunology and Rheumatology, Birmingham, United States, ²University of Alabama at Birmingham, Microbiology, Birmingham, United States, ³University of Düsseldorf, Department of Biology, Düsseldorf, Germany, ⁴University of Alabama at Birmingham, Medicine, Birmingham, United States

The preB cell receptor (preBCR) is formed by binding of VpreB and λ5 to μ heavy chain (μHC) and selects for μHCs ultimately capable of binding to conventional light chains. VpreB and λ5 also create a CDR-H3 sensing site that interacts with HC antigen binding sites. We examined preB cells from mice with altered CDR-H3 amino acid content. Reducing incorporation of tyrosine into CDR-H3 impaired preB cell development. Furthermore, Y101 and Y102 were enriched in living, but not apoptotic, preB cells. Both tyrosines interact extensively with the VpreB component of the CDR-H3 sensing site, yet also contact antigen in several antibody-antigen complexes. The VpreB CDR-H3 sensing site can thus select for specific CDR-H3 amino acids, potentially shaping the antigen specificity of the primary humoral response.

1160**SRSF1-3 has a role in nuclear localization of AID by regulating its nuclear export**

Kanayama, N., Kawaguchi, Y., Kawamoto, N., Nariki, H., Miyazaki, S., Yokoyama, K., Magari, M., Ohmori, H., Tokumitsu, H.
Okayama University Graduate School of Science and Technology, Department of Medical Bioengineering, Okayama, Japan

Activation induced cytidine deaminase (AID) is an essential factor for somatic hypermutation (SHM) and class switch recombination (CSR) on the immunoglobulin gene. We previously found that serine/arginine-rich protein splicing factor 1-3 (SRSF1-3) is an important factor in for SHM mechanism by using a chicken B cell line DT40, in which SHM occurs spontaneously⁽¹⁾. Here, we examined whether SRSF1-3 contributes to regulating subcellular localization of AID, by confocal microscopic analyses using AID-GFP and mCherry-SRSF1-3 fusion proteins. When AID-GFP was expressed in NIH3T3 cells, AID was observed predominantly in the cytoplasm. However, co-expression

of AID-GFP with mCherry-SRSF1-3 altered this predominant cytoplasmic localization into accumulation in the nucleus. Although C-terminus-truncated SRSF1-3 mutants showed various subcellular localizations, AID was colocalized with SRSF1-3 mutants. Thus, SRSF1-3 might be accompanied with AID in subcellular localization processes. In addition, whereas expression of a C-terminal nuclear export signal-deleted AID enhanced SHM in DT40 cells likely due to increased nuclear localization of the truncated AID, over-expression of SRSF1-3 with the mutant AID did not show any additional increase of SHM. On the other hand, when DT40 cells were treated with a proteasome inhibitor and a nuclear export inhibitor, AID could be observed in the nucleus both in the absence and presence of SRSF1-3, indicating that nuclear import of AID is intact in the SRSF1-3-deficient cells. Taken together, these results suggest that SRSF1-3 promotes nuclear localization of AID by regulating nuclear export of AID.

TLR9-mediated B cells activation leads to production of brain-derived neurotrophic factor: possible neuroprotective role of B cells following infection

Lou, C.¹, Xu, J.-M.², Zhou, X.-F.¹, Hurtado, P.R.³

¹University of South Australia, School of Pharmacy and Medical Sciences, Adelaide, Australia, ²The Second Xiang-Ya Hospital of Central South University, Department of Anesthesiology, Changsh, China, ³Royal Adelaide Hospital, Renal Medicine, Adelaide, Australia

B cells constitutively express Toll-like receptor 9 (TLR-9), this receptors allows B cells to detect the presence of bacteria infection by recognizing unmethylated CpG sequences in bacteria-derived DNA. The engagement of TLR9 elicits strong activation signals, resulting in B cell proliferation and differentiation into plasma cells as well as the production of cytokines responsible for recruitment and activation of other immune cells and inflammation. Therefore, it would be expected that TLR9 activation should be associated with exacerbation of inflammatory neurodegenerative diseases such as multiple sclerosis, however, several studies has shown that TLR9 activation ameliorate disease progression. Our studies have shown that following TLR9 activation, B cells also produce brain-derived neurotrophic factor (BDNF), in a time and dose dependent manner. This effect only is observed with CpGB but not CpGA. BDNF is a neurotrophic factor best known for its ability to support neuron survival and to promote nerve regeneration. BDNF exerts its function by binding to Tropomyosin receptor kinase B (TrkB). Here, we propose that TLR9 activation of B cells during infections leads to the production of BDNF providing a neuroprotective safeguard against nerve damage that may result from the infection itself or the inflammatory immune response. Consequently, dysfunctions in B cells to produce, process or release BDNF following TLR9 signalling could contribute to the development and progression of neurodegenerative diseases.

The role of NFκB1 in B cell homeostasis and function

Cornish, J.^{1,2}, de Valle, E.^{1,2}, Banerjee, A.³, Grigoriadis, G.³, Ramslund, P.^{2,4}, Gugasyan, R.^{1,2}

¹Monash University Central Clinical School, Immunology, Melbourne, Australia, ²Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, ³Hudson Institute of Medical Research, Centre for Cancer Research, Melbourne, Australia, ⁴School of Science, RMIT University, Bundoora, Australia

NFκB1 (p50/p105) is a member of the NFκB family of transcription factors. Signalling through this pathway regulates numerous target genes, controlling cell survival, proliferation and inflammation. Polymorphisms in the human *Nfkb1* gene are associated with the development of autoimmune disease and haematopoietic malignancies. In a murine model, deletion of *Nfkb1* gives rise to an autoimmune disease in ageing mice, characterised by increased immunoglobulins, pathogenic auto-antibodies and a multi-organ immune cell infiltrate. Our analysis of peripheral B cells in both young and ageing *Nfkb1*^{-/-} mice revealed an increased number of follicular and germinal centre B cells, which coincided with the enhanced differentiation of follicular helper T cells. To our surprise, the *Nfkb1*^{-/-} GC B cells were phenotypically different and failed to form distinct GC structures in the spleen. However, the analysis of BM chimeric mice that consisted of an equal mix of wild-type and *Nfkb1*^{-/-} haematopoietic cells revealed distinct GC structures, suggesting that wild-type immune cells contribute to the formation of GC structures. Furthermore, the analysis of ageing *Nfkb1*^{-/-} mice revealed a striking overexpansion of plasma cells. This suggests that the absence of NFκB1 leads to altered terminal B cell differentiation. Collectively, these findings suggest that NFκB1 prevents the development of autoimmune disease in part by controlling peripheral B cell homeostasis and differentiation.

Early IL-4-producing B cells regulate T helper cell dichotomy during cutaneous Leishmaniasis in BALB/c mice

Hurdajal, R., Revaz-Breton, M., Parihar, S.P., Govender, M., Brombacher, F.

International Centre for Genetic Engineering & Biotechnology, Cape Town Component and Institute of Infectious Diseases & Molecular Medicine, University of Cape Town, Immunology, Cape Town, South Africa

Immunity to the protozoan parasite *Leishmania major* is dependent on a polarised T helper 1 response whilst interleukin 4 receptor alpha (IL-4Rα)-driven Th2 immunity renders susceptibility to this parasite in BALB/c mice. B cells have also been implicated in disease progression but it is unclear if IL-4Rα-responsive B cells play a significant role. Here we investigated a role for IL-4Rα-responsive B cells in host immunity to cutaneous leishmaniasis. We used a novel BALB/c mouse lacking IL-4Rα expression on B cells (*mb1^{cre}IL-4Rα^{-lox}*), generated by gene targeting and site-specific recombination using the *cre/loxP* system under control of the *mb1* locus. Following subcutaneous infection in the footpad with *L. major* parasites, *mb1^{cre}IL-4Rα^{-lox}* BALB/c mice efficiently controlled cutaneous disease as shown

by significantly reduced footpad swelling and parasite burdens due to a shift to a protective CD4⁺ Th1 and type 1 immune response. In addition, IL-4R α -deficient B cells from resistant *mb1^{cre}IL-4R α ^{-lox}* BALB/c mice transcribed *ifn- γ* as early as day 1 after infection whilst transcription of *il-4* was barely induced in comparison to IL-4R α -responsive B cells from littermate control IL-4R α ^{-lox} BALB/c mice. Lastly, B cell-deficient (μ MT BALB/c) mice only slightly ameliorated fulminant cutaneous disease in comparison to *mb1^{cre}IL-4R α ^{-lox}* BALB/c mice during acute LV39 infection. Altogether our data indicate that while IL-4R α -unresponsive B cells are beneficial in cutaneous leishmaniasis and lead to host protective Th1 immunity in *mb1^{cre}IL-4R α ^{-lox}* BALB/c mice, early IL-4R α -responsive B cells producing IL-4 influence early T helper dichotomy towards detrimental Th2 responses, which leads to *L. major*-induced cutaneous leishmaniasis in BALB/c mice.

1164

Human memory B cells in clinically healthy gingiva

Mahanonda, R., Sa-Ard-Iam, N., Rerkyen, P., Subbalekha, K., Champaiboon, C.
Chulalongkorn University, Bangkok, Thailand

Large infiltrations of B cells, specifically plasma cells are the hallmark of periodontitis lesions. The role of the B cell response in periodontal health or disease has not been thoroughly studied. In this study, different B cell subsets were identified in human clinically healthy gingiva, gingivitis and periodontitis tissues. Flow cytometry analysis of gingival tissues showed very few CD19⁺CD27⁻CD38⁻ naïve B cells in all clinical groups. CD19⁺CD27⁺CD38⁻ memory B cells represented the majority in the B cell population in clinically healthy gingiva and gingivitis tissues, whereas CD19⁺CD27⁺CD38⁺ antibody secreting cells (ASCs) were the majority in periodontitis tissues. Unlike in gingival tissues, there were no differences in peripheral blood B cell subsets between the healthy or diseased stages. Peripheral blood-naïve B cells represented the majority followed by memory B cells and very few ASCs. Very little is known about memory B cells residing in human non-lymphoid tissues. The anatomical location of this specific population in histological sections was investigated. A cluster of memory B cells in clinically healthy gingiva was detected in the connective tissue subjacent to the apical region of the junctional epithelium. In this vicinity, blood vessels expressed peripheral node addressin (PNAd⁺) and ICAM-1⁺, which may be responsible for recruitment and an appropriate niche for memory B cells. Upon polyclonal B cell activation with TLR7/8 (R848) and IL-2, these healthy gingival tissue-memory B cells were functional and able to be differentiated *in vitro* into ASCs. This suggested a role of memory B cells in maintaining periodontal homeostasis.

B lymphocyte single nucleotide polymorphisms and exomes in transient receptor potential ion channel and acetylcholine receptors in chronic fatigue syndrome

Johnston, S.¹, Marshall-Gradisnik, S.^{1,2}, Chacko, A.^{1,2}, Nguyen, T.^{1,2}, Smith, P.¹, Staines, D.¹

¹Menzies Health Institute Queensland, National Centre for

Neuroimmunology and Emerging Diseases, Parklands, Australia,
²Griffith University, School of Medical Science, Parklands, Australia

Background: Given the important roles in calcium (Ca²⁺) and acetylcholine (ACh) signaling in B cell activation and potential antibody development, the aim was to identify key SNPs and their genotypes from isolated B cells in Chronic Fatigue Syndrome (CFS).

Methods: 11 CFS patients (aged=31.82± 5.50years) defined according to the Fukuda criteria and 11 non-fatigued controls (aged=33.91±5.06 years) were included. Flow cytometric protocols were used to determine B cell purity, followed by SNP and genotype analysis from 21 TRP ion channel genes and 9 ACh receptor genes examined by iPLEX Gold assay. Exome analysis was conducted using Illumina HiSeq platform and SNP association and genotype was determined using ANOVA and PLINK analysis.

Results: Seventy-eight SNPs were associated with nicotinic and muscarinic ACh receptors in the CFS group: 35 were mAChM3, the remaining were nAChR delta, nAChR alpha 9, TRPV2, TRPM3, TRPM4, mAChRM2 and mAChRM5. Nine genotypes were identified from SNPs that were significant for TRPM3, TRPC6, mAChRM3, nAChR α 4 and nAChR β 1 located in intron and 3'untranslated regions in CFS compared with non-fatigued controls (OR 7.11-26.67). Two missense SNPs located on exome 1 for the subunit TRPP, and a synonymous SNP for TRPC3 were also significantly associated with CFS compared with non-fatigued controls.

Conclusions: We identified a number of SNPs and genotypes for TRP ion channels and AChRs from B cells in patients with CFS that may be involved in changes in B cell function and suggest a role for dysregulation of Ca²⁺ in the pathomechanism of CFS.

1166

A critical role for NK cells in exosome-induced CD8⁺ T cell cytotoxicity

Saunderson, S.C., McLellan, A.D.

University of Otago, Department of Microbiology & Immunology, Dunedin, New Zealand

We have previously shown that T cell help via CD40 and the IL-4 receptor induces exosome release from human and mouse B cells. Exosomes are lipid-bound vesicles derived from the endosomal pathway that play a role in cellular communication and immune function. Exosomes act as endogenous adjuvants to enhance T cell proliferative and endogenous cytotoxic lymphocyte (CTL) responses to exosome-associated antigens. However, the mechanisms of exosome-induced immunity are poorly understood. Intravenous immunisation of mice with ovalbumin incorporated into the exosome pathway resulted in significantly greater CTL responses, as compared to molar equivalents of soluble or latex bead-bound ovalbumin. Exosome immunisation greatly increased splenic cellularity, including ovalbumin-specific B cells. Antibody-mediated cell depletions showed that exosome-induced cytotoxicity was absolutely dependent on CD4⁺ T cells, CD8⁺ T cells and NK cells; the loss of any one of these subsets led to a complete loss of CTL activity. Furthermore, this NK cell involvement was independent

of IFN γ and perforin expression. Despite the high level of exosome capture within the marginal zone, and the known ability of MZ B cells to shuttle antigens into the white pulp, B cells were dispensable for exosome-induced cytotoxicity. While there was no clear role for B cells in exosome-induced cytotoxicity, preliminary data suggested a role for circulating immunoglobulin, which may implicate NK cell-expressed Fc and/or C3 receptors in the response to exosomes. We are currently utilising D(H)LMP2A mice that lack immunoglobulin, but retain B cells, to further investigate the role of circulating immunoglobulin in exosome-induced immune responses.

1167

CD28 regulates long lived plasma cell (LLPC) survival through Indoleamine 2,3-dioxygenase (IDO) mediated induction of autophagy in LLPCs

Maharaj, S., Nair, J., Utley, A., Carlson, L., Lee, K.

Roswell Park Cancer Institute, Immunology, Buffalo, United States

Long lived plasma cells (LLPCs) are essential for sustained antibody responses and protective humoral immunity. How these cells maintain longevity and a durable antibody response is largely dependent on the complex nature of the bone marrow microenvironment, in which they reside, and the pro survival factors produced in this niche. It has been published that CD28 signaling and autophagy are required for long lived plasma cell survival. Therefore we wanted to know if CD28 induces autophagy, which could contribute to LLPCs competitiveness within the bone marrow microenvironment. We have observed that there is no direct effect of CD28 signaling intrinsically on autophagy, however we have published that Indoleamine 2,3-dioxygenase (IDO) - which depletes tryptophan - is produced as a result of back signaling from CD28:CD80/86 interactions between plasma cells and bone marrow myeloid derived DCs. IDO is classically known to contribute to an immunosuppressive environment (specifically with respect to T cell activity). Paradoxically, we found that there are fewer LLPCs present in IDO KO mice in comparison to wild type mice. This leads us to a model where CD28, through back signaling to CD80/86 induces IDO production which leads to depletion of tryptophan, an essential amino acid, and this depletion then causes induction of autophagy a mechanism LLPCs use to compete and survive within the bone marrow microenvironment.

1168

Human B-1 and B-2 cells come from a Lin-CD34+CD38^{lo} progenitor population

Quach, T.D., Hopkins, T.J., Holodick, N.E., Rothstein, T.L.

Feinstein Institute for Medical Research, Manhasset, United States

B-1 cell population is an important bridge between innate and adaptive immunity owing in part to their natural antibody production. Murine B-1 and B-2 cells derive from two distinct progenitors. However, the origin of human B-1 and B-2 cells is unknown. To characterize the potential progenitors that delineate differentiation of human B-1 and B-2 cells, we separated cord blood (CB) and bone marrow Lin-CD34+

hematopoietic stem cells (HSC) into Lin-CD34+CD38^{lo} and Lin-CD34+CD38^{hi} populations. We found that only CD34+CD38^{lo} cells generate human CD19+ B cell engraftment after being transferred into immuno-deficient NOD.Cg-Prkdc^{scid} Il2rg^{tm1wjl}/SxJ neonates. Importantly, engrafted CD19+ B cells found in the spleen, bone marrow and peritoneal cavity of humanized mice display phenotypes of B-1 and B-2 cell subsets. Developmental marker analyses of engrafted splenic B-1 cells reveal that B-1 cells have a mature phenotype as evidenced by low-to-intermediate CD24 and CD38 expression levels. Repertoire analysis of engrafted B-1 cells shows a similar VDJ composition to fresh CB B-1 cells, including high usage of Vh4-34 sequences (8% versus 10%, respectively). Furthermore, in patients with hematologic malignancies undergoing HSC transplantation, human B-1-phenotype cells are found in the circulation as early as 8 weeks post-transplantation (and/or as soon as 5 CD19+ B cells are detected). Altogether, our data suggest that unlike mouse B-1 cells, human B-1 and B-2 cells come from the same HSC progenitor cell population, and more precisely from the Lin-CD34+CD38^{lo} cell population, and engrafted B-1 cells in humanized mice are comparable to native B-1 cells in term of Vh usage.

1169

B cells have a key role in aggravated atherosclerosis following myocardial infarction

Kyaw, T.^{1,2}, Loverland, P.¹, Kanellaki, P.¹, Cao, A.¹, Deswaerte, V.¹, Tipping, P.², Toh, B.-H.², Bobik, A.^{1,3}

¹*Baker IDI Heart and Diabetes Institute, Melbourne, Australia,*

²*Faculty of Medicine, Nursing and Health Sciences, Monash University, Centre for Inflammatory Diseases, Department of Medicine, Southern Clinical School, Melbourne, Australia,* ³*Faculty of Medicine, Nursing and Health Sciences, Monash University, Department of Immunology, Central Clinical School,, Melbourne, Australia*

The risk of re-infarction and death following Myocardial infarction (MI) is markedly increased in hyperlipidemic and atherosclerotic patients treated with conventional therapies. Recent mouse studies have shown that MI aggravates atherosclerosis and that B cells are activated following MI; but their role in post-MI aggravated atherosclerosis is unknown.

We found that that MI resulted in a 37% increase in aortic atherosclerosis, compared to sham-operated mice, confirming that MI aggravates atherosclerosis. Increased lesion B cells by 130% in MI-aggravated atherosclerosis suggest a possible role for atherogenic B cells in MI-aggravated atherosclerosis. B cell depletion in MI mice decreased atherosclerosis lesion size by 55% without affecting the extent of MI or cardiac function, compared to MI mice without B cell depletion. The reduced atherosclerosis was accompanied by decreased lipid and immune cell accumulation and reduced VCAM-1 and MCP-1 in atherosclerotic lesions. Serum IgG antibodies specific to oxidised lipid were reduced. A trend of decreased inflammatory TNF- α , IL-1 β and IL-6 mRNA levels was observed.

We then transferred B cells isolated from MI mice into high fat diet-fed mice and found that B cells from MI mice increased lesion size by 48% compared to vehicle control; in contrast, non-

MI B cells failed to increase atherosclerosis.

We conclude that, B cells are highly atherogenic following MI and contribute to accelerated progression of existing atherosclerosis. Our findings suggest B cell depletion in patients with MI as a potential therapeutic strategy to reduce the risk of re-infarction, especially within the first year following the acute event.

1170

Contact hypersensitivity enhanced in mice with B cell-specific-peroxisome proliferator-activated receptor-gamma deficiency

Wang, K.¹, Su, J.¹, Zhou, X.², Zeng, X.¹, Tao, L.¹, Bai, X.², Li, X.¹

¹School of Pharmaceutical Sciences, Southern Medical University, Guangzhou, China, ²School of Basic Medical Sciences, Southern Medical University, Guangzhou, China

Peroxisome proliferator-activated receptor γ (PPAR- γ) is a member of the nuclear hormone receptor superfamily that plays important roles not only in lipid metabolism but also in dampening inflammation by inhibiting pro-inflammatory cytokine production by dendritic cells and T cells. Recently we observed that mice with B cell-specific PPAR- γ -deficiency exhibited increased oxazolone-induced ear swelling, suggesting that the regulatory functions of B cells are dampened. The peripheral CD4⁺CD25⁺Foxp3⁺ regulatory T cell number and CD19⁺CD5⁺CD1d^{hi} regulatory B cell number were not obviously changed in this mice. While the IL-10 producing in splenic CD5⁺CD1d^{hi} regulatory B cells was reduced after activation. At the same time, deficiency of PPAR- γ didn't affect the CD86 expression in splenic CD5⁺CD1d^{hi} regulatory B cells after activation. These suggested the possible role of PPAR- γ involved in the inhibitory function of B cells by disturbing the activation of regulatory B cells.

1171

High-affinity IgM⁺ memory B cells are deficient in terminal differentiation potential to secrete IgM antibodies by restimulation with (4-hydroxy-3-nitrophenyl) acetyl-chicken γ -globulin

Tashiro, Y.^{1,2}, Murakami, A.³, Shimizu, T.⁴, Goitsuka, R.¹, Kishimoto, H.³, Azuma, T.²

¹Research Institute for Biomedical Sciences, Tokyo Univ of Science, Division of Development and Aging, Noda, Chiba, Japan,

²Antibody Technology Research Center, Co., Ltd., Noda, Chiba, Japan, ³University of Ryukyus, Department of Parasitology & Immunopathoetiology, Okinawa, Japan, ⁴Kochi Medical School, Department of Immunology, Kochi, Japan

IgM antibodies are thought to be secreted only by plasma cells differentiated from naive B cells but not by those generated from memory B cells throughout immune response. We found that high-affinity IgM⁺ memory B cells (MBCs) possessing somatic hypermutation (SHM⁺) are generated through germinal center (GC)-dependent pathway (GC-MBCs) in addition to SHM⁻ MBCs generated through GC-independent (non-GC) pathway (non-GC-MBCs). However, the V_H nucleotide

sequences of cells secreting anti-(4-hydroxy-3-nitrophenyl) acetyl (NP) IgM antibodies after secondary immunization had few SHMs, indicating that only non-GC-MBCs have the terminal differentiation potential, although GC-MBCs are maintained throughout immune response. Secondary IgM antibodies bound to several NP analogues, implying that IgM antibodies with broad cross reactivity might be selected at the stage of memory response to deal with reexposure of antigens with a wide range of structures similar to but changed from an original one.

1172

Plasma cell differentiation driven by antigen-independent signaling activity of the IgE B cell receptor

Yang, Z., Allen, C.D.C.

University of California, San Francisco (UCSF), Cardiovascular Research Institute, Department of Anatomy, and Sandler Asthma Basic Research Center, San Francisco, United States

Antigen-engaged B cells may undergo terminal differentiation into plasma cells (PC), the professional antibody-secreting cells, following activation by several extrinsic signals. However, the role of the isotype of the B cell receptor (BCR) in this process is unclear. It was previously reported that B cells expressing IgE, compared with IgG1, showed an increased propensity to differentiate into PCs. We sought to determine whether the BCR isotype has an intrinsic effect on PC differentiation. By ectopic expression of BCRs of different isotypes in primary B cells *in vitro*, we revealed that particular isotypes promoted PC differentiation to distinct extent in the absence of cognate antigen, whereas most isotypes mediated similar levels of PC differentiation in the presence of cognate antigen. B cells expressing IgE exhibited the highest propensity of PC differentiation in the absence of cognate antigen, correlating with *in vivo* observations of IgE⁺ B cells. The frequency of IgE⁺ PCs was reduced when B cells were treated with inhibitors of BCR signaling in the absence of antigen, further suggesting that the IgE BCR has antigen-independent signaling activity that can drive PC differentiation. By domain-swap experiments, we have determined contributions of different IgE domains in driving PC differentiation. In summary, we have identified that the IgE BCR drives antigen-independent PC differentiation, suggesting that the BCR isotype modulates cell fate in an intrinsic manner. Our study may allow a better understanding of the biology of IgE⁺ B cells and the BCR signals mediating PC differentiation.

Increased recruitment of human lymphocyte subsets in renal fibrosis and chronic kidney disease

Kassianos, A.^{1,2,3,4}, Lo, B.^{1,2,3}, Lindner, M.^{1,2,4}, Wang, X.^{1,2}, Beagley, K.³, Wilkinson, R.^{1,2,3,4}, Healy, H.^{1,2}

¹Pathology Queensland, Brisbane, Australia, ²Royal Brisbane and Women's Hospital, Brisbane, Australia, ³Queensland University of Technology, Brisbane, Australia, ⁴University of Queensland, Brisbane, Australia

Lymphocytes play pivotal roles in immune-mediated kidney diseases. However, the respective contributions of different lymphocyte subsets in diseased human kidneys are not certain, with previous studies limited by the methodology of immunohistochemistry in identifying infiltrating cells. In this study, we developed novel protocols for extracting renal lymphocytes from healthy kidney tissue and diseased biopsies with and without fibrosis. Lymphocyte subsets were identified, enumerated and phenotyped by twelve-colour flow cytometry. We detected significantly elevated numbers of total T cells (CD45⁺CD3⁺), consisting of increased T helper cells (CD3⁺CD4⁺), cytotoxic T cells (CD3⁺CD8⁺), γ/δ T cells (CD3⁺ γ/δ ⁺) and natural killer (NK)-T cells (CD3⁺CD19⁺), in diseased biopsies with interstitial fibrosis compared with diseased biopsies without fibrosis and healthy kidney tissue. Of CD3⁺ lymphoid cells, numbers of B cells (CD3⁺CD19⁺) and NK cells (CD3⁺CD56⁺), in particular CD56^{bright} NK cells, the major cytokine-producing NK subtype in human peripheral tissues, were also significantly elevated in fibrotic kidney tissue. The increased numbers of γ/δ T cells, NK-T and CD56^{bright} NK cells correlated significantly with loss of kidney function (based on eGFR levels). Furthermore, the expression of activation molecule CD69 on CD56^{bright} NK cells was significantly increased in fibrotic biopsies compared with non-fibrotic kidney tissue, indicative of a pathogenic phenotype. Collectively, our data show that lymphocyte subsets are differentially recruited into diseased human kidneys. The representation of specific lymphocyte subsets also correlates with the clinical severity of chronic kidney disease. Further identification and functional dissection of these lymphocyte subsets are necessary for the development of targeted anti-inflammatory treatment strategies.

1174

The atypical chemokine receptor ACKR4 regulates dermal chemokine bioavailability and dendritic cell egress

Bastow, C.¹, Bunting, M.², Kara, E.¹, McColl, S.¹, Comerford, I.¹

¹University of Adelaide, Molecular and Cellular Biology, Adelaide, Australia, ²Queensland Institute of Medical Research, Brisbane, Australia

Directional migration of cells toward chemokine gradients underpins a multitude of processes required for the initiation, differentiation and effector phases of adaptive immune responses. In skin, a rising gradient of immobilized CCL21 produced by lymphatic endothelial cells guides CCR7-dependent haptotaxis of mature dendritic cells into afferent lymphatic vessels, facilitating the priming of immune responses in draining lymph nodes. This CCL21 gradient must be intact to permit efficient dendritic cell homing, however the molecular mechanisms that maintain chemokine gradients *in vivo* are not well understood. Whilst it is widely thought that immobilized chemokine gradients are established and controlled by chemokine diffusion and distribution of chemokine binding sites, here we identify a novel role for the atypical chemokine receptor 4 (ACKR4) in maintaining the abundance of interstitial CCR7 ligands: CCL19 and CCL21. ACKR4-deficient mice displayed a greater abundance of dermal CCL19 and CCL21 that

was dependent on radio-resistant ACKR4 expression. Within the skin, ACKR4 mRNA and scavenging function was limited to dermal fibroblasts. Ligand hyperabundance in the absence of ACKR4 impeded CCR7-dependent homing of mature dendritic cells to lymphatic vessels, resulting in dendritic cell retention in the skin. These findings identify a novel mechanism that regulates immobilized chemokine availability in peripheral sites, consistent with the ligand scavenging role of atypical chemokine receptors, and emphasises the physiological importance of chemokine sequestration by ACKR4.

1175

Effector T helper cell recruitment to inflammatory sites via CCR2

Gregor, C., Kara, E., Comerford, I., McColl, S.

University of Adelaide, Department of Molecular and Cellular Biology, Adelaide, Australia

Migration of CD4⁺ T helper (Th) cells to extralymphoid sites of inflammation is pivotal for execution of their effector function. Differentiation of distinct Th cell subsets is coupled with induction of subset-specific and tissue-tropic chemokine receptors that drive their recruitment into diverse inflammatory lesions. However, increasing evidence indicates that trafficking of Th cell subsets to inflammatory sites can occur independently of subset-specific chemokine receptors. Thus, coordinated migration is likely to involve multiple integrated receptor inputs that are spatiotemporally regulated, but knowledge of this complexity in migration is limited. Recently, we demonstrated that homing of IL-23-driven pathogenic Th17 cells to the central nervous system was coordinated through the chemokine receptor CCR2 in experimental autoimmune encephalomyelitis, a murine model of the human autoimmune disease multiple sclerosis. Our more recent data indicates that functional CCR2 is induced on various effector Th cell subsets under disparate inflammatory settings. CCR2 ligands are not present at homeostasis, but are rapidly elicited by numerous cell types in response to pan-inflammatory stimuli including IL-1 and TNF. Here, we present evidence that CCR2 serves as a pan-inflammatory chemokine receptor driving Th cell trafficking to effector sites. Understanding how CCR2 functions in collaboration with subset-specific and tissue-tropic receptors to coordinate Th cell trafficking will inform the rational design of therapeutic strategies to intervene in this process in Th cell-driven pathology.

1176

Intravascular patrolling monocytes initiate CD4⁺ T cell-mediated inflammation in the glomerular microvasculature

Westhorpe, C.¹, Hall, P.¹, Li, A.¹, Finsterbusch, M.¹, Snelgrove, S.¹, Lo, C.², Kitching, A.R.^{1,3}, Hickey, M.¹

¹Monash University, Centre for Inflammatory Diseases, Clayton, Australia, ²Monash University, Monash Micro Imaging, Clayton, Australia, ³Monash Health, Departments of Nephrology and Paediatric Nephrology, Clayton, Australia

Autoimmune glomerulonephritis is a leading cause of end-stage renal failure. Effector CD4⁺ T cells can rapidly induce glomerular

inflammation in an antigen-dependent manner. However it is unclear how these cells recognise antigens within the glomerular microvasculature. The aim of this study was to investigate the mechanisms by which effector CD4+ T cells initiate glomerular inflammation. Intravital multiphoton microscopy of kidneys of MHCII-eGFP mice revealed that in the absence of inflammation, intraglomerular expression of MHCII was restricted to circulating leukocytes. Following transfer of activated OT-II (CD4+) T cells, both intravascular MHCII+ leukocytes and effector CD4+ T cells underwent periods of retention and migration in the glomerular capillaries and regularly interacted with each other. To induce antigen-dependent glomerular inflammation, the OT-II peptide pOVA₃₂₃₋₃₃₉ was deposited in glomeruli via conjugation to 8D1, a mAb specific for the glomerular basement membrane. Mice administered the 8D1/pOVA conjugate displayed increased retention of activated CD4+ T cells within 2 hours, indicating local antigen recognition. Of the circulating MHCII-expressing leukocytes, both B cells and monocytes underwent retention in the glomerular capillaries, although MHCII+ monocytes were retained in the glomerulus for significantly longer periods. Furthermore, while the absence of B cells did not affect CD4+ T cell-dependent inflammation, monocyte depletion significantly reduced this response. These data indicate that intravascular MHCII+ patrolling monocytes initiate CD4+ T cell responses in the glomerular microcirculation and this can result in glomerular inflammation.

1177

Investigating the role of invariant natural killer T cells in leukocyte recruitment following acute murine colitis

Shen, S.¹, Hickey, M.², Wong, C.²

¹Monash University, Medicine, Melbourne, Australia, ²Monash University, Melbourne, Australia

Inflammatory bowel disease (IBD) is a group of idiopathic, chronic, and relapsing inflammatory disease of the gut. The immunopathology of IBD involves decreased epithelial integrity, increased bacterial translocation, and elevated recruitment of neutrophils. However, it is still unknown what the precise roles of neutrophils and invariant natural killer T (iNKT) iNKT cells play in this disease. Therefore, this study aims to investigate the contributions of iNKT cells and neutrophils in a mouse model of dextran sodium sulphate (DSS)-induced colitis. Eight to ten weeks old male wildtype (WT) and *Ja18^{-/-}* were administered with 2% DSS in drinking water for a maximum of 7 days to induce acute colitis. Body weight, clinical and histopathological scores were assessed. Flow cytometry of immune cell populations were performed and intravital microscopy of the colon was conducted at different stages of disease to assess for neutrophil trafficking and leukocyte behaviour dynamics. Despite the reduced weight loss and improved clinical score in mice deficient of iNKT cells following DSS-induced colitis, we found no differences in colon length and histological score between DSS-treated WT and *Ja18^{-/-}* mice. There was a significant infiltration of neutrophils into the colon of WT mice at day 7 of DSS treatment, and this increase was exacerbated in *Ja18^{-/-}* mice. In contrast, the proportion of T cells was significantly reduced in DSS-treated *Ja18^{-/-}* mice compared to their wildtype counterparts. Therefore, our data

suggest iNKT cells play a modulatory role in the recruitment of leukocytes following a mouse model of acute colitis.

GPR65 regulates neutrophil chemotaxis

McKenzie, C.¹, Tan, J.¹, Mason, L.¹, Mackay, C.¹, Macia, L.²

¹Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ²University of Sydney, Charles Perkins Centre, Sydney, Australia

Inflammatory bowel disease (IBD) is a debilitating illness with a global incidence of approximately 4 million people. It is characterized by chronic gut inflammation resulting in severe diarrhoea and abdominal pain. This inflammation is due to the migration of activated neutrophils in the intestinal wall resulting in tissue damage. While the triggers of this inflammation are unknown, single-nucleotide polymorphisms in the G-protein coupled receptor 65 (GPR65) gene have been associated with IBD. GPR65 is expressed on neutrophils and is a proton-sensing receptor activated by low pH in sites of inflammation. The aim of this study was to determine the functional role of GPR65 in neutrophil migration and the pathogenesis of colitis. Colitis development was assessed in *Gpr65^{-/-}* mice versus wild-type mice treated with dextran sulphate sodium (DSS). Daily monitoring of diarrhoea and histological analysis of colonic sections demonstrated exacerbated colitis development in *Gpr65^{-/-}* mice as well as more of infiltration of neutrophils in the colon. An *in vitro* chemotaxis assay towards IL-8 demonstrated increased migration of *Gpr65^{-/-}* neutrophils under both basal and acidic conditions. To confirm the enhanced migratory phenotype of *Gpr65^{-/-}* neutrophils *in vivo*, we conducted a neutrophil-dependent KRN serum-transfer model of arthritis on *Gpr65^{-/-}* mice. Swelling, redness and neutrophil infiltration of the joints were increased in arthritic *Gpr65^{-/-}* mice. Taken together, our results suggest GPR65 regulates neutrophil chemotaxis. Single-nucleotide polymorphisms in *Gpr65* associated with IBD may therefore enhance neutrophil migration to the gut and promote IBD pathogenesis.

The role of heparanase in NK cell migration and NK cell-mediated tumour surveillance

Putz, E.M.¹, Souza-Fonseca-Guimaraes, F.^{1,2}, Barkauskas, D.S.¹, Town, L.¹, Hulett, M.D.³, Smyth, M.J.¹

¹QIMR Berghofer Medical Research Institute, Immunology in Cancer and Infection, Herston, Australia, ²University of Queensland, School of Medicine, St. Lucia, Australia, ³La Trobe University, Department of Biochemistry, Melbourne, Australia

Natural Killer (NK) cells belong to the family of innate lymphoid cells, and they are known for their ability to spontaneously kill malignant cells. It is a long-standing paradigm that NK cells are highly efficient in the prevention of cancer metastasis; however they are less potent against primary tumours and are hardly found within a tumour mass. Heparanase is the only known mammalian glycosidase responsible for the cleavage of heparan sulfate proteoglycans, a major component of the extracellular

matrix. Heparanase is frequently upregulated in tumour cells and its expression correlates with metastatic potential. So far the impact of heparanase in NK cells has not been investigated. Our preliminary data show that the expression of heparanase is highly upregulated after NK cell activation *in vitro*. The NK cell-specific loss of heparanase in B6.*Hpse*^{fl/fl} NKp46-iCre/wt mice does not affect the development and maturation of NK cells. However, preliminary experiments show that NK cell invasion of matrigel plugs *in vivo* and the surveillance of B16F10 metastasis is impaired in the absence of heparanase. Further investigations will address the questions of (i) whether the loss of heparanase will have an impact on the surveillance of solid tumours and (ii) how the expression of heparanase could be driven to improve the NK cell infiltration of tumours. We hypothesize that triggering the expression of heparanase will allow NK cells to infiltrate and attack tumours. Augmenting the invasive potential of NK cells might constitute a promising novel way to improve and complement the surveillance of primary tumours.

The *Leishmania* pathogenicity factors GP63 and LPG traffic in vesicular structures via a Sec22b-mediated pathway

Arango Duque, G.¹, Jardim, A.², Desjardins, M.³, Descoteaux, A.¹

¹INRS-Institut Armand-Frappier and Centre for Host-Parasite Interactions, Laval, Canada, ²Institute of Parasitology and Centre for Host-Parasite Interactions, McGill, Ste. Anne de Bellevue, Canada, ³Département de Microbiologie et Immunologie, IRCM, Université de Montréal, Montreal, Canada

Leishmania parasites conquer their hosts by sabotaging phagocytosis. Phagosomes become microbicidal via membrane exchanges that are mediated by soluble NSF attachment protein receptors (SNAREs), with organelles such as the ER-Golgi intermediate compartment (ERGIC). *Leishmania* uses pathogenicity factors such as the GP63 protease and lipophosphoglycan (LPG) to cleave host proteins involved in immunity and retard phagosome maturation, respectively. How GP63 and LPG traffic from the phagosome to the cytoplasm remained unknown. We hypothesized that these molecules are redistributed in the cytoplasm of infected cells in vesicles whose trafficking is mediated by host organelles. Using confocal microscopy, we demonstrated that GP63 and LPG were found in vesicles dispersed in the cytoplasm of infected phagocytes. Flotation assays showed that GP63 and LPG localize to low-density fractions containing vesicles, and to denser fractions enriched in ER/ERGIC proteins. We observed via immunofluorescence that these markers also colocalized with GP63 and LPG. Interestingly, Brefeldin A- and Monensin-mediated disruption of ER-Golgi transport hindered the redistribution of GP63 and LPG, as well as the cleavage of Syt XI, a GP63 substrate. This prompted us to study the role of the SNARE Sec22b - which regulates ER-Golgi transport - on the redistribution of these parasite molecules. In infected cells transduced with shRNA to Sec22b, the trafficking of GP63 and LPG was hampered. Moreover, this ensued in lessened cleavage of Syt XI. Together, our data revealed a novel mechanism by which an intracellular pathogen hijacks membrane fusion regulators in the ER/ERGIC to promote the trafficking of the pathogen's pathogenicity factors.

Multifaceted regulation of immune responses by the atypical chemokine receptors ACKR4 and ACKR2

Comerford, I.¹, Bastow, C.¹, Kara, E.¹, Gregor, C.¹, Foeng, J.¹, Harata-Lee, Y.¹, Bunting, M.², McColl, S.¹

¹University of Adelaide, Molecular and Cellular Biology, Adelaide, Australia, ²Queensland Institute of Medical Research, Brisbane, Australia

Chemokines direct immune cell migration through cognate interactions with chemokine receptors expressed on distinct leukocyte subsets. Recently, members of a subfamily of atypical chemokine receptors that control chemokine distribution and bioavailability rather than mediate cell migration have been identified. We have used knock-out, knock-down and conditional transgenic approaches to explore the function of ACKR4 and ACKR2, two of the members of this subfamily of atypical chemokine receptors. Our data reveal various important roles for ACKR4 in many aspects of immune system function including immune system development and homeostasis, cell migration during inflammation, responses to infection, autoimmunity and in anti-tumour immunity. ACKR4 operates, at least in part, by removing the chemokine CCL21 from tissue micro-environments to establish optimal extracellular chemokine gradients *in vivo*, an effect that is mediated by its expression on tissue stromal cells. However, we also reveal that expression of ACKR4 or ACKR2 by lymphocytes can directly compete with classical signalling chemokine receptors expressed on the same cell to negatively regulate cell migration. Together these data point toward a complex system of regulation of the chemokine system exerted by atypical chemokine receptors that is relevant to numerous aspects of immune system function in a variety of pathological scenarios.

CTL centrosomes dock with the immune synapse and direct lytic protein secretion during killing

Stinchcombe, J., Randzavola, L., Griffiths, G.

University of Cambridge, Cambridge Institute for Medical Research, Cambridge, United Kingdom

Cytotoxic T-Lymphocytes (CTL) kill by releasing granzymes and perforin which induce apoptosis. Release is controlled to maximise the 'lytic hit' and prevent healthy cell death. Lytic proteins are stored in lysosomes and released only on target contact, at the secretory domain of the immune synapse which forms at the contact site. We previously showed CTL centrosome polarisation directs lysosome to the contact site by aligning microtubules to run under secretory sites. Centrosome polarisation is unusual but found in ciliated cells. Haemopoietic cells do not make cilia. Therefore CTL could use similar mechanisms during killing.

We used high resolution TEM tomography and siRNA knockdown to investigate centrosome behaviour during killing. We find, like cilia, CTL centrosomes dock with membranes via mother centriole distal appendages. Docking occurs at specific sites at the immune synapse, often at membrane bumps. CTL can contain multiple centrosomes and duplicating centrioles,

but this does not affect centrosome docking. Unlike cilia, CTL centriole membrane association is transient and docked centrosomes retain the regulatory CP110/Cep97 complex and do not extend axonemes. CTL killing therefore resembles early but not late ciliogenesis. Failure to progress into ciliogenesis is probably important for killing multiple targets. Importantly, we find depletion of distal appendage protein Cep83 reduces CTL lysosome degranulation, supporting the role of centrosome docking in lysosome delivery.

CTL centrosome polarisation therefore provides fast directed delivery of the killing machinery towards a target, and rapid repolarisation allowing serial killing.

1183

The role of vascular adhesion protein (VAP)-1 in hepatic leukocyte recruitment during acute liver injury

Tickle, J., Shepherd, E., Adams, D., Weston, C., David Adams and Christopher Weston

University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom

Introduction: Vascular adhesion protein (VAP)-1 is expressed within the liver where it is thought to modulate inflammation and fibrosis. The catalytic activity of VAP-1 has been associated with immune trafficking. We sought to define the role of VAP-1 during acute inflammatory liver disease and to determine the importance of its enzymatic activity in this process.

Materials and methods: VAP-1 expression in patient tissue was assessed by immunohistochemistry. Catalytic activity was quantified by a novel Amplex UltraRed assay. Leukocyte adhesion to primary human hepatic sinusoidal endothelial cells or recombinant protein was assayed by flow-based assay and confocal microscopy. SSAO-KO mice, which possess a catalytically inactive form of VAP-1, were used to assess importance of VAP-1 in leukocyte recruitment during acute CCl₄ injury.

Results: Although the expression of VAP-1 was altered in patients with acute liver disease the enzyme had impaired catalytic activity. Adhesion assays demonstrated an important role for VAP-1 in neutrophil recruitment and the formation of neutrophil extracellular traps, suggesting that impairment of VAP-1 function may impact on disease severity. Acute CCl₄-induced hepatic injury in mice confirmed an important role for the enzyme activity of VAP-1 in leukocyte recruitment. Confocal microscopy of HSEC transfected with GFP-tagged VAP-1 protein (wild-type and catalytically inactive variant) revealed an intimate association between endothelial VAP-1 and leukocytes in an inflammatory environment.

Conclusions: Human VAP-1 is upregulated in acute inflammatory liver disease where it plays an important role in leukocyte extravasation. The enzymatic activity of VAP-1 is likely to play a key role in this process.

1184

CCR2 upregulated on T-cell populations in peripheral circulation among patients with osteoarthritis compared to bone marrow and to healthy control

Arkestål, K.¹, Enocson, A.², Linton, L.¹, Marits, P.¹, Eberhartsson, M.¹, Glise, H.¹, Andersson, J.¹, Winqvist, O.¹

¹Karolinska Institute, Translational Immunology unit (MED S), Stockholm, Sweden, ²Karolinska Institute and Karolinska University Hospital, Department of Clinical Sciences and Education, Section of Orthopaedics, Södersjukhuset, Stockholm, Sweden

A large portion of lymphocytes reside in bone marrow and early development of all leukocytes occurs in this locality. Although being the main primary lymphoid organ and although many questions on leukocyte maturation remain unanswered, relatively few studies have been conducted on bone marrow material if compared to peripheral blood. We have devised a protocol for extracting seemingly healthy bone marrow from patients undergoing orthopaedic surgery in large quantities without additional discomfort for the patients. Chemokine receptors reveal migratory characteristics of lymphoid cells and can also contribute in phenotyping cell populations into functional subcategories. This study show a difference in chemokine receptor 2 expression on T cell populations in peripheral blood among osteoarthritis patients compared with healthy controls which could prove useful as a screening tool for osteoarthritis patients. The difference in chemokine receptor 2 expression between peripheral circulation and bone marrow also suggest a mechanism for T-cell bone marrow egression.

1185

Tetraspanin CD53 regulates L-selectin shedding and promotes leukocyte transmigration

Yeung, L.^{1,2}, Demaria, M.², Wee, J.², Anderson, J.¹, Wright, M.D.², Hickey, M.J.¹

¹Monash University, Centre for Inflammatory Diseases, Melbourne, Australia, ²Monash University Central Clinical School, Immunology, Melbourne, Australia

Leukocyte recruitment requires the actions of adhesion molecules and their associated ligands. Tetraspanins are a superfamily of transmembrane proteins that promote the formation of tetraspanin-enriched microdomains (TEMs) in which molecules such as leukocyte integrins form associations with a range of other proteins. The leukocyte-expressed tetraspanin CD53 has recently been identified as a potential regulator of leukocyte recruitment. While the mechanism by which CD53 accomplishes this remains unknown, unpublished data suggest that it may occur through the regulation of L-selectin expression. Using mice deficient in CD53, it was observed that CD53-deficient T cells displayed an accelerated rate of L-selectin shedding following PMA activation, compared to wild type mice. Similarly, levels of L-selectin were reduced in neutrophils from CD53^{-/-} mice. Upon leukocyte activation, L-selectin is cleaved by the matrix metalloprotease (MMP) ADAM17, and congruent with this, the increased L-selectin shedding from CD53^{-/-} T cells could be partially rescued via treatment with the general MMP inhibitor GM6001. Furthermore, intravital microscopy analysis of chemokine-induced leukocyte recruitment in the cremaster

muscle demonstrated that transmigration of both neutrophils and monocytes was significantly inhibited in CD53^{-/-} mice. This observation was corroborated by confocal imaging of fixed cremaster muscles, where leukocytes of CD53^{-/-} mice were unable to fully transmigrate into surrounding tissues, instead, aggregating in the vascular lumen and within the vessel wall. This work indicates that the absence of CD53 results in impaired chemokine-induced leukocyte recruitment *in vivo*, and that this impairment may be a result of increased loss of L-selectin through uncontrolled cleavage by ADAM17.

1186

Tetraspanins CD37 and CD53 regulate successive stages of the inflammatory cascade

Wee, J.¹, Demaria, M.¹, Yeung, L.², Anderson, J.², Hammerling, G.³, Wright, M.¹, Hickey, M.²

¹Monash, Immunology, Melbourne, Australia, ²Monash, Centre for Inflammatory Diseases, Dept of Medicine, Clayton, Australia,

³German Cancer Research Center, Molecular Immunology, Heidelberg, Germany

Molecules that regulate leukocyte trafficking to sites of inflammation or homing to secondary lymphoid organs are crucial for an effective immune response. In particular adhesion molecules such as selectins and integrins play a critical role in mediating the molecular recognition and adhesion events that occur between leukocytes and the vascular endothelium in the classical inflammatory cascade. Here we will present evidence that CD37 and CD53 are two tetraspanins critical for the inflammatory cascade. Intravital microscopic analyses of CD37^{-/-} mice show an impairment in leukocyte (both neutrophils and monocytes) recruitment, as CD37 is critical for the β 2 integrin-mediated stable adhesion that occurs between leukocytes and the endothelium. CD37 is critical both for regulating β 2-integrin internalization, and also cytoskeletal-dependent processes such as neutrophil spreading and polarization. Similarly, leukocyte recruitment is also impaired in CD53^{-/-} mice; but, by contrast, CD53 has no discernable effect on integrin function but is critical for the function and expression of L-selectin. Consequently CD53^{-/-} leukocytes show no impairment in stable adhesion, but in both rolling along the endothelium, and in subsequent transmigration. Lymphocyte homing to peripheral lymph nodes is dramatically reduced in CD53^{-/-} mice, leading to a delay in adaptive immune responses. The role of CD37 and CD53 in leukocyte recruitment in inflammatory disorders will be discussed.

1187

Monocytes contribute to neutrophil-dependent kidney injury in acute glomerulonephritis

Finsterbusch, M.¹, Hall, P.¹, Li, A.¹, Kitching, R.A.^{1,2}, Hickey, M.J.¹

¹Monash University, Centre for Inflammatory Disease, Department of Medicine, Melbourne, Australia, ²Monash Health, Departments of Nephrology and Paediatric Nephrology, Clayton, Australia

Glomerulonephritis is a leading cause of end-stage renal failure, a condition characterised by injurious inflammation of glomeruli.

We recently showed that monocytes, similar to neutrophils, constitutively migrate within glomerular capillaries. The aim of this study was to investigate the contribution of monocytes to the pathology of acute glomerulonephritis. Using multiphoton and spinning disk confocal intravital microscopy, leukocyte behaviour was examined in the mouse kidney in a model of acute glomerulonephritis (using anti-glomerular basement membrane (GBM) antibodies). In this model, monocyte depletion reduced renal injury as assessed by albuminuria. Neutrophil recruitment, dwell time and the number of reactive oxygen species (ROS)-producing neutrophils were also diminished following monocyte depletion, suggesting a role for intercellular cross-talk between monocytes and neutrophils in mediating glomerular injury. Consistent with this, monocytes and neutrophils were seen to undergo cell-cell interactions in the glomerular microvasculature, and these interactions were prolonged during anti-GBM Ab-induced inflammation. Notably, neutrophils that underwent interactions with monocytes showed longer dwell times and were more likely to produce ROS relative to non-interacting neutrophils. In addition, renal monocytes, but not neutrophils, displayed TNF production upon inflammation as detected via flow cytometry, and TNF inhibition reduced neutrophil dwell time and ROS production, and renal injury. Together, our data indicate an important role for monocytes in mediating neutrophil recruitment, activation and triggering harmful neutrophil-dependent tissue damage. Moreover, evidence indicates that this response is associated with interactions between monocytes and neutrophils and promoted by monocyte-derived TNF.

1188

Plasmin and regulators of plasmin activity modulate the presentation and function of the homeostatic chemokine CCL21

Birch, N.P.^{1,2}, Lorenz, N.^{1,3}, Loef, E.J.^{1,3}, Kelch, I.D.^{1,3}, Verdon, D.J.^{1,3}, Black, M.M.¹, Middleditch, M.J.^{1,4}, Greenwood, D.R.^{1,3}, Graham, E.S.⁵, Brooks, A.E.S.^{1,3}, Dunbar, P.R.^{1,3}

¹University of Auckland, School of Biological Sciences, Auckland, New Zealand, ²University of Auckland, Centre for Brain Research, University of Auckland and Brain Research New Zealand, Rangahau Roro Aotearoa, Auckland, New Zealand, ³University of Auckland, Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand, ⁴University of Auckland, Auckland Science Analytical Services, Auckland, New Zealand, ⁵University of Auckland, School of Medical Sciences, Auckland, New Zealand

The homeostatic chemokine CCL21 playing a pivotal role in lymphocyte homing and compartment localization within the lymph node. CCL21's effects are modulated by its mode of presentation, with different cellular responses observed for surface-bound and soluble forms. In this study we report that the plasmin cleaves surface-bound CCL21 to release the C-terminal peptide responsible for CCL21 binding to cell surfaces and extracellular matrix, thereby generating the soluble form. Loss of this anchoring peptide enabled the chemotactic activity of CCL21 and reduced cell tethering. The plasmin-specific inhibitor α_2 -antiplasmin inhibits the migration of human T cells and DCs towards CCL21. We show that plasmin cleaves CCL21

in a concentration- and time-dependent manner to release the carboxyl terminus anchoring peptide. Plasmin is cleaved from the zymogen plasminogen by the enzyme tissue plasminogen activator (tPA). We found that tPA enhanced CCL21 processing through cleavage of plasminogen to plasmin. We also show that the tPA inhibitor neuroserpin blocked T cell and DC processing of CCL21 and partially inhibited cell migration. Finally, we show that plasmin reduced the tethering of T cells to DCs and this effect was blocked by α_2 -antiplasmin. These studies reveal a cellular mechanism where modified presentation of CCL21 by the plasmin system proteins plasmin, tPA, α_2 -antiplasmin and neuroserpin regulate CCL21 function.

1189

B-lymphocyte trafficking in human lymph nodes: CXCL13 does not derive from follicular dendritic cells

Park, S.M.^{1,2}, McIntosh, J.D.^{1,2}, Sheppard, H.M.^{1,2}, Brooks, A.E.S.^{1,2}, Chen, C.-J.J.¹, Cebon, J.³, Dunbar, P.R.^{1,2}

¹University of Auckland, School of Biological Sciences, Auckland, New Zealand, ²Maurice Wilkins Centre, Auckland, New Zealand,

³Olivia Newton-John Cancer Research Institute, Melbourne, Australia

During their transit through lymph nodes (LNs), B cells migrate through different microenvironments where they encounter antigen, become activated, and differentiate into plasma cells and memory B cells. Studies in mice have demonstrated that each stage of B cell trafficking is elegantly coordinated by migration cues from stromal cell populations, collectively ensuring efficient immune surveillance and generation of humoral responses. Compared with the extensive knowledge derived from murine models, regulation of B cell trafficking in human LNs remains relatively unexplored. We have examined the cells and molecules involved in controlling B cell trafficking in human LNs using 4-colour immunofluorescence microscopy, flow cytometry and *in vitro* functional assays. Our data reveal several important findings. Both the blood and lymphatic vasculature that enable ingress and egress of B cells are positioned very close to B cell follicles, potentially rendering trafficking through T cell zones unnecessary. Dynamic changes in CXCR5 expression support a crucial role for CXCL13 in driving B cell migration, but the main cell population producing CXCL13 in human LNs is not Follicular Dendritic Cells as reported in mice. Our results also point to an essential role of CD68+ antigen presenting cells (APCs) in maintaining a sphingosine 1-phosphate (S1P) gradient required for B cell egress from the LN. Collectively, these findings extend knowledge gained from murine models and highlight potentially unique features of B cell trafficking in human LNs.

1190

Trafficking of E7 specific CD8 T cells from the host to hyperproliferative graft

Jazayeri, S.D., Frazer, I.H.

University of Queensland, Diamantina Institute, Brisbane, Australia

Expression of Human Papilloma Virus (HPV) type 16 E7 in murine epidermis from a keratin 14 promoter causes epithelial

hyperplasia and chronic inflammation, characteristic of premalignant lesions associated with HPV infection in humans, and is characterised by an infiltrate of CD8+ve T cells. Further, E7-expressing epidermis is not rejected when transplanted onto immune competent mice. In this study we aimed to determine whether E7 specific CD8 T cells migrate to E7 transgenic grafts. To address this issue, ear skin of E7 transgenic and non transgenic control mice was transplanted to Nzeg-GFP mice, which have a normal T cell repertoire expressing green fluorescent protein (GFP), and E7 TCR269xNzeg-GFP mice, in which >10% of CD8 T cells are E7 peptide specific and express GFP. The number of migrated GFP positive T cells were determined post grafting in E7 transgenic and non transgenic grafts. Many more CD8 T cells migrated to E7 transgenic than to non transgenic grafts. However, there was no excess of graft recipient derived T cells in E7 transgenic grafts on E7 TCR transgenic mice when compared with E7 grafts on mice with a normal T cell repertoire. We conclude that E7 transgenic skin attracts T cells non specifically, and that there is no significant migration of E7 specific T cells to E7 transgenic skin grafts.

1191

Beneficial and detrimental effects of VLA-4 and LFA-1 blockade on T cell and monocyte infiltration of the CNS and clinical severity of Experimental Autoimmune Encephalitis

Issekutz, T.

Dalhousie University, Pediatrics, Halifax, Canada

Autoreactive T cell migration into the CNS is critical to induce disease in MS and EAE. Studies have shown that blocking VLA-4 inhibits T cell accumulation in the CNS and reduces clinical disease in animal models and in humans with MS. Anti-VLA-4 treatment of rats with EAE abolished spleen T cell infiltration into the CNS, and almost completely prevented CNS disease. Interestingly, VLA-4 blockade also prevented the migration of monocytes into the inflamed CNS despite the expression of LFA-1 and Mac-1 on these cells, and had no effect on infiltration in dermal inflammation which was highly dependent on CD11a and CD11b in these animals. Neutrophil migration to the CNS in EAE was minimal and not affected by VLA-4 or anti-CD18 mAbs which abolished neutrophil accumulation in dermal inflammation. Blockade of LFA-1 reduced T cell migration to the CNS by 40 - 50% but treatment with anti-LFA-1 significantly increased the clinical severity of EAE. Thus, monocytes appear to require VLA-4 for migration to the inflamed CNS in EAE and $\alpha 4$ integrin blockade in MS may have part of its beneficial effects through inhibiting monocyte infiltration. Blocking LFA-1 may inhibit T regulatory cell accumulation thereby increasing the severity of the CNS inflammation.

1192

S1P gradients position NK cells in lymph nodes and regulate the early IFN γ response to infection*Fang, V.¹, Ramos-Perez, W.D.¹, Chaluvadi, V.S.¹, Mendoza, A.¹, Chun, J.², Cammer, M.¹, Schwab, S.R.¹*¹*NYU School of Medicine, Skirball Institute of Biomolecular Medicine, New York, United States, ²The Scripps Research Institute, Department of Molecular and Cellular Neuroscience, Dorris Neuroscience Center, La Jolla, United States*

The lymph node periphery is an important site for many immune functions, from pathogen containment to T helper cell differentiation, yet we are only beginning to define the cues that position cells in this region. For example, NK cells sit near the medullary sinuses, poised to help sinus-lining macrophages after lymph-borne infection, yet the signals regulating NK cell localization are unknown. Here, using a sphingosine 1-phosphate (S1P) reporter, we find that cells sense higher levels of S1P in the medullary cords than the T zone, and the S1P transporter SPNS2 generates this gradient. SPNS2 on lymphatic endothelial cells, S1P receptor 5 on NK cells, and the chemokine receptor CXCR4 are all required for NK cell localization during homeostasis and rapid IFN γ production by NK cells after challenge. Our findings elucidate the spatial cues required for NK cell organization, and reveal a novel role of S1P in positioning cells within the medulla.

Computational Immunology & Systems**Biology**

1193

Introduction to PlasmoSIP: an interactive online tool for exploring relevant structural, immunological and polymorphic features of *Plasmodium* proteomes*Guy, A.^{1,2}, Irani, V.^{1,3}, Ramsland, P.^{1,2,4}, Richards, J.^{1,3,5}*¹*Burnet Institute, Melbourne, Australia, ²Monash University, Department of Immunology, Melbourne, Australia, ³University of Melbourne, Department of Medicine, Melbourne, Australia, ⁴RMIT University, School of Science, Melbourne, Australia, ⁵Victorian Infectious Diseases Service, Royal Melbourne Hospital, Melbourne, Australia*

Malaria remains a significant global health burden. Development of a long-lasting, efficacious vaccine remains a major goal as part of a global push towards malaria eradication. The precise targets of protective immunity are still unknown, and there is a need for new tools to bring together existing computational and experimental data to assist in selection and design of vaccines. We will present a newly developed online tool (PlasmoSIP) for the visualisation of protein structural features, predicted immunological features, and known polymorphisms for proteins from various *Plasmodium* species including *P. falciparum* and *P. vivax*. This tool integrates a number of computational predictions, including predictors of protein disorder, MHC class I and class II binding peptides, predicted structural models and predicted B-cell epitopes. PlasmoSIP also utilises a number of experimental datasets, including data from multiple population genomics studies. Genomic markers of immune selection pressure are displayed in the context of

structural protein models alongside various physicochemical features. Within this package, we have also included an interactive 'proteome explorer', designed to enable users to view summary statistics for proteins within the proteome and then proceed to design custom filters to narrow down the selection of proteins for further analysis. Manipulation of data is both intuitive and responsive, with a particular focus on ease-of-use while maintaining a high level of functionality. This tool has utility in both the fields of vaccine design and biomarker selection.

1194

Cohort method for lymphocyte proliferation analysis: theory and applications*Kan, A.^{1,2}, Bryant, V.L.^{1,2}, Heinzl, S.^{1,2}, Lye, B.K.^{1,2}, Marchingo, J.M.^{1,2}, Slade, C.^{1,2,3}, Zhou, J.H.S.^{1,2}, Hodgkin, P.D.^{1,2}*¹*Walter and Eliza Hall Institute, Immunology, Parkville, Australia, ²The University of Melbourne, Department of Medical Biology, Parkville, Australia, ³Royal Melbourne Hospital, Department of Clinical Immunology and Allergy, Parkville, Australia*

Lymphocyte responses are dynamic processes whereby B and T cells undergo expansion and contraction triggered by pathogenic stimuli. Obtaining a quantitative understanding of response regulation poses a significant theoretical and experimental challenge for immunology. Flow cytometry coupled with division tracking dyes is a major method for measuring progression of lymphocyte responses. We have introduced a quantitative methodology for analysing proliferation assay results. This method is termed Cohort analysis, and it aims to estimate the core kinetic parameters that characterise cell division, death and the limit in the number of division rounds. This methodology has already proven insightful in recent work where it was used as an integral part of a proliferation assay [Hawkins et al., *Nature Communications* 2013 (doi:10.1038/ncomms3406); Marchingo et al., *Science* 2014 (doi:10.1126/science.1260044)].

Here we perform a meta-analysis of proliferation kinetics across a variety of stimulatory conditions. These include data from in vitro murine B cell activation via T-cell dependent and T-cell independent pathways, CD4 and CD8 T cell proliferation, as well as human lymphocyte responses. Our unified framework enables defining a "kinetic signature" that summarises the functional outcome for different responses. Next we introduce new developments in mathematical theory behind Cohort methodology. In particular, we explore stochastic properties of two of the variables that are used to quantify the responses: Mean Division Number and Division Destiny. Finally, we present open source software that implements Cohort, and we put forward the corresponding data format for proliferation assay results to facilitate data exchange and development of a global repository.

1195**Mathematical modelling of lymphocyte responses measured using time lapse microscopy***Kan, A.^{1,2}, Heinzel, S.^{1,2}, Marchingo, J.M.^{1,2}, Zhou, J.H.S.^{1,2}, Hodgkin, P.D.^{1,2}*¹Walter and Eliza Hall Institute, Immunology, Parkville, Australia,²The University of Melbourne, Department of Medical Biology, Parkville, Australia

Mathematical modelling plays an increasingly important role in studies of B and T lymphocyte responses. Based on accumulated experimental data, recent stochastic models of lymphocyte kinetics provided novel insights into response regulation, and allowed an accurate prediction of population progression over time. Such models are typically fitted and validated against data resulting from flow cytometry experiments. At the same time, time lapse microscopy coupled with single cell tracking offers an increased information resolution compared to bulk culture studies. Hence, parameter estimation and model selection based on microscopy data are significant yet still outstanding challenges to be addressed.

A statistical approach to these problems involves defining the likelihood of the data. Difficulties of defining such a likelihood include inter-dependency of individual cell measurements; lost or partially tracked cells; and age-dependency of clone proliferation process. Here we develop a framework to define a computationally tractable joint distribution function for measured single cell data that takes into account lineage relations. We show how the joint distribution can be decomposed, and how unobserved cells can be efficiently marginalised out. Moreover, we account for age-dependency by passing state variables between generations. Importantly, our method is based on biologically plausible assumptions supported by experimental evidence. We develop this framework for a generic lymphocyte response model, but also in application to a major proliferation model called Cyton. We successfully applied the proposed methodology to tracked movies showing lymphocyte responses, and thus demonstrated how our framework can release the potential of lymphocyte response modelling for microscopy data.

1196**An analysis of stochastic variation in T-cell pedigrees***Hicks, D.¹, Yassin, M.², Russell, S.²*¹Swinburne University of Technology, Physics and Astronomy, Hawthorn, Australia, ²Peter MacCallum Cancer Centre, Melbourne, Australia

The process by which T cells differentiate to form effector and memory cells continues to be an open question. To address this, time-lapse fluorescence microscopy has been used to track post-activation naive T cells and their progeny, recording the ancestral relationships over many generations and the phenotypic characteristics of individual cells. By organizing cells by their most recent common ancestors and examining the variation between and within groupings of descendants it has been possible to partition the observed variability. The resulting distribution of stochasticity shows which stages represent

dominant differentiation points and thus when commitment to a particular fate occurs. Improved understanding of this commitment process has potential implications for vaccination and cancer immunotherapeutic strategies.

1197**Determining the epigenetic mechanisms that underpin CD8+ T cell exhaustion during chronic infection***Piovesan, D., Olshansky, M., Mueller, S.N., Turner, S.J.**University of Melbourne, Peter Doherty Institute for Infection and Immunity, Microbiology and Immunology, Melbourne, Australia*

Functional exhaustion involves the hierarchical and progressive loss of CD8+ T cell effector functions due to persistent antigen stimulation during chronic infection with viruses such as HIV and hepatitis C. These changes are underscored by differences in the transcriptional profiles of exhausted versus functional T cells but the underlying molecular mechanisms regulating the transcriptional and functional differences observed in exhausted T cells is still not well understood. Since epigenetic mechanisms are known to be a key regulator of the transcriptional changes that accompany T cell differentiation, we hypothesize that qualitative differences between exhausted and functional T cells can be explained at the epigenetic level. To address this hypothesis, we used a murine lymphocytic choriomeningitis virus (LCMV) infection model with either the acute (Armstrong) or chronic (Clone-13) LCMV strain to generate functional and exhausted LCMV-specific CD8+ T cells for molecular comparisons. Using as few as 8×10^5 cells, we were able to optimize a low input ChIP-sequencing technique to compare genome-wide deposition of the active (H3K4me3) and repressive (H3K27me3) histone modification in antigen-specific effector (day 7) and memory/exhausted (day 28) CD8+ T cells. This novel approach enables the detection of regulatory DNA regions enriched for H3K4me3 or H3K27me3 to ultimately identify genes and pathways that are differentially regulated epigenetically in exhausted CD8+ T cells. They can then be selectively targeted via epigenetic modifiers or novel immunotherapies to rescue exhaustion and boost T cell immunity.

1198**Murine haematopoietic B-cell development during West Nile viral encephalitis***Cox, D., Ashhurst, T.M., King, N.J.**University of Sydney, Pathology, Sydney, Australia*

Central nervous system (CNS) infection with neurotropic West Nile virus (WNV), triggers infiltration of pathogenic bone marrow (BM)-derived monocytes, associated with enhanced myelopoiesis, with increased monocyte production, culminating in seizures and lethal immunopathology, all of which are absent in asymptomatic WNV-infected mice, which become immune. Antibodies are crucial to WNV immunity, but little is known about the haematopoietic B-cell response during WNV encephalitis. General B-cell progenitor depletion has been observed during systemic murine influenza virus infection and we showed a similar reduction in immature B cells in WNV

encephalitis, where virus infection is limited to the CNS. Detailed subset discrimination revealed that pro-, pre-, immature- and transitional-B-cells decreased during WNV encephalitis, however a population of mature B-cells was retained in the BM. Additionally, upregulation of the stem cell marker, SCA-1, was observed on B-cells, dendritic cells and monocytes, although not on BM neutrophils. This molecule is induced by interferons (IFN), suggesting a role in anti-viral haematopoiesis. Comparing symptomatic and asymptomatic mice, we found no significant difference in cell numbers in the BM. However, SCA-1 was upregulated on both B cells and cDC prior to the onset of symptoms, suggesting a role for these cells prior to the onset of symptomatic disease. Furthermore, SCA-1 was substantially upregulated on monocytes in lethal disease, but not in asymptomatic infected mice. This study provides an opportunity to better map and highlight disease-specific hematopoietic cell signaling mechanisms in inflammatory conditions, informing improved future targeted immunomodulatory therapies.

CD40 signal strength regulates the rate of B cell differentiation to plasmablasts by altering the time to divide

Zhou, J.^{1,2}, Duffy, K.³, Kan, A.^{1,2}, Hawkins, E.^{1,2}, Markham, J.⁴, Dowling, M.^{1,2}, Hodgkin, P.^{1,2}

¹The Walter and Eliza Hall Institute of Medical Research, Immunology, Parkville, Australia, ²The University of Melbourne, Medical Biology, Melbourne, Australia, ³Hamilton Institute, Kildare, Ireland, ⁴Peter MacCallum Cancer Centre, Melbourne, Australia

B cells activated by helper T cells proliferate and rapidly generate a heterogeneous population of lymphoblasts and plasmablasts. Perhaps surprisingly, similar patterns of heterogeneity emerge when B cells are stimulated *in vitro* despite highly controlled conditions. Video-microscopy of single cell fates reveals that allocation of alternative fates is consistent with competition for different outcomes within single cells [Duffy *et al*, Science 2012]. By this model, complex population outcomes will arise with even small changes in times to each fate.

To explore how varying stimulation might control fate, we filmed cells under different conditions. Earlier flow cytometry data demonstrated that reducing CD40 stimulation had two effects on B cell fates: it slowed down B cell division, and produced a greater proportion of differentiated plasmablasts in each generation [Hawkins *et al*, Nat Comms 2014]. Modelling our filming data revealed that the competition hypothesis could explain these observations with a simple effect on division time alone: by slowing division, B cells gain more time to undergo differentiation before their next mitotic event. These data demonstrate how subtle changes to cell fate allocation can have greater, cumulative effects across the population. We are currently assessing how other cytokine dose effects operate to alter the population outcome, in particular IL-4 and IL-5.

By understanding how different components of the B cell response are controlled, we aim to build a better model of how these fates interact to form the overall outcome. Such a model has many potential applications in both immune deficiency diagnoses and immunotherapy.

1200

Effective diversity of T-cell repertoire

Xu, J.^{1,2}, Jo, J.^{1,2}

¹APCTP, Pohang, Korea, Republic of, ²POSTECH, Physics, Pohang, Korea, Republic of

To detect countless pathogen invaders in our life, we should equip with diverse immune receptors. Each immune cell expresses copies of one specific receptor. Therefore, one individual cannot have infinite diversity of receptors with a finite number of immune cells, but should have an effective repertoire. The immune system shapes the repertoire by filtering immature immune cells which express randomly-generated receptors. Thymus selects the thymocytes whose receptors have sufficient, but not too strong, interactions with self-peptides. The positive and negative selection prevents the maturation of negligible and autoimmune cells. We wonder why there is the certain diversity of T-cell repertoire, in order to understand the optimal coding of the immune system. Here we make use of the TCR-pMHC pairwise string model and T-cell activation model, to examine the risk of autoimmunity and immunodeficiency simultaneously. Through the models, important factors are discussed, i.e. T-cell repertoire diversity and the number of activated T cells required to initiate a response. It suggests that the thymic selection minimizes the risk of responding to safe self-peptides and ignoring dangerous nonself-peptides.

Thorough screening the interacting proteins with tumor suppressor candidate 3 using NAPPA chip

Du, J.¹, Yu, X.², Yu, X.^{3,4}

¹Central Laboratory, Shandong Provincial Qianfoshan Hospital, Jinan, China, ²Department of Radiation Oncology, Shandong Provincial Qianfoshan Hospital, Jinan, China, ³National Center for Protein Sciences (Beijing), State Key Lab of Proteomics, Beijing Proteome Research Center, Beijing, China, ⁴Virginia G. Piper Center for Personalized Diagnostics, Biodesign Institute, Arizona State University, TEMPE, United States

Tumor suppressor candidate 3 (TUSC3) gene is located on chromosome region 8p22 and encodes the 34 kDa TUSC3 protein, which is a subunit of the oligosaccharyl transferase (OST) responsible for the N-glycosylation of proteins. Only recently was TUSC3 identified as a potential tumor suppressor gene when it was found deleted in a variety of human malignancies, including hepatocellular carcinoma. However, its thorough functions in liver cancer are still not clear. Nucleic Acid Protein Programmable Array (NAPPA), is a new type of protein chip on which containing about 20,000 disease-associated proteins and is adept at protein interaction. To probe the interacting proteins with TUSC3 in whole, we hybridized TUSC3 protein on NAPPA chip. Here, we present the first demonstration of using NAPPA protein microarrays to detect interacting proteins with TUSC3. These 28 proteins were screened using NAPPA and a 96-well protein ELISA (well-NAPPA). Four proteins (NF2, BIRC2, RTBND and BIRC8) were finally confirmed using Co-IP and intracellular localization in hepatocytes. However, it is need to be illuminated that the interactions play the vital roles in the development of liver cancer in the future. Our results will contribute to a

deeper understanding of carcinogenic mechanism of TUSC3 in hepatocellular carcinoma.

Using correlative microscopy to understand dynamics of T cell signalling

Zibaei, K.¹, Chen, Y.^{1,2}, Yasin, M.², Ludford-Menting, M.², Russell, S.^{1,2}

¹Swinburne University of Technology, Centre for Micro-Photonics, Melbourne, Australia, ²Immune Signalling Laboratory, Peter MacCallum Cancer Centre, Melbourne, Australia

As the central players of adaptive immune responses, T cells and their responses to the external stimuli have been widely investigated. Time lapse microscopy provides a powerful method for understanding signalling, but quantitation of fluorescent microscopy remains a challenge.

Using combined microscopy methods (time lapse and super resolution microscopy) as well as new analysis methods, we can now draw a picture of the different events that contribute to the T cell activation and fate determination. In particular, we can quantify characteristics of how the T cell docks onto the Dendritic cell (DC), how this relates to T cells signals such as calcium flux and shedding of the surface protein, CD62L, and how this impacts upon subsequent formation of the synapse (as measured by confocal and super resolution microscopy), and on the progeny of that naive T cell. In this work I will present new findings regarding T cell signalling which has been achieved through our approach.

1203

A framework for digital RNA sequencing (dRNA-Seq) and its application for gene expression profiling of small number of immune-related cells

Matsumoto, Y.¹, Kryukov, K.², Ikawa, T.¹, Imanishi, T.², Shiroguchi, K.¹

¹RIKEN, IMS, Yokohama, Japan, ²Tokai University School of Medicine, Molecular Life Science, Isehara, Japan

Recently developed molecular barcoding techniques enable digital quantification of pre-amplified nucleic acid molecules genome-wide by massively parallel sequencing of amplicons. In the barcode sequence, random bases were widely used due to advantages including higher dynamic range and lower cost. However, the efficacy of random base barcodes for accurate quantification of nucleic acids has not been studied well. We established, by combination of experiments and computational analyses, criteria which ensure that the digital quantification of nucleic acid molecules using random base barcodes works. Through this process, we found that alterations in the original barcode sequences, likely from errors generated in amplification and/or sequencing, caused over-estimation of the number of molecules. Thus, we developed the following framework to remove the effect of these errors during downstream analysis: designing barcode sequences to

include error detection codes and developing original analysis software. We show that this framework provides accurate quantification of nucleic acid molecules; the measured number of molecules was highly consistent with the original number of molecules before amplification. These results enable us to propose parameters for barcode design and also sequencing depth required to accurately quantify nucleic acid molecules, which may become a standard guideline for the use of random base molecular barcodes. Using this framework, we developed dRNA-Seq which provides absolute quantification of RNA molecules genome-wide. We will present the gene expression profile of immunology-related cells during different stages of differentiation measured by dRNA-Seq from small number of cells.

1204

From healthy to transformed B cells - a model of how chemotherapeutic drugs act against lymphoma

Pham, K.¹, Zhou, J.H.S.¹, Kan, A.¹, Dowling, M.R.¹, Duffy, K.², Hodgkin, P.D.¹

¹The Walter and Eliza Hall Institute, Division of Immunology, Parkville, Australia, ²Hamilton Institute, Maynooth, Ireland

B lymphocytes balance division and death during a normal immune response. Homogeneous populations of naive B cells can generate significant heterogeneity upon activation that can be described by a competing cell fate model (Duffy K, *Science*, 2012; Hawkins ED, *Nat Comms*, 2014). We hypothesise that this same competition model could explain why mitosis inhibiting drugs that are commonly used in cancer chemotherapy, lead to the death of lymphoma cells. By blocking division, the underlying time to die is revealed and death is an inevitable consequence.

To explore this we exposed dividing B cell lymphoma lines (J558, NS.1) to cell cycle inhibiting or apoptosis promoting chemotherapeutic drugs and measured times to fate from a previous mitotic event using single cell microscopy. After examining >1000 single cell fate outcomes we find that these results are generally consistent with our hypothesis. Chemotherapeutic S-phase inhibitors etoposide and aphidicolin delay and inhibit division in the J558 cell line, and lead to a time to die that is unaffected by increasing concentrations. In contrast, these drugs simultaneously delay both division and death times in the NS.1 cell line.

Using mathematical modelling we can quantify the changes for each lymphoma cell on the frequency of division, time to divide and time to die in the population. Our model of therapeutic drug action opens up new possibilities for assessing drug efficacies or synergies. We are now using these results to predict the combined effects of multiple chemotherapeutic agents and explore effective combinations in B cell malignancies.

1205**Immunosequencing reveals diagnostic signatures of pathogen infection and HLA type in the T-cell receptor repertoire**

DeWitt, W.¹, Emerson, R.¹, Vignali, M.¹, House, S.¹, Desmarais, C.¹, Rieder, M.¹, Carlson, C.², Gravley, J.², Hansen, J.², Robins, H.²

¹*Adaptive Biotechnologies Corp, Seattle, United States, ²Fred Hutchinson Cancer Research Center, Seattle, United States*

We analyzed the T-cell response to cytomegalovirus (CMV) by sequencing rearranged T cell receptors (TCRs) from 650 subjects (294 CMV+, 356 CMV-). We assessed association with CMV serostatus for ~90 million unique TCRs, identifying 157 CMV-associated TCRs (FDR \approx 0.15). Training a classifier on these features, we predict CMV serostatus in a cross-validation procedure on the same cohort with a diagnostic odds ratio of 44. Testing on an independent cohort of 120 subjects with known CMV serostatus yielded a diagnostic odds ratio of 49.

HLA-restriction of each CMV-associated TCR was determined by enrichment of specific HLA alleles among subjects that carry each CMV-associated TCR. Of 157 CMV-associated TCRs, 61 were HLA-restricted at $p \leq 10^{-3}$, and none of these were significantly associated with multiple alleles in any locus. We find substantial concordance between our data and previously published CMV-specific TCRs. Most previously-reported CMV-specific TCRs are present in our data, however only 5/157 CMV-associated TCRs identified in this study have been previously reported. Of these, 4 were significantly HLA-restricted and confirmed previous findings.

We separately investigated association of TCRs with each HLA allele present in the cohort. Cross validation indicated accurate prediction for over a broad range of allele frequencies, demonstrating that HLA type can be inferred from immunosequencing data.

In summary, we demonstrate the validity of association studies using immunosequencing for detection of public T-cell responses to infection, and report that assessing the presence of associated TCRs can serve as a powerful diagnostic classifier.

1206**Changes in T cell receptor repertoire associated with combined variable immune-deficiency (CVID)**

Ismail, M.¹, Matjeka, T.¹, Husovsky, C.¹, Heather, J.¹, Best, K.^{1,2}, Burns, S.³, Chain, B.¹

¹*University College London, Division of Infection and Immunity, London, United Kingdom, ²UCL Centre for Mathematics, Physics and Engineering in the Life Sciences and Experimental Biology (CoMPLEX), London, United Kingdom, ³UCL Institute of Immunity and Transplantation, Department of Immunology, Royal Free Hospital, London, United Kingdom*

We have recently developed a reliable and economical amplification protocol that can be used to characterise the T cell receptor (TCR) repertoire using high-throughput sequencing, and a robust computational pipeline for quantitative downstream analysis. Introduction of barcodes, which label every cDNA molecule before amplification allow for correction of PCR bias, and PCR and sequencing error. The protocol can be

used to sequence TCR repertoires of diverse types of samples, including ex vivo collection of whole or FACS fractionated blood or tissue, or after in vitro culture and expansion.

We have recently used this protocol to better define the multiple levels of immune dysregulation which characterise chronic infection with HIV. In this study, we analyse the TCR sequences of a small number of individuals with CVID and develop metrics to characterise their TCR repertoire and compare it to a cohort of healthy controls. We detected a reduced number of TCRs shared between the CVID patients and healthy volunteers, suggesting that the CVID repertoires were abnormal. Changes were detected in the number of beta J gene deletions, the lengths of the CDR3 sequences and in V alpha and beta gene usage in CVID patients. Strikingly, the CVID patients showed a marked deficiency in alpha genes associated with mucosal associated invariant T (MAIT) cells.

Quantitative analysis of the TCR repertoire in a larger CVID cohort may give insights into the pathogenesis leading to immunodeficiency in these individuals, as well as providing additional information with which to stratify this heterogeneous group of immunodeficiencies.

1207**Patterns of single cell fate discoverable via novel multidimensional analyses and dynamic visualization**

Gao, J.¹, Crampin, E.², Naik, S.³

¹*The Walter and Eliza Hall Institute of Medical Research, Molecular Medicine, Melbourne, Australia, ²The University of Melbourne, Systems Biology Laboratory, Melbourne, Australia, ³WEHI, Melbourne, Australia*

Identifying the progeny of many single progenitor cells simultaneously can be achieved by tagging progenitors with unique heritable DNA barcodes, and allows inferences of lineage relationships. While this approach has shed new light on single cell fate heterogeneity, data interpretation remains a major challenge. In this study, we applied the t-Distributed Stochastic Neighbor Embedding (tSNE) algorithm with novel customizations to derive a refined classification of hematopoietic stem and progenitor cells. We further classify lymphoid-primed multipotent progenitors into discrete categories based on cell output. We also use "tSNE pie map movies" to visualize clonal dynamics of hematopoietic reconstitution in primates and identify novel developmental patterns, namely hematopoietic progenitors with early T cell and later granulocyte production. Augmenting tSNE visualizations of high-dimensional data can be widely applied across biology to explore data, perform systems-level analyses and generate novel hypotheses for subsequent validation.

Interaction of aloe emodin with lipoxygenase towards the development of novel NSAIDs*Suresh, S.¹, Sabu, A.², Haridas, M.¹*¹Kannur University, Inter University Centre for Bioscience, Kannur, India, ²Kannur University, Department of Biotechnology and Microbiology, Kannur, India

LOXs are potential drug targets in the treatment of diseases such as asthma, atherosclerosis, cancer, and a variety of inflammatory conditions. It is assumed that blocking the arachidonic acid (AA) metabolism via COX inhibition by either traditional NSAIDs or selective COX-2 inhibitors could lead to the generation of pro-inflammatory leukotrienes and lipoxins via the LOX pathway partly accounting for the side effects seen with traditional NSAIDs and selective COX-2 inhibitors. To counter this, several LOX, PLA₂ inhibitors have been reported nowadays. Investigations on LOX inhibitory activity of *Cassia angustifolia* (Vahl.), elucidation of bioactive compound responsible for inhibition and their binding interactions were reported in this study. Results indicate that ethyl acetate extract of *Cassia angustifolia* (Vahl.) could inhibit LOX with 79 ± 0.002% of inhibition rate. Bioactive compound responsible for inhibition isolated via standard protocols and MS data revealed the presence of Aloe emodin (270.2 m/z) which was already reported from this plant. The binding potential of the compounds with LOX was determined using molecular docking studies. In order to corroborate the in silico results, enzyme kinetics and isothermal titration calorimetric analysis were performed. From the analysis, it was concluded that aloe emodin can act as competitive inhibitors to the enzyme with an IC₅₀ of 29.49 µM and may be used as anti-inflammatory agent. ITC results indicated the interaction of LOX with aloe emodin is endothermic in nature with a stoichiometry of n= 3 and binding free energy found to be -7.69 kcal/mol.

1209

A computational framework for simultaneous single-cell characterization of surface phenotype and gene expression profile of antigen specific lymphocytes*Rizzetto, S.¹, Elthala, A.¹, Rasoli Pirozyan, M.¹, Keoshkerian, E.¹, Brownlee, C.², Lloyd, A.¹, Bull, R.¹, Luciani, F.¹*¹University of New South Wales, Systems Medicine in Infectious Diseases, Sydney, Australia, ²University of New South Wales, Bio Resources Imaging Lab, Sydney, Australia

Upon recognition of an antigen, activated lymphocytes (both B and T cells) proliferate and differentiate, generating a heterogeneous progeny able to perform a vast array of functions. The phenotype of the initial naive repertoire, as well as the specificity between T and B cell receptors (TCR and BCR) for the antigen are critical components that determine the success of the immune response and establishment of protective immunity. Single cell technologies are now significantly improving the understanding of these highly dynamic and heterogeneous molecules. The rise of multi-omics approaches inevitably requires computational workflows to analyse and integrate large and multiple datasets together. We have developed a computational pipeline to link the cell

surface phenotype with the full transcriptome profile, including TCR and BCR. This model combines gene expression profile from scRNA-Seq with surface markers identified with flow cytometry index sorting on the same single cell. TCR and BCR were detected from scRNA-Seq reads using an updated version of the in-house developed tool to reconstruct VDJ sequence, called VDJPuzzle. This pipeline has been applied to Ag specific B cells and T cells derived from human peripheral blood mononuclear cells (PBMC) collected from a patient infected with Hepatitis C Virus and allowed us to identify surprisingly high heterogeneity. Our computational analysis contributes to the understanding of the evolution of lymphocytes during an immune response both at the population and molecular level providing insight into the interrelation and functioning of larger systems.

1210

AbDesigner3D*Saethang, T.¹, Payne, M.¹, Pisitkun, T.^{1,2}*¹Faculty of Medicine, Chulalongkorn University, Systems Biology Center, Research Affairs, Bangkok, Thailand, ²Epithelial Systems Biology Laboratory, NHLBI, National Institutes of Health, Bethesda, United States

Antibody-based techniques have been widely used in system biology-based experiments. The key of success for such techniques is the antibody-design procedure. AbDesigner, an online tool for the design of peptide-directed antibodies, was previously developed and implemented as the web application (helixweb.nih.gov/AbDesigner/). This software provides crucial information of target immunogen including immunogenicity (antigenicity) score, uniqueness (predictor of specificity), conservation (predictor of multispecies cross-reactivity), and protein features such as PTMs, domain architecture, site of sequence variation, and other regions or site of interest extracted from the corresponding Swiss-Prot record. AbDesigner successfully applied in antibodies productions that are human nephrin antibody, human podocin antibody, and human apolipoprotein L1 antibody. Although AbDesigner has been widely used in the community, it omits the 3D structure information of protein which is commonly used in studies of protein binding nowadays. In this study, AbDesigner3D was developed by integrating 3D structures information from PDB into the previous AbDesigner. New features that are accessible surface area and contact residues are also included in AbDesigner3D to enable users to optimize their target peptides with more confidence. In addition, interactive user interface was created to help user judge which region of peptide should be used as an epitope by displaying trade-offs between features of that region.

1211**The influence of nature, nurture and noise on humoral immunity**

Menzel, U., Greiff, V., Miho, E., Weber, C., Cook, S.C., Reddy, S.T. ETH Zürich, D-BSSE, Basel, Switzerland

The humoral immune system manages host protection and body maintenance by accessing an immensely diverse antibody repertoire; the exact balance between the forces that control repertoire formation and selection is however still unknown. Therefore, we set out to quantify the fraction of antibody repertoire diversity, which is *predetermined* by genetic composition (nature) or antigen challenge (nurture) or *unpredictable* due to stochastic variation (noise). In order to accomplish this, we performed high-throughput antibody repertoire sequencing throughout the entire progression of the B-lymphocyte lineage (pre B cells/PreBC, naïve follicular B cells/NFBC, memory plasma cells/BMPC). This resulted in a dataset comprising ≈ 100 samples and ≈ 600 million total sequence reads, originating from four C57BL/6 cohorts ($n=5$), (i) unimmunized, (ii-iv) prime-boost immunized with Ovalbumin/NP-hen egg lysozyme/Hepatitis B surface antigen). Leveraging a multi-scale linear regression approach, we found that the germline V gene usage of PreBC and NFBC was highly similar across all mice and was thus dominated by nature (germline correlation $R^2 \approx 90\%$) whereas it was predominantly stochastic in the BMPC population (noise $\approx 90\%$). On the antibody clonal level, we found antigen-specific and plasma cell-specific repertoire fragmentation into clonal clusters of reproducibly high CDR3 sequence similarity (nature and nurture $\approx 90\%$). Throughout B-cell development, we found unexpected and hitherto unreported high clonal overlap ($\approx 15\%$) among mice (exception: unimmunized BMPC). Extrapolation of the convergent repertoires allowed us to quantify the total murine naïve repertoire diversity to a size of $\approx 10^{14}$ clones. In conclusion, nature, nurture and noise dictate the structure and size of antibody repertoires in an ontogenetic fashion.

Emerging Technologies

1212**Immunomedia project: learning, lecturing and spreading Immunology**

Corell, A.¹, Martín Alonso, C.¹, Zarzuela, J.C.¹, Sanz, L.A.², Aragón, J.C.², Sempere, J.M.³, Hudrisier, D.⁴, Rodrigues Santos, P.⁵, Álvarez Álvarez, S.⁶, Arnaiz, V.⁶, Verdú Perez, M.J.⁷, Regueras Santos, L.M.⁷, de Castro Fernández, J.P.⁷, Martínez-Quiles, N.⁸, Reche Gallardo, P.A.⁸, Pascual García, S.³, Martínez Peinado, P.³, Regueiro, J.R.⁸

¹Universidad de Valladolid, Inmunología, Facultad de Medicina, Valladolid, Spain, ²Universidad de Valladolid, Servicio de Medios Audiovisuales, Valladolid, Spain, ³Universidad de Alicante, Biotecnología, Alicante, Spain, ⁴Université de Toulouse, UPS, IPBS, CNRS, Toulouse, France, ⁵Universidade do Coimbra, Instituto de Inmunologia, Coimbra, Portugal, ⁶Universidad de Valladolid, Lengua Española, Soria, Spain, ⁷Universidad de Valladolid, Teoría de la Señal y Comunicaciones e Ingeniería Telemática, Valladolid, Spain, ⁸Universidad Complutense de Madrid, Inmunología, Madrid, Spain

In the ICTs era, the universities have novel roles (using social media, designing multimedia materials among others). In this context, the Immunomedia project (with the participation of 5 Universities from Spain, France and Portugal) try to fill some needs and gaps in the lecturing of Immunology, mainly, in Biomedical degrees.

The project has been structured in 7 axis: first "Developing and disseminating high quality minivideos" on Immunology, under the name "Inmunepills" (youtube) with a high impact (>800.000 views) among Spanish-speaking universities; second "Collecting, selecting and tagging OAMs and other lecturing materials" ("Content Curation") onto boards which provide students and lecturers with useful information, verified and organized by modules. Among the used content curation tools, "Scoop.it" and Pinterest gave the greatest impacts; third "involving actively the students into their learning process" and collaborating among universities with the "University Journal of Immunology, Immunopathology and Immunotherapy": the students tweet relevant immunology news using #hashtags, which are tracked and generate a journal at "Paper.li"; fourth, "Opening the University to all the people" by developing multimedia materials in immunology and disseminating them on social media, patients associations and public places (video collection "Defences'Channel" at YouTube); fifth, universalising the materials by subtitling the Immunepills into Spanish (for deafs), English and French or dubbing them into Portuguese; sixth, developing and designing a gamification approach to assess learning success at different levels and with an interactive interface between students; and finally, developing an Immunomedia site to connect all the material, activities, lecturers and students.

1213**Releasable RapidSpheres™ enable immunomagnetic purification of highly viable and functional immune cells from complex tissues in less than 30 minutes**

Clarke, S.J.¹, Kokaji, A.I.¹, Kellerman, D.W.¹, Ewen, C.L.¹, Chambers, M.N.¹, Chan, M.¹, Woodside, S.M.¹, Eaves, A.C.^{1,2}, Thomas, T.E.¹
¹STEMCELL Technologies Inc., Vancouver, Canada, ²Terry Fox Laboratory, BC Cancer Agency, Vancouver, Canada

Understanding how the cells of the immune system communicate relies on the success of cell-based assays; however, it remains challenging and time-consuming to purify large numbers of high-quality cells from complex tissues. EasySep™ Release is a fast and easy cell isolation method that utilizes Releasable RapidSpheres™. This novel magnetic particle technology improves cell purities by reducing contaminants and allows for gentle particle removal to mitigate potential interference in downstream assays. The 29-minute protocol requires first labelling target cells with Releasable RapidSpheres™ and then separating the labelled cells using a hand-held magnet. Particle-free purified cells are obtained by applying a mild dissociation reagent followed by a final magnetic separation.

We tested EasySep™ Release by purifying T, B and NK cells from peripheral blood mononuclear cell samples containing 5 to 800 million cells. Cell purities were $99.7 \pm 0.1\%$ (SD, $n=17$) for CD3+ T cells, $99.4 \pm 0.4\%$ ($n=17$) for CD4+ cells, $98.8 \pm 0.5\%$ ($n=17$) for

CD8+ T cells, $98.6 \pm 0.7\%$ (n=6) for CD19+ cells and $95.6 \pm 1.7\%$ (n=6) for CD56+ cells. Isolated cells were confirmed particle-free, viable and functional. We obtained similar high performance using unprocessed leukapheresis samples of up to 5 billion cells, demonstrating excellent scalability and compatibility with more complex samples. Finally, we show how EasySep™ Release can be paired with commercially available antibodies or sequential separations to isolate almost any cell type, including those with a complex phenotype.

Soluble biomarkers for pressure ulcers therapy monitoring - protein microarray technology view

Constantin, C.¹, Boda, D.², Căruntu, C.², Păunică-Panea, G.³, Constantin, V.D.³, Neagu, M.¹

¹Victor Babeş' National Institute of Pathology, Immunology, Bucharest, Romania, ²Carol Davila' University of Medicine and Pharmacy, Dermatology, Bucharest, Romania, ³Sf. Pantelimon' Emergency Hospital, Surgery Clinics, Bucharest, Romania

Proteomics is a tremendous domain with a real-time development bringing continuous updates in biological process serving elucidation in therapeutical approaches. The protein microarray technology gains a definite place in innovative attempts such as biomarkers discovery and validation, and elucidation of cellular pathways involved in various pathologies. Wound healing is a continuous challenge, latest 'omic data identifying cellular networks and molecular events which outlines markers for healing monitoring according with therapeutical endeavor. Thus, the aim of the study was to establish biomarkers panels in pressure ulcers of different pathogenesis reflecting the best evolution of wound healing in the presence of some innovative patches. Using a protein microarray platform 42 analytes were semi-quantitatively detected in serum obtained from patients suffering of pressure ulcers, harvested at different time points. Three types of patches (classic cotton; 84, 8% poly-2-hydroxyethylmetylacrilate based; collagen of animal origin based) were used in patient treatment and biological samples were harvested before, during and after therapy procedure. As controls were enrolled subjects with age and gender matched. All enrolled subjects given their written informed consent and the study had all the Ethical approvals. Several panels of markers were outlined defined by level of expression and protein family in every experimental group tested. Especially markers from chemokines family (e.g. ENA-78 or MDC) display different level of expression depending on experimental condition making protein microarray a very accessible and very actual tool for identification of useful (bio) markers for management of pressure ulcers.

This study was financed by PN-II-PT-PCCA-2013-4-1386 (NANOPATCH)

1215

Gallium (III) phthalocyanine for photodynamic therapy of epithelial type transformed cells - approaches on SHSY5Y cell line

Constantin, C.¹, Matei, C.N.², Tampa, M.Ş.², Lupu, A.-R.¹, Ion, R.-M.^{3,4}, Neagu, M.¹

¹Victor Babeş' National Institute of Pathology, Immunology, Bucharest, Romania, ²Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania, ³The National Institute for Research & Development in Chemistry and Petrochemistry, Bucharest, Romania, ⁴Valahia' University, Târgovişte, Romania

Gallium (III) phthalocyanine is less investigated in comparison with other metallated phthalocyanines (e.g. with Zn²⁺ or Al³⁺) in experimental photodynamic therapy. Neuroblastoma is a solid tumor that comprises on its therapeutical list Ga (III), as such Ga(III) nitrate is clinically approved by FDA for the treatment of different cancers, but its administration is somewhat invasive. Therefore it is highly imperative to find new compounds, especially for localized and inaccessible tumors. Ga(III) as phthalocyanine chloride form represents a drug option combining its already acknowledged biomedical benefits with PDT procedure in order to induce cancer cells' death. Our study focuses on the dark toxicity testing of a Chloro-Gallium-phthalocyanine photosensitizer (Ga-Pc) upon neuroblastoma SHSY5Y cell line, and further on the efficacy of experimental PDT. Thus, evaluating Ga-Pc we have shown that cellular proliferation restrain a similar pattern for all incubations times designating a "protective" effect-like of Ga(III)Pc upon SHSY5Y cells. In addition, cellular impedance evaluations have shown that long time co-incubation of cells in Ga-Pc (over 125 h) does not significantly affect cell proliferation even at $\geq 20 \mu\text{g/mL}$ Ga-Pc. When irradiating neuroblastoma cells loaded with non-toxic concentration of Ga-Pc we have obtained a massive cell death and the remaining proliferative capacity of treated cells is due to a fraction that escapes the PDT protocol. This fraction, after 4 h post- PDT, drastically declines as well. Ga-Pc represents a potential photosensitizer that can display exploitable PDT properties in solid tumors.

Gliadin-containing, tolerogenic immune modifying nanoparticles (TIMP) reverse gluten-dependent enteropathy in a celiac disease mouse model

Freitag, T.¹, Podojil, J.R.², Shea, L.³, Miller, S.D.⁴, King, N.J.⁵, Getts, D.R.²

¹Helsinki University Hospital Laboratory (HUSLAB), Helsinki, Finland, ²Cour Pharmaceuticals Development Co, Chicago, United States, ³University of Michigan Medical School, Ann Arbor, United States, ⁴Northwestern University Feinberg School of Medicine, Chicago, United States, ⁵The University of Sydney, Sydney, Australia

In celiac disease, tolerance to gluten proteins from cereals is lost. Tolerogenic Immune Modifying Nanoparticles (TIMP) encapsulating autoreactive antigens induce peripheral, antigen-specific tolerance in numerous models of autoimmune disease. The identification of gliadins as primary epitopes in Celiac

Disease suggested that this approach may also be applied to the treatment of CD. As such, TIMP encapsulating full gliadin proteins (TIMP-GLIA) were developed and tested in rodents for their therapeutic potential.

The ability of TIMP-GLIA to inhibit antigen specific T cell responses was initially examined using Delayed Type Hypersensitivity (DTH). The intravenous infusion of TIMP-GLIA not only ameliorated the DTH response, by greater than 60%, but was associated with an antigen specific diminution of T cell proliferation and cytokine responses in gliadin immunized mice. Subsequent experiments tested the ability for TIMP-GLIA to reverse gliadin-induced enteropathy in a mouse model of celiac disease. TIMP-GLIA or TIMP-LYS (irrelevant antigen control containing lysosyme) were intravenously infused into Rag1-/- reconstituted with gliadin-sensitized memory T cells. TIMP-GLIA treatment resulted in the reversal of weight loss and reduced the severity of duodenitis, as determined by histology. This disease amelioration was further associated with a significant reduction in antigen specific TH1 responses. Observations in TIMP-GLIA treated animals were similar to mice maintained on a gluten-free diet, suggesting that this treatment was capable of restoring gliadin tolerance and supports the introduction of gluten into the diet of animals with gluten sensitivity.

Main body: Enhanced, modified T cell receptors (TCRs), are currently being developed for a wide range of cancer targets, included in a number of current clinical trials. However, there are potential dangers associated with mutating TCRs outside of the rigors of thymic selection. Indeed, we recently demonstrated that one of these reagents, intended to target the MAGE-A3 cancer antigen, displayed an unexpected cross-reactivity leading to fatal cardiac toxicity in 2 patients enrolled in phase I clinical trials. Here, we reveal the structural basis for lethal the toxicity against cardiac tissue of a MAGE-A3 specific TCRs and establish the need for a better understanding of the mechanisms that govern T cell cross-reactivity when developing engineered TCR cancer therapies.

A biomimetic glyceride prodrug approach to promote the delivery of immune-modulating drugs to targets in the lymphatics and immune cells

Gracia, G., Han, S., Quach, T., Hu, L., Simpson, J.S., Trevaskis, N.L., Porter, C.J.
Monash Institute of Pharmaceutical Sciences, Monash University, Melbourne, Australia

Background: The lymphatics and associated immune cells have three main physiological functions: the preservation of fluid balance, dietary lipid absorption and regulation of immunity. Additionally, the lymphatics play key roles in modulating the pathogenesis of immune/inflammatory disease, allergy, cancer, metabolic disease, infection etc. Site-specific delivery of drugs to lymph-associated targets has the potential to enhance the efficacy and reduce the toxicity of treatments for these diseases.

Aim: To establish the potential to enhance drug delivery to the lymphatics by linking a model immunosuppressant drug, mycophenolic acid (MPA), to a glyceride backbone to form a biomimetic glyceride prodrug (2-MPA-TG) that integrates into the physiological process of dietary triglyceride absorption.

Methods: 2-MPA-TG vs. MPA were administered intestinally to rats or orally to dogs. Intestinal lymph fluid and lymph nodes at different sites in the body were collected at set time points. Lymphocytes were separated from lymph. Sample concentrations of drug and prodrug were analysed via LC-MS/MS.

Results: 2-MPA-TG efficiently incorporated into the dietary triglyceride absorption pathway, thereby markedly increasing intestinal lymph transport of MPA derivatives in rats (90-fold) and dogs (288-fold) and lymph lymphocyte concentrations of active MPA in dogs (19-fold) when compared to parent drug MPA. 2-MPA-TG also facilitated a significant increase in the accumulation of active MPA in local mesenteric lymph nodes, but not peripheral lymph nodes, in rats.

Conclusion: Biomimetic glyceride prodrugs increase drug exposure to lymphatic-associated targets, particularly in the mesentery, thereby representing a promising strategy to enhance the treatment of disease involving lymphatics such as immune/inflammatory disease.

Identifying exosome binding and internalization in blood cell subsets by imaging flow cytometry

Pugsley, H., Friend, S., Probst, C., Morrissey, P.
Amnis part of Merck, Seattle, United States

Only recently has the importance of extracellular vesicles as key mediators of intercellular communication been appreciated. Extracellular vesicles are membrane derived structures that include exosomes, microvesicles and apoptotic bodies. Exosomes have been shown to transfer molecules between cells and have the potential to transfer signals between cells. Exosomes are released under normal physiological conditions; however, they are also believed to serve as mediators in the pathogenesis of neurological, vascular, hematological and autoimmune diseases as well as cancer. Quantifying and characterizing exosomes in a reproducible and reliable manner has been difficult due to their small size (50 - 100 nm in diameter). Exosomes analysis can be done using high-magnification microscopy however this technique has a very low throughput. Attempts to analyze exosomes using traditional flow cytometers has been hampered by the limit of detection of such small particles and low refractive index. To overcome these limitations we have employed multispectral imaging flow cytometry that has the advantage of combining

high throughput flow cytometry with higher sensitivity to small particles and the added benefit of imaging that can provide visual confirmation of particle integrity and characterization. In this study we use multispectral imaging flow cytometry to investigate the interaction of exosomes with white blood cells. Exosomes derived from different cell types will be investigated for their preferential interactions with blood cell subsets by combining immunophenotyping with morphological parameters to measure their binding and internalization.

T cells are core regulators of innate and adaptive immune system function and are key players in the defence against foreign invaders and cancer. A detailed knowledge of the proteomes of human T cells is obligatory if we are to understand the function and behaviour of this important compartment and to clearly identify, sort and target unique lineages via distinctive cytosolic and plasma membrane markers. Detailed phenotyping can be achieved through mass spectrometry based proteomics due to the unmatched capability of this platform in identifying thousands of proteins in complex mixtures. Relative quantification of proteins across large number of samples can also be performed using a new label free quantification method termed SWATH (sequential window acquisition of all theoretical fragment masses). In this study, we generated a vast human T cell library (>4,000 proteins) using cell multiparametric sorting, OFFGEL electrophoresis and tandem mass spectrometry. We identified 22% of the protein library to be of plasma membrane origin. Using quantitative SWATH technology, we observed hundreds of proteins to be differentially expressed on defined T cell subsets, which were further differentially expressed during the course of cell activation. These data suggest that SWATH will likely be an important tool to both study protein expression patterns among different T cell lineages and uncover new immunological correlates of disease.

Zealand, ⁵Faculty of Medical and Health Sciences, The University of Auckland, Department of Physiology, Auckland, New Zealand

A network of fibroblastic reticular cells forms a complex 3D mesh within lymph nodes (LNs) and constructs a conduit filtering system that distributes lymph-born immune stimulants and antigens within different cell compartments. Despite its crucial function in immune surveillance, the organisation of the labyrinthine conduit network and structural changes following immune challenge are still insufficiently defined. We developed innovative 3D imaging and computational techniques to produce high resolution images of entire murine lymph nodes, in order to explore their organisation at whole organ scale. Using the automated extended-volume confocal imaging system (EVIS), we generated unprecedented 3D images of the conduit network in a murine LN at 1 µm pixel resolution. The extensive imagery disclosed the precise arrangement of individual fibres within LN subcompartments, around high endothelial venules (HEVs), and revealed increasingly wider spacing within the T cell zone. We employed custom-designed computational tools to re-visualise these image data as a continuous 3D model and quantify topological features such as fibre diameters, lengths, and spacing. Our ongoing investigations are focussed on utilising this 3D map to compare fibre dimensions within functional LN subregions, as we have recently shown for the LN blood vasculature, and track structural changes after immune stimulation. The resulting data have the potential to advance current models of immune cell migration and improve our understanding of LN remodelling and its implications for LN functionality.

We have developed and patented technologies for the extensive molecular analysis of human antibody responses which allow for the direct comparison of protein-level serum antibody repertoires to DNA-level repertoires in circulating peripheral blood B cells. These techniques uncover completely new facets of the response to the inactivated poliovirus and seasonal influenza vaccines that have major implications for human health. To perform this analysis we capitalized on a series of interrelated, recently published technologies developed by the Georgiou lab including:

- an LC-MS/MS proteomic strategy for the quantitation and identification of the IgG antibody clonotypes that comprise the serum polyclonal repertoire to a given vaccine antigen;
- very high-throughput determination of natively paired VH and VL sequences in hundreds of thousands of B cells; and
- expression and functional characterization of representative serum antibodies.

In contrast to extensive prior studies by many labs, using small numbers of antibodies encoded by peripheral B cells and isolated by B-cell immortalization of single-cell cloning techniques—which have generally shown that B-cell receptors with very broad binding to different viral strains are generally quite rare—our data now show that broadly cross-reactive immunoglobulins are strikingly prevalent in human serum. When cloned and expressed as monoclonal antibodies, we document that top-ranking, highly abundant serum IgG clonotypes are enriched for cross-neutralizing and even cross-protective biologic activity.

Aim: The capacity to predict interactions between nanomaterials and cells will benefit the rational design of novel nanomedicines. These fundamental relationships have not been adequately defined. By examining various nanoparticle systems with primary human blood cells, we are establishing principles of bio-nano interactions and aim to generate predictive relationships that can inform the next generation of nanomedicines.

Methods: Nanoparticles were generated with varying charge and surface chemistries, and incubated with primary human blood (cell association/uptake) or purified cells (immunoactivation) at 37°C and 4°C. Nanoparticle cell-association or activation markers were analysed by flow cytometry.

Results: We have determined that the properties of nanoparticles can significantly impact immunological outcomes, including immunoactivation and leukocyte uptake.

a. Hyperbranched polymers (HBPs) differentially activated primary human blood dendritic cells based on charge. HBP of 8 nm diameter were prepared and tested under endotoxin-free conditions. Cationic (+16 mV) HBPs activated myeloid but

not plasmacytoid dendritic cell populations while neutral and anionic (-15 mV) HBPs were not immunostimulatory.

b. Charge dictated HBP association with different immune cell subsets. All cell types associated with cationic HBPs, while at 37°C anionic HBPs preferentially associated with cells specialized for pathogen clearance and processing.

c. Terminal disulphide groups enhanced nanoparticle association with human blood components, particularly phagocytic cells.

d. Altering the chemical composition of nanoparticle surfaces can reduce phagocytic clearance. Brushed (vs. linear) poly(ethylene)glycol of same molecular weight enhanced phagocytic uptake.

Conclusion and future: By creating a nanoparticle 'characteristic matrix', we will apply mathematical modelling principles to generate a predictive model of bio-nano interactions.

Standardization and quality control using control samples to minimize batch effects and improve reproducibility of mass cytometry (CyTOF) assays in human immunology studies

Kleinsteuber, K.^{1,2,3}, Corleis, B.¹, Rashidi, N.¹, Nchinda, N.^{1,2}, Lisanti, A.¹, Kwon, D.¹, Walker, B.^{1,2}

¹Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, ²Howard Hughes Medical Institute, Chevy Chase, United States, ³Heinrich-Pette-Institute, Hamburg, Germany

Mass cytometry, a mass spectrometry based single cell technology, allows utilization of 35+ antibodies in a single sample and is a promising screening and surveillance tool in translational immunology. Despite availability of several analysis tools, a straightforward method for standardization and quality control within longitudinal mass cytometry studies is still lacking. We sought to develop a method to monitor batch effects and quality of individual samples in human immunology studies. Here, we demonstrate a protocol requiring only minimal changes to established staining protocols and propose a standardized analysis procedure allowing efficient quality control of mass cytometry experiments. Each sample is spiked with control PBMCs from a healthy donor, derived from a single large blood draw. Thus, all subsequent experiments are performed using the same control PBMCs. This method facilitates reproducible data analysis by:

1) performing quality control of each antibody in the panel, 2) monitoring batch effects, and 3) application of a robust gating strategy for patient samples. We demonstrate the utility of this method using two different experimental setups:

1) phenotyping of CD8⁺ T cells in HIV⁺ patients and 2) comparison of cytokine expression in bronchoalveolar lavage and peripheral blood samples from HIV-infected subjects. Control PBMCs within these experiments facilitated quality control based on positive populations for each antibody and exhibited potential substandard sample preparations. Semi-automated gating for each antibody using negative populations in the control PBMCs revealed a robust gating strategy and resulted in reproducible downstream analysis with diminished batch effects.

1225**Deep sequencing of T-cells specific for a mycobacterial glycolipid reveals shared T-cell receptor motifs with diagnostic potential in population-based studies**

DeWitt, W.¹, Quan, K.², Emerson, R.¹, Sherwood, A.¹, DeRosa, S.³, Finak, G.³, Gottardo, R.³, Day, C.⁴, Scriba, T.⁵, Robins, H.¹, Seshadri, C.²

⁴Emory University, Atlanta, United States, ⁵University of Cape Town, Capetown, South Africa

The somatically rearranged complementarity determining region 3 (CDR3) of the T-cell receptor (TCR) α and β chains determine antigen-specificity of T cells, so CDR3 sequences are potential biomarkers of antigen-specific T-cell responses. Population-level convergence in TCRs binding a specific antigen presented by major histocompatibility complex (MHC) proteins is complicated by polymorphisms that modulate binding strategies across individuals with differing MHC haplotypes. We hypothesized that the non-polymorphic CD1 family of lipid antigen-presenting molecules would provide a structural constraint lacking in the MHC and facilitate population level convergence in CDR3 usage for a single lipid antigen. We used CD1b tetramers loaded with glucose monomycolate (GMM) to isolate GMM-specific T-cells from four subjects infected with *Mycobacterium tuberculosis* (*M.tb*). We used TCR immunosequencing to characterize the CDR3 sequences of *in-vitro* expanded and re-sorted tetramer-positive T-cells. We identified highly stereotyped TCR-a and TCR-b motifs present in all four donors, and clonal analysis support the co-expression of these motifs by a single T-cell. The TCR-b motif was largely absent in PBMC from 587 healthy bone marrow donors at low risk for *M.tb* infection in the USA. By contrast, we found significant enrichment in both the TCR-a ($p < 0.01$) and TCR-b ($p = 0.09$) motifs among active tuberculosis patients when compared to uninfected control subjects in South Africa. We confirmed the expansion of GMM-specific T-cells among tuberculosis patients using flow cytometry ($p = 0.001$). These data reveal the existence of an antigen-specific shared T-cell repertoire that could be used to develop molecular diagnostics for diseases such as tuberculosis.

1226**In vivo cellular barcoding using a novel Cre Lox system**

Miles, D.¹, Weber, T.², Dukes, M.³, Glaser, S.¹, Duffy, K.², Naik, S.¹

¹Walter and Eliza Hall Institute, Parkville, Australia, ²Hamilton Institute, Maynooth, Ireland, ³University of Strathclyde, Glasgow, United Kingdom

Cellular barcoding is a useful biotechnology tool that allows single cell lineage tracing in various biological systems by marking cells with unique DNA barcodes *ex vivo* using lentivirus, followed by transplantation in a live animal. Subsequent comparison of barcode profiles between progeny cell types establishes the lineage relationship between these cell types (e.g. shared barcodes indicate a 'common' progenitor, differing

barcodes indicates 'distinct' progenitors). The best characterised example of its utility is in the study of haematopoiesis. However, there are limitations to this current system including its relatively low barcode diversity (~2,500) and the inability to barcode cells in their living native environment (*in vivo*). To overcome these restrictions we have devised a barcoding method that relies upon the well-established Cre Lox system through use of multiple in-tandem barcodes flanked by alternating LoxP sites. By exploiting inherent sequence distance constraints during site-specific recombination we identify a cassette combination that allows maximal code diversity, greater than 10^{12} . Once constructed, we aim to use this tool to create stable barcodes to better understand haematopoiesis at the single cell level in a native *in vivo* context.

1227**Protective immunity against botulinum neurotoxin elicited by genetic immunization with PLGA nanoparticle formulated DNA vaccine**

Zeng, M.¹, Ruwona, T.², Xu, H.², Li, J.¹, Diaz-Arévalo, D.¹, Kumar, A.², Chen, Y.¹, Cui, Z.²

¹Texas Tech University Health Sciences Center El Paso, Center of Emphasis in Infectious Diseases, El Paso, United States, ²University of Texas at Austin, College of Pharmacy, Pharmaceutics Division, Austin, United States

Botulism is a rare but potentially life-threatening bacterial illness that is caused by botulinum neurotoxins (BoNTs) for which there is currently no approved vaccine. Recent efforts in developing vaccine candidates against botulism have been directed at the heavy chain fragment of BoNT, because antibodies against this region have been shown to prevent BoNT from binding to its receptor and thus to nerve cell surface, offering protection against BoNT intoxication. In the present study, it was shown that genetic immunization with plasmid DNA that encodes the 50 kDa C terminal fragment of the heavy chain of BoNT serotype C (i.e., BoNT/C-Hc50) and is carried by cationic poly (lactic-co-glycolic) acid (PLGA) nanoparticles induces stronger BoNT/C-specific antibody responses, as compared to immunization with the plasmid alone. Importantly, the antibodies have BoNT/C-neutralizing activity, protecting the immunized mice from a lethal dose of BoNT/C challenge. A PLGA nanoparticle formulated DNA vaccine encoding the Hc50 fragments of BoNT serotypes that cause human botulism may represent a viable vaccine candidate for protecting against botulinum neurotoxin intoxication.

1228**Identification of CD99 counter-receptor by pull-down method using dimeric CD99-human IgG Fc fusion proteins in combination with DTSSP crosslinking**

Takheaw, N.¹, Kasinrer, W.^{1,2}, Pata, S.^{1,2}

¹Division of Clinical Immunology, Department of Medical Technology, Faculty of Associated Medical Sciences, Chiang Mai University, Chiang Mai, Thailand, ²Biomedical Technology Research Center, National Center for Genetic Engineering and Biotechnology, National Science and Technology Development

Agency at the Faculty of Associated Medical Sciences, Chiang Mai University, Chiang Mai, Thailand

CD99 is a human leukocyte surface molecule involving T cell activation, cell adhesion, cell migration and cell death. Its counter-receptor is, however, still a matter of controversy. In an attempt to identify CD99 counter-receptor, a pull-down assay was developed. The successful of the pull-down method is indeed depending on the bait protein structure. To obtain bait protein composed of a similar structure and post-translational modification to native CD99 protein, we produced secreted dimeric CD99-human IgG Fc fusion proteins in 293T cell line. The CD99-IgG Fc fusion proteins were, then, used to search for the CD99 ligand, in combination with 3,3'-dithiobissulfosuccinimidylpropionate (DTSSP) crosslinking, in various human cell lines by indirect immunofluorescence staining. Upon several cell lines tested, only THP-1 cell line showed positive staining with CD99 bait protein. To pull down CD99 counter-receptor, THP-1 cells were stained with CD99-IgG Fc fusion proteins, crosslinked with DTSSP and pulled down by protein G beads. By western blotting, the molecular weight of the pulled down protein was higher than the CD99 bait protein indicating the presence of CD99 counter-receptor in the pulled down material. In this study, we introduced here the pull-down method using a flexible-dimeric CD99 fusion protein in combination with DTSSP crosslinking for identification of its counter-receptor.

1229

Monoclonal mouse antibodies against PBMC subpopulations of New World camelids

Holzlohner, P.¹, Butze, M.¹, Hebel, N.¹, Weschke, D.¹, Schliebs, E.², Naumann, F.², Fünér, J.², Micheel, B.¹, Hanack, K.¹

¹University of Potsdam, Immunotechnology, Potsdam, Germany,

²Preclinics GmbH, Potsdam, Germany

The immune system of New and Old World camels is of special interest because it expresses besides the conventional four chain antibodies also heavy chain only antibodies. Furthermore camelids gain more and more significance as livestock. To investigate the immune system of camelids and to have a diagnostic tool, it would be advantageous to divide the different immune cell populations with the help of specific antibodies. The generation of immune cell-specific murine antibodies was performed by immunization of Balb/c mice with different camelid PBMC subclasses. For this llama blood was centrifuged and erythrocytes lysed with Geys Media. Different cell preparations were used for immunization. Monocytes were gained after a 2 hour plastic adhesion. Dendritic cells were generated from camelid monocytes after a 7 day treatment with human IL-4 and GM-CSF. In addition to that mice were immunized with total alpaca spleen or lymph nodes cell population, respectively. Monoclonal antibody-producing cells were generated by hybridoma technology. Immune cell-specific hybridomas were selected using a cell-based ELISA. Purified antibodies were used to stain different blood cell populations and investigate them via flow cytometry. Furthermore we used the generated monoclonal antibodies for magnetic cell sorting

of camelid PBMCs. We were able to generate monoclonal antibodies that could bind all populations of camelid PBMCs as well as antibodies that bind only to different populations of PBMCs. Due to their position and scattering in flow cytometry the cell populations could be related to camelid lymphocyte, granulocyte and monocyte populations.

Whole organ imaging for analysis of immune responses in lymph nodes

Devi, S.^{1,2}, Hor, J.L.^{1,2}, Loi, J.K.^{1,2}, Heath, W.R.^{1,2}, Mueller, S.N.^{1,2}

¹The Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Parkville, Australia,

²The ARC Centre of Excellence in Advanced Molecular Imaging, University of Melbourne, Parkville, Australia

Interactions between immune cells are critical for the initiation and effector phases of immunity. To understand the cellular events involved in the priming of T cell responses to viral infection we have examined T cell interactions with dendritic cell (DC) subsets by intravital 2-photon microscopy. However, this method limits analysis to defined regions of the lymph nodes (LN). To examine and quantify interactions between T cells and DC in whole lymphoid organs, we utilised a novel clearing method that preserves fluorescent protein function and allows immunofluorescent antibody labelling *ex vivo* to identify multiple cell types concurrently. Using 2-photon microscopy on cleared LN we visualised the vascular and lymphatic networks, and remodeling after infection. We imaged CD4 and CD8 T cell clustering with migratory and resident DC after infection to determine regional differences in T cell subset activation by DC in whole LN. Thus, we describe a method to imaging whole cleared lymphoid organs *ex vivo* by 2-photon microscopy for quantitative spatial analysis of immune responses.

1231

Development and characterization of a novel cell-based biosensor for screening of inflammatory agents in bioaerosols

Khera, S.¹, Sharma, V.¹, Fejer, G.¹, Tyrrel, S.², Bennett, A.³, Jackson, S.¹

¹Plymouth University, Plymouth, United Kingdom, ²Cranfield University, Milton Keynes, United Kingdom, ³Public Health England, Porton Down, United Kingdom

Bioaerosol exposure has been associated with adverse effects on human health and airborne transmission of infections. The lack of technology to determine exposure-response relationship has hampered the assessment of health risks and development of regulatory frameworks associated with bioaerosol emissions. Cell-based biosensors have been recognized as potential leaders in the next generation of functional biosensing as they provide rapid and useful information on physiological responses to a variety of bioactive analytes. We have developed 2D and 3D cell cultures which show promise as cell-based biosensors in a variety of settings. Alveolar macrophages (AM) are the first line of defence against airborne environmental microbes. Recently, we have described a novel, continuously

growing, non-transformed, model of lung AMs (MPI cells). This robust system provides an excellent new model for AMs without restricted availability. We used MPI cells and bronchial epithelial cells to develop novel biosensors to characterize bioaerosol components (such as LPS) and their unique inflammatory signatures. Detection and characterization of responses to bioaerosol-derived microbial ligands was achieved through macrophage gene expression, including cytokine responses using Luminex multiplex platforms, RT-PCRs and proteomic analysis. The results from these experiments will provide the first direct model of human airway cell responses to LPS and other microbial molecules from bioaerosols. Moreover, understanding these cell responses will allow the future development of high throughput and potentially 'in-field' use of these cell-based biosensors.

1232

Immunobiosensor for measurement and characterization of soluble CD147 molecule

¹Faculty of Associated Medical Sciences, Chiang Mai University, Department of Medical Technology, Chiangmai, Thailand,

²Biomedical Technology Research Center, National Center for Genetic Engineering and Biotechnology, National Science and Technology Development Agency at the Faculty of Associated Medical Sciences, Chiang Mai University, Department of Medical Technology, Chiangmai, Thailand

Soluble CD147 (sCD147) is the shedding form of membrane bound CD147 which share at least two extracellular Immunoglobulin (Ig)-like domains and also has the ability to control cell functions. The evaluated expression of sCD147 is related to many diseases and can be observed in human body fluids. In this study, we developed the system to detect sCD147 by using anti-CD147 monoclonal antibody (mAb) which recognized the different domain epitopes of extracellular part of CD147 and BLItz biosensor. The single antibody system, anti-CD147-domain 1 mAb clone M6-1E9 showed the highest limit of detection (LOD) at concentration 890 ng/ml of CD147 recombinant protein (CD147Rg). For CD147 domain 2 detection, MEM6/6, anti-CD147 domain 2 mAb showed the LOD at 8.137 µg/ml. In sandwich system which can define the shedding structure of sCD147, a pair of primary mAb MEM6/3 (anti-CD147 domain 1) and secondary MEM6/6 antibodies showed the best LOD at concentration 66 ng/ml. In contrast, using MEM6/6 as primary mAb, M6-1E9 showed the good LOD at 1.093 µg/ml. All in all, the real time sCD147 detection systems were established which can be investigate the presence of sCD147 and also clarify the shedding structure. The generated strategies could be used as tools for better understanding CD147 associated- diseases, diagnosis and prognosis in the future.

Performing systems immunology using next generation high-dimensional single-cell cytometry systems: bright lights and heavy metals

Ashhurst, T.^{1,2}, Lim, A.³, Duckett, L.⁴, Balderas, R.⁴, Fazekas de St Groth, B.^{2,5}, Smith, A.^{2,6}, King, N.^{1,2,6}

¹The University of Sydney, Pathology, Sydney, Australia, ²The University of Sydney and the Centenary Institute, The Ramaciotti Facility for Human Systems Biology (RFHSB), Sydney, Australia, ³BD Biosciences, Macquarie Park, NSW, Australia, ⁴BD Biosciences, San Jose, United States, ⁵The Centenary Institute, Camperdown, Australia, ⁶The University of Sydney and the Centenary Institute, Sydney Cytometry Facility, Sydney, Australia

The rise of mass cytometry has allowed for characterisation of the immune system in unprecedented detail, enabling the detection of more than 40 parameters simultaneously on single cells. Additionally, the comparative lack of spillover between reagents, when compared with fluorescence cytometry, has led to the development of assays capable of interrogating highly related cellular subsets. However, the development of new fluorescent dyes, and enhancement of acquisition electronics has led the way in the development of next generation fluorescence flow cytometers. Here we sought to employ these new cytometry techniques to move beyond bulk measurement of a system, and towards interrogating the complex interaction of large numbers of cells that define the behavior of the immune system. For mass cytometry, we utilised a CyTOF2/Helios (Fluidigm) platform. For fluorescence cytometry we equipped a 10-laser Becton Dickinson (BD) LSR-II special order research product (SORP) platform with a newly developed electronics system, increasing the number of detectable signals to ~30. We incorporated a range of traditional dyes into our panels, in addition to novel polymer dyes developed by Sirigen. Here we also describe the development of a novel optimisation program, combining the use of the existing cytometer setup and tracking (CS&T) program, with newer methods to generate optimised voltage target values for panels of up to 30-colours. Using both systems, we conducted comprehensive profiling of the murine haematopoietic system in the bone marrow during viral infection. Our investigation revealed cell cycle and signaling modifications that resulted in enhanced monopoietic outputs.

1234

Selelction of PBMC from whole blood with FABian[®] by using CD81+ marker

Stanar, K.¹, Stadler, H.¹, Gerdes, W.², Bergmann, S.², Kiene, M.-L.¹

¹IBA GmbH, Göttingen, Germany, ²IBA GmbH, Leipzig, Germany

Objective: Peripheral blood mononuclear cells (PBMCs) selections often apply methods that are time consuming and complex. Additionally, target cells are manipulated by diverse selection reagents. To cope with these disadvantages we applied the magnet-free, mild and fast T-CATCHM technology to the automatic system FABian[®]. The research was aimed at the isolation of PBMCs from whole blood in highest yields, purity and viability without using Ficoll.

Method: FABian® was equipped with a column containing an Agarose-Strep-Tactin® matrix and 11 tubes as carriers for the required reagents. After drawing up CD81-Fab-fragment into the column, whole blood was passed through the matrix. Only CD81+ cells bind to the Fab -Strep-agarose matrix. Unbound cells were washed out. Washing steps were followed by an elution with biotin resulting in the release of PBMCs.

Results: The average purity of the selected CD81+ cells was >90% with a viability of >90% and a yield >10x10⁶ CD81+ cells out of samples of 9ml whole blood. During washing steps only a loss of 6% of CD81+ cells was detected and led to the elimination of neutrophil and basophil granulocytes.

Conclusion: The isolation of PBMCs with the T-CATCHTM technology applied with FABian® presents a valid method to isolate non-activated, label-free authentic target cells in high purity, viability and yields. PBMCs isolated with FABian® far exceed the results of Ficoll-based isolations in purity and yield. With Fabian® various cell types can be selected from whole blood and buffy coats. Sequential isolations to select specific cells (eg. CD14 or CD19) are possible.

1235

Simultaneous flow cytometric measurement of attachment and phagocytic processes of phagocytes

Laopajon, W.¹, Takheaw, N.¹, Pata, S.^{1,2}, Kasinrerk, W.^{1,2}

¹Division of Clinical Immunology, Department of Medical Technology, Faculty of Associated Medical Sciences, Chiang Mai University, Chiangmai, Thailand, ²Biomedical Technology Research Center, National Center for Genetic Engineering and Biotechnology, National Science and Technology Development Agency at the Faculty of Associated Medical Sciences, Chiang Mai University, Chiangmai, Thailand

Phagocytosis can be divided into three stages including attachment, internalization, and degradation of the microbes. The available phagocytosis assays, however, could not differentiate the stages of phagocytosis. In this study, the method for concurrent detection the attachment and engulfment of phagocytosis was developed by using latex beads coated with lipopolysaccharide (LPS), rabbit IgG, and carboxyfluorescein diacetate succinimidyl ester (CFSE). The generated CFSE-LPS-IgG coated latex beads were incubated with whole blood at 37°C for 1 hour. After incubation, the cells were stained with PE-Cy5.5 anti-rabbit IgG antibody. The phagocytosis was analyzed by flow cytometry. The results demonstrated that CFSE and IgG coated on beads could be detected by flow cytometer. The developed methods could be used for determination of attachment and phagocytic processes. In the presence of NaN₃ and NaF, phagocytosis inhibitors, inhibition of both the attachment and the engulfment was demonstrated. Under on-ice condition, the engulfment step was blocked, while the attachment process could still be observed. In summary, the established methods could be employed for the detection of both attachment and engulfment of phagocytes, simultaneously. This method is a valuable tool for the diagnosis of phagocytosis disorder as well as the study of the molecules involved in phagocytosis.

Genetics

Interethnic variability in sickle cell disease pathophysiology is associated with polymorphisms of the endothelin-1 gene

Noble, J., Pirela, L., Thomas, B.

Rochester Institute of Technology, Biomedical Sciences, Rochester, United States

Sickle cell disease, a multisystem disorder arising from the mutation of the beta globin gene, and characterized by multiple complications has been shown to demonstrate extensive variability in disease severity among and between individuals, the variability highlighted by differing genetic haplotypes.

Reports of functional significance due to polymorphisms of endothelial nitric oxide synthase (eNOS) and endothelin-1 genes abound. The role of these polymorphisms in regulating disease complications among African Americans is presently unclear.

To deconvolute African American SCD, we examined the genetic diversity and haplotype frequency of eNOS and ET-1 polymorphisms in disease (n=331) and control (n=379) groups, utilizing a PCR-RFLP assay. We report that allelic and genotypic frequencies of eNOS polymorphic variants are not significantly different between cases and controls. eNOS homozygote mutants, shown to have clinical significance elsewhere, demonstrated no statistical significance in our study. Contrary to our African cases, the endothelin-1 homozygote mutant (5665T) showed significant difference between disease and control groups in genotypic (P=2.84E-12) and allelic frequencies (P=2.20E-16). Additionally, the most common haplotype in our study is the combination of T786C wild-type variant with mutant variants of 5665T (ET-1) and 298Asp (eNOS). The lack of difference in eNOS polymorphisms between African and American groups implies disease has retained its evolutionary origin.

The significance of this observation per disease severity or individual clinical outcomes and implications for advancing personalized care for sickle cell disease patients, utilizing pharmacogenomics tools based on ethnic population structure is discussed.

1237**Australian Autoinflammatory Diseases RegistrY (AADRY): a national approach to the genetic and immunological evaluation of patients with suspected autoinflammatory disease**

Traditionally defined as periodic fever syndromes lacking markers of autoimmunity such as high titre self reactive T cells and auto-antibodies, the spectrum of monogenic autoinflammatory diseases has broadened substantially in recent years. The clinical heterogeneity of newly described conditions such as STING associated vasculopathy with onset in infancy (SAVI) and Deficiency in ADA2 (DADA2) has forced reconsideration of traditional designations, with the common link between these disorders being inappropriate inflammation and cytokine dysregulation. These new diagnoses can be attributed to the introduction of whole exome sequencing (WES) into the diagnostic algorithm of patients with suspected, but currently genetically undefined, autoinflammatory diseases. We believe it's important to take a national approach to the diagnosis of autoinflammatory disorders given their rarity and introduce the establishment of AADRY, an Australian Autoinflammatory Diseases RegistrY. AADRY proposes to collect epidemiological and clinical data on patients with suspected and confirmed autoinflammatory diseases, and will perform whole exome sequencing in patients who are yet to be genetically characterised. We also aim to perform in vitro testing and harness CRISPR-Cas9 gene editing technology to determine the functional significance of novel variants and their potential contribution to clinical phenotype. We describe bioinformatic analyses and other results from the first 12 AADRY cases analysed, including one trio and one family of five.

1238**HLA class II protein stability and disease susceptibility**

Miyadera, H.^{1,2}, Ohashi, J.³, Tokunaga, K.²

¹National Center for Global Health and Medicine, Research Center for Hepatitis and Immunology, Ichikawa, Japan, ²University of Tokyo, Graduate School of Medicine, Bunkyo-ku, Japan, ³University of Tokyo, Graduate School of Science, Bunkyo-ku, Japan

Genes encoding the human leukocyte antigens (HLA) are associated strongly with susceptibility/protection to various immunological diseases; however, underlying mechanisms have not been fully explained. We hypothesized that allelic variation in the protein stability of HLA, in addition to variation in the peptide-binding spectrum, might contribute to disease susceptibility. We tested this hypothesis by analyzing the association between the stability of HLA-DQ and genetic risk for type 1 diabetes (T1D). As reported previously through the SDS-stability assay (Ettinger et al. *J Immunol* 1998), we found a correlation between HLA-DQ instability and susceptibility to T1D (Miyadera, et al. *J Clin Invest* 2015). Moreover, polymorphic variants that decrease the intrinsic stability of HLA-DQ were associated with T1D risk. We next estimated the stability of HLA-DR and -DP allele products through the cell-surface expression assay and analyzed their associations with various disorders, including T1D, narcolepsy, and chronic hepatitis B. In this presentation, we show the stability profiles for HLA-DR and -DP allele products and their relation with disease risk, and discuss potential mechanisms that might underlie genetic associations of HLA with diseases.

1239**ATG16L1 gene polymorphism associated with chronic hepatitis B virus infection in a Thai population**

Kimkong, I.^{1,2}, Tantithavorn, V.¹, Hirankarn, N.³, Tangkijvanich, P.⁴

¹Faculty of Science, Kasetsart University, Department of Microbiology, Bangkok, Thailand, ²Kasetsart University, Center for Advanced Studies in Tropical Natural Resources, National Research University, Bangkok, Thailand, ³Faculty of Medicine, Chulalongkorn University, Center of Excellence in Immunology and Immune Mediated Diseases, Department of Microbiology, Bangkok, Thailand, ⁴Faculty of Medicine, Chulalongkorn University, Research Unit of Hepatitis and Liver Cancer, Department of Biochemistry, Bangkok, Thailand

Hepatitis B virus (HBV) infection is a serious and life-threatening health problem. Approximately 350 million people are chronically infected with HBV and estimated 1 million deaths per year from HBV-related liver disease. Autophagy is an important pathway for host defense against viral infection. Various studies have reported the association of autophagy 16-like 1 (ATG16L1) polymorphisms with certain diseases. However, the association of this gene with chronic HBV infection is still not investigated. Therefore, we explored the effect of single nucleotide polymorphism (SNP) of ATG16L1 (rs2241880) in chronic HBV infection. We recruited 237 Thai patients with chronic HBV infection (110 with HCC and 127 without HCC), 124 recovered individuals and 139 healthy controls in this study. The rs2241880 polymorphism was analyzed by polymerase chain

reaction-restriction fragment length polymorphism (PCR-RFLP) method. The results showed that A allele of ATG16L1 rs2241880 was associated with an increased risk in chronic HBV infection as compared to healthy controls [OR (95% CI) = 1.50 (1.07-2.11), $P = 0.014$]. To test the effect of rs2241880 genotypes, we compared mRNA expression level of ATG16L1 among individuals containing different genotypes (AA, AG and GG). We found that ATG16L1 mRNA level of the subjects carrying AA and AG genotypes of rs2241880 was down-regulated when compared with GG genotype ($P = 0.018$; $P = 0.051$, respectively). Our study suggested that A allele of ATG16L1 rs2241880 may provide a risk effect in this disease.

1240

Replication of the reported deletion of the GLUT3 gene SLC2A3 on chromosome 12 conferring substantial protection against rheumatoid arthritis

Simpfendorfer, K.R., Kothari, H., Shih, A., Li, W., Armstead, B., Lee, A., Gregersen, P.K.

Feinstein Institute for Medical Research, Robert S. Boas Center for Genomics and Human Genetics, Manhasset, United States

The deletion of a 129kb segment on chromosome 12p13.31 is a low frequency copy number variant resulting in loss of the glucose transporter genes encoding GLUT3 and GLUT14. Recently, deletion of the 129kb segment at 12p13.31 was shown to be substantially protective for Rheumatoid Arthritis in Swedish, UK and US cohorts (Veal *et al* Human Mutation 2013). *SLC2A3* (encoding GLUT3) is most highly expressed in brain and human white blood cells, predominantly in granulocytes. Neutrophils are the predominant infiltrating cell type in inflamed RA joints, and neutrophil derived neutrophil extracellular traps (NETs) may be the primary source of antigen such as citrullinated proteins to which RA autoantibodies (anti-citrullinated protein antibodies, ACPA) arise. Given the principal role of neutrophils in RA, and the high expression of *SLC2A3* in neutrophils, we hypothesize that subjects lacking one copy of *SLC2A3* are protected against RA because their neutrophils are deprived of glucose. To replicate the association between 12p13.31 deletion and protection against RA we have designed a fast and reliable genotyping assay to screen a US cohort of RA cases and matching controls. This assay negates the requirement for the previously used lengthy and unreliable P1 PCR assay, or for SNP chip PennCNV analysis. If replication of the initial report is achieved, we will proceed with functional studies to investigate the association between loss of *SLC2A3* and pathogenic neutrophil phenotypes.

1241

Slc11a1 gene modulates immune-inflammation genes in macrophages during pristane-induced arthritis in mice

Correa, M.A.¹, Canhamero, T.¹, Borrego, A.¹, Katz, I.², Jensen, J.R.¹, Guerra, J.L.³, Cabrera, W.H.K.¹, Starobinas, N.¹, Gonçalves, J.F.¹, Ribeiro, O.G.¹, Ibañez, O.M.¹, De Franco, M.¹

¹Instituto Butantan, Sao Paulo, Brazil, ²Instituto Pasteur, Sao Paulo, Brazil, ³Universidade Anhembi Morumbi, Sao Paulo, Brazil

Pristane-induced arthritis (PIA) in AIRmax mice homozygous for *Slc11a1 R* and *S* allele was used in this study to characterize the role of *Slc11a1* gene on immune response. Previous reports showed that the presence of *Slc11a1 S* allele increased the incidence and severity PIA in AIRmaxSS, suggesting that this gene could interact with inflammatory loci to modulate PIA. AIRmaxSS macrophages demonstrated exacerbated cellular and gene expression profiles during PIA, with higher expression/production of H2O2, NO, IL-1 β , IL-6, TNF- α and several chemokines. On the other hand, *Slc11a1 R* allele could control the intensity of macrophage activation, restricting the arthritis development. Our data demonstrated the fine tune role of *Slc11a1* alleles modulating macrophage activation and consequently PIA susceptibility in these lines.

1242

The H2-Ab1 Class II gene regulates the level of susceptibility and immune responses in the mouse model of tuberculosis infection

Korotetskaya, M., Apt, A., Logunova, N.

Central Institute for Tuberculosis, Immunology, Moscow, Russian Federation

Tuberculosis (TB) pathogenesis is multistage, highly complex sequence of events, with many cell types involved. To identify genetic loci determining the spectrum of natural genetic resistance to *Mycobacterium tuberculosis* (MTB) three teams of researchers applied the forward genetic approach (from the phenotype to gene) for genome-wide association studies on the basis of different combinations of inbred mouse strains displaying resistant and susceptible phenotypes. Regardless of parental combinations, all three groups reported complex, polygenic control of host susceptibility/resistance to TB. Our group mapped three quantitative trait loci (QTL) on chromosomes 3, 9 and 17. The latter QTL was located within the mouse major histocompatibility complex (H2).

We have established a panel of congenic, MHC-recombinant mouse strains bearing differential small segments of chromosome 17 transferred from the TB-susceptible I/St (*H2^b*) strain onto the genetic background of TB-resistant C57BL/6 (B6) mice (*H2^b*). This allowed narrowing the QTL interval to 17Ch: 33, 77-34, 34 Mb, containing 36 protein-encoding genes. In two recombinant strains, B6.I.100 and B6.I.139, recombination breakpoints occurred in different sites of the *H2-Ab1* gene, providing polymorphic variations in the domain $\beta 1$ of the $A\beta$ -chain. These variations were sufficient to produce different TB-relevant phenotypes: the more susceptible B6.I-100 strain demonstrated shorter survival time, more rapid body weight loss, higher mycobacterial loads in the lungs and more severe lung histopathology compared to the more resistant B6.I.139 strain. Thus, we directly demonstrated for the first time that the classical *H2-Ab1* Class II gene is involved in TB control.

1243**An examination of single nucleotide polymorphisms in transient receptor potential ion channels and acetylcholine receptors in chronic fatigue syndrome patients**

Marshall-Gradisnik, S.^{1,2}, Chacko, A.^{1,2}, Johnston, S.^{1,2}, Smith, P.¹, Nilus, B.³, Staines, D.¹

¹*Menzies Health Institute Queensland, National Centre for Neuroimmunology and Emerging Diseases, Parklands, Australia,*

²*Griffith University, School of Medical Science, Parklands, Australia,*

³*University of Leuven, Leuven, Belgium*

Background: Chronic fatigue syndrome (CFS) is an unexplained disorder characterised by debilitating fatigue, neurocognitive, immune, gastrointestinal, cardiovascular and autonomic symptoms. Transient receptor potential (TRP) ion channels as well as Acetylcholine receptors (AChRs) have important roles in calcium and ACh signaling vital for physiological functioning. The purpose of this study was to examine their role in CFS.

Methods: The study comprised 115 CFS patients (age = 48.68±1.06 years) and 90 non-fatigued controls (age = 46.48±1.22 years). CFS patients were defined according to the Fukuda criteria for CFS. A total of 240 single nucleotide polymorphisms (SNPs) for 21 TRP genes and 464 SNPs for 9 AChR genes were examined via the Agena Biosciences iPLEX Gold assay. Statistical analysis was performed using the PLINK analysis software.

Results: Thirteen SNPs for TRPs and 17 SNPs for AChRs were significantly associated with CFS patients compared with the controls. The majority were associated with TRPM3, TRPC4, mAChRM3 and nAChRa10. Furthermore, 11 genotypes were identified from these SNPs that were significant in TRPM3 (rs12682832; rs11142508; rs3763619) and mAChM3R (rs12036141; rs589962; rs1072320; rs7543259; rs7520974; rs726169; rs6669810; rs6429157) in CFS patients compared with non-fatigued controls.

Conclusion: The findings of this pilot study suggest TRP ion channels and AChRs that are predominantly M3, are associated with CFS. SNP anomalies in TRP and AChR genes may contribute to the aetiology and pathomechanism of CFS.

1244**Comprehensive analysis of cytokine gene polymorphisms defines the association of IL-12 gene with ophthalmopathy in Korean children with autoimmune thyroid disease**

Jang, J.-P.¹, Cho, W.-K.², Baek, I.-C.¹, Choi, E.-J.³, Shin, D.-H.¹, Suh, B.-K.², Kim, T.-G.¹

¹*The Catholic University of Korea, Department of Microbiology, Seoul, Korea, Republic of,*

²*The Catholic University of Korea, Department of Pediatrics, College of Medicine, Seoul, Korea,*

³*The Catholic University of Korea, Hematopoietic Stem Cell Bank, College of Medicine, Seoul, Korea, Republic of*

In early onset autoimmune thyroid disease (AITD) showing a strong genetic tendency, cytokines have been suggested to play a critical role in the development of AITD. To directly compare the influences of several cytokine gene polymorphisms, 25 single nucleotide polymorphisms (SNPs) in 17 cytokine genes were analyzed on 104 Korean children with AITD [Hashimoto's

disease (HD) = 44, Graves disease (GD) = 60 (thyroid-associated ophthalmopathy (TAO) = 29, non-TAO = 31)] and 192 controls. Compared with healthy controls, any significant association with polymorphisms of cytokine genes was not found in HD and GD. Among GD patients, non-TAO group only showed significant associations with IL-12 C allele (rs3212227: A>C) (76.6% vs. 51.6%, OR = 0.3 [0.15-0.71], *P* = 0.007). Particularly, the frequency of IL-12 C allele was significantly lower in the non-TAO group than in the TAO group (82.8% vs. 51.6%, *P* = 0.018). Our comprehensive analysis of cytokine gene polymorphisms suggests that IL-12 gene may play impact on specific pathogenesis of ophthalmopathy in Korean children with AITD.

1245**Haplotype investigation of Killer cell immunoglobulin-like receptor genes from natural killer cells in chronic fatigue syndrome/myalgic encephalomyelitis patients**

Huth, T.^{1,2}, Brenu, E.^{1,2}, Staines, D.^{1,2}, Marshall-Gradisnik, S.^{1,2}

¹*National Centre for Neuroimmunology and Emerging Diseases, Menzies Health Institute Queensland, Gold Coast, Australia,*

²*School of Medical Sciences, Griffith University, Gold Coast, Australia*

Sixteen Killer cell immunoglobulin-like receptor (KIR) genes encoding inhibitory or activating receptors on Natural Killer (NK) cells have been characterised. KIRs are genetically diverse and can be classified as haplotype A or B. The predominance of inhibitory genes in haplotype A and activating genes in haplotype B suggests a distinct role of KIR haplotypes in governing effector functions of NK cells. Reduced NK cell cytotoxic activity has been consistently reported in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) patients and KIR haplotypes remain to be investigated. Therefore, the aim of this paper was to examine KIR haplotypes in CFS/ME patients. NK cells were isolated and deoxyribonucleic acid was extracted from CFS/ME patients and non-fatigued controls (NFC). KIR genotyping was performed on an Illumina MiSeq platform and the sequencing data was aligned to the Immuno Polymorphism-KIR Database to determine KIR haplotypes. A total of 20 CFS/ME patients and 20 non-fatigued controls (NFC) were included in this study. A lower frequency of the telomeric A/B motif (*p* < 0.05) was observed in CFS/ME patients compared to NFC. This pilot study is the first to report differences in the frequency of KIR on the telomeric A/B motif in CFS/ME patients. As the activity of NK cells is governed by the balance between activating and inhibitory signals, differences in the gene content profile of KIR haplotypes may create different activation thresholds for NK cells in CFS/ME patients. Further investigations are required to validate these findings in a larger cohort of CFS/ME patients.

1246

Association of CD40 functional genetic variants and CD40 mRNA expression with rheumatoid arthritis from western Mexico

Román Fernández, I.V.¹, Ávila Castillo, D.F.¹, Cerpa Cruz, S.², Gutiérrez Ureña, S.², de la Cruz Mosso, U.¹, Hernández Bello, J.¹, Muñoz Valle, J.F.¹

¹Universidad de Guadalajara, Instituto de Investigación en Ciencias Biomédicas (IICB), Guadalajara, Mexico, ²O.P.D. Hospital Civil de Guadalajara Fray Antonio Alcalde, Servicio de Reumatología, Guadalajara, Mexico

Rheumatoid arthritis (RA) is a multifactorial chronic inflammatory autoimmune disease. The *CD40* locus has been identified as a genetic susceptibility marker for RA. In RA, CD40 is involved in the production of autoantibodies, proinflammatory cytokines and other molecules that promotes joint destruction. The *CD40* single nucleotide polymorphisms (SNPs) rs1883832 and rs4810485 have been associated with RA and other autoimmune inflammatory diseases. Several studies suggest that both SNPs affect *CD40* mRNA and protein expression. The aim of this study was to investigate the association of these *CD40* SNPs with susceptibility to RA and their influence in *CD40* mRNA levels in western Mexican population. A total of 278 RA patients and 318 healthy subjects (HS) were included. Genomic DNA and total RNA were obtained from peripheral blood leukocytes. Genotyping was performed by PCR-RFLP method and mRNA levels were determined by real-time qPCR. Minor allele frequencies for rs1883832 and 4810485 were 18.5% and 18.9% in the RA group and 19.5% and 19.8% in HS, respectively; no significant differences were found. In addition, these genetic variants were not associated with the presence of autoantibodies or the clinical activity of the disease, when stratified by genotype. *CD40* mRNA expression was elevated in RA patients compared to HS (1.5 fold), however, no differences were found between mRNA expression and the different genotypes. These results suggest that the *CD40* SNPs rs1883832 and rs4810485 are not susceptibility markers for RA in western Mexican population; moreover, further studies are needed to clarify its role in *CD40* mRNA expression.

1247

Expression of Interferon Regulatory Factor-5 (IRF5) in asthmatic and non-asthmatic patients

Voon, Y.N.¹, Lim, K.C.¹, Wong, S.F.¹, Mak, J.W.¹, Lee, K.M.¹, Woo, K.²

¹International Medical University, Bukit Jalil, Malaysia, ²Gleneagles Medical Centre, Kuala Lumpur, Malaysia

Asthma is a very common inflammatory disease of the respiratory system. Asthma affects about 1 million people in the United States and 24% of children in the state of Selangor, Malaysia. It is postulated that an imbalance in the Th1 and Th2 immune responses may contribute to the pathophysiology of atopic asthma. IRF5 encodes key transcription factors in the production of Type 1 interferons and a number of inflammatory cytokines. Polymorphism in IRF-5 expression had been found to be associated with several autoimmune diseases such as systemic lupus erythematosus, rheumatoid

arthritis and systemic sclerosis. Interestingly, polymorphism in IRF5 expression had also been associated with atopic asthma in Dutch and English populations. However, the association between IRF5 polymorphism and asthma in the Asian population has yet to be established. Therefore, this study was conducted to determine the association of IRF5 gene polymorphisms (rs10954213/rs11770589 and rs2004640) and asthma in the Malaysian population. Genomic DNA was isolated from buccal cells and sequenced to identify IRF5 polymorphisms (rs10954213/rs11770589 and rs2004640). So far, 187 non-asthmatic samples and 152 asthmatic samples had been sequenced for the detection of IRF5 gene polymorphisms at rs10954213 and rs11770589, whereas 147 non-asthmatic samples and 150 asthmatic samples had been sequenced for the detection of IRF5 gene polymorphism at rs2004640. Results showed no association between IRF5 gene polymorphisms (rs10954213/rs11770589 and rs2004640) and asthma in the Malaysian population. Through this study, IRF5 polymorphisms (rs10954213/rs11770589 and rs2004640) may not be applicable biomarkers for the Malaysian population.

FcγRIIB-independent mechanisms controlling membrane localization of the inhibitory phosphatase SHIP in human B cells

Pauls, S.¹, Ray, A.¹, Hou, S.¹, Vaughan, A.², Cragg, M.², Marshall, A.¹

¹University of Manitoba, Immunology, Winnipeg, Canada,

²University of Southampton, Southampton, United Kingdom

SHIP is an important regulator of immune cell signaling that functions to dephosphorylate the phosphoinositide PIP₃ at the plasma membrane and mediate protein-protein interactions. One established paradigm for SHIP activation involves its recruitment to the phosphoITIM motif of the inhibitory receptor FcγRIIB. While SHIP is essential for the inhibitory function of FcγRIIB, it also has critical modulating functions in signaling initiated from activating immunoreceptors such as B cell antigen receptor. Here we find that SHIP is indistinguishably recruited to the plasma membrane after BCR stimulation with or without FcγRIIB co-ligation in human cell lines and primary cells. Interestingly, fluorescence recovery after photobleaching analysis reveals differential mobility of SHIP-EGFP depending on the mode of stimulation, suggesting that while BCR and FcγRIIB can both recruit SHIP, this occurs via distinct molecular complexes. Mutagenesis of a SHIP-EGFP fusion protein reveals that the SHIP-SH2 domain is essential in both cases while the C-terminus is required for recruitment via BCR stimulation, but is less important with FcγRIIB co-ligation. Experiments with pharmacological inhibitors reveal that Syk activity is required for optimal stimulation-induced membrane localization of SHIP, while neither PI 3-kinase or Src kinase activity are essential. BCR-induced association of SHIP with binding partner Shc1 is dependent on Syk, as is tyrosine phosphorylation of both partners. Our results indicate that FcγRIIB is not uniquely able to promote membrane recruitment of SHIP, but rather modulates

its function via formation of distinct signaling complexes. Membrane recruitment of SHIP via Syk-dependant mechanisms may be an important factor modulating immunoreceptor signalling.

1249

Control of B cell activation and migration by PI 3-kinase: role of inositol polyphosphate 4-phosphatases

Hou, S., Li, H., Marshall, A.

University of Manitoba, Immunology, Winnipeg, Canada

Balanced activation of the PI3K pathway by antigen and other stimuli is required for effective humoral immunity while avoiding autoimmunity and lymphoproliferative disease. The critical regulatory phosphatase SHIP dephosphorylates the PIP3 generated by PI3K to produce a distinct molecule PI(3,4)P2. A number of key signaling molecules bind to PIP3, including the protein kinase Btk; however much less is known about the function of PI(3,4)P2. The inositol phosphatase INPP4A can specifically hydrolyze PI(3,4)P2; however the functions of this phosphatase in B cell activation are unknown. We hypothesized that INPP4A can provide a tool to deplete PI(3,4)P2 and determine its range of functions. Human B lymphocytes over-expressing active or phosphatase-dead INPP4A were generated, and the cells expressing active enzyme were found to generate lower levels of PI(3,4)P2 upon chemokine or BCR stimulation. Chemokine-induced migration responses were inhibited by active, but not inactive INPP4A. An assessment of BCR signaling was carried out that compared BCR-stimulated cells expressing active versus inactive INPP4A in a screen encompassing over 800 protein phosphorylation sites. The results indicate that active INPP4A can suppress phosphorylation of Akt and known Akt targets. We are currently assessing whether PDK1, a major kinase upstream of Akt which also directly binds PI(3,4)P2, is regulated by INPP4A. Interestingly, other kinases known to interact with PDK1 (PKC δ , RSK) or to be directly phosphorylated by PDK1 (PKC γ) showed decreased phosphorylation in cells expressing active INPP4A. We are currently testing the hypothesis that PDK1/Akt and Btk/PLC γ 2 signalosomes are differentially regulated by INPP4A.

Interleukin-21 mediated STAT1 activation in the germinal centre response to T-dependent antigen

Jandl, C.^{1,2}, Loetsch, C.^{1,2}, Warren, J.¹, King, C.^{1,2}

¹Garvan Institute of Medical Research, Immunology Division, Sydney, Australia, ²St. Vincent's Clinical School, UNSW Australia, Department of Medicine, Sydney, Australia

Interleukin-21 (IL-21) signalling plays a fundamental role for the germinal centre (GC) reaction to T-dependent antigen supporting both the generation of high-affinity antibody producing GC B cells as well as T follicular helper (Tfh) cells. Although the importance of IL-21 mediated signalling for Tfh cells is widely appreciated, the signalling events downstream of the IL-21 receptor remain largely unknown. Here, we investigate the importance signal transducer and activator of transcription

(STAT) proteins activated by IL-21 receptor ligation on Tfh cells, with the help of mice harbouring a damaging point mutation within the cytoplasmic tail of the IL-21 receptor (*Il21r^{STAT}* mice). In response to IL-21, *Il21r^{STAT}* lymphocytes exhibited diminished STAT1 phosphorylation whereas STAT3 signalling remained intact. In response to T dependent antigen *Il21r^{STAT}* mice exhibited decreased GCs with a T cell intrinsic reduction in Tfh cells as well as a B cell extrinsic reduction in both GC B cell and IgG1+ class-switched B cells. The reduction of Tfh cells was more profound in *Il21r^{STAT}* mice than in *Il21r^{-/-}* mice, indicating a failure of IL-6 redundancy in the former. RNAseq analysis of *Il21r^{STAT}* CD4+ T cells exhibited a unique gene expression profile after *in vitro* stimulation with IL-21, with an anticipated decrease in the expression of STAT1 target genes, MAP kinase pathway genes as well as a profound increase in unique ubiquitination pathway genes that modulate the Jak-STAT pathways. Taken together, these findings indicate a hitherto unappreciated role for IL-21 mediated STAT1 signalling on T cells in the GC reaction.

Search for endogenous molecules recognized by C-type lectin receptor Dectin-2

Mori, D.¹, Saijo, S.², Yamasaki, S.¹

¹Kyushu University, Medical Institute of Bioregulation, Division of Molecular Immunology, Fukuoka, Japan, ²Chiba University, Medical Mycology Research Center, Department of Molecular Immunology, Chiba, Japan

C-type lectin receptors (CLRs) recognize various ligands derived from both damaged-self and pathogens to trigger immune responses. It is known that CLRs recognize various pathogen-derived ligands, however only a few self-ligands for CLRs have been identified thus far. To search for novel endogenous CLR ligands, we co-cultured CLR-bearing reporter cells with various tissues and cells. We found that peritoneal exudate cells (PEC) potentially activated reporter cells expressing Dectin-2, whereas cells from other lymphoid organs, such as thymus, spleen, and lymph node did not activate the reporter cells. In addition, bone marrow derived dendritic cells (BMDCs) strongly activated the Dectin-2 expressing reporter cells. This activity was decreased when BMDCs were stimulated with LPS. Moreover, an excessive amount of mannose inhibited the reporter activity, implying the contribution of terminal mannose to the ligand recognition. BMDCs were also positively stained by Dectin-2-Ig fusion protein, suggesting that Dectin-2 recognizes glycosylated molecule(s) expressed on the surface of resting BMDCs. We therefore purified Dectin-2-Ig-binding protein using the plasma membrane fraction of BMDCs and identified gp68 as a Dectin-2 ligand. Indeed, Dectin-2 reporter cells were strongly activated when co-cultured with macrophage cell line overexpressing gp68. These results suggest that Dectin-2 may sense particular glycosylation status on the surface of myeloid cells to modulate immune responses.

1252**Binding of membrane lipids by the SH2 domain of ZAP70 is critical for T cell receptor signaling**

Jung, D.-J.¹, Park, M.-J.¹, Sheng, R.², Silkov, A.³, Wang, Z.-G.², Xin, Y.², Kim, H.², Thiagarajan-Rosenkranz, P.², Song, S.¹, Yoon, Y.², Nam, W.¹, Kim, I.⁴, Kim, E.¹, Lee, D.-G.¹, Chen, Y.², Singaram, I.², Jang, M.H.⁴, Hwang, C.-S.⁵, Honig, B.³, Ryu, S.⁵, Lorieau, J.², Kim, Y.-M.^{1,5}, Cho, W.²

T cells are activated by antigen recognition of T cell receptors (TCRs). The TCR signaling pathway involves several cytosolic tyrosine kinases, phosphatases and adaptor molecules, many of which have Src-homology 2 (SH2) domains. SH2 domain is a prototypic protein-interaction domain that reads phosphotyrosine (pY) signals to link various tyrosine kinase substrates to downstream signaling molecules. Since most of the SH2 domain-containing proteins are thought to function near the plasma membrane, we purified 76 human SH2 domains to analyze the membrane lipid binding and found that the majority of them effectively bind the plasma membrane-mimetic vesicles with submicromolar affinities. These SH2 domains have alternative cationic patches for lipid binding separate from the pY-binding pockets and simultaneously interact with pY-peptides and membrane lipids independently of each other. Among the proteins expressed in T cells, we found that the C-terminal SH2 domain (cSH2) of ZAP70 strongly binds membrane lipids with high selectivity for PI(3,4,5)P₃. To analyze the role of lipid binding by cSH2 of ZAP70, we mutated specific residues involved in the lipid binding and reconstituted T cell lines lacking the endogenous ZAP70 with the mutants. We found that many aspects of the TCR signaling were significantly down-regulated in the cells expressing lipid binding-defective ZAP70. In contrast, cells expressing a gain-of-function mutant with a higher lipid binding affinity showed enhanced TCR signaling compared to the ones expressing wild type proteins. Our data demonstrate that the direct lipid binding by SH2 domains confers exquisite modulation of ZAP70 functions and TCR signaling.

1253**Nano-clustering of the T cell receptor (TCR) explains the high signaling efficacy in antigen experienced T cells**

Segal, G.¹, Gaus, K.^{1,2}

¹UNSW, School of Medical Sciences, Single Molecule Science, Sydney, Australia, ²UNSW, School of Medical Sciences, ARC Centre for Advanced Molecular Imaging and Australian Centre for NanoMedicine, Sydney, Australia

T cells scan and recognize antigens in a process that is highly specific and mediated by the interaction between a T cell

receptor (TCR) and an antigen-MHC complex. This process is tightly regulated by several molecular and cellular factors to avoid unwanted attack to self to occur. Our group had recently described a mechanism of immune regulation based on the pre-existence of TCR clusters. The presence of this dense TCRs cluster regulates the signaling efficacy and ultimately translates into effective immune responses. We hypothesize that an antigen experienced T cell will have physical differences to a naïve T cell at the cell membrane level. Using single molecule localization techniques combined with computational analysis we have determined the clustering of single TCRs and how these are triggered in different scenarios. By using memory T cells generated *in vivo* and comparing those with naïve T cells, we have established the topographic differences that partially explain why memory.

T cells are faster and more efficient in responding to antigen. This understanding allows us to engineer the TCR distribution in T cells and rearrange it to enhance their effector functions in strategies such as vaccination and immunotherapies.

1254**The role of Themis in T cell activation and effector function**

Fu, G.^{1,2}, Liu, C.¹, Tang, J.¹, Ma, L.¹, Jia, X.¹, Chen, X.¹, Liu, W.-H.¹

¹Xiamen University, School of Life Sciences, Xiamen, China,

²Xiamen University, State Key Laboratory of Cellular Stress Biology, Xiamen, China

Themis, a T cell specifically expressed protein, is required for proper T cell development. Previous studies using germline knockout or ENU-mutant mice from our lab and others showed that Themis is an adaptor molecule involved in TCR proximal signaling by binding to LAT signalosome and negatively regulating TCR signal strength. However, the physiological role of Themis in peripheral T cells is not clear and needs detailed investigation. By specifically deleting Themis gene in mature T cells using distal-Lck Cre mice, we found that Themis is required for mature T cell activation and T_{FH} differentiation. In primary response, upon OVA/Alum/LPS immunization, Themis conditional knockout mice showed impaired T_{FH} differentiation and slightly reduced antibody production. In contrast, in secondary response after NP-OVA/Alum immunization, antibody production was more dramatically reduced in Themis conditional knockout mice. Mechanistically, upon *in vitro* anti-CD3 and anti-CD28 stimulation, Themis deficient naïve CD4⁺ T cells showed sustained lower CD69 and CD44 expression. In addition, IFN γ and IL-2 production was reduced in Themis-deficient T cells when stimulated with PMA/Ionomycin *ex vivo*. Thus our findings demonstrated an essential role of Themis in T cell activation, T_{FH} differentiation, and memory response development. To further understand the function of Themis in T cell activation and helper T cell differentiation (such as T_H1, T_H2, T_H17 and Treg), we will explore the signaling pathways that Themis may be involved in mature T cells. Our study will provide new insights of how Themis functions in the context of immune responses and autoimmune diseases.

1255**Characterisation of the tissue distribution and function of the C-type lectin receptor CD302 in humans and mice**

Lo, T.H.^{1,2}, Fromm, P.^{1,2}, Verma, N.¹, Vu, A.¹, Kupresanin, F.¹, Kato, M.³, Clark, G.J.^{1,2}, Hart, D.N.J.^{1,2}, Silveira, P.A.^{1,2}

¹ANZAC Research Institute, Dendritic Cell Research, Sydney, Australia, ²University of Sydney, Sydney Medical School, Sydney, Australia, ³Mater Medical Research Institute - University of Queensland, Brisbane, Australia

The majority of C-type lectin receptor (CLR) family members are used by the immune system to recognise danger associated molecular patterns, but some contribute to physiological functions including adhesion, migration or glycoprotein turnover. We identified CD302, a CLR expressed by human myeloid phagocytes that co-localises to podosomes, suggesting a role in cellular adhesion or migration. Our study investigated the tissue expression of CD302 and its immunological functions. We characterised the transcriptional expression of CD302 in mouse and human tissues as well as immune cells using quantitative PCR. Mouse CD302 transcripts were highest in the liver, as in humans. Moderate expression of CD302 transcripts was also detected in mouse lungs, lymph nodes (LN) and spleen with myeloid cells expressing the highest levels. Interestingly, greater CD302 expression was detected in migratory compared to resident DC populations and M1 versus M2 macrophages. CD302 knockout (KO) mice generated for functional studies showed a partial deficiency in migratory DC proportion and number within the LN of CD302KO mice. *In vitro* studies showed that CD302KO and wild-type (WT) DC had equivalent capacity to prime T cells and migrate towards the lymphoid-homing chemokines, CCL19/CCL21. However, *in vivo*, fewer CD302KO migratory DC trafficked into draining LN after FITC skin painting and reduced OT-IT cell priming occurred after OVA immunisation. Our data indicates a specialist role for CD302 in DC and macrophage membrane functions, which contribute to the interactions required for DC migration to draining LN. This knowledge of CD302 function will be applied to future translational studies.

1256**Cis-interaction of TCRs and antigen/MHC class I complexes on CD8⁺ T cells causes their activation**

Kishi, H.¹, Jin, A.², Hiroshi Hamana, H.¹, Shitaoka, K.¹, Tajiri, K.¹, Kobayashi, E.¹, Kusano, S.³, Yokoyama, S.³, Ozawa, T.¹, Nagai, T.¹, Obata, T.⁴, Hatakeyama, S.¹, Horii, M.¹, Hu, Y.², Zhang, F.², Muraguchi, A.¹

T-cells play an important role in defending against intracellular microbes and tumors. A central dogma in T-cell immunology is that T-cells are activated by the recognition of antigenic peptides presented by major histocompatibility complex (MHC) molecules on antigen-presenting cells or tumor cells by antigenic T-cell receptors (TCRs) (*trans*-interaction). Here, we demonstrate that TCRs and MHC-class I (MHC-I) molecules

can interact on a single CD8⁺ T-cell (*cis*-interaction), leading to the activation of that T-cell. We analyzed CD8⁺ T-cells at the single-cell level using microwell-array chips. We observed that antigenic peptide/MHC-I complexes (p/MHC-I) on a T-cell could bind a TCR on the same T-cell to induce cytokine secretion. In addition, CD28 costimulatory molecules, as well as adhesion molecules involved in forming the immunological synapse, play important roles in T-cell activation through *cis*-interaction of TCR and p/MHC-I. Furthermore antigenic proteins expressed internally in CD8⁺ T cells induced the differentiation of the T cells to express CD107a at the single cell level. Our results demonstrate that a TCR on a T-cell can interact with not only antigenic peptides presented on MHC-I molecules on antigen-presenting cells (*trans*-interaction) but also those on the same T-cell (*cis*-interaction), leading to their activation. Our findings indicate a new T-cell activation mechanism, which has significant implications for peptide-based immunotherapy of cancer patients as well as the onset of autoimmune diseases.

1257**Mesenchymal stem cells regulate AMPK/mTOR pathway and mRNA translation to potentiate T cell suppression via nitric oxide production**

Yoo, H.S.^{1,2}, Lee, G.^{1,3}, Na, K.^{1,3}, Jeon, M.-S.^{1,2,3}

¹Translational Research Center INHA University Hospital, Incheon, Korea, Republic of, ²INHA University School of Medicine, Department of Molecular Biomedicine, Incheon, Korea, Republic of, ³IRIMS, Incheon, Korea, Republic of

Mesenchymal stem cells (MSCs) are known to suppress T cell activation and proliferation. However, the molecular mechanisms how MSCs directly regulate the T cell signaling are not completely understood. We found that mouse MSCs inhibit protein expression of IL-2 receptor alpha (CD25), but not mRNA expression in activated T cells. In this study, we investigated to understand the mechanism how MSCs influences on the CD25 protein expression. We obtained the following results;

1) IL-2 production was significantly increased in MSC-treated T cell culture medium. Thus, in the presence of MSCs, initial TCR signaling is intact and the increased IL-2 detection was occurred by the decreased CD25 expression.

2) Nitric oxide (NO) produced by MSCs was involved in the decreased CD25 expression.

3) MSCs induced phosphorylation of AMPK and TSC2 and reduced phosphorylation of S6K and 4E-BP1 in T cells. Similar results were obtained when T cells were cultured with NO donor. Thus, NO produced by MSCs inhibit the AMPK/mTOR-mediated mRNA translation.

4) 4EGI-1 treatment, an inhibitor of translation, reduced the CD25 expression in T cells.

Taken together, NO produced by MSCs inhibit the CD25 translation through the regulation of AMPK/mTOR pathway to potentiate T cell suppression.

1258

Epigenetic regulator PRC2 modulates proliferative response in CD4⁺ T cells*Kong, L.^{1,2}, Marchingo, J.^{1,2}, Hodgkin, P.^{1,2}, Allan, R.^{1,2}, Heinzl, S.^{1,2}**¹The Walter and Eliza Hall Institute of Medical Research (WEHI), Parkville, Australia, ²The University of Melbourne, Department of Medical Biology, Parkville, Australia*

The Polycomb Repressive Complex 2 (PRC2) is an epigenetic silencing complex that acts by trimethylating H3K27. Loss of PRC2 in T cells leads to severe inhibition of T cell expansion during the primary in vivo immune response. However whether this is due to defects in activation, proliferation or survival is not well understood. To address this, we investigated the proliferative response of PRC2 deficient cells in vitro.

The expansion of T cells after activation is a tightly controlled process governed by division rates, number of divisions undergone before returning to quiescence (termed division destiny) and life span, which are controlled by both internal and external factors such as the type and strength of stimulation.

As expected, a dose-dependent increase in division destiny was observed in response to anti-CD28 stimulation in naïve CD4⁺ T cells from control mice. In contrast, naïve CD4⁺ T cells deficient for the PRC2 components (EZH2, the catalytic enzyme, or the scaffold proteins SUZ12 and EED) were able to expand after activation but showed a markedly defect in their proliferative capacity in response to CD28. Quantitative analysis revealed that division rate was unaffected, but PRC2 deficient cells underwent fewer divisions and died sooner than wild type cells. This defect was not due to CD28 cell surface receptor levels and could not be overcome by increasing CD28 stimulation strength, suggesting that PRC2 acts downstream of CD28 receptor.

Cumulatively, these results demonstrate that PRC2 modifies sensitivity to CD28 co-stimulation in naïve CD4 T cells, thereby affecting their proliferative capacity.

1259

The calpain-calpastatin system activity is necessary for human T cell proliferation and development*Mikosik, A.¹, Frąckowiak, J.E.¹, Bryl, E.², Dąca, A.², Henc, I.², Ruckemann-Dziurdzińska, K.², Fulop, T.³, Haponiuk, I.⁴, Witkowski, J.M.¹**¹Medical University of Gdańsk, Pathophysiology, Gdańsk, Poland,**²Medical University of Gdańsk, Pathology and Experimental Rheumatology, Gdańsk, Poland, ³University of Sherbrooke, Center for Ageing Research, Sherbrooke, Canada, ⁴Nicolaus Copernicus Hospital, Pediatric Cardiac Surgery, Gdańsk, Poland*

Ubiquitous, strictly Ca²⁺ - dependent neutral proteases called μ - and m-calpain, together with their endogenous inhibitor - calpastatin - form the calpain-calpastatin system (CCS) involved in physiological and pathological signal transduction, proliferation and apoptosis of many cell types. We have previously demonstrated its existence in both leukemic and normal human lymphocytes. However, the role of the CCS in the function and development of human T cells is poorly understood. Using multicolor flow cytometry to detect and quantify the CCS proteins, to measure calpains' activities in the

adult peripheral blood T cells and thymocytes obtained during cardio-surgical interventions in young children, and to quantify the cytokines released during in vitro cultures, we have shown that constitutive activity of these proteases is present in all peripheral T cells and that its inhibition greatly reduces their proliferation and cytokine production in vitro. This activity is paralleled by constitutive expression of genes for both calpains (CANP1 and CANP2) and for calpastatin (CAST) in the T cells, as shown by quantitative real time PCR. We have also seen strong expression of CCS components in all thymocytes, as well as high proteolytic activity of calpains in the CD4⁺CD8⁺ and CD4⁺CD8⁻, and much weaker in the CD4⁺CD8⁻ and CD4⁻CD8⁻ thymocytes. Together, these data suggest strong involvement of the CCS activity in the development of T cells and in the maintaining of readiness of peripheral T lymphocytes for proliferative and secretory response to antigenic challenges.

1260

Ubiquitination role in TCR signaling and costimulation via GITR*Muller, J.¹, Zhang, G.², Silva, H.M.², Neubert, T.², Dustin, M.³**¹New York University Langone Medical Center, Sackler Institute**/ Immunology, New York, United States, ²New York University Langone Medical Center, Skirball Institute of Biomolecular Medicine, New York, United States, ³Oxford University, Kennedy Institute of Rheumatology, Oxford, United Kingdom*

Essential steps in TCR sorting, signaling, and degradation, are mediated by ubiquitination of components in TCR microclusters. Signaling through the costimulatory family of TNF receptors (GITR, OX40, 4-1BB, etc.) utilize a series of ubiquitination events that regulate the signaling process. A number of substrates of ubiquitin ligase like Cbl-B, ITCH, and CIAP1/2 have been identified. However, a detailed analysis of the global pattern of ubiquitination from TCR signaling is lacking. To address this we have utilized SILAC labeling and proteomics to profile the dynamic changes in ubiquitination that result from TCR signaling alone or in combination with GITR signaling. We have identified 4,500 ubiquitination sites with 44 regulated by TCR or TCR and GITR signaling. Using bioinformatics, we have identified key ubiquitin ligases that are responsible for the dynamic ubiquitination observed in our screen and confirmed their function by knock down, IP and ubiquitination of targets by western blot. Moreover, we have used IP with linkage specific antibodies to identify the specificity of the chains on specific ubiquitinated signaling molecules. Our work demonstrates the application of ubiquitin proteomics to primary murine antigen specific T cells, cross talk between TCR and GITR signaling, and the ubiquitination events downstream of the TCR and GITR that regulate their signaling.

1261**Mechanisms controlling activation-induced chromatin decondensation and proliferative competence in peripheral T cells**

Eikenbusch, S., Shields, M., Swatzel, H., Ward, A., Bingham, K., Lee, M., Meredith, J., Mitchell, T., Rawlings, J.
Furman University, Greenville, United States

Antigen presentation to the T cell receptor (TCR) initiates multiple signaling cascades required for the activation and proliferation of peripheral T cells during an immune response. Clonal proliferation of activated cells is achieved, in part, due to the changes in chromatin status as a function of activation: naïve T cells possess a condensed chromatin that decondenses during T cell activation. Previously, we demonstrated that chromatin decondensation is required for the acquisition of competence to respond to cytokines such as IL-2, providing mechanism such that only activated T cells will proliferate during an immune response. Here, we analyze the signaling pathways downstream of the TCR for their role in chromatin decondensation and the acquisition of competence to respond to IL-2. Upon TCR stimulation, phosphatidylinositol 4,5-bisphosphate (PIP₂) is hydrolyzed into inositol triphosphate (IP₃) and diacylglycerol (DAG); the former induces calcium flux from the endoplasmic reticulum while the latter activates protein kinase C (PKC). We demonstrate that both IP₃ and DAG signaling are required for the proper initiation of chromatin decondensation. However, DAG, but not IP₃ signaling, is sufficient to make T cells competent to respond to IL-2. Our findings suggest that there may be multiple TCR-driven mechanisms leading to the decondensation of distinct domains chromatin during T cell activation.

1262**Novel functions of necroptotic and apoptotic pathways in T cell proliferative and survival signaling**

Zhang, J.
Thomas Jefferson University, Microbiology and Immunology,
Philadelphia, United States

Apoptotic cell death is executed by caspases, which help digest cellular molecules to minimize tissue damage. Recent studies reveal a new type of programmed cell death pathway, namely necroptosis, which is activated when caspase-mediated apoptosis is defective. Apoptosis plays an important role in homeostasis in the immune system. Mutations in the Fas receptor or its ligand, FasL, lead to autoimmune-lymphoproliferation (lpr) diseases characterized by lymphadenopathy, splenomegaly and autoantibody production. FADD binds to Fas, recruits and activates the initiator caspase 8. However, unlike Fas mutant mice which have no developmental defect, FADD knockout mice die during midgestation. This paradox has been resolved by recent studies including ours which reveal a novel function for FADD in suppressing necroptosis, while promoting apoptosis. Other proteins including Daxx have also been suggested to interact with Fas. Interestingly, deletion of Daxx also leads to early embryonic lethality. It is unclear whether necroptosis and/or apoptosis play a role in cell death in Daxx-deficient embryos. Moreover, the role of Daxx in Fas-induced cell death *in vivo*

remains a controversy. In the current study, the function of Daxx in relationship with necroptosis and apoptosis was analyzed, using novel animal models. Our data reveals an unexpected interplay between necroptosis and apoptosis in Daxx-mediated pathways, as well as a novel function of Daxx in primary T cells, which is unrelated to Fas signaling.

1263**Investigating the regulation of protein translation by kindlin-3 in chronic myeloid leukemia cells**

Qu, J., Tan, S.M.
Nanyang Technological University, School of Biological Sciences,
Singapore, Singapore

Kindlin-1, 2 and 3 are 4.1-ezrin-radixin-moesin-containing cytoplasmic proteins that regulate integrin-mediated cell-cell and cell-extracellular matrix attachments. Kindlin-3 is expressed in hematopoietic cells, platelets, osteoclasts, and endothelial cells. The importance of kindlin-3 is underscored by the bleeding and immune compromised disease Leukocyte Adhesion Deficiency III, which is attributed to mutations in kindlin-3. Kindlin-3 is well established to regulate immune cell adhesion, migration and signaling. Kindlin-3 stabilizes cell adhesion mediated by β 1, β 2 and β 3 integrins. Recent studies suggest a role of kindlin-3 in tumor progression. Herein, we showed that kindlin-3 via its interaction with the receptor for activated-C kinase (RACK1) regulates protein translation in human chronic myeloid leukemia cell line K562. Data suggest that kindlin-3 associates with the ribosome and RACK1 serves as the bridging molecule. We showed that silencing of kindlin-3 expression in K562 cells reduced c-Myc protein expression but not its mRNA expression. Consequently, there was a decrease in the proliferation rate of these cells *in vitro* and a significant reduction in tumor mass in xenograft experiments. Our data suggest that kindlin-3 may regulate protein translation indirectly via the integrin α 5 β 1 Akt-mTOR-p70S6K pathway and directly via its association with RACK-1-containing ribosome. These data also suggest the possibility of similar signaling conduits in other immune cells.

1264**A conserved T cell receptor transmembrane structure mediates transbilayer signalling**

Krishnan, L.^{1,2}, Park, S.³, Im, W.³, Call, M.^{1,2}, Call, M.^{1,2}
¹Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, ²The University of Melbourne, Department of Medical Biology, Parkville, Australia, ³The University of Kansas, Department of Molecular Biosciences and Center for Computational Biology, Lawrence, United States

Signalling through the T cell receptor (TCR) is crucial for T cell development and functions during infection, and provides the basis for immune responses against tumour antigens. The TCR is an assembly of eight single-pass membrane proteins that are held together by an intra-membrane electrostatic network. Upon encountering peptide:MHC ligand presented on antigen-presenting cells, the $\alpha\beta$ TCR heterodimer transmits activating

signals through the constitutively associated CD3 $\epsilon\delta$, CD3 $\epsilon\gamma$ and ζ modules. The mechanism by which ligand binding to TCR $\alpha\beta$ is communicated to the CD3 dimers is unknown. We hypothesised that upon ligand engagement, conformational changes are transmitted through the transmembrane domains (TMDs) of the receptor complex to cause alteration in the cytoplasmic domains. To test this hypothesis, we combined intra-membrane cysteine-scanning, solution nuclear magnetic resonance (NMR) spectroscopy and computational modelling methods to interrogate the arrangement of interacting TMDs within the assembled, un-liganded receptor complex. Our results revealed a specific helix-helix interface between TCR α and TCR β TMDs governed by a novel polar interaction that is absolutely conserved across vertebrate evolution. We also found that similar interface is present and conserved in the $\gamma\delta$ TCR sequences, suggesting a fundamental role for this polar interaction. Using a cellular assay measuring IL-2 production upon TCR stimulation, we showed that mutations within the key contact residues resulted in impaired T cell signalling. Collectively, these findings provide evidence for receptor-intrinsic, conformationally-regulated transbilayer signalling during TCR triggering. Additionally, these findings highlight the role of intra-membrane polar interactions for membrane receptor assembly and functions.

1265

Centrosome and Golgi-associated proteins are novel substrates of protein kinase A in T-lymphocytes

Chalasani, M.L.S.¹, Ong, S.T.¹, Fazil, M.H.U.T.¹, Low, J.H.^{1,2}, Prasannan, P.¹, Kelleher, D.³, Verma, N.K.^{1,4}

¹Nanyang Technological University (NTU), Lee Kong Chian School of Medicine, Singapore, Singapore, ²Nanyang Technological University (NTU), School of Biological Sciences, Singapore, Singapore, ³University of British Columbia, Faculty of Medicine, Vancouver, Canada, ⁴Singapore Eye Research Institute, Singapore, Singapore

Background: Protein Kinase A (PKA) is a cAMP-dependent serine/threonine kinase with wide substrate specificity. PKA substrate phosphorylation is crucial in many cellular processes, including cell adhesion and migration. This study aims to determine the role of PKA and its substrates in LFA-1 integrin-induced T-cell migration.

Methods: Human T-cells were triggered to migrate via LFA-1 stimulation by incubating on the ICAM-1 ligand-coated plates. Cellular responses were determined using RNA interference-mediated gene knockdown, co-immunoprecipitation, Western-immunoblotting, confocal microscopy and High Content Analysis.

Results: Previous High Content Analysis showed an active involvement of PKA in T-cell migratory phenotypes. To further clarify the scope of PKA signalling cascades in T-cell migration, we performed immunoprecipitation-based assays focussed on the identification of PKA substrates. We identified CG-NAP, pericentrin and dynein as substrates for PKA phosphorylation. Pre-treatment of T-cells with forskolin, a potent activator of adenylyl cyclase that elevates cAMP-dependent PKA activity, increased the phosphorylation levels of pericentrin and

dynein (>2-fold). Co-immunoprecipitation of cellular lysates further confirmed a direct interaction of these proteins with PKARII α , which was found to be co-localized with pericentrin at centrosome and GM130 at the cis-Golgi. RNA interference-mediated knockdown of CG-NAP (>70% knockdown) in T-cells disrupted PKARII α /pericentrin/ α -tubulin co-localization at centrosome.

Conclusion: This study, for the first time, provides a mechanistic insight into the role of PKA in T-cell signalling. The identification of novel substrates for PKA at centrosomal and Golgi region may open a potential new avenue for fine-tuning of T-cell migration and the development of specific peptide inhibitors targeting T-cell-mediated immune regulations.

1266

Role of Mincle in the recognition of *Helicobacter pylori*

Nagata, M.¹, Doi, R.¹, Iwai, S.¹, Ishikawa, E.¹, Miyamoto, T.², Yamasaki, S.¹

¹Division of Molecular Immunology, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan, ²Department of Natural Products Chemistry, Graduate School of Pharmaceutical Sciences, Kyushu University, Fukuoka, Japan

Helicobacter pylori (*H. pylori*) is a Gram-negative bacterial pathogen which causes gastrointestinal disorders, such as gastric ulcers and carcinoma. *H. pylori* possess various unique glycolipids that are thought to be beneficial for their survival in host. However, it is unclear whether these glycolipids are recognized as pathogen-associated molecular patterns (PAMPs) by innate immune receptors.

To investigate immunostimulatory activity of *H. pylori* lipids and identify the active constituents, we extracted lipophilic components and co-cultured with reporter cells expressing various pattern recognition receptors (PRRs). We found that macrophage-inducible C-type lectin (Mincle) recognizes the lipid extract of *H. pylori*. Subfractionation and further purification of this extract revealed that Mincle recognizes two particular fractions which gave single spots on thin-layer chromatography (TLC). Both glycolipids activated bone marrow-derived dendritic cells (BMDCs) to produce inflammatory cytokines, whereas these were abrogated in Mincle^{-/-} BMDCs. In addition, these glycolipids potently activated BMDCs to promote IL-17 production in CD4⁺ T cells from OT-II mice.

Finally, we investigated the role of Mincle against infection of *H. pylori* SS1. Mincle deficiency led to an increase of bacterial number in the stomach at 2 weeks after infection.

These results suggested that Mincle is involved in immune responses against *H. pylori* through the recognition of their characteristic glycolipids.

K33-linked polyubiquitination of Zap70 by E3 ligase Nrdp1 controls activation of CD8⁺ T cells

Yang, M.¹, Chen, T.¹, Li, X.¹, Yu, Z.², Cao, X.^{1,2,3}

¹Second Military Medical University, Institute of Immunology and National Key Laboratory of Medical Immunology, Shanghai, China, ²Zhejiang University School of Medicine, Institute of Immunology,

Hangzhou, China, ³Chinese Academy of Medical Sciences, Institute of Basic Medical Sciences, Beijing, China

Nrdp1 (neuregulin receptor degrading protein 1, also known as RNF41, FLRF or RBCC) is a C3HC4 type ring-finger-containing E3 ligase implicated in the ubiquitination of various substrates and regulation of several pathological processes, such as cancer, Parkin's disease, ischemia-reperfusion injury and diabetes. Previously we find that Nrdp1 preferentially promotes the production of type I interferons triggered by Toll-like receptor response. Until now roles of Nrdp1 in regulating T cell activation or anergy have not been reported. Here we also find that Nrdp1 may play a role in T cell activation. We find that Nrdp1 is expressed highly in naïve CD8⁺ T cells than in naïve CD4⁺ T cells, which inspires us to investigate the roles of Nrdp1 in CD8⁺ T cell activation. By using CD8⁺ T cells derived from *Nrdp1*^{-/-} mice, we found that Nrdp1 deficiency promotes proliferation and cytokine production of CD8⁺ T cells, leading to enhanced antiviral and antitumor effector functions of CD8⁺ T cells. Further analysis of Nrdp1-interacting molecules and the signaling pathways indicate that Nrdp1 can interact with Zap70 and Sts1/2 (acidic phosphatase-like proteins), polyubiquitinate Zap70 and promote the dephosphorylation of Zap70 by Sts1/2. Our study indicates that Nrdp1 may be a Zap70-targeted E3 ligase that links Sts1/2 to activated/polyubiquitinated Zap70. Nrdp1-mediated inactivation of polyubiquitinated Zap70 through Sts1/2 may represent an important machinery for negative regulation of proximal TCR signaling.

Dual regulation of T lymphocyte function in autoimmunity by O-GlcNAc glycosylation

Ramakrishnan, P., Tomalka, J., de Jesus, T.

Case Western Reserve University, School of Medicine, Department of Pathology, Cleveland, United States

T lymphocytes play a major role in autoimmunity. CD4⁺ T cells produce pro-autoimmune cytokines and promote the cytotoxic activity of CD8⁺ T cells, while T regulatory (T reg) cells act to suppress autoimmunity. Type 1 diabetes is an autoimmune disease where T cells destroy pancreatic beta cells leading to hyperglycemia and chronic inflammatory complications. Adverse pathological effects of hyperglycemia include posttranslational modification of proteins by the sugar N-acetyl glucosamine (GlcNAc) in a process called O-GlcNAcylation. We found that hyperglycemia induces O-GlcNAcylation of NF-kappaB protein c-Rel, which is a critical regulator of T cell function and T regulatory cell development. O-GlcNAcylation of c-Rel at serine residue 350 activates the transcription of c-Rel-dependent pro-autoimmune cytokines interleukin-2 (IL-2), interferon gamma (IFNG) and granulocyte macrophage colony-stimulating factor (GM-CSF). Our recent results show that c-Rel O-GlcNAcylation inhibits the expression of T regulatory cell specific transcription factor FOXP3. We explored the molecular mechanism and found that O-GlcNAcylation differentially regulates the DNA binding of c-Rel at the promoters of cytokines and FOXP3. Thus, c-Rel O-GlcNAcylation may serve as a key regulatory switch with dual, but reciprocal, roles in positively regulating autoimmune T cell

and negatively regulating immunosuppressive T regulatory cell functions. The net result of these two opposing effects may exacerbate autoimmunity in type 1 diabetes. Despite decades of research, drugs based on molecular targets to treat autoimmune diabetes have remained elusive. This study reveals c-Rel O-GlcNAcylation as a potential therapeutic target for autoimmune diabetes and a novel molecular mechanism regulating T lymphocyte function in autoimmunity.

Rapid multiplex analysis of lipid raft signaling components with single lymphocyte resolution

Schatzmaier, P.¹, Göschl, L.², Ellmeier, W.², Huppa, J.B.¹, Stockinger, H.¹

¹Medical University of Vienna, Institute for Hygiene and Applied Immunology, Vienna, Austria, ²Medical University of Vienna, Institute of Immunology, Vienna, Austria

Lipid rafts, a distinct class of highly dynamic cell membrane microdomains, are integral to cell homeostasis, differentiation and signaling. Raft-association of important lymphocyte receptor signaling molecules - e.g. Src family kinases - and stimulation-induced variations in raft composition was demonstrated as well as a clear correlation of their raft-association with signaling function. However, biochemical quantitative analysis of lipid raft components involves laborious and time-consuming cell lysate fractionation via sucrose density gradient ultracentrifugation. Further, this method needs a large number of input cells and single cell information is completely lost. This complicates or even precludes the examination of rare cells, developmentally heterogeneous cell populations or weakly raft-associated factors. We established a fast and reliable method that is based on the low g centrifugation of cells through a detergent gradient, requiring little starting material and effort. Our widely applicable protocol enables multidimensional and sensitive flow cytometric quantitation of raft-associated proteins with single cell resolution. It allows easy and precise assessment of endogenously and ectopically expressed membrane components from a few cells in complex isolates as well as their dynamics due to cell differentiation, signaling and mutation. In conclusion, our approach is well suited to elucidate the role of lipid rafts in regulation of factors that govern proximal signaling thresholds of crucial leukocyte receptors, including the T cell antigen receptor. This work was supported by the Cell Communication in Health and Disease (CCHD) PhD Program.

1270

Low concentration of hydroxychloroquine potentiates TLR-9 signalling: potential implications for clinical practice

Hurtado, P.R.¹, Hurtado-Perez, E.², Peh, C.A.^{1,2}

¹Royal Adelaide Hospital, Renal Medicine, Adelaide, Australia, ²Adelaide University, Medicine, Adelaide, Australia

The antimalarial drug hydroxychloroquine (HCQ) is widely used for the treatment of a variety of systemic autoimmune diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). This effect seems to be mediated by its

ability to increase the pH in intracellular endosomes, inhibiting intracellular pathways involved in the pathogenesis RA and SLE such as antigen presentation, autophagy and signalling of endosome-bound toll-like receptors such as TLR-3, 7, 8 and 9. There are, however, a number of reports where the use of HCQ has also been associated with unexplained increase in disease activity. In this study we show that HCQ has a bimodal effect on its capacity to influence the immune response mediated by TLR-9 signalling. While HCQ strongly inhibits TLR signalling at pharmacological concentrations (1 to 10 μ M), at low concentrations (1-100 nM), HCQ exerts the opposite effect, potentiating the stimulatory effects of CpG, a TLR-9 ligand. The presence of HCQ at low concentration results in a significant increase in the expression of MHC class II and co-stimulatory molecules CD40 and CD86 by B cells as well as increase in *in vitro* antibody synthesis and cytokine production by B cells. This *in vitro* finding may be highly relevant to clinical practice, and stresses the importance of appropriate dosing as well as patient compliance.

1271

A novel two-ligand system to analyse signal integration by non-catalytic tyrosine-phosphorylated receptors

Paterson, R., Denham, E., Goyette, J., van der Merwe, P.A.

University of Oxford, Sir William Dunn School of Pathology, Oxford, United Kingdom

Appropriate immune responses require integration of a variety of activating, inhibitory and co-stimulatory signals from cell surface receptors. One important class of receptors are the non-catalytic tyrosine-phosphorylated receptors (NTRs), a group of over 100 receptors, such as PD-1, CTLA4, CD28, and the T cell antigen receptor (TCR). The mechanism through which NTR receptor-ligand engagement leads to signal initiation and integration is not well understood and may offer novel targets for disease treatments.

We are using a cellular system to analyse NTRs by manipulating their extra- and intra-cellular dimensions. We hypothesise that proximity of receptors is important for optimal signal integration and requires compatible receptor-ligand dimensions. We also hypothesise that intracellular domain length influences the effectiveness of inhibitory receptors such as PD-1.

To manipulate the dimensions of receptor-ligand interactions, CHO.K1 cells ("ligand cells") have been transfected with Spy-tag constructs of different lengths and either CD48 or HLA-A2 single chain dimer (SCD) constructs, also of different lengths. Spy-tag can be covalently coupled via Spy-catcher to Strep-Tactin[®], which binds the short peptide tag Strep-tagII[®]. CD48 and the HLA-A2 SCD presenting cognate peptide can be used to provide activating signals by binding to a 2B4-CD64 fusion protein and the 1G4 TCR, respectively, in THP-1 and Jurkat "receptor cells".

Initial experiments show that "ligand cells" are able to activate IL-8 production by THP-1 "receptor cells" expressing 2B4-CD64 and this is inhibited by engagement of Strep-tagII-tagged PD-1 with the Strep-Tactin ligand. These cells and assays are now being used to further analyse NTR signal integration.

1272

Completing the pro-survival BCL-2 family portrait: characterization of the A1 knockout mouse model

Schenk, R.^{1,2}, Tuzlak, S.^{1,3}, Vasanthakumar, A.¹, Preston, S.^{1,2}, Tai, L.¹, Strasser, A.^{1,2}, Herold, M.J.^{1,2}

¹Walter & Eliza Hall Institute, Melbourne, Australia, ²University of Melbourne, Medical Biology, Melbourne, Australia, ³University Innsbruck, Innsbruck, Austria

The BCL-2 family proteins are the regulators of the form of programmed cell death known as apoptosis. The family is subdivided into pro-survival and pro-apoptotic proteins, with the balance between the two groups determining whether a cell lives or dies. This apoptotic control is important in the context of disease, as defects in apoptosis are associated with cancer and autoimmunity. In particular, deregulation of the pro-survival group of proteins can see the survival of potentially harmful cells. There are five known pro-survival proteins: BCL-2, BCL-XL, BCL-W, MCL-1 and A1. Of these, A1 is poorly studied, but it appears to be specifically expressed in haematopoietic cells, with suggested roles in B cells, T cells and granulocytes. It has been difficult to generate an A1-deficient mouse model, as there are three functional A1 isoforms in the mouse (A1-a, -b and -d). However, our lab has successfully created a novel mouse model that lacks all functional A1 isoforms, and here I present the phenotypic characterisation of these mice. Overall, we observed no major differences in the haematopoietic compartment between A1-deficient and wild-type mice. Since A1 has been reported to be important upon antigenic challenge for B and T cell survival, we have started to challenge mice with different antigenic stimuli, such as influenza virus and LCMV. Initial results suggest that A1-deficient and wild-type cells respond similarly to viral infection. We are currently performing more in-depth analysis of A1-deficient mice challenged with different antigenic stimuli to further elucidate its role in the haematopoietic lineage.

1273

Inducible T cell kinase regulates late stages of CD8+ T lymphocyte effector function

Kapnick, S.¹, Ritter, A.¹, Stinchcombe, J.², Lippincott-Schwartz, J.¹, Griffiths, G.², Schwartzberg, P.¹

¹National Institutes of Health (NIH), Bethesda, United States,

²Cambridge Institute for Medical Research, Cambridge, United Kingdom

CD8+ cytotoxic T-lymphocytes (CTLs) are critical for killing virally infected cells, and defects in CTL responses can lead to secondary lymphoproliferative syndromes. Patients with mutations in Inducible T-cell Kinase (ITK), a kinase required for full activation of PLC γ 1 that serves as an amplifier of T-cell receptor (TCR) signaling, develop lymphoproliferative disease associated with high EBV viral loads. We found CTLs from ITK-deficient mice exhibit impaired killing of multiple targets, suggesting ITK-deficiency leads to global defects in cytolysis. Killing by CTLs occurs when TCR signaling triggers adherence to targets, centrosome polarization, and release of secretory granules inducing cytolysis of cells. Although early events

such as adhesion, actin ring formation, and cell polarization were intact in ITK-deficient murine CTLs, we found defects in degranulation, suggesting ITK may play an unappreciated role in the final stages of killing. Surprisingly, prolonged culture of ITK-deficient CTLs in IL-2 could rescue defects in killing and degranulation, similar to known effects of IL-2 on promoting NK cytotoxicity. Together these experiments provide clues to novel roles for ITK and TCR signaling in regulating late stages of CTL function that may contribute to reduced viral clearance in patients with mutations in ITK. To further understand what regulates cytotoxic granule release, we are also examining the role of actin in degranulation. Similar to the role of actin in regulating the initiation of secretion, we see that actin recovery can affect the termination of secretion. We are currently evaluating mechanisms that may control actin clearance and recovery at the synapse.

1274

Maintenance of microtubule architecture by an adaptor protein CG-NAP/AKAP450 is crucial for T-cell migration

Ong, S.T.¹, Chalasani, M.L.S.¹, Fazil, M.H.U.T.¹, Low, J.H.^{1,2}, Prasannan, P.¹, Wright, G.³, Kelleher, D.^{1,4}, Verma, N.K.^{1,5}

¹Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore, ²Nanyang Technological University, School of Biological Sciences, Singapore, Singapore,

³Institute of Medical Biology, A*STAR, Singapore, Singapore,

⁴University of British Columbia, Vancouver, Canada, ⁵Singapore Eye Research Institute, Singapore, Singapore

Background: Centrosome- and Golgi-localized protein kinase N-Associated Protein (CG-NAP/AKAP450) is an adaptor protein, which provides a platform for targeted positioning of multiple signalling molecules and their interactions that are critical for cellular functioning. Here, we investigated the mechanism of CG-NAP involvement in migrating T-cells.

Methods: Human primary and cultured T-cells were stimulated to migrate via the integrin LFA-1/ICAM-1 cross-linking. Standard molecular and imaging assays, including RNA interference-mediated gene knockdown, co-immunoprecipitation, Western immunoblotting, High Content Analysis, confocal and 3D Structured Illumination super-resolution Microscopy (3D-SIM) were performed.

Results: We observed that CG-NAP, a 450kDa protein, was predominantly expressed in activated primary T-cells as compared to monocytes, platelets, naïve CD4+ and CD8+ T-cells. CG-NAP was found to co-localize with γ -tubulin and pericentrin at the centrosome as well as CLASP2, GM130 and TGN46 at the Golgi. RNA interference-mediated silencing of CG-NAP (>70% knockdown) in T-cells caused Golgi fragmentation accompanied by ~2-fold decrease in the expression of GM130 and CLASP2 proteins. CG-NAP depletion significantly inhibited LFA-1/ICAM-1-induced T-cell migration and transwell chemotaxis towards the chemokine SDF-1 α . Western-immunoblotting and confocal microscopy showed that CG-NAP knockdown interfered with tubulin acetylation and detyrosination, which regulate microtubule dynamics in migrating T-cells. 3D-SIM revealed that microtubule arrays emanating from either the centrosome or the Golgi were disrupted in CG-NAP depleted T-cells.

Conclusion: CG-NAP plays a central role in regulating microtubule nucleation, maintaining Golgi architecture and acting as a downstream effector of LFA-1 signalling in migrating T-cells. This information enhances the fundamental understanding of T-cell migration mechanism implicated in adaptive immune responses.

1275

Nanoscale clustering of the T cell receptor regulates T cell signalling efficiency

Pageon, S.V., Tabarin, T., Yamamoto, Y., Gaus, K.

University of New South Wales, EMBL Australia Node in Single Molecule Science & ARC Centre of Excellence in Advanced Molecular Imaging, Sydney, Australia

T cells are crucial players in the adaptive immune system. When the T cell receptor (TCR) recognises a peptide ligand bound to the restricting major histocompatibility complex molecule (pMHC), it transmits a signal *via* the associated CD3 complex. The mechanism by which the extracellular antigen recognition event leads to intracellular phosphorylation remains unclear. Recent advances in imaging technologies have provided new tools for biologists to observe the organisation of receptors and signalling proteins at the membrane of immune cells at unprecedented resolution. Using single-molecule localisation microscopy techniques (SMLM) such as PALM and dSTORM, we show that the TCR is organised into nanometre-scale clusters in resting cells and that TCR engagement reorganises the TCR-CD3 complex into clusters of increased molecular density. By combining two-colour imaging with a degree-of-colocalisation (DoC) analysis, we determined where TCR molecules are being phosphorylated within a cell. Our data show that the TCR is preferentially phosphorylated, i.e. *triggered*, in clusters of higher TCR density. These dense clusters were also associated with downstream signalling proteins, suggesting that an intrinsic biological threshold, namely the molecular density within clusters, dictates signal initiation and amplification. Both pMHC dose and TCR-pMHC affinity determined the density of molecules in TCR-CD3 clusters, which in turn scaled with the overall level of receptor phosphorylation. Thus, we demonstrate that the formation of dense signalling-competent clusters is a process of antigen discrimination.

1276

T cell-intrinsic role of the cytosolic DNA-sensing for T cell function

Imanishi, T., Saito, T.

RIKEN Center for Integrative Medical Sciences (IMS), Yokohama, Japan

STING has a key role in detecting the cytosolic DNA in innate immune system, which results in the induction of type I interferon and interferon-stimulated genes (ISGs) to serve as the first line of host defense against infectious agents. However, the physiological role of the cytosolic DNA-sensing pathway in T cells remains unclear. Here we show that STING ligands induce the expression of type I interferon, ISGs and co-stimulation

to enhance IL-2 production in T cells upon TCR stimulation. Concomitantly, we found that stimulation by STING ligands strongly inhibits T cell growth. This STING-mediated growth arrest is partly dependent on IRF3, but not TBK1. These analyses demonstrate that cytosolic DNA-sensing in T cells induces both cytokine responses and growth arrest.

1277

Critical role of the DHR-1 domain in localization and function of DOCK8

Sakurai, T., Uruno, T., Fukui, Y.

Kyushu University, Division of Immunogenetics, Medical Institute of Bioregulation, Fukuoka, Japan

Cell migration involves membrane polarization and cytoskeletal dynamics, both of which are regulated by Rho family of GTPases, Rho, Rac, and Cdc42. These molecules act as molecular switches by cycling between GDP-bound inactive and GTP-bound active states, and stimulus-induced formation of the active form is mediated by guanine nucleotide exchange factors (GEFs). There are two distinct families of GEFs: Dbl-homology (DH) domain-containing proteins and DOCK proteins. Until recently, DH domain containing proteins have been considered to be the universal GEFs in eukaryotes. However, accumulating evidence indicates that the DOCK proteins act as major GEFs in varied biological settings. DOCK family proteins have two highly conserved domains, DHR-1 and DHR-2. We recently found that DOCK8 plays a key role in interstitial migration of dendritic cells. Although this function of DOCK8 critically depends on the DHR-2 domain mediating Cdc42 activation, the role of DHR-1 domain remains unknown. In this study, we will discuss the binding partner of DOCK8 DHR-1 and its physiological relevance to localization and function of DOCK8.

1278

Engagement of CD99 surface molecules inhibits T cell responses

Laopajon, W.¹, Pata, S.^{1,2}, Kasinrer, W.^{1,2}

¹Division of Clinical Immunology, Department of Medical Technology, Faculty of Associated Medical Sciences, Chiang Mai University, Chiangmai, Thailand, ²Biomedical Technology Research Center, National Center for Genetic Engineering and Biotechnology, National Science and Technology Development Agency at the Faculty of Associated Medical Sciences, Chiang Mai University, Chiangmai, Thailand

CD99 is a broadly expressed transmembrane glycoprotein which has been described as a T cells- co-stimulator. We previously demonstrated that CD99 molecules were translocated into immunological synapse during T cell activation. However, the complete function of CD99 involving in T cell activation is still unclear. In this study, the role of CD99 on T cell responses was investigated. T cells proliferation, induced by anti-CD3 mAb, was inhibited by an anti-CD99 monoclonal antibody (mAb). The inhibition ability of anti-CD99 mAb was neutralized by CD99 recombinant proteins indicated that blocking of T cell proliferation was resulted from the engagement of CD99

molecules by anti-CD99 mAb. In addition, we found that engagement of CD99 before CD3 activation could not induce the T cell proliferation inhibition. This data suggested that stimulation of CD3 was required for induction of inhibition of T responses by CD99. The mechanism underlying this phenomenon was investigated. The expression of IL2 receptor (CD25) and IL2 was altered upon CD99 engagement. Our results illustrated that, during T cell activation, stimulation of CD3 molecules may provide a signal involving CD99 function. Subsequently, ligation of CD99 will generate T cell inhibitory signal. The generated inhibitory signal by CD99 molecules might be the negative feedback mechanism of T cell activation.

1279

Altered peptide ligands: qualitative or quantitative effects on signaling in monoclonal T cells?

Yazicioglu, Y.F.^{1,2}, Ellestad, K.K.^{2,3}, Anderson, C.C.^{2,3,4,5}

¹Gulhane Military Medical Faculty, Ankara, Turkey, ²Alberta Diabetes Institute, Edmonton, Canada, ³University of Alberta, Department of Medical Microbiology and Immunology, Edmonton, Canada, ⁴University of Alberta, Department of Surgery, Edmonton, Canada, ⁵Alberta Transplant Institute, Edmonton, Canada

Altered peptide ligands (APLs) are derivatives of antigenic peptides containing substitutions at residues involved in T cell receptor (TCR) contact or major histocompatibility complex (MHC) binding. While these substitutions can quantitatively affect T cell signaling following APL stimulation, the question remains whether APLs can also have qualitatively different TCR signaling effects. In this study, we employed the Marilyn (CD4+ anti-H-Y) TCR transgenic system and designed several H-Y-derived APLs bearing substitutions at MHC-II anchor or TCR contact residues. Marilyn PD-1^{-/-}

T cells lacking a co-inhibitor and thus thought to be biased toward enhanced TCR signaling were also included in the assays to examine threshold effects that could mediate qualitatively different responses to APLs. The proliferative response to different concentrations of native H-Y or these APLs was examined by both in vivo and in vitro proliferation assays using mixed Marilyn and Marilyn PD-1^{-/-} T cells. The ability of the APLs to bind MHC-II and potential for particular APLs unable to stimulate proliferation to inhibit T cell responses to native H-Y peptide were also assessed. We found that Marilyn and Marilyn PD-1^{-/-} T cells proliferated similarly in response to H-Y and all of the APLs tested in a dose dependent manner and in accordance with their predicted TCR and MHC affinity. Particular APLs could block the proliferative response of T cells to H-Y in co-culture. Overall our data suggest that APLs have primarily quantitatively different signaling effects on T cells, although some APLs may have utility in blocking the response to native epitopes.

1280

A negative regulatory role of SARM in TCR signaling

Tian, S.-H., Chen, Z.-L., Wang, Q.-L., Li, Y.

Sun Yat-Sen University, Guangzhou, China

The TIR domain containing adaptor SARM was first identified as

a negative regulator of TRIF-dependent TLR signaling in innate immunity. In this study, we described a novel function of SARM in response to TCR stimulation. Knockdown of SARM enhanced TCR-induced tyrosine phosphorylation and Lck protein level, which were reduced by overexpression of SARM. SARM-induced reduction of Lck protein level was partially lysosome-dependent. Upon TCR stimulation, Lck phosphorylated SARM and recruited it to the immunological synapse, which in turn promoted the degradation of activated Lck. Our results reveal a negative regulatory role of SARM in TCR signaling and provide a new insight into the mechanism of Lck regulation in T cells.

1281

Detection of immunomodulatory polysaccharides in food materials using the enzyme-fused innate immune receptors

Adachi, Y., Kasahara, K., Tetsui, J., Yamanaka, D., Ishibashi, K.-I., Ohno, N.

Tokyo University of Pharmacy and Life Sciences, School of Pharmacy, Laboratory for Immunopharmacology of Microbial Products, Tokyo, Japan

Beta-glucans from seaweed and fungi bind to innate immune receptor, dectin-1. Recently, the oral administration of a water soluble beta-glucan, laminarin, has been reported to modify the microbiota in gut and control the Treg function. To measure the content of beta-glucans in food materials, luciferase-based split enzyme immune assay specific for beta-glucans are prepared. In this paper, specificity and sensitivity of this new assay system will be reported.

A recombinant beta-glucan recognition protein (BGRP) from invertebrate was expressed as luciferase-fusion proteins, N-terminal and C-terminal fragments. The nLuc-BGRP and/or cLuc-BGRP were subjected to various polysaccharides, then substrate for luciferase was added and chemiluminescence was monitored.

To examine the assay specificity, various polysaccharides from bacteria, plants, algae, and fungi were tested. The positive enzyme activity was not observed with lipopolysaccharides, mannan, agarose, pectins, and cellulose. Whereas, 1,3-beta-glucans from mushrooms, yeast, and seaweeds showed significantly positive. The luciferase activity requires the both fragments in response to the beta-glucans, suggesting that cross-linking luciferase fragments, nLuc and cLuc, were induced by interaction of BGRP with 1,3-beta-glucans. The sensitivity of the Luc-BGRP split enzyme system was above the ng/mL order of beta-glucans. These results suggest that the split enzyme assay using BGRP and Luciferase fragments might be applicable to detect 1,3-beta-glucans in food ingredients.

1282

Spatiotemporal organisation of CD4 during T cell activation

Yamamoto, Y., Pigeon, S., Rossy, J., Gaus, K.

EMBL Australia Node in Single Molecule Science & ARC Centre of Excellence in Advanced Molecular Imaging, University of New South Wales, School of Medical Science, Sydney, Australia

CD4 is a co-receptor that plays an important role during initiation

of T cell receptor (TCR) activation by interacting with MHC class II molecules on the surface of antigen presenting cells (APCs). Past studies have shown that while CD4 is not required for TCR activation, it can significantly enhance the process by promoting associations with APCs, leading to increased cytokine secretion and cell proliferation.

While CD4 mediated enhancement of T cell responses is widely observed and a well-established phenomenon, the mechanisms that facilitate this enhancement remain poorly understood. In this study, we constructed supported lipid bilayers containing pMHC to mimic APC and found that OTII T cell activation only occurred robustly in the presence of CD4. Using this setup, we performed single-molecule localisation microscopy (PALM/dSTORM) to look at the nanoscale organisation of CD4 on the surface of activated T cells. The results revealed that upon TCR activation, the number of CD4 clusters observed on the cell surface is reduced and the CD4 clusters were denser than in non-activating conditions. These clusters of CD4 were also found to co-localise with some of the TCR clusters. Our data support a model in which CD4-mediated enhancement of T cell activation is dependent on TCR-complexed CD4. Further studies looking at the lateral organisation of CD4 in relation to other T cell signalling proteins would contribute to better understanding of how CD4 enhances T cell activation.

Therapeutic Antibodies

1283

Production of anti-MICA antibodies for targeting cancer therapy

Phumyen, A.¹, Chuangchot, N.^{2,3}, Jantasorn, S.³, Jumnainsong, A.^{3,4}, Leelayuwat, C.^{3,4,5,6}

¹Chulabhorn International College of Medicine, Thammasat University, Rangsit Campus, Pathum Thani, Thailand, ²Khon Kaen University, Biomedical Sciences Program, Graduate School, Khon Kaen, Thailand, ³Khon Kaen University, Centre for Research and Development of Medical Diagnostic Laboratories (CMDL), Faculty of Associated Medical Sciences, Khon Kaen, Thailand, ⁴Khon Kaen University, Department of Clinical Immunology and Transfusion Sciences, Faculty of Associated Medical Sciences, Khon Kaen, Thailand, ⁵Khon Kaen University, Research Cluster: Specific Health Problems of Greater Maekong Subregion (SHeP-GMS), Khon Kaen, Thailand, ⁶Khon Kaen University, Liver Fluke and Cholangiocarcinoma Research Center, Faculty of Medicine, Khon Kaen, Thailand

Major histocompatibility complex (MHC) class I chain-related (MIC) gene A (MICA) is NKG2D ligands able to stimulate immune activities of NKG2D-expressing effector cells. Abnormal cells such as tumor cells that express NKG2D ligands can be eliminated. Our previous study found that MICA antigens was over expressed in 85% of cholangiocarcinoma (CCA) lesion. So, the expression of MICA on tumor cells might be the target molecules for killing tumor cells. In this study, PCR-random mutagenesis and phage display technology was employed to produce the high binding activity of anti-MICA antibodies, doxorubicin conjugated phages displaying anti-MICA antibodies was developed for targeted delivery of anti cancer drug to MICA expressing cell lines. The drug-conjugated phages

were analyzed by flow cytometry. Our study found that DOX-phages were more efficient than free drug in killing cancer cell lines approximately 1.6-6 times on Hela cells, and CCA cell lines. To avoid the immunogenicity, we aim to produce soluble anti-MICA antibodies from our previous experiment and tag them on another nanoparticle such as liposome which contain anti-cancer drug. E.coli HB2151 was brought to produce soluble antibodies and the indirect ELISA method was employed to confirm their antigen-binding specificity against MICA antigens. We obtained the clones of soluble antibodies that exhibit high antigen-binding activity indicated by OD. These clones of antibodies can be further modified, the new delivery platforms may able to target selectively and show specificity to cancer cells over-expressing MICA proteins.

1284

Isolation and characterization of target antigen specific VHHs from alpaca synthetic VHH phage display libraries

Murakami, A.¹, Yoshida, M.², Muraoka, J.³, Tsukahara, N.¹, Azuma, T.², Nakayama, H.³, Kishimoto, H.¹

¹University of Ryukyus, Graduate School of Medicine, Okinawa, Japan, ²Antibody Engineering Research Center Inc., Chiba, Japan, ³Panasonic, Bioscience Technology, Kyoto, Japan

A single domain antibody is an antibody fragment consisting of a monomeric variable antibody domain. The first single domain antibodies were engineered from heavy chain antibodies found in camelids and those are called VHH (variable domain of heavy chain of heavy-chain antibody). The VHHs represent the smallest antibody that was proven of diagnostic and therapeutic usefulness. Because of their small size (~15KDa), VHHs can penetrate tissues faster than other antibodies, and break through the brain's blood barrier. VHHs also have higher stability to changes in temperature and chemical environments, so that these have the great potential of gastrointestinal stability and oral availability. Here we present two major strategies to construct large (>1 billion variants) alpaca synthetic VHH libraries. One of the strategies is replacing the heavy chain CDR3 region of alpaca VHH by a random sequence of seventeen amino acids. The other is mimicking the strategy of V(D)J recombination. After several cycles of panning with those libraries, antigen-specific VHHs against more than 10 antigens were obtained. (Target antigen: influenza hemagglutinin, norovirus capsid protein, human/mouse serum albumin, cannabinoids, etc.). These VHH libraries enable the generation of panels of high-affinity VHHs within a week.

1285

Comparison of an *in vitro* cytokine release model with *in vivo* serum cytokine responses in AML patients administered CSL362 in a Phase 1 study (CSLCT-AML-11-73)

Dyson, A.R.¹, Millar, C.¹, Hung, D.², Barnden, M.¹, Souravi, G.¹

¹CSL Limited, Clinical and Translational Science, Parkville, Australia, ²CSL Limited, Bioprocess Development, Parkville, Australia

Pharmaceutical manufacturers of therapeutic antibodies are requested by regulatory agencies to investigate the possible

release of cytokines *in vivo* directly related to the administration of the therapeutic antibodies, which may induce cytokine related infusion reactions in patients. The U.S. Food and Drug Administration (FDA) recommend, "*in vitro* assessments of cellular activation, including proliferation and cytokine release in human whole blood or peripheral blood mononuclear cells" prior to first-in-human (FIH) infusion. In this study, *in vitro* methods have been investigated to develop a model to evaluate the ability of CSL362, an anti-IL-3R α (anti-CD123) monoclonal antibody, to elicit cytokine responses that may mimic *in vivo* responses seen in patients. The *in vitro* model was able to detect cytokine release when whole blood from healthy volunteers (N=30) was exposed to CSL362. Thirteen cytokines/chemokines were evaluated and eleven of these (IL-6, IL-8, GM-CSF, IL-1 α , IL-1RA, IFN- γ , IL-12p70, IL-2, TNF- α , IL-12p40 and IL-1 β) were measured at concentrations >2-fold in some of the healthy volunteer blood samples exposed to CSL362 compared to buffer control. Acute myeloid leukemia (AML) patients administered CSL362 during a Phase 1 clinical study (CSLCT-AML-11-73) demonstrated transient elevation of seven (IL-6, IL-8, GM-CSF, IL-1RA, IFN- γ , IL-1 β and TNF- α) of the eleven cytokines/chemokines detected with the *in vitro* assay. This study demonstrates that *in vitro* models can be used to assess the potential of therapeutic antibodies' to elicit *in vivo* cytokine responses in humans.

Bispecific antibodies

Gazumyan, A.

Rockefeller University, New York, United States

Cloning and expression of IgG genes from single B cell provided a powerful tool for the isolation and characterization of anti-Env antibodies with broad neutralizing activity.

BNabs (broadly neutralizing antibodies), that target four distinct epitopes, including the CD4-binding site, the V1V2-glycan region, the V3-glycan site, the gp41 membrane-proximal external region (MPER) were characterized.

In vitro neutralizing activities of double, triple and quadruple Ab combinations against a large panel of pseudo-viruses showed substantially improved the potency and the breadth compared to the corresponding single Abs.

Development of bispecific anti-HIV1 antibodies offers significant advantages over conventional monoclonal antibodies, as they combine the breadth and potency of two broadly neutralizing antibodies and overcome viral escape mechanisms associated with the use of single antibody.

We generated bispecific Abs by fusing two full-sized IgG antibodies via their C-termini utilizing sortase transpeptidation and click-chemistry, creating a covalently linked IgG antibody heterodimer. The neutralization by antibody dimer with bispecific activity that retains the activity and stability of the two original antibodies will be discussed.

1287**Composite molecules with EGF and its mutants as targeting elements and bundles of cytotoxic molecules or toll-like receptor agonists as effector elements**

Lin, C.-J.¹, Duh, Y.¹, Lin, C.Y.¹, Tian, W.-T.¹, Chen, J.-H.¹, Chu, H.-M.¹, Chang, T.-W.^{1,2}

¹Immwork Inc., Taipei, Taiwan, Republic of China, ²Genomics Research Center, Academia Sinica, Taipei, Taiwan, Republic of China

While anti-EGFR mAbs, such as Cetuximab, and anti-HER2/neu mAbs, such as trastuzumab, represent major advancement in the treatment of tumors expressing EGFR and HER2/neu, developing new drugs to increase response rates and decrease side effects in treating those tumors remains a major challenge. Herein, we report the development of a new class of pharmaceuticals with both targeting and effector moieties (T-E drugs), which adopt Fc-fusion, extended IgG, or/and multi-arm linker configurations. The targeting elements in those molecules are EGF or its EGF(S2W/D3V) mutants, which bind to multiple EGFR types. The effector elements are bundles of cytotoxic drugs or toll-like receptor (TLR) agonists, such as LPS and imiquimod. Each bundle carried 5 or more molecules and an Fc-fusion construct or IgG molecule with a C-terminal peptide linker and a cysteine residue extended from the CH3 domains was coupled with 2 of such bundles of drugs. In other T-E constructs, the scFv specific for PD-1 (CD279) or CD3 was fused to the C-termini of the Fc-fusion protein. Our results showed that the T-E drugs bound to EGFR- or ERBB3-overexpressed cancer cell lines in fluorescence flow cytometric assays. Furthermore, the T-E molecules with bundles of cytotoxic drugs or scFv against CD3 induced enhanced cytotoxicity of human epidermoid carcinoma cell line A431 and breast adenocarcinoma cell line MDA-MB-231 as compared to that of fusion protein with only targeting moiety. These results suggest that the T-E pharmaceuticals designed in this study may confer increased therapeutic efficacy and decreased side effects.

1288**Understanding the biology of the CD300f inhibitory receptor as a target for anti-AML antibodies**

Clark, G.^{1,2}, Gasirowski, R.¹, Kupresanin, F.¹, Mekkawy, A.¹, Hart, D.^{1,2}

¹ANZAC Research Institute, Sydney, Australia, ²University of Sydney, Sydney, Australia

Each year around 900 Australians will be affected by acute myeloid leukemia (AML) and, with currently available treatments, the majority will die from their disease. Therapeutic antibodies to immune cell surface molecules have revolutionised the treatment of many cancers but there is a need to develop human antibodies to more targets. CD300f belongs to the evolutionarily conserved CD300 family. It has a number of signalling motifs that both inhibit and activate cell functions. Human CD300f binds phosphatidylserine, an "eat-me" receptor inducing phagocytosis of dead cells. CD300f is expressed on myeloid lineage cells. Antibodies to CD300f prevent proliferation of AML cell lines in immunosuppressed mice. Our work has investigated CD300f as a potential anti leukemic target.

We showed by multiparameter flow cytometry that primary AML blasts from 78% (28/33) of patients and the CD34+CD38-leukaemia stem cell enriched fraction from 65% (13/20) of patients are CD300f+. We have used a panel of CD300f mAbs to demonstrate distinct epitopes on AML and healthy CD34+ cord blood (CB) cells. One mAb bound most AML samples and healthy CB Lin-CD34+CD38-CD45RA-CD90+ cells, whilst another bound only to monocytic AML samples and not healthy CB HSC. We found different CD300f protein isoforms on leukemic cell lines and identified differential expression of CD300f splice variants. These results indicate that isoforms of CD300f are differentially expressed across AML blasts and HSC. Only antibodies to key epitopes will be suitable for developing into AML therapeutic antibodies and these are now the focus of our program.

1289**Increment in drug loading on an antibody drug conjugate induces higher binding to the human Neonatal Fc receptor in acidic conditions *in vitro***

Brachet, G.¹, Respaud, R.², Arnoult, C.¹, Henriquet, C.³, Dhommée, C.¹, Viaud-Massuard, M.-C.¹, Heuzé-Vourc'h, N.⁴, Joubert, N.¹, Pugnère, M.³, Gouilleux-Gruart, V.¹

¹Université François Rabelais de Tours, CNRS, UMR 7292 Génétique, Immunothérapie, Chimie et Cancer, Tours cedex, France, ²CHRU de Tours, Pharmacie, Tours, France, ³Institut de Recherche en Cancérologie de Montpellier, INSERM, U 1194, Montpellier, France, ⁴Université François Rabelais de Tours, INSERM U 1100, Tours cedex, France

Antibody drug conjugates are an innovative class of biomedicine. They combine the high specificity of monoclonal antibodies to the power of cytotoxic drugs such as tubulin inhibitors, allowing specific delivery of the toxic payload and therefore fewer adverse effects. However, the technologies currently used for bioconjugation lead to highly heterogeneous solutions, composed of several species with different drug-to-antibody ratios. In the case of brentuximab vedotin, which is bioconjugated via the chemical reduction of cysteine residues involved in disulfide bonds, five main species are present inside the stock solution. These species have a drug-to-antibody ratio of zero, two, four, six or eight vedotin molecules per antibody. Monoclonal antibodies have an important half-life *in vivo*, notably thanks to neonatal Fc Receptor-mediated recycling. We investigated the influence of drug loading on the binding of the antibody to neonatal Fc Receptor (FcRn). We developed a hydrophobic interaction chromatography method for separating the different species of brentuximab vedotin. Physicochemical characterization showed that species with higher antibody-drug ratios tended to form more aggregates. We assessed the binding of these different species to FcRn in a cellular assay based on flow cytometry and surface plasmon resonance. FcRn binding assays showed that the most conjugated species, particularly those with saturated loading, interacted more strongly than unconjugated brentuximab vedotin with the FcRn in acidic conditions. However, affinity at neutral pH was negligible whatever the drug-to-antibody ratio, suggesting that the shorter half-life of these species is due to a factor other than modifications in the antibody-FcRn interaction.

Immune signature profiles in cancer immunotherapy revealed by mass cytometric analysis

McGuire, H.^{1,2}, Asad, S.¹, Choi, C.¹, Smith, A.^{2,3}, McNeil, C.⁴, Hersey, P.⁵, Fazekas de St Groth, B.^{1,2}

¹Centenary Institute, T Cell Biology, Sydney, Australia, ²University of Sydney, Ramaciotti Facility for Human Systems Biology, Sydney, Australia, ³University of Sydney, Advanced Cytometry Facility, Sydney, Australia, ⁴Chris O'Brien Lifehouse, Sydney, Australia, ⁵Centenary Institute, Immuno Oncology, Sydney, Australia

The introduction of monoclonal antibodies that block immune checkpoint pathways represents a major advance in treatment of cancers such as melanoma and lung cancer. Check-point inhibitors targeting CTLA-4, PD-1 and PD-L1 can generate objective responses in patients with advanced disease that has proven refractory to treatment with chemo- and/or radio-therapy. However not all patients respond and we currently lack the ability to *predict* which individuals within a group of patients can be successfully treated. Further limitations include debilitating autoimmune-related side-effects in a subset of patients. Our previous lab findings of 'immune signatures' in autoimmune disease, combined with the essentially autoimmune nature of responses to autologous tumour, suggested that immune signature analysis could provide important insights into anti-tumour responses during checkpoint inhibitor therapy.

Utilising a highly innovative frontier technology; mass Cytometry with Time Of Flight analysis (CyTOF), we have investigated immune signatures in cancer patients both before and during treatment with checkpoint inhibitors. Using CyTOF we were able to quantitatively analyse 40 different surface and intracellular markers to profile each patient's immune system to an unprecedented resolution. We mapped progressive changes in circulating immune subset phenotypes and marker expression in metastatic melanoma patients following initiation of check-point inhibitor therapy. Our ultimate aim is to identify candidate immune signatures for prediction of response to cancer immunotherapy and likely severity of side-effects. We envisage that this strategy will facilitate selection of individually appropriate therapy options with minimal side effects across a broad range of diseases - the ultimate goal of personalised medicine.

1291

High levels of IgG antibodies against malondialdehyde modified collagen type IV predict coronary events

Vallejo, J., Dunér, P., Nilsson, J., Bengtsson, E.

Lund University, Department of Clinical Sciences, Malmö, Sweden

Objectives: In atherosclerosis, LDL particles are accumulated and oxidized in the vessel wall, which are considered as key events in the development of atherosclerotic lesions. During lipid oxidation, reactive adducts such as malondialdehyde (MDA) are formed and may leak out modifying surrounding extracellular matrix proteins, which could activate immune responses. Collagen type IV is the most abundant protein in the basement membranes and has an important role in the

maintenance of basement membrane integrity.

Approach and results: This study analyzed whether autoantibodies against MDA-modified collagen IV predict coronary events in a 15 years follow up study consisting of 795 subjects (385 individuals with coronary events and 410 age and gender matched controls) from Malmö Diet and Cancer study. IgG MDA-collagen IV antibodies were higher in individuals with coronary events compared to controls [0.7 (0.6 - 1.0) versus 0.6 (0.5 - 0.9); p= 0.0001]. Subjects from the highest tertile of MDA-collagen IV IgG, had an increased risk to develop coronary events [hazard ratio 1.561 (95 % confidence interval, 1.219 - 1.999); p for trend 0.0004]. This association remained significant after adjusting for Framingham risk factors and diabetes mellitus [HR 1.471 (1.121 - 1.930); p for trend 0.005]. Positive correlations between anti MDA-collagen IV IgG antibodies and plasma IL-6, MMP-10, MMP-12, cathepsin D and cystatin B were observed.

Conclusions: Individuals with higher levels of IgG MDA-collagen IV antibodies have an increased risk to develop coronary events. These antibodies were associated to proteases, which may reflect an increased degradation of the extracellular matrix.

1292

Cytokine-neutralizing therapeutic antibodies designed with tissue-targeting functions for increased delivery to diseased sites

Chen, J.-H.¹, Chu, H.-M.¹, Lin, C.Y.¹, Tian, W.-T.¹, Lin, C.-J.¹, Duh, Y.¹, Chang, T.W.^{1,2}

¹Immunwork Inc., Taipei, Taiwan, Republic of China, ²Academia Sinica, Genomics Research Center, Taipei, Taiwan, Republic of China

Therapeutics, such as adalimumab and etanercept specific for tumor necrosis factor- α (TNF- α), have been approved for treating rheumatoid arthritis, secukinumab specific for interleukin 17 (IL-17) for psoriasis, belimumab specific for B cell-activating factor (BAFF) for systemic lupus erythematosus (SLE), and denosumab specific for receptor activator of nuclear factor kappa-B ligand (RANKL) for osteoporosis and tumor metastases to bone. Those antibodies neutralize key cytokines and mediate therapeutic effects, but also cause a wide range of side effects, such as serious infections. We have engineered single-chain variable fragments (scFv) specific for extracellular matrix proteins, which are relatively abundant in the affected connective tissues, onto the respective therapeutic antibodies, so that they can be channeled to those tissues upon administration. For this purpose, adalimumab is fused *via* the CH3 domain with scFv against collagen type II, which is abundant in cartilage of the joints, secukinumab and belimumab with scFv against collagen type VII, a key component of anchoring fibrils between epidermis and dermis of the skin, and denosumab with scFv against osteonectin, which is uniquely prominent in bone matrix. Herein, we describe the generation and characterization of denosumab-scFv anti-osteonectin in an "extended IgG configuration". The bispecific molecule retained the binding and functional characteristics of denosumab, but with the additional activity to bind to osteonectin. In BALB/c mice, denosumab-

(scFv anti-osteonectin) showed a distribution pattern similar to an anti-osteonectin monoclonal antibody, reaching to bones at larger proportions than denosumab. These antibodies with tissue-targeting functions may have better therapeutic efficacy and fewer side effects.

1293

Interleukin-17 blockade in rheumatoid arthritis: a systematic review and meta-analysis

Shan, J.¹, Chen, Z.², Chen, X.³, Chen, W.¹, Jin, H.¹, Xu, Y.¹, Cheng, X.¹

¹Chengdu Medical College, Chengdu, China, ²Chengdu First People Hospital, Chengdu, China, ³Sichuan University, Chengdu, China

Background: The interleukin-17 (IL-17) plays an important role in the pathogenesis of rheumatoid arthritis (RA). Several IL-17 blockers, including the anti-IL-17A antibodies secukinumab and ixekizumab, and the anti-IL-17 receptor subunit A antibody brodalumab have been used in patients with RA. In this study, we aim to evaluate the efficacy and safety of the IL-17 blockers for the treatment of RA.

Methods: The Cochrane Central Register of Clinical Trials, MEDLINE, and EMBASE were searched for identification of relevant trials. All controlled trials comparing IL-17 blockers versus placebo were eligible for inclusion.

Main results: Six trials (a total of 1126 participants) were included. The trials were generally of low risk of bias. Follow-up ranged from 12 to 16 weeks. Meta-analysis showed that IL-17 blockade could significantly improve the ACR20 (RR = 1.36; 95% CI: 1.14-1.61), ACR50 (RR = 2.12; 95% CI: 1.42-3.15) and ACR70 (RR = 2.86; 95% CI: 1.29-6.37). A greater reduction in DAS28-CRP score from baseline was observed when secukinumab and ixekizumab used. There was no evidence of statistically significant differences in the overall AE incidence rate (RR = 1.05; 95% CI: 0.93-1.18) and infections (RR = 1.32; 95% CI: 0.98-1.77) between IL-17 blocker and placebo.

Conclusions: IL-17 blockade results in significant improvement in clinical signs and symptoms of RA, and there was no evidence of a difference in the rates of AE between groups, suggesting that IL-17 blocker may offer an alternative treatment for RA, especially among patients who with inadequate response to other treatments, including TNF blocker therapy.

1294

Synergistic therapeutic efficacy of Unituxin and PD-1 blockade in a murine neuroblastoma model

Hung, J.-T., Huang, J.-R., Yu, A.L.

Institute of Stem Cell & Translational Cancer Research, Taoyuan, Taiwan, Republic of China

The approval of Unituxin, a chimeric anti-GD2 antibody, for the treatment of high-risk neuroblastoma by US FDA and European Commission in 2015 marks the first new agent targeting a glycolipid molecule, thereby widening the net of potential pharmaceutical targets. Dr. Yu has led the development of ch14.18 from IND to the randomized phase III clinical trial, which showed a significant improvement in 2-year event-free survival from 46% with standard therapy to 66% with immunotherapy.

However, at least 1/3 of high-risk neuroblastoma patients still fail this immunotherapy. To improve the efficacy of anti-GD2, we evaluated its combination with anti-PD-1 antibody in a murine NXS2 neuroblastoma model, given the reported expression of PD-L1 in neuroblastoma. The suboptimal dosages of murine anti-GD2 mAb14G2a and anti-PD-1 mAbJ43 antibodies were first determined in mice bearing neuroblastoma NXS2 cells. At 31 days after tumor injection, the percentage of CD4+ cells and CD8+ cells in spleen was greater but the percentage of MDSCs was lower in mice treated with suboptimal dose of mAb14G2a than those treated with PBS control. Notably, the percentage of CD3+PD-1+ was higher in mice treated with mAb14G2a than control mice. Next, mice were treated with mAb14G2a, anti-PD-1 alone, or in combination, three days after tumor injection. The median survival of NXS2-bearing mice treated with combined anti-GD2/anti-PD-1 antibodies (40 days) was significantly longer than those treated with anti-GD2 (33 days) or anti-PD-1 (33 days) ($p < 0.001$). Our findings provide preclinical evidence for future clinical trials of Unituxin combined with anti-PD-1 in patients with neuroblastoma.

1295

Targeting Epstein-Barr virus transformed B lymphoblastoid cells using antibodies with TCR-like specificities

Lai, J.¹, Tan, W.J.^{1,2}, Too, C.T.¹, Choo, J.A.L.¹, Wong, L.H.², Mustafa, F.¹, Srinivasan, N.³, Lim, A.P.C.⁴, Zhong, Y.¹, Gascoigne, N.¹, Hanson, B.⁴, Chan, S.H.³, Chen, J.², Macary, P.¹

¹National University of Singapore, Department of Microbiology and Immunology, Singapore, Singapore, ²Infectious Disease Interdisciplinary Research Group, Singapore-MIT Alliance for Research and Technology (SMART), Singapore, Singapore,

³National University of Singapore, WHO Immunology and Training Research Centre, Singapore, Singapore, ⁴Defense Medical and Environmental Research Institute, Defence Science Organization National Laboratories, Singapore, Singapore

Epstein-Barr virus (EBV) is an oncovirus associated with several human malignancies including Hodgkin's and Burkitt's lymphomas, nasopharyngeal carcinoma as well as post-transplant lymphoma in immunosuppressed patients. While EBV displays restricted gene expression during different latency programmes, the viral gene products that are frequently detected in EBV-associated tumors include EBNA1, LMP1 and LMP2A. We showed here that anti-EBV T cell receptor-like monoclonal antibodies (TCR-like mAbs) E1, L1 and L2 bound to their respective HLA-A*0201-restricted EBV peptides EBNA1₅₆₂₋₅₇₀ (FMVFLQTHI), LMP1₁₂₅₋₁₃₃ (YLLEMLWRL) and LMP2A₄₂₆₋₄₃₄ (CLGGLTMV) with high affinities and specificities. These mAbs recognized endogenously presented targets on EBV B lymphoblastoid cell lines (BLCLs) but not to PBMCs from which they were derived. Furthermore, these mAbs displayed similar binding activities on several BLCLs despite inherent heterogeneities between different donor samples. A single weekly administration of the naked mAbs reduced splenomegaly, liver tumor spots and tumor burden in BLCL-engrafted immunodeficient mice. In particular, mice that were treated with the E1 mAb displayed delayed weight loss and significantly prolonged survival. *In vitro*, these TCR-like mAbs

induced the upregulation of surface phosphatidylserine and early apoptosis of BLCLs, thereby enhancing their Fc-dependent phagocytic uptake by macrophages. Taken together, these data demonstrate anti-EBV TCR-like mAbs as potential therapeutic candidates to treat EBV-associated diseases.

1296

Characterization of human CD83 expression on immune cells identifies a unique CD83+ T cell population

Ju, X.¹, Silveira, P.A.^{1,2}, Elgundi, Z.¹, Verma, N.¹, Alingcastre, R.¹, Hsu, W.-H.^{1,2}, Fromm, P.D.^{1,2}, Kupresanin, F.¹, Li, Z.^{1,2}, Lo, T.H.^{1,2}, Clark, G.J.^{1,2}, Hart, D.N.J.^{1,2}

¹ANZAC Research Institute, Dendritic Cell Research, Sydney, Australia, ²University of Sydney, Sydney Medical School, Sydney, Australia

CD83 is an important marker of activated dendritic cells (DC). We targeted CD83 using a rabbit polyclonal anti-CD83 antibody and a human anti-human CD83 monoclonal antibody (mAb), 3C12C, to deplete activated DC as a novel approach to immunosuppression. Anti-CD83 prevented graft versus host disease (GVHD) and preserved human T cell responses after transplantation in SCID mice. Because CD83 is also expressed on other immune cells, we undertook a comprehensive analysis of its expression and glycosylation pattern on various immune cell populations. There were distinct CD83 splice variants (full length CD83 plus splice variants CD83a, CD83b and CD83c) in different immune cells. CD83 glycosylation status also differed, with glycosylation required for expression on activated DC, whereas its expression on activated B cells and monocytes was resistant to de-glycosylation. Monocytes released more soluble CD83 than DC. Interestingly, different T cell stimuli (PHA, CD3/CD28 beads and mixed leukocyte reaction (MLR) culture) increased CD83 expression on T cells with different kinetics, underlining the distinct signaling pathways involved. Our investigations established that human T cell activation induced transient transcription and surface expression of CD83 on a specific responding T cell subpopulation, which co-express MHC class II and exhibit a memory phenotype. These distinct expression profiles of CD83 isoforms in different human immune cells are likely to contribute to several immune regulatory pathways.

1297

IPH4301, an antibody targeting MICA and MICB exhibits potent cytotoxic activity and immunomodulatory properties for the treatment of cancer

Morel, A., Viaud, N., Bonnafous, C., Trichard, S., Joulin-Giet, A., Grondin, G., Mizari, S., Cohen-Tannoudji, L., Morel, Y., Rossi, B., Patrel, C., Buffet, R., Gauthier, L., Wagtmann, N., Bléry, M.
Innate Pharma, Marseille, France

MICA, MICB, and ULPB1-6 are ligands for NKG2D, an activating receptor expressed on NK cells and subsets of T cells. As markers of cellular stress and tumorigenesis, MICA and MICB proteins are attractive targets for cancer therapy. MICA/B are also compelling targets for immunomodulation. Chronic exposure to MICA and -B cause internalization of NKG2D,

leading to desensitization of cytotoxic NK and T cells in cancer patients. Moreover, NKG2D ligand expression is induced on immunosuppressive macrophages in cancer patients raising the possibility that anti-MICA/B antibodies may be used to counter local immunosuppression by targeting myeloid derived suppressor cells.

We have identified and humanized an anti-MICA/B antibody, IPH4301, that binds to all allotypes of MICA and MICB. First, IPH4301 induces killing of MICA/B expressing tumor cells through antibody-dependent cell cytotoxicity and antibody-dependent cell phagocytosis measured towards MICA expressing cells. Second, IPH4301 blocks the binding of MICA/B to NKG2D. In tumor, NKG2D down-modulation is primarily induced by expression of MICA/B. By blocking the NKG2D-MICA/B interaction, IPH4301 effectively restored NKG2D expression *in vitro* on primary NK and T cells. Third, *In vitro* differentiated M2 macrophages, but not M1 macrophages, impaired the cytotoxic functions of autologous NK cells towards MICA expressing tumor cell lines. This suppression could be overcome by IPH4301, which triggered ADCC by these otherwise impaired NK cells.

Altogether, IPH4301 is a novel, first-in-class anti-MICA/B mAb with both cytotoxic and immunomodulatory properties. Ongoing work aims to perform regulatory toxicology studies and manufacture a clinical grade product for testing in a clinical trial.

1298

Lymphatic access of therapeutic proteins after IV administration is size-dependent and primarily occurs within the liver and mesentery

Yadav, P., McLeod, V., Johnston, A.P.R., Kaminskas, L.M., Trevaskis, N.L.
Monash University, MIPS, Drug Delivery, Disposition and Dynamics, Melbourne, Australia

Background: The lymphatic system is implicated in cancer metastasis, infectious disease and inflammatory disease. These diseases are typically treated with small molecule drugs that display limited lymphatic affinity. Therapeutic proteins may better target and treat lymphatic diseases since they are cleared from the interstitium via lymphatics. Recent studies demonstrate substantial lymph access of IV administered therapeutic proteins but the mechanism is unknown.

Aim: To determine the major sites and protein properties that facilitate lymph access of IV administered therapeutic proteins.

Methods: Cannulas were inserted into rat's jugular vein (IV injection), carotid artery (blood collection) and liver, intestine or thoracic lymph duct (lymph collection). Therapeutic proteins (PEGylated-interferons IFN-PEG12 (31kDa), IFN-PEG40 (60kDa) and trastuzumab (150kDa) were administered IV, plasma and lymph collected over time and protein concentrations quantified via ELISA.

Results: Thoracic lymph recovery was significantly greater for trastuzumab and IFN-PEG40 (4-7% dose) vs IFN-PEG12 (1-2% dose). Conversely, the thoracic lymph/plasma (L/P) concentration ratio, an indication of lymph transfer efficiency, was highest for IFN-PEG12 (90-100%) and similar for IFN-PEG40 and trastuzumab (15-30%). The lower lymph transport

of IFN-PEG12 reflected more rapid plasma clearance. For all proteins, lymph access primarily occurred in the liver (>40%) and mesentery (>40%) but lymph access mechanism differed in these tissues.

Conclusions: Lymph access of IV therapeutic proteins is enhanced for proteins with long circulation half-lives and that are small enough to readily transfer to lymph. Access predominantly occurs in the intestine and liver. Optimising therapeutic proteins represents a viable approach to target and treat lymphatic diseases.

1299

Idiopathic mast cell activation disorder: control of idiopathic and venom immunotherapy associated anaphylaxis with low dose Omalizumab

Berry, R.¹, Hollingsworth, P.¹, Lucas, M.^{1,2,3,4}

¹Sir Charles Gairdner Hospital, Department of Clinical Immunology, Perth, Australia, ²University of Western Australia, School of Medicine and Pharmacology, Perth, Australia, ³University of Western Australia, School of Pathology and Laboratory Medicine, Perth, Australia, ⁴Murdoch University, Institute for Immunology and Infectious Disease, Perth, Australia

Mast cell disorders (MCD) are classified as primary (mastocytosis and monoclonal mast cell activation syndrome; MMAS), secondary (known trigger and polyclonal) and idiopathic. MCD patients are at increased risk of anaphylaxis to hymenoptera stings and to its treatment with venom specific immunotherapy (VIT). Omalizumab, an anti-IgE antibody has been reported to permit safer VIT application and prevent anaphylaxis associated with VIT.

Here we present a patient who suffers from severe bee venom anaphylaxis, who was found to have a constant elevation of his mast cell tryptase (MCT; range 14.9-25.0 µg/L) and was initiated on bee VIT. Adrenaline auto-injectors were prescribed for anaphylaxis management. He suffered recurrent anaphylaxis to VIT, and remained symptomatic in the weeks between VIT injections with cognitive difficulty, mood disorder and hypotension to the extent of disability. His clinical symptoms and elevated MCT were reflective of a MCD, however clonality markers, bone marrow biopsy and FDG-PET revealed no evidence for primary MCD. VIT could not be continued and treatment with high dose anti-histamines and montelukast did not alter his symptoms. We initiated low dose Omalizumab treatment at 150mg SC monthly. This allowed for reintroduction of VIT and also led to a resolution of clinical symptoms. The patient was able to return to work while on bee VIT maintenance. His MCT remains stable at 20 µg/L.

This presents the first case reported in the literature where low dose Omalizumab has been a successful treatment in idiopathic non-clonal MCD with symptomatic improvement and prevention of anaphylaxis during bee VIT.

1300

Potent antitumor activity of IL-2-Fc fusion proteins through FcγR-dependent depletion of CD4⁺ CD25⁺ Tregs

Vazquez-Lombardi, R., Webster, K.E., Sprent, J., Christ, D.

Garvan Institute of Medical Research, Immunology Division, Sydney, Australia

Interleukin-2 (IL-2)-mediated expansion of cytotoxic CD8⁺T-cells and natural killer cells has been successfully used in cancer immunotherapy. However, clinical use of IL-2 is complicated by dose-limiting toxicities and inevitable expansion of CD4⁺ CD25⁺ regulatory T-cells (Tregs). Previous attempts to overcome these limitations have focused on maximization of cytotoxic cell expansion, as exemplified by IL-2/anti-IL-2 immune complexes and IL-2 'superagonist' proteins. Here, we report potent and selective activity of engineered fusion proteins consisting of IL-2 and the antibody Fc region. As expected, disruption of CD25 binding through mutation of the IL-2 component led to strong expansion of CD25⁻ cytotoxic subsets. Surprisingly, however, when tested for tumor rejection, such constructs were in fact less effective than wild-type IL-2-Fc protein. Further analyses revealed that efficacy was crucially dependent on selective depletion of Tregs through Fc-mediated immune effector functions. Our results reveal an unexpected mechanism of action of IL-2-Fc fusion proteins and provide important guidelines for the development of next-generation IL-2 immunotherapies.

1301

Low-dose doxorubicin reduces an immunosuppressive Ly6C^{lo} monocyte population to improve efficacy of anti-41BB monoclonal antibody against B cell lymphoma

McKee, S.J., Doff, B.L., Gandhi, M.K., Mattarollo, S.R.

University of Queensland Diamantina Institute, Translational Research Institute, Woolloongabba, Australia

Tumours promote the expansion of myeloid populations with immunosuppressive activity. This immunosuppressive microenvironment has a negative impact on the efficacy of therapeutic monoclonal antibodies that aim to stimulate anti-tumour lymphocyte populations. In a murine model of *c-myc* driven B cell lymphoma (Eµmyc) we have observed a significant expansion of a CD115⁺ Ly6C^{lo} monocyte population. Expansion of immunosuppressive monocytes was also observed in Hodgkin's lymphoma patient samples. These cells displayed immunosuppressive activity against effector T cell populations via high expression of PDL-1. Granulocytes and classical Ly6C^{hi} monocytes expressed significantly lower levels of PDL-1. Intravenous administration of low dose (1 mg/kg) soluble or liposomal doxorubicin into tumour bearing hosts was able to reduce the abundance of CD115⁺ Ly6C^{lo} PDL-1^{hi} monocytes without affecting T cell populations. Doxorubicin-mediated reduction of the immunosuppressive monocyte population improved the efficacy of therapeutic anti-41BB monoclonal antibody to stimulate T cells and correspondingly decreased PD-1 expression on CD8⁺ and CD4⁺ T cells. When used in combination, low dose doxorubicin and anti-41BB monoclonal antibody were able to significantly reduce the number of lymphoma cells and improve survival of lymphoma bearing

mice. Low dose doxorubicin is a promising pre-conditioning step to improve the efficacy of anti-41BB monoclonal antibody therapy against lymphoma via selective reduction of immunosuppressive myeloid cells.

IL3R-alpha as a novel therapeutic target in systemic lupus erythematosus

Oon, S.^{1,2,3}, Huynh, H.⁴, Tai, T.Y.⁴, Ng, M.⁴, Monaghan, K.⁴, Biondo, M.⁴, Vairo, G.⁴, Maraskovsky, E.⁴, Nash, A.⁴, Wicks, I.^{1,2,3}, Wilson, N.⁴

¹The Walter and Eliza Hall Institute of Medical Research, Inflammation Division, Parkville, Australia, ²The Royal Melbourne Hospital, Department of Rheumatology, Parkville, Australia, ³The University of Melbourne, Department of Medical Biology, Parkville, Australia, ⁴CSL Limited, Parkville, Australia

There remains significant morbidity in SLE despite current therapeutics. The autoantibody-producing B cell has been a major therapeutic target as has, more recently, type I IFN, produced by pDCs in response to TLR7 and TLR9 activation by SLE immune complexes. We have developed a novel mAb targeting the IL3R-alpha, CSL362, and demonstrate here that it affects multiple pathogenic cell types and cytokines. Via antibody-dependent cell-mediated cytotoxicity, CSL362 potently and specifically depletes CD123^{high} pDCs and basophils. Through pDC depletion, TLR7-, TLR9- and SLE serum-stimulated IFN-alpha production, and IFN-inducible gene expression is markedly reduced. These effects were seen *in vitro* in a heterogeneous population of SLE donors and healthy controls, and confirmed *in vivo* in cynomolgus macaques. We also found that TLR7- and TLR9-induced plasmablast expansion was inhibited by CSL362. This depended upon decreasing not only IFN-alpha, but IL-6, production, through depleting pDCs. Importantly, we show that CSL362 more effectively inhibits IFN-inducible gene expression and plasmablast expansion than IFN-alpha blockade alone. This may be because pDC depletion by CSL362 reduces production of cytokines other than IFN-alpha, such as IL-6, and interferon types other than type I. Indeed, we found that CSL362 reduced production of type III IFN, a cytokine which is postulated to cause ongoing disease activity despite type I IFN blockade. The unique ability of CSL362 to affect two major contributors to SLE, and newer pathogenic targets such as the basophil, IL-3 and type III IFN, presents a strong rationale for its therapeutic evaluation in SLE.

1303

Establishment of a therapeutic anti-pan HLA-class II monoclonal antibody that directly induces lymphoma cell death via large pore formation

Matsuoka, S.¹, Ishii, Y.², Abe, M.¹, Ohtsuji, N.¹, Mizutani, N.³, Nakao, A.⁴, Yagita, H.⁵, Hino, O.¹

¹Juntendo University School of Medicine, Pathology and Oncology, Tokyo, Japan, ²RIKEN Center for Integrative Medical Sciences, Vaccine Design, Yokohama, Japan, ³Kyorin University of Medicine, Pathology, Tokyo, Japan, ⁴Department of Research Interdisciplinary Graduate School of Medicine and Engineering, Immunology, Yamanashi, Japan, ⁵Juntendo University School of

Medicine, Immunology, Tokyo, Japan

To develop a new therapeutic monoclonal Antibody (mAb) for Hodgkin lymphoma (HL), we immunized a BALB/c mouse with live HL cell lines, alternating between two HL cell lines. After hybridization, we screened the hybridoma clones by assessing direct cytotoxicity against a HL cell line not used for immunization. We developed this strategy for establishing mAb to reduce the risk of obtaining clonotypic mAb specific for single HL cell line. A newly established mouse anti-human mAb (4713) triggered cytoskeleton-dependent, but complement- and caspase-independent, cell death in HL cell lines, Burkitt lymphoma cell lines, and advanced adult T-cell leukemia cell lines. Intravenous injection of mAb 4713 in tumor-bearing SCID mice improved survival significantly. mAb 4713 was revealed to be a mouse anti-human pan-HLA class II mAb. Treatment with this mAb induced the formation of large pores on the surface of target lymphoma cells within 30 min. This finding suggests that the cell death process induced by this anti-pan HLA-class II mAb may involve the same death signals stimulated by a cytolytic anti-pan MHC class I mAb that also induces large pores formation. This multifaceted study supports the therapeutic potential of mAb 4713 for various forms of lymphoma.

Targeting Sperm protein 17 for developing an immunotherapeutic treatment for ovarian cancer

Xiang, S.D.¹, Gao, Q.¹, Wilson, K.L.¹, Heyerick, A.², Stephens, A.³, Plebanski, M.¹

¹Monash University, Centra Clinical School, Department of Immunology and Pathology, Melbourne, Australia, ²PX Biosolutions Pty Ltd, South Melbourne, Australia, ³Hudson Institute of Medical Research, Ovarian Cancer Biomarker Laboratory, Clayton, Australia

Ovarian cancer (OC) is the leading cause of death from gynaecological malignancy. Immunotherapeutic strategies are considered less toxic and more specific than current treatments. Sperm protein (Sp17) is a protein aberrantly expressed in ovarian tumors and other cancers, but undetectable on normal tissues except on male spermatozoa, making it a highly specific target for treatment of OC. Our previous studies identified a specific region (hSp17₁₁₁₋₁₄₂) in the human Sp17 sequence which is highly immunogenic, induced high levels of antibodies and IFN-γ producing T cells both in C57BL/6 and in C57BL/6-HLA-A2.1 transgenic mice, when adjuvanted with CpG or nanoparticles. C57BL/6 mice immunised with CpG adjuvanted hSp17₁₁₁₋₁₄₂ significantly prolonged the life-span of the mice bearing the ovarian carcinoma ID8 cell line. We further mapped the immuno-dominant B and T cell epitope regions within the hSp17₁₁₁₋₁₄₂ and identified a single immuno-dominant B cell (134-142 aa) epitope and 2T helper 1 (Th1) cell epitopes (111-124 and 124-138 aa). Further exploring the therapeutic potential of the hSp17₁₁₁₋₁₄₂, our recent studies showed that anti-hSp17₁₁₁₋₁₄₂ serum antibody can directly kill the OC tumor cell lines derived from either mouse or human origins *in vitro*. Sp17 expression is indispensable for tumor survival *in vivo*, and highly co-localized with 2 markers (patent pending) which associate with the tumor escape and drug resistant. This provides an opportunity

to design an immunotherapeutic regiment targeting Sp17 and combing other immune based therapies/drugs to eliminate the “toughest” cancer cells which often resistant to chemotherapy, and offers a new and tremendous advantages.

Targeting EBV positive cancers with affinity enhanced T cell receptors

Wong, Y.¹, Gostick, E.², Lomax, M.³, Vuidepot, A.³, Baston, E.³, Shingler, W.³, Hassan, N.³, Dukes, J.³, Smith, C.¹, Khanna, R.¹, Ladell, K.², Cole, D.K.², Sewell, A.K.², Burrows, S.R.¹, Jakobsen, B.³, Price, D.A.², Miles, J.J.¹

¹QIMR Berghofer Medical Research Institute, Immunology, Herston, Australia, ²Cardiff University School of Medicine, Infection and Immunity, Cardiff, United Kingdom, ³Immunocore Ltd, Abingdon, United Kingdom

Epstein-Barr virus (EBV) is associated with over 30 different diseases and malignancies. The pathogen is associated with over 300,000 cases of cancer annually and is thought to be involved in various pathologies affecting over one million people annually. Currently, no commercially available EBV specific therapy or vaccine exists. Using phage display directed evolution; we generated a panel of affinity enhanced T cell receptors (TCR) that targeted an EBV antigen from LMP2. We then generated Immune Mobilising Monoclonal TCRs Against Cancer (ImmTACs) by fusing an anti-CD3 effector payload to the constant region of the TCR. In soluble form, EBV ImmTACs were able to redirect T cell specificity *in vitro* in low picomolar concentrations against nasopharyngeal carcinoma, Burkitt's lymphoma, gastric carcinoma, diffuse large B-cell lymphoma and lymphoblastic cell lines. Using multiparametric flow cytometry, we observed EBV ImmTACs could redirect large numbers of polyfunctional CD8+ and CD4+ T cells against EBV positive cancers. We are currently testing these soluble therapeutics in humanised and tumor xenograft EBV mouse models to gauge safety and *in vivo* efficacy. EBV ImmTACs are first in class and represent a promising new “off-the-shelf” therapy against EBV associated cancers and could be a significant stride forward in treating the wide spectrum of diseases associated with this pathogen.

1306

Identification of the single immunodominant epitope of the native human CC chemokine receptor 6

Yssel, H.¹, Dorgham, K.¹, Dejou, C.², Piesse, C.³, Pène, J.⁴, Gorochov, G.⁵

Chemokines and their receptors play an important role in cell trafficking and recruitment. The CCR6 chemokine receptor, selectively expressed on leukocyte populations, has been

shown to play a deleterious role in the pathogenesis of various chronic inflammatory diseases and, as such, may constitute a prime target for the development of novel immunotherapeutic treatment. However, the development of strategies to modulate inflammation mediated by this chemokine receptor in human has been hampered by the lack of specific inhibitory small molecules. Moreover, several anti-human CCR6 (huCCR6) antibodies have been developed in different species, but to date none have proven function-blocking activity. Here, we report strategies to generate neutralizing mouse mAbs specific for huCCR6. Immunization of mice with peptides mimicking extracellular domains, potentially involved in CCR6 function, failed to induce Abs reactive with the native receptor. In contrast, although the use of NIH-3T3 cells expressing huCCR6 resulted in the isolation of mAbs specific for this receptor, they were not able to block the interaction between huCCR6 and huCCL20. Finally, the results show that all mouse mAbs generated by immunization with native huCCR6, will invariably recognize a unique, but non-neutralizing, immunodominant epitope in the first part of its N-terminal domain. All together, this work allows a better understanding of the impediments to generate specific inhibitory molecules against the huCCR6.

Transcription Factors

1308

Transcription factor availability rather than modulated enhancer availability regulates CD8⁺ T cell differentiation

Russ, B.¹, Olshansky, M.¹, Li, J.¹, Nguyen, M.¹, Chen, E.¹, Khoury, G.¹, Nussing, S.¹, Nguyen, T.¹, Olson, M.¹, Purcell, D.¹, Speed, T.², Rao, S.³, Turner, S.¹

¹The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Walter & Eliza Hall Institute, Melbourne, Australia, ³Canberra University, Canberra, Australia

The changes in phenotype and function that characterize the differentiation of naïve T cells to effector and memory states are underscored by large-scale, coordinated, and stable changes in transcription. In-turn, these changes are choreographed by the interplay between transcription factors (TFs) and epigenetic regulators that restructure the genome, ensuring lineage-appropriate gene expression. To better understand how differentiation state-specific transcriptional profiles arise and are maintained during lymphocyte differentiation, we have studied transcriptional enhancer (TE) usage within virus-specific naïve, effector and memory CD8⁺ T cells. TEs serve as binding sites for lineage specific TFs, and are thus key determinants of transcriptional regulation and cellular differentiation. Using ChIP-Seq to map TEs based on their chromatin state, we identified ~45,000 T cell TEs as putative regulators of virus-specific T cell differentiation; Strikingly, the majority of these are shared by naïve, effector and memory cells, implying that T cell differentiation is largely coordinated by differentiation state-specific TF binding, rather than *de novo* TE acquisition and loss. Indeed, combining RNA-seq data with genome-wide mapping of TFs, we show that many of the TEs that we have identified show an “active” chromatin signature within naïve T cells, and

prior to expression the TFs they bind. Finally, we identified a subset of TEs with a non-canonical enhancer chromatin signature that mark immune and other highly expressed genes. This unique class of TEs are strongly enriched for binding of key T cell TFs including BATF and IRF4 upon effector differentiation, suggesting they are critical determinants of T cell differentiation.

1309

Epigenetic control of Gata3 gene expression in T helper 2 cells via histone modification and DNA conformation

Tumes, D.^{1,2}, Onodera, A.², Papadopoulos, M.², Nakayama, T.²

¹South Australian Health and Medical Research Institute, Infection and Immunity Theme, Adelaide, Australia, ²Chiba University, Department of Immunology, Graduate School of Medicine, Chiba, Japan

Expression of the transcription factor Gata3 is both necessary and sufficient for differentiation of Type-2 cytokine-producing CD4⁺ T helper 2 (Th2) cells. IL-4 induces Gata3 expression by signalling through STAT6. We recently reported that loss of the polycomb repressive complex 2 protein Ezh2 results in increased sensitivity to IL-4-induced Th2 polarisation and spontaneous development of Type-2 inflammation *in vivo*, but how Ezh2 physically regulated Th2 cell differentiation remained unknown. This study aimed to determine if conformational changes to the Gata3 gene occur during Th2 differentiation and if Ezh2 regulates these changes. Using formaldehyde-assisted isolation of regulatory elements and next-generation sequencing (FAIRE-Seq), we found that IL-4-induced Th2 differentiation resulted in increased accessibility of a functional STAT6 binding site within the Gata3 gene. Interestingly, loss of Ezh2 function mimicked this effect, but in an IL-4-independent fashion, and this was accompanied by increased levels of the histone acetyltransferase CBP and accumulation of H3K27-acetylation. Using chromatin conformation capture (3C) we found that the Gata3 transcriptional start site (TSS) physically associated with this same STAT6 binding site within the nuclei of differentiated Th2 cells. We propose a new model of physical epigenetic regulation of Gata3 expression whereby Ezh2 regulates accessibility of the Gata3 gene to STAT6. STAT6 binding then results in a conformational change to the Gata3 gene that forms a transcriptional hub bringing the TSS into direct contact with the STAT6 binding site and initiating transcription. These findings will likely have implications for rational drug design for the treatment of Type-2 inflammatory diseases.

1310

Cathelicidin binds to transcriptional complexes in cancer cells

Pinheiro da Silva, F.¹, Munoz, M.², Martins de Lima, T.¹, Severino, P.³, Cerqueira César Machado, M.¹, Moraes Reis, E.⁴, Nakaya, H.², Irineu, V.¹

²University of Sao Paulo, Pharmacology, Sao Paulo, Brazil,

³Hospital Albert Einstein, Sao Paulo, Brazil, ⁴University of Sao Paulo, Chemistry, Sao Paulo, Brazil

Antimicrobial peptides (AMPs) are key molecules of innate immunity, but the cellular mechanisms regulated by these molecules and how these pathways are activated remain poorly understood by the scientific community. Our group was the first to describe that LL-37, an antimicrobial peptide, migrates to the nucleus during systemic bacterial infections and was the first to suggest that, under certain conditions, this peptide could act as a transcription factor. We therefore decided to investigate whether such translocation occurs in other complex diseases, such as autoimmune diseases and cancer. A ChIP DNA was processed into a standard Illumina ChIP-Seq library and sequenced to generate >>2 million reads. Reads were aligned to the human genome (hg19), and after removal of duplicate reads, 4.6 million alignments were obtained. A signal map showing fragment densities along the genome was generated and visualized in the Integrated Genome Browser (IGB). The results show that the Cathelicidin ChIP-Seq data show a small number of strong to very strong peaks, fewer than in the positive data set shown, but clearly many more than in the negative Input data in the middle track. To further examine the specificity of these peaks, we analyzed their location in more detail and found that 85% of the 421 peaks are located in promoter regions, and the peak sequences are enriched in the binding sites for transcription factors NFYA and SP1. Thus, we conclude that Cathelicidin may participate in transcriptional complexes.

1311

Tumor suppressor WW domain-containing oxidoreductase regulates hematopoiesis

Lo, J.-Y.¹, Hsu, L.-J.^{2,3,4}

¹National Cheng Kung University, Basic Medical Sciences, Tainan, Taiwan, Republic of China, ²National Cheng Kung University Medical College, Medical Laboratory Science and Biotechnology, Tainan, Taiwan, Republic of China, ³National Cheng Kung University Medical College, Center of Infectious Disease and Signaling Research, Tainan, Taiwan, Republic of China, ⁴National Cheng Kung University Medical College, Research Center for Medical Laboratory Biotechnology, Tainan, Taiwan, Republic of China

Human *WWOX* gene resides in the common fragile site FRA16D on chromosome 16q23.3-24.1, and encodes a candidate tumor suppressor WW domain-containing oxidoreductase (designated *WWOX*, *FOR* or *WOX1*). Previous studies have suggested that *WOX1* mediates cell apoptosis upon stress responses. Downregulation of *WOX1* protein expression has been found in many types of human cancers. Strikingly, using our generated *Wwox* knockout murine models, significantly reduced hematopoietic cell numbers were determined in the periphery of *Wwox*^{-/-} mice as compared with wild-type and heterozygous littermates. A pronounced defect in multilineage hematopoiesis was observed in *Wwox*^{-/-} bone marrow. We determined that *WOX1* deficiency caused significantly reduced cell proliferation of both myeloid and lymphoid lineage precursors. We demonstrated that, compared with wild-type controls, *Wwox*^{-/-} lineage-negative bone marrow cells failed to differentiate into mature myeloid cells or lymphocytes *in vitro*

using soft agar colony formation assay or stromal coculture systems, respectively. Adoptive transfer experiments revealed similar results *in vivo*. These data indicate an intrinsic defect in *Wwox*^{-/-} progenitor cells during hematopoiesis. Interestingly, we determined significantly reduced expression of transcription factor FoxO1 in *Wwox*^{-/-} hematopoietic progenitor cells, suggesting that WOX1 may regulate hematopoiesis via controlling FoxO1 expression. Together, our findings unravel a novel function of tumor suppressor WOX1 as a crucial regulator of transcription factor FoxO1 in hematopoiesis.

1312

T-bet mediates rapid CD8+ T cell programming via interaction with regulatory genetic elements

Prier, J., Olshansky, M., Turner, S.

Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia

T-bet (encoded by *Tbx21*) is a transcription factor whose expression is essential for terminal CD8+ T cell effector function. While it has long been appreciated that T-bet expression is required for effective CD8+

T cell responses to infection, little is known about the timing and precise mechanism of action.

Using an Influenza A virus (IAV) infection model in mice, we demonstrate that while *Tbx21* deficient CD8+ T cells are able to undergo early events associated with T cell activation, including several rounds of cellular division, there is a failure to sustain CD8+ T cell lineage specific cytokine expression. This is further supported with whole transcriptome analysis at this early time point demonstrating that *Tbx21* deficient CD8+ T cells exhibit global dysregulation in early programming events. Importantly, the *Ifng* locus within *Tbx21* deficient IAV-specific CD8+T cells, exhibited a transcriptionally inactive chromatin signature compared to WT cells. Importantly, this chromatin signature correlated with an inability of *Tbx21*-deficient CD8+ T cells to activate "poised" *Ifng* enhancer elements, a step required for transcriptional activation of the *Ifng* locus.

In all, we propose a model whereby TCR stimulation of CD8+ T cells induces rapid induction of T-bet. This ultimately leads to correct CD8+ T cell programming and differentiation via T-bet binding to specific regulatory elements that then promote chromatin remodeling and transcriptional activation of key gene loci.

1313

Studying signal transduction pathways using multi-spectral imaging flow cytometry

Friend, S., Vaidyanathan, S., Kong, R., Pugsley, H., Morrissey, P.

Amnis - part of Merck, Seattle, United States

Signals from extracellular stimuli on the cell surface cascade along intracellular pathways to the nucleus to regulate genes that are critical for orchestrating the immune system. Immune responses against pathogens, self, tolerance and the normal development of immune cells all rely on signal transduction pathways. The translocation of NFκB into the nucleus is one

of the key steps in the activation of monocytes through LPS receptor engagement; translocation of NFAT is important for T cell activation and subsequent activation of the IL2 gene. Traditional methods to study the messengers that move from the cytoplasm into the nucleus include western blot analysis or staining for phosphorylated versions of proteins for flow cytometry as well as visual evaluation of location using microscopy. However, western blot does not provide a per-cell measurement, the phosphoprotein staining for flow cytometry analysis does not provide sub-cellular, localization and microscopy is low throughput. Multispectral imaging flow cytometry overcomes these obstacles by providing multiple spatially registered fluorescent images of every cell in flow, and unlike microscopy, is high throughput and not subject to operator interpretation. Simultaneous staining of cell surface markers along with intracellular staining of transcription factors and DNA allow the direct measurement of the transcription factor location in specifically identified cell subsets at the single cell level, but in numbers that are statistically robust. Data will be presented using the multi-spectral imaging flow cytometer to measure the translocation of NFκB, MAP Kinase, Stat 3 and NFAT in cell lines and subsets of peripheral blood mononuclear cells.

1314

Validating the contribution of microRNAs and lncRNAs to the molecular signature and plasticity of iTreg vs. nTreg in humans

Malatesta, K.¹, Sadlon, T.², Pederson, S.¹, Brown, C.¹, Barry, S.C.^{1,2}

¹Molecular Immunology, Robinson Research Institute, Adelaide, Australia, ²Women's and Children's Health Network, Gastroenterology, Adelaide, Australia

Regulatory T cells (Treg) play a key role in tolerance and immune homeostasis. Recent research has revealed that Treg generation, function and stability rely on gene networks regulated by FOXP3 and microRNAs. It has been suggested that these gene networks facilitate functional plasticity within T cell subsets, including peripheral Tregs (pTreg) and Tconv cells. Mouse models indicate that pTregs have an important physiological role in the gut and contribute to mucosal immunity, however a lack of discriminatory biomarkers hinders pTreg research in the human. FOXP3⁺ Tregs (iTregs) can be generated *in vitro* from CD25⁺ Tconv and are proposed to be closely related to pTreg in mouse. In order to discover the molecular basis for the induction of FOXP3 and the functional plasticity in the human, we have profiled microRNA expression in donor matched human tTreg, Tconv and iTregs and found that iTregs express a unique microRNA signature comprising both Treg and Tconv specific miRs. In contrast with nTreg, we find that microRNA-31 is elevated in iTreg compared with nTreg, and this inversely correlates with levels of FOXP3. Our FOXP3 ChIP data and bioinformatics suggest that miR31 is a putative target of FOXP3 and FOXP3 is a putative target of miR31. This may provide the rheostat for regulating plasticity in Treg subsets.

1315**FOXP3 tightly controls target gene expression using microRNAs in human regulatory T cells, and regulates Treg plasticity**

Brown, C.¹, Beyer, M.², Pederson, S.¹, Goodall, G.³, Schultze, J.², Sadlon, T.⁴, Barry, S.C.^{1,5}

¹Molecular Immunology, Robinson Research Institute, Adelaide, Australia, ²LIMES, University of Bonn, Bonn, Germany, ³Centre for Cancer Biology, University of South Australia and SA Pathology, Gene Regulation, Adelaide, Australia, ⁴Women's and Children's health Network, Gastroenterology, Adelaide, Australia, ⁵Women's and Children's Health Network, Gastroenterology, Adelaide, Australia

FOXP3 is essential for the formation and function of regulatory T cells (Tregs) as demonstrated by autoimmune disease in the scurfy mouse and in IPEX patients. However, little is known about the molecular basis of human FOXP3 function or the relationship between direct and indirect target genes in human Treg. A genome wide analysis for human FOXP3 target genes in natural regulatory cells using chromatin immunoprecipitation (ChIP) combined with gene expression profiling and micro RNA profiling identified 63 micro RNAs that are potential human FOXP3 target genes. A subset of these are up regulated in Treg compared with CD25- T-helper cells, and when we used shRNAi to ablate FOXP3, expression levels were also reduced for a subset of these miRs, suggesting regulation by FOXP3. We next identified putative miR target genes in our down regulated human Treg gene signature, and analysed their expression in FOXP3 ablated Treg. This identified a number of genes that are direct targets of the miRs that are dependent on FOXP3, and suggest that these target genes may be tightly regulated as part of the human Treg gene network. These targets include the chromatin remodelling gene SATB1, and this gene is tightly repressed to maintain Treg function (Beyer *et al* Nat Immunol 2011). We are now investigating the repression of ZEB2 by FOXP3 and miR 155 in human Treg as part of a transcription factor network. These results confirm the importance of miRs in human Treg and provide new insights into the mechanism of action of FOXP3.

1316**Methylation status and clinical significance of Bin1 in esophageal squamous cell cancer**

Jia, Y., Liu, L.

Hebei Medical University, Shijiazhuang, China

Objective: To detect the expression and methylation status of Bin1 and analyze their association with clinical characteristics of esophageal squamous cell cancer (ESCC) patients.

Methods: The expression of Bin1 mRNA and its methylation status in ESCC tissues and corresponding para-carcinoma normal tissues were detected with real-time PCR and methylation specific PCR (MSP).

Results: The methylation frequency of Bin1 in ESCC tissues (58.62%, 34/58) was significantly higher than that in the corresponding para-cancerous normal tissues (25.86%, 15/58) ($P < 0.01$), and it was closely correlated with TNM stage,

tumor invasion depth, tumor differentiation and lymph node metastasis status. Compared with para-carcinoma tissue specimens, carcinoma tissue specimens had significantly lower Bin1 mRNA abundance ($2^{-\Delta\Delta CT} = 0.78 \pm 0.05$, $P < 0.01$). The expression of Bin1 in ESCC tissues with Bin1 methylation was significantly lower than that in ESCC tissues without methylated Bin1 gene (0.68 ± 0.04 vs 0.85 ± 0.07 , $P < 0.05$).

Conclusion: In ESCC tissue, the expression of Bin1 is negatively correlated at mRNA level and its methylation, and the DNA methylation of its promoter is one of the possible mechanisms that leads to low expression or deletion of Bin1 in ESCC. The DNA methylation of Bin1 is closely associated with tumor invasion and lymph node metastasis of ESCC.

Vaccines

1317

Evaluation of DNA vaccines based on the BAB1_0267 and BAB1_0270 open reading frame of pathogenic *Brucella abortus* 2308 strain in a mice model

Oñate, A., Gómez, L., Alvarez, F.

Universidad de Concepción, Department of Microbiology, Laboratory of Molecular Immunology, Concepción, Chile

Brucella abortus is the etiological agent of brucellosis, a zoonosis affecting bovines and humans. This bacterium is a facultative intracellular pathogen capable to evade the immune response because it expresses several virulence factors. Some of these factors are codified in open reading frames (ORFs) present in the genomic island 3 (GI3). It was previously demonstrated that BAB1_0267 and BAB1_0270 ORFs of *B. abortus* 2308, located at GI3, play important roles in the intracellular survival and replication of this pathogen. Based on these reports, we used both ORFs to construct DNA vaccines, named pV267 and pV270, and to evaluate their immunogenicity in mice. Results showed that the immunization with pV267 significantly increased the production of IgM, IgG and IgG1 immunoglobulins, IFN- γ and the lymphoproliferative response of splenocytes. On the other hand, the pV270 DNA vaccine significantly increased the IgM, IgG and IgG2a immunoglobulins, IFN- γ , TNF α and IL-6, and the lymphoproliferative response of splenocytes. These results indicated that both vaccines increased the level of IFN- γ , a pivotal cytokine in the Th1 immune response, effective against intracellular pathogens. Nevertheless, although the immunization with either of these vaccines induced an immune response, none of them was able to confer significant protection against 10⁶ CFU of the pathogenic *B. abortus* 2308 strain, a higher dose than the described in the literature. Therefore, although pV267 and pV270 induced an immune response against the product codified by either of these ORFs, under the conditions of protection assayed, is insufficient to confer a significant protection against *B. abortus*.

1318

The specific antibody production against HER2 peptide CH401MAP in NOG-IL4-Tg mice

Miyamoto, A.¹, Katano, I.², Kikuchi, Y.¹, Tsuda, B.³, Tokuda, Y.³, Ito, M.², Habu, S.⁴, Kametani, Y.¹

¹Tokai University School of Medicine, Department of Immunology, Isehara, Japan, ²Central Institute for Experimental Animals, Kawasaki, Japan, ³Tokai University School of Medicine, Department of Breast and Endocrine Surgery, Isehara, Japan, ⁴Juntendo University School of Medicine, Department of Immunology, Tokyo, Japan

Background: We previously reported that a 20mer HER2 peptide CH401MAP induced specific IgG in immunized BALB/c mice. This peptide is predicted to bind to more than 90% of class- I HLA and 30-50% of class- II HLA of Japanese breast cancer patients.

Objective: To detect the specific antibody production against HER2 CH401MAP in humanized NOG-IL4-Tg mice.

Materials and methods: Human peripheral blood mononuclear cells (PBMCs) were transplanted into NOD/Shi-scid, IL-2gc-null(NOD/SCID/gc-null; NOG)-IL4-Tg mice (i.v.). These mice were predicted to have Th2 immuno-environment by constitutively producing human IL4 proteins. After stimulation with CH401MAP at Day 0 and Day 14, spleen cells and plasma were collected at Day 28. Human immune cells were analyzed by FACS analysis. Specific antibody was measured by ELISA.

Results: Almost all lymphocytes of transplanted mice had memory phenotype. B cell ratio was significantly increased and CD8+ T cell ratio was significantly decreased 28 days after the transplantation. CH401 MAP specific IgG level was increased in the immunized mouse plasma. Antibody productivity was not directly correlated with the binding affinity predicted by the algorithm (SYFPEITHI).

Conclusion: NOG-IL4-Tg mice maintained human Th cells and B cells for 4 weeks, and induced specific IgG production by CH401MAP immunization. This mouse system may become an effective tool for the screening of immune response of human immunity.

1319

Characterization of *L.tropica* secreted exosomes and development of exosome-based preventive vaccine against *L.tropica* induced cutaneous leishmaniasis

Gungor, B.¹, Ayanoglu, İ.C.¹, Tincer Konig, G.^{2,3}, Ozbel, Y.⁴, Ozbilgin, A.⁵, Girinkardesler, N.⁵, Ozensoy Toz, S.⁴, Gursel, I.², Gursel, M.¹

¹Middle East Technical University, Ankara, Turkey, ²Bilkent University, Ankara, Turkey, ³CRTD / DFG-Center for Regenerative Therapies, Dresden, Germany, ⁴Ege University, Izmir, Turkey, ⁵Celal Bayar University, Manisa, Turkey

Leishmaniasis is an infectious disease caused by *Leishmania* protozoa transmitted to mammalian hosts by infected sand flies. The World Health Organization considers leishmaniasis to be the second most serious tropical parasitic diseases after malaria. The absence of a good protective vaccine against leishmaniasis limits prevention options and enforces the use of highly toxic pentavalent antimonials for treatment. Herein, we aimed to develop a prototype preventive vaccine against *L.tropica* cutaneous infection in mice. For vaccine development, first purified, *Leishmania* antigen-rich small vesicles (exosomes) secreted from *L.tropica* amastigotes. Following their physical and biochemical characterization, the exosomes were combined with several different vaccine adjuvants or their combinations, including, cyclic-di-GMP, different classes of CpG ODNs, CpG nanorings and their immunoprotective activity were tested in a mouse model of cutaneous leishmaniasis. To monitor disease progression, lesion sizes were monitored for 10 months and parasite burdens in each group was predicted by real time PCR. *Leishmania* soluble antigen-specific serum IgG1 and IgG2a antibody titers were assessed by ELISA and Th1/Th2/Th17 cytokine profiles was analyzed by cytometric bead array shortly after initiation of infection. Our results show that Th1 type vaccine adjuvanted exosomes (particularly the combination of CpG ODN and cyclic-di-GMP) suppressed parasite burden, increased serum anti leishmania IgG2a antibody titers and enhanced the protective ability of the exosomes. In conclusion,

the exosome based vaccine approach tested herein plus the proposed adjuvants constitute a novel approach in design of vaccines against neglected parasitic diseases.

1320

Dendritic cell-targeting DNA vaccines elicited distinct immune responses directs by intracellular antigen trafficking

Lee, B.K., Chen, Z.W.

University of Hong Kong, Aids Institute, Dept. of Microbiology, Hong Kong, Hong Kong

Understanding antigen processing in dendritic cells (DCs) can improve HIV vaccine immunogenicity. Targeting antigen to DCs has been explored as novel strategy of HIV vaccine design, while few studies have investigated the influence of intracellular antigen processing on vaccine immunogenicity when various DC surface receptors are engaged. Here, we conduct parallel experiments to determine the immunogenicity and possible underlying mechanism of DC-targeting HIV vaccines via the native ligands of PD-1 and CTLA-4, respectively.

A panel of DNA fusion vaccines was constructed including soluble PD-1 (sPD1)-p24, soluble CTLA-4 (sCTLA-4)-p24, deletion mutant sΔPD1-p24, sΔCTLA4-p24 and p24 alone. BALB/c mice were immunized with each of these DNA vaccines at 100µg dose via intramuscular *in vivo* electroporation following a prime/2-boost regimen with 3-week intervals. Post vaccination, immunogenicity profiles were analyzed using ELISA and ELISpot. Confocal microscopy was used to investigate antigen trafficking to MHC-I or -II compartments in DC based on several endosomal markers.

DC-targeting HIV vaccines were significantly more potent than corresponding deletion mutant controls. sPD1-p24 is superior to CTLA4-p24 with following distinct immune responses:

(1) enhanced IgG2a (Th1) antibody responses,
(2) greater p24-specific CD8⁺ T cell responses besides increase in CD4⁺ T cells by IFN-γ ELISpots. Mechanistically, both sPD1-p24 and sCTLA4-p24 routed antigen to Lamp-1 endosomes for MHC-II presentation, but only sPD1-p24 routed to Rab14 endosomes for MHC-I cross-presentation.

PD-1 and CTLA-4 lead to distinct immunogenicity outcomes in our DC-targeting vaccines. Our findings provide evidence that the intracellular antigen processing in DC influences vaccine immunogenicity when different DC surface receptors are engaged.

Technologies (Commissariat à l'Energie Atomique), Laboratory of Immunochemistry of Cellular Immune Response, Gif-Sur-Yvette, France, ⁶Vaxeal Holding SA, Vevey, Switzerland

A central aim of novel cancer therapies is the induction of effective anti-tumor immunity in cancer patients leading to elimination of tumors and long-lasting protection against relapses. In this regard, modern therapeutic vaccination has been shown to elicit tumor antigen specific T-cell immunity but showed only modest clinical effects as several factors negatively impact their therapeutic effect in cancer patients. In this project, we developed an innovative therapeutic cancer vaccine enabling to overcome limitations to current vaccine approaches. The vaccine is composed of 3 long synthetic peptides (LSP) derived from the Survivin antigen, an ubiquitous protein over expressed and playing vital functions in large number of human tumors. The therapeutic efficacy of the formulated vaccine candidate was evaluated during tumor rejection assays performed in BALB/c mice engrafted with various syngeneic tumor models expressing the human Survivin. Results clearly demonstrated the high therapeutic efficacy of the Survivin vaccine against various established tumor models, such as colorectal carcinoma (CT26), renal adenocarcinoma (Renca) and B cell lymphoma (A20) models. This was associated with the induction of intense and long-lasting Survivin specific T-cell responses not impaired by the presence of the tumor cells. Tumor rejection assays performed in CD8 or CD4 depleted mice, demonstrated that both CD8⁺ and to a lesser extent CD4⁺ T cells are involved in the high efficacy of Survivin vaccine. Together, these results constitute a relevant proof-of-concept to bring this vaccine as a first-generation product in human trial.

1322

Intranasal delivery of Enterovirus 71 vaccine with Zymosan and Chitosan as adjuvants to enhance mucosal and systemic immune responses

Chin, C.-L.¹, Lin, Y.-L.², Cheng, P.-Y.², Lin, S.-Y.¹, Yuan, H.-P.², Chiang, B.-L.^{1,2}

¹National Taiwan University, Immunology, Taipei, Taiwan, Republic of China, ²National Taiwan University Hospital, Medical Research, Taipei, Taiwan, Republic of China

To prevent or constrain viral infection at the site of entry, mucosal vaccine is a potent tool to induce IgA secretion for defense. Since innate receptor ligands could serve as strong adjuvants, two ligands as cell wall components of microbes are of our interests. Zymosan, a glucan in the cell wall of yeast, interacts with Toll-like receptor 2/6 heterodimer and C-type lectin receptor dectin-1 to induce inflammatory signaling pathways. Chitosan, a deacetylated chitin, takes charge of activating NOD-like receptor family, pyrin domain containing 3 (NLRP3) inflammasome. Thus, we aimed to study the potential immuno-inducibility of zymosan and chitosan as adjuvants in enterovirus 71 (EV71) mucosal vaccine. Bone-marrow derived dendritic cells (BMDCs) were targeted for the *ex vivo* screening assay, cytokine production being analyzed by ELISA. Naïve BALB/c mice were intranasally immunized with zymosan and/or chitosan at five-, eight-, and eleven-week-old to investigate the

in vivo effects of the vaccine and adjuvants. The EV71-specific IgA in nasal wash and feces were assayed, and the proliferation level, cytokine production, and numbers of IgA secreting cells of EV71 stimulated splenocytes were measured. The results showed IL-12 and IL-1 β production were induced upon treatment of BMDCs with zymosan and chitosan respectively. Furthermore, not only the level of EV71-specific IgA from nasal wash, feces, and splenocytes, but the proliferative responses and the production of IL-17 in groups with either of the adjuvants were higher than those of EV71 alone. Our data revealed the high immune-inducibility of zymosan and chitosan as adjuvants in EV71 mucosal vaccine.

1323

A streptococcal multiple-epitope recombinant protein protects mice against group A streptococcal infection

Kuo, C.F.¹, Hsieh, I.C.², Tsao, N.²

¹I-SHOU University, Department of Nursing, Kaohsiung, Taiwan, Republic of China, ²I-SHOU University, Department of Biological Science and Technology, Kaohsiung, Taiwan, Republic of China

Group A streptococcus (GAS) is an important human pathogen. Virulence factors such as streptococcal pyrogenic exotoxin B (SPE B), streptolysin S (SLS), M proteins, and streptococcal fibronectin-binding proteins (Sfb1), were known to involve the GAS evasion from host immune defense. In our previous study, we found that the C-terminal residues 345~398 of SPE B is a major binding site for human IgG and complement C3. Immunization of BALB/c mice using this C-terminal domain peptides was able to protect mice from M49 strain GAS-induced death but not significantly protected mice against invasive M1 strain GAS infection. To achieve the comprehensive protection, we further constructed and expressed a multiple-epitope recombinant protein FSBM, which contained four different epitopes including of the conserve segment of M protein, the immunogenic domain of Sfb1, the N-terminal segment of SLS, and the C-terminal domain of SPE B. Immunization of BALB/c mice with FSBM induced high titers of antibodies against Sfb1, SLS, SPE B and different serotypes of M proteins. *In vitro* experiments also indicated the opsonization activity and phagocytic killing of group A streptococci were enhanced by anti-FSBM antisera. The immunization of FSBM efficiently protected mice against lethal infection with different M-types of group A streptococci, even the invasive M1 strain GAS. These findings suggest that the recombinant antigen FSBM could be applied as a vaccine to protect group A streptococcal infection.

1324

Improving delivery system for malaria vaccines

Krastev, C., Walters, A., Milicic, A., Hill, A.

University of Oxford, Jenner Institute, Oxford, United Kingdom

Most commercial vaccines are administered in multiple doses with prime-boost intervals ranging from one to several months or years.

We aim to develop a novel vaccine delivery platform for single-injection prime-boost immunisation regime that would be

applicable to current and future vaccines requiring a prime-boost approach. By producing biodegradable polymeric microparticles into which the boost vaccine is incorporated and then released in a delayed time fashion, we could reduce the number of injected doses from multiple into a single immunisation where both un-encapsulated and encapsulated vaccine are administered simultaneously. To demonstrate this, we are using our leading malaria candidate vaccine with a heterologous prime-boost regime: chimpanzee adenoviral vector encoding the *Plasmodium falciparum* pre-erythrocytic thrombospondin related adhesion protein (ME-TRAP) followed by a boost using modified vaccinia Ankara (MVA) ME-TRAP virus. If successful, this technology would greatly improve immunisation coverage benefitting public health systems worldwide.

1325

Should we boost or supplement the *M. bovis* BCG antigen repertoire?

Aagaard, C., Thomsen, I., Kristiansen, E., Agger, E.M., Andersen, P.
Statens Serum Institut, Department of Infectious Immunology, Copenhagen, Denmark

Although the current vaccine for human use (*Mycobacterium bovis* (*M. bovis*) BCG) is effective in protecting infants against childhood forms of the disease, a more effective and longer lasting vaccine is needed for protection of adolescents and adults against pulmonary tuberculosis (TB).

The *M. tuberculosis* (*M.tb*) and *M. bovis* genomes are >99,95 % identical and share a large number of proteins and potential vaccine antigens. The majority of proteins expressed by *M. tuberculosis* are also correctly expressed by *M. bovis*. However, all *M bovis* BCG strains used for immunization are attenuated substrains of *M. bovis*. During the attenuation process *M bovis* BCG lost >100 genes, including genes encoding virulence factors and proteins involved in secretion through a type VII secretion system termed ESX-1. Because of the gene loss, a number of proteins are not expressed or secreted correctly by *M bovis* BCG and therefore dysfunctional. The ESX-1 secretion system secretes important virulence factors including well-known T cell antigens used for diagnosis of tuberculosis (ESAT-6, CFP10 and Rv3615).

In addition to ESX-1, *M.tb* has four additional type VII secretion systems (ESX-2 - ESX-5). The genes encoding these systems are present in *M. bovis* BCG and these secretion systems are therefore functional and secrete well-known antigens (TB10.4, Rv3619, Rv3620, and PPE42).

The functional difference between secretion systems that secretes highly expressed and protective antigens allows us to investigate if it is preferable to supplement *M. bovis* BCG with antigens or boost and modifying an *M. bovis* induced immune response.

1326**Tumor cell lysates as maturation stimulus and antigen source for therapeutic dendritic cells against gallbladder cancer**

Rojas-Sepúlveda, D.^{1,2}, Gleisner, M.A.^{1,2}, Pereda, C.^{1,2}, López, M.^{1,2}, Salazar-Onfray, F.^{1,2}

¹Universidad de Chile, Institute of Biomedical Sciences, Santiago, Chile, ²Millennium Institute on Immunology and Immunotherapy, Santiago, Chile

Introduction: Gallbladder cancer is a leading cause of death in women over 65 years in Chile and five-year survival rate is less than 10%. We have been able to produce therapeutic dendritic cells (DC) using a heat-shocked melanoma cell lysate named TRIMEL. Sixty percent of patients treated with these DCs showed a delayed type hypersensitivity reaction against TRIMEL that correlated with a three-fold prolonged patient survival. Here, we investigated the effect of tumor lysates derived from gallbladder cancer cell (GCC) lines on immature DCs.

Material and methods: DCs were stimulated with different individual (8) or mixed lysates (8) from GCC lines and analyzed by flow cytometry for MHC-I, MHC-II, CD80, CD83, CD86, CCR7, CD1d. DCs supernatants were analyzed by flow cytometry for IL-1 β , IL-8, IL-10, IL-12p70, TNF- α . Finally, allogeneic CD3+ T cells were co-cultured with DCs and analyzed by flow cytometry for CD4, CD8, and cytokine release.

Results: All GCC lysates induced DCs maturation, increasing expression of MHC-I and II, CD80, CD83, CD86, CCR7, CD1d and the release of IL-1 β , IL-10 and IL-12p70. GCC lysate mix number 2 and 5 achieved the highest maturation of DCs indicating that diverse maturation factors may be present in different cell lines. CD3+ T cells co-cultured with DCs increased the percentage of CD4+ IFN γ + and CD8+ IFN γ + T cells.

Discussion: Based on these results, GCC lysates induces DCs maturation and activation capacity and may be considered in future new treatments.

1327**Self-adjuvanting glycolipopeptide cancer vaccines**

McDonald, D.M.^{1,2}, Corcilus, L.², Byrne, S.N.¹, Payne, R.J.²

¹The University of Sydney, Infectious Diseases and Immunology, Sydney, Australia, ²The University of Sydney, School of Chemistry, Sydney, Australia

Mucin 1 (MUC1) is a transmembrane glycoprotein that is highly overexpressed in a range of epithelial tumours. During cancer development, aberrant expression of glycosyltransferases leads to expression of tumour-associated carbohydrate antigens (TACAs), which are absent from healthy cells. For this reason, MUC1 has been ranked 2nd/75 of the most promising cancer antigens.

We have designed and synthesised novel cancer vaccine candidates comprising lipopeptide adjuvants covalently attached to MUC1 glycopeptides. These vaccines were

constructed in an iterative manner, conjugating MUC1 peptides glycosylated with different TACAs to lipopeptide adjuvants to generate the fully synthetic, self-adjuvanting vaccines. When injected into C57/BL6 mice, these vaccines induced high titres of class-switched, MUC1-specific antibodies. Surprisingly, we could detect no *in vivo* CTL response to MUC1-expressing targets nor could we detect any IFN γ or IL-4-producing CD4+ T cells. These vaccine candidates induced robust humoral immune responses despite the lack of observed CD8+ and CD4+ T cell responses.

In order to increase T cell recognition of the MUC1 vaccines, we considered the effect of the position and identity of MUC1 glycosylation. Subsequently, we synthesised a series of vaccines bearing a range of TACAs at just two sites within the MUC1 VNTR sequence, which generated MUC1-specific antibodies as well as giving rise to MUC1-specific *in vivo* cytotoxicity. The investigation of these vaccines in tumour-bearing mice will be discussed.

This work demonstrates that targeting tumour-associated changes in post-translational protein modification with self-adjuvanting vaccines is a viable route towards cancer vaccination, giving rise to potent humoral and cell-mediated immune responses.

1328**Pneumococcal *pep27* mutant immunization stimulates cytokine secretion and confers long-term immunity with a wide range of protection, including against non-typeable strains**

Kim, G.-L., Seon, S.-H., Rhee, D.-K.

Sungkyunkwan University, Pharmacy, Su-Won, Korea, Republic of

Streptococcus pneumoniae is comprised of more than 90 serotypes and is the major causative agent of pneumonia, which results in over 1 million deaths worldwide every year. However, currently available injectable vaccines can protect against only 13-23 serotypes, and none of them protect against initial colonization in the nasopharynx. Thus, development of a vaccine conveying broader protection at the colonization stage is required. This study examined whether the $\Delta pep27$ mutant could provide protection at the nasopharynx against a broad range of serotypes. $\Delta pep27$ immunization stimulated secretion of IL-4, IL-10, TNF- α , and INF- γ in the lung, and significantly increased secretory-IgA levels in bronchoalveolar lavage fluid. Colonization and opsonophagocytosis assays demonstrated that $\Delta pep27$ immunization could protect against many heterologous infections, including non-typeable strains, at the nasopharynx, and prompted efficient killing of heterologous strains, suggesting that $\Delta pep27$ immunization provides a wide range of cross-protection. Furthermore, $\Delta pep27$ immunization significantly increased both the survival rate and the level of IgG 3 months post-immunization, demonstrating long-lasting immunity. Thus, $\Delta pep27$ could serve as a highly feasible mucosal vaccine once it is further developed into a non-transformable strain.

1329**Investigation of specific immunological memory in prostate cancer patients vaccinated with the li-key modified HER-2/neu peptide AE37**

Anastasopoulou, E., Voutsas, I., Baxevanis, C., Perez, S. St Savas Cancer Hospital, Cancer Immunology and Immunotherapy Center, Athens, Greece

Introduction: Cancer vaccines seem to be a promising therapeutic approach in cancer, aiming at prevention of recurrence through the generation of immunological memory. Therefore, investigating specific-antitumor responses along with immunological memory is essential in the context of vaccine evaluation. We have previously reported that prostate cancer patients, vaccinated the modified li-key hybrid of the HER-2/neu (HER2) native peptide AE36 (HER2(776-790)), developed specific immune responses that could be detected even 3 years after the last inoculation. Here, we aim to investigate the potential of AE37 vaccine to induce long-lasting antigen-specific T cells. **Materials and methods:** Using a MHC class II tetramer (AE37/DR11), we assessed DRB1*11/AE37(LRMKGVGSPYVSRLLGICL) specific CD4+ T-cells in peptide-stimulated cultures of pre- and post-vaccination PBMCs samples of DRB1*11+ prostate cancer patients. Phenotypic characterization of antigen-specific CD4+ T-cells was performed with multicolor flow-cytometry. In order to ascertain the *in vivo* generation of antigen-specific memory, we assessed antigen specificity in sorted memory cell subsets, using Fluorescent-Activated Cell Sorting.

Results: AE37 vaccine induced HER2-specific memory CD4+ T-cells in all analyzed prostate cancer patients. Most CD4+ T-cells acquired an effector memory phenotype (CD45RA-CCR7-CD28+) upon *in vitro* AE37 stimulation. HER2 specific T-cells could be detected in all sorted memory subsets. Interestingly, stem cell memory T cells (Tscm) were generated *in vitro* in sorted naïve CD4+ T-cells, indicating the potential of AE37 vaccine to induce Tscm, a finding that merits further investigation.

Conclusions: Our data clearly demonstrate that the AE37 vaccine can induce long-lasting HER2 specific CD4+ T-cells, possibly including Tscm, in AE37-vaccinated prostate cancer patients.

1330**Evaluation of the adjuvant effect of gold nanocages *in vitro***

Hepatitis B is a potentially life-threatening disease caused by the hepatitis B virus (HBV). Unfortunately, despite the ongoing vaccine campaigns HBV infection is not completely managed. In order to increase the immune modulation capacities of Hepatitis B vaccines different adjuvant systems have been studied. Especially nanoparticle-based adjuvants are being widely investigated. Biocompatible and bioinert gold

nanoparticles have been commonly used *in vitro* and *in vivo* biological research. Recently, gold nanocages (AuNCs), a special design with ultra thin porous walls and hollow interiors, have shown ample potential and have a promising future in the fields of cancer diagnostics and treatment. Our goal is to use AuNCs as an adjuvant in Hepatitis B model *in vitro*.

In this project, synthesized and characterized Au nanocages are used. Following the adsorption of HBsAg protein onto Au nanocages, adsorption efficiency of AuNCs is investigated. The uptake of HBsAg-AuNC by macrophages and its colocalization within the cell are analyzed by flow cytometry and confocal microscopy. The *in vitro* effect of the internalization of only AuNCs or HBsAg-AuNC on macrophage activation, antigen presentation and the cytokine profile are analyzed by flow cytometry and ELISA techniques. Here we aim to study the immunomodulation properties of the porous gold nanoparticles as an adjuvant *in vitro*.

1331**Successive intramuscular boosting with IFN-alpha protects *Mycobacterium bovis* BCG- vaccinated mice against *M. lepraemurium* infection**

Guerrero M, G.G.¹, Rangel-Moreno, J.², Islas-Trujillo, S.³, Rojas-Espinosa, O.³

¹Universidad Autonoma de Zacatecas, Unidad Academica de Ciencias Biologicas, Zacatecas, Mexico, ²University of Rochester Medical Center, Department of Medicine, Division of Allergy, Immunology and Rheumatology, Rochester, United States, ³Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Immunology, Distrito Federal, Mexico

Leprosy caused by *Mycobacterium leprae*, primarily affects the skin and peripheral nerves. As a human infectious disease, is still a significant health and economic burden on developing countries. Although multidrug therapy is reducing the number of active cases to approximately 0.5 million, the number of cases per year is not declining. Therefore, alternative host-directed strategies should be addressed to improve treatment efficacy and outcome. In this work, using murine leprosy as a model, -a very similar granulomatous skin lesion to human leprosy-, we have found that successive IFN-alpha boosting protects BCG-vaccinated mice against *M. lepraemurium* infection. Not difference in the seric isotype and all IgG subclasses measured, neither in the Th1 or Th2 type cytokine production was seen. However, an enhanced iNOS/NO production in BCG-vaccinated/ *i.m.* IFN-alpha boosted mice was observed. The data provided in this study suggest a promising use for IFN-alpha boosting as a new prophylactic alternative to be explored in human leprosy by targeting host innate cell response.

1332**Vaccination enhances the ability of ovine macrophage to kill *Mycobacterium avium* subspecies *paratuberculosis* in vitro**

Pooley, H., de Silva, K., Purdie, A., Begg, D., Whittington, R., Plain, K.
The University of Sydney, School of Life and Environmental Sciences, Faculty of Veterinary Science, Camden, Australia

This work examines whether clinical outcomes in ruminant vaccine trials can be correlated with the *in vitro* ability of peripheral blood mononuclear cells (PBMCs) to kill bacteria. *In vitro* killing ability was examined with adherent monocytes infected with *Mycobacterium avium* subspecies *paratuberculosis* (MAP) and co-cultured with autologous lymphocytes. The viability of intracellular MAP was determined with a novel method using the relationship between the rate of MAP growth and the concentration of live MAP at the start of culture. A pilot study was carried out on cells from Gudair® vaccinated MAP exposed diseased (histopathological lesions with a score of Perez type 3) and non-diseased (no histopathological lesions) sheep as well as vaccinated and non-vaccinated unexposed control sheep. The MAP exposed sheep were orally exposed to MAP 12 months prior to the collection of cells for the *in vitro* assay. Two sheep were used for each vaccinated treatment group and four in the non-vaccinated controls. Variations in the killing ability of PBMCs from non-vaccinated control animals were found. In contrast, vaccination decreased variability between animals and increased *in vitro* killing of MAP. However we were unable to differentiate between diseased and non-diseased vaccinates, so further testing of a larger number of animals is planned. In conclusion the assay has proven to be a useful tool for examining the host response to vaccination. Use of the assay to test earlier infection time points would improve our understanding of the effects of vaccination on the ability of PBMCs to kill MAP.

1333**Impact of early life exposure to ionizing radiation on influenza vaccine response in an elderly Japanese cohort**

Lynch, H.¹, Hayashi, T.², Geyer, S.³, Yoshida, K.², Furudoi, K.², Sasaki, K.², Morishita, Y.², Nagamura, H.², Maki, M.², Hu, Y.², Hayashi, I.⁴, Kyoizumi, S.², Kusunoki, Y.², Ohishi, W.⁵, Fujiwara, S.⁶, Shterev, I.¹, Nikolich-Zugich, J.⁷, Murasko, D.⁸, Sempowski, G.¹, Nakachi, K.²

¹Duke University, Duke Human Vaccine Institute, Durham, United States, ²Radiation Effects Research Foundation, Department of Radiobiology/Molecular Epidemiology, Hiroshima, Japan, ³University of South Florida, Department of Pediatrics Health Informatics Institute, Tampa, United States, ⁴Hiroshima University Faculty of Dentistry, Central Research Laboratory, Hiroshima, Japan, ⁵Radiation Effects Research Foundation, Department of Clinical Studies, Hiroshima, Japan, ⁶Hiroshima Atomic Bomb Casualty Council, Hiroshima, Japan, ⁷University of Arizona College of Medicine, Department of Immunobiology and the Arizona Center on Aging, Tucson, United States, ⁸Drexel University, Department of Biology, College of Arts and Sciences, Philadelphia, United States

Negative effects of age and acute radiation exposure on vaccine response are well characterized, but compounding late radiation

effects and increased age have not been investigated. The Adult Health Study (AHS; Hiroshima, Japan) consists of a unique study population of atomic bomb survivors who are all aged 65 years or more. The hypothesis that early radiation exposure exacerbates age-associated decreased immune response to influenza vaccination was tested in 292 AHS subjects over two influenza vaccination seasons. Humoral response to each of three vaccine antigens and immune cell function were assessed using hemagglutination inhibition antibody titers and *in vitro* stimulated PBMC cytokine production, respectively. Impact of sex, age, and exposure dose on antigen-specific humoral response were evaluated. Although complete vaccine failure was more likely in females than in males, sex was not found to have a consistent and significant impact on strain-specific flu vaccine response in the elderly population. Advanced age did not have a consistent nor significant impact on strain-specific response in this unique elderly population. Interestingly, subjects exposed to 1 Gy or higher dose were more likely to seroconvert to two antigens than lower dose exposure, but the effect was not consistent in both study years. No cytokine profiles were consistently associated with sex, age, or dose effects on response to all three antigens, although some cytokines were associated with response to individual antigens. Data from this unique study suggest overall constitutional and immunological "robustness" of individuals who survived more than 65 years following high-dose radiation exposure.

1334**A novel mucosal vaccine targeting Peyer's patch M cells induces protective antigen-specific IgA responses**

¹Showa Pharmaceutical University, Machida, Japan, ²RIKEN Center for Integrative Medical Sciences (IMS), Yokohama, Japan, ³Keio University, Tsuruoka, Japan, ⁴Aoyama Gakuen University, Kanagawa, Japan

Mucosal vaccines can induce mucosal immunity, including antigen-specific secretory IgA production, to protect from invasion by pathogens and to neutralize toxins at mucosal surfaces. We established an effective antigen-delivering fusion protein, anti-GP2-SA, as a mucosal vaccine. The anti-GP2-SA consists of streptavidin (SA) fused to the antigen-binding fragment region from a mono clonal antibody against glycoprotein 2 (GP2), an antigen-uptake receptor specifically expressed on M cells. Anti-GP2-SA targets antigen-sampling M cells in the follicle-associated epithelium covering Peyer's patches. Immunofluorescence showed that anti-GP2-SA specifically bound to M cells. Orally administered biotinylated ovalbumin peptide (bOVA) conjugated with anti-GP2-SA more efficiently induced OVA-specific fecal IgA secretion compared with bOVA alone or bOVA conjugated with SA. Furthermore, mice immunized by oral administration of the biotinylated *Salmonella enterica* serovar Typhimurium (S. Typhimurium) lysate conjugated with anti-GP2-SA were significantly better protected from subsequent infection by virulent S. Typhimurium than mice treated with the bacterial lysate alone or conjugated with SA. These results suggest

that anti-GP2-SA-based M-cell-targeting vaccines are a novel strategy for inducing efficient mucosal immunity.

1335

Immunological involvement of airway mucociliary function in the claudin-4-targeting pneumococcal nasal vaccine

Suzuki, H.¹, Nagatake, T.¹, Nasu, A.¹, Ikegami, K.², Setou, M.², Kiyono, H.³, Yagi, K.⁴, Kondoh, M.⁴, Kunisawa, J.^{1,3}

¹National Institute of Biomedical Innovation, Health and Nutrition, Laboratory of Vaccine Materials, Ibaraki, Japan, ²Hamamatsu University School of Medicine, Department of Cell Biology and Anatomy, Hamamatsu, Japan, ³Institute of Medical Sciences, University of Tokyo, Division of Mucosal Immunology, Department of Microbiology and Immunology/International Research and Development Center for Mucosal Vaccines, Minato-ku, Japan, ⁴Graduate School of Pharmaceutical Sciences, Osaka University, Laboratory of Bio-Functional Molecular Chemistry, Suita, Japan

Mucosal vaccine requires efficient vaccine delivery system to mucosal tissues including mucosa-associated lymphoid tissues. We previously reported that C-terminal fragment of *Clostridium perfringens* enterotoxin (C-CPE) targeted claudin-4 which is highly expressed on nasopharynx-associated lymphoid tissue (NALT) epithelium, and thus C-CPE is an effective as a nasal antigen delivery system for respiratory vaccine antigen. In this study, we aimed to elucidate the immunological role of airway ciliary function on C-CPE mediated vaccine antigen delivery using mice lacking tubulin tyrosine ligase-like family, member 1 (Ttll1). Ttll1 KO mice show the accumulation of mucus in nasal cavity due to the impaired airway ciliary motility. When Ttll1 KO mice were nasally immunized with C-CPE fused with pneumococcal surface protein A (PspA-C-CPE), insufficient binding of PspA-C-CPE to NALT epithelium was noted due to the mucus accumulation in the nasal cavity, although Ttll1 KO mice showed normal expression of claudin-4 on NALT epithelium. As a result, Ttll1 KO mice showed the decreased levels of nasal PspA-specific IgA responses against nasally immunized PspA-C-CPE. In those mice, the numbers of germinal center B cells and follicular helper T cells were decreased in the NALT, suggesting the impaired germinal center formation. These results collectively indicate that accumulation of nasal mucus caused by impaired airway mucociliary function is an impedimental factor in the claudin-4-targeting pneumococcal nasal vaccine.

1336

Development of a synthetic virus for enterovirus A71 vaccine candidate

Wang, J.-R.^{1,2,3}, Cheng, C.-K.¹, Huang, S.-W.²

¹National Cheng Kung University, Medical Laboratory Science and Biotechnology, Tainan, Taiwan, Republic of China, ²National Cheng Kung University, Center of Infectious Disease and Signaling Research, Tainan, Taiwan, Republic of China, ³National Health Research Institutes, National Institute of Infectious Diseases and Vaccinology, Tainan, Taiwan, Republic of China

Human enterovirus A71 (EV-A71) has become an emergent infectious disease worldwide most notably in Asia. EV-A71

infection occasionally causes neurological diseases with pulmonary edema, which is fatal for children. Based on phylogenetic analysis of VP1 protein coding sequences, most EV-A71 isolates are classified into genotypes A, B and C, while some isolates belong to the recently discovered genotypes D, E, and F. Synthetic viruses have been applied to produce vaccine seed viruses for influenza virus and others. To produce a synthetic virus of EV-A71, we used 4643-TW-98 (genotype C2) as the template (r4643), de novo synthesized the capsid protein genome of genotype C4 and introduced into the cDNA clone of r4643 to produce reverse genetics virus (r4643-C4VP). We then compared the viral properties of this r4643-C4VP with parental r4643 and native 4643 virus. The r4643-C4VP showed relatively smaller plaque morphology than native 4643, but the virus-induced cytopathic effect was similar to both r4643 and native 4643. Synthetic reverse genetics viruses and native virus showed no significant difference in growth rate in both RD and Vero cell lines. In addition, mouse anti-r4643 and anti-r4643-C4VP sera showed similar neutralizing antibody titers against both r4643-C4VP and r4643 viruses, suggesting that both viruses had similar antigenicity. Furthermore, both antisera had similar neutralization activity to different genotypes of EV-A71, including genotypes B2, B4, B5, C2, and C4. Collectively, these results prove that the synthetic virus could be applied to EV-A71 vaccine seed candidate which will contribute to next generation vaccine development.

SCV platform: a novel replication-incompetent vaccinia viral vaccine vector system

Hayball, J.¹, Liu, L.¹, Cooper, T.¹, Eldi, P.¹, Howley, P.²

¹University of South Australia, Pharmacy and Medical Sciences, Adelaide, Australia, ²Sementis Ltd, Melbourne, Australia

Vaccinia virus is known for its use as the vaccine for smallpox which led to the first human disease to be eradicated. Vaccinia is now one of the most promising live viral vector systems for antigen delivery. However, severe site reactions and the potential for life threatening complications significantly limit its usage. To address these limitations a novel vaccine delivery system based on Vaccinia virus has been engineered that maintains the best qualities of the parent vector. This system consists of a replication-defective Vaccinia virus (SCV) and a co-developed rescue cell line for virus production. To render SCV completely attenuated, an essential viral assembly gene was deleted. Virus production was rescued by genetically engineering CHO cells to express the essential genes. In vitro and in vivo mice studies demonstrated that the SCV vector was completely attenuated and has an increased safety profile compared to its parental Vaccinia. A single immunization (10^6 pfu) conferred long-lived protection against mousepox infection showing SCV retained the ability to evoke superior immune responses. Multiple foreign genes could be inserted and a model ovalbumin antigen, elicited antigen-specific cellular and humoral immune responses. In summary, SCV is a safe and effective vaccine platform capable of delivering a payload of antigens for multivalent vaccine development. The SCV vector system has the potential to be tailored to an array

of prophylactic or therapeutic vaccine applications requiring antigen-driven humoral and cell-mediated immune responses.

Poly(amino acid)/squalene nanocomplex (PA/S-NCs) as efficient vaccine adjuvants for immune activity enhancement

Lim, J.-W.¹, Kim, H.-O.¹, Na, W.², Yeom, M.², Yun, D.¹, Kim, J.¹, Park, G.¹, Chun, H.¹, Song, D.², Haam, S.¹

¹Yonsei University, Chemical and Biomolecular Engineering, Seoul, Korea, Republic of, ²Korea University College of Pharmacy, Department of Pharmacy, Sejong, Korea, Republic of

As the outbreak of infectious disease is getting more frequent and devastated year by year, the advent of more efficient anti-infectious disease vaccines is greatly expected. Therefore, the development of better vaccine adjuvant accompanied with vaccine to boosting immune response for enhancing immunogenicity has been greatly required. Herein, we address nanocomplex of amphiphilic grafted poly(amino acid) and hydrophobic squalene (PA/S-NC) as a strongly potent vaccine adjuvant against influenza virus. The results showed that these nanocomplex performed proper loading efficiency and stability. More importantly, intramuscular co-administration of PA/S-NCs and an H1N1 pandemic strain (CA04) produced antibodies and cytokines in a conditional mouse model. Furthermore, The PA/S-NC/CA04 immunization prevented disease symptoms and protected mouse model against lethal infection with H1N1 influenza virus. Consequently, our PA/S-NCs could be one of great potent vaccine adjuvant for enhancing vaccine-induced immune responses.

1339

A murine cytomegalovirus vaccine vector protects against murine gamma herpesvirus 68

Stevenson, P.G.^{1,2,3,4,5}, Yunis, J.⁶

¹School of Chemistry and Molecular Biosciences, University of Queensland, Viral Immunology Research Laboratory, St Lucia, Australia, ²Australian Infectious Diseases Research Centre, University of Queensland, Brisbane, Australia, ³Centre for Children's Health Research, South Brisbane, Australia, ⁴National Institutes of Health (NIH), Bethesda, United States, ⁵Australian Research Council, Canberra, Australia, ⁶School of Chemistry and Molecular Biosciences, University of Queensland, St Lucia, Australia

EBV, a human gamma herpesvirus, causes Burkitt's lymphoma and nasopharyngeal carcinoma in susceptible hosts. Currently, there are no effective vaccines. Vaccine design is hindered by species specificity. Murine gamma herpesvirus 68 (MHV-68) provides a model to develop new vaccines. Mice infected with MHV-68 develop B cell lymphoproliferation, which we aim to abolish using a CD4+

T cell-based vaccine. The rationale is that CD4+ T cells have proved essential for long-term virus control, and a lack of CD4+ T cells in humans is associated with a high frequency of EBV disease.

Cytomegaloviruses (CMV) are of interest as possible live-attenuated vector vaccines to elicit protection against

persistent viruses. BALB/c and C57BL/6 mice were vaccinated intraperitoneally with murine CMV (MCMV WT) or a recombinant expressing membrane bound ovalbumin (MCMV mOVA) from the viral genome as a model CD4+ T cell antigen in the BALB/c strain and a model CD8+ T cell antigen in the C57BL/6 strain. MCMV WT and MCMV mOVA vaccinated mice were challenged intranasally with recombinant MHV-68 expressing membrane bound ovalbumin (MHV-68 mOVA). MCMV mOVA vaccinated C57BL/6 mice were protected from lytic infection in the nose and lung compared to MCMV WT while in BALB/c mice, virus titers were reduced. MCMV mOVA vaccinated C57BL/6 mice had no detectable latent virus in the lymph nodes or spleens while in BALB/c mice, lymph node and spleen titers were comparable to MCMV WT.

Results show vaccine induced CD4+ T cells reduce lytic infection while CD8+ T cells control lytic and latent infection.

1340

Modified liposomes for the delivery of cancer vaccines to the cytosol of antigen presenting cells through the proton sponge effect

Lee, K., Gamble, A., Hook, S.

University of Otago, School of Pharmacy, Dunedin, New Zealand

Despite our advances in cancer therapies, chemotherapy remains the main mode of treatment. Chemotherapy results in adverse effects due to off-target activity of drugs, and efficacy remains poor in some types of tumours. To alleviate these issues, alternative methods of treatment such as immunotherapies, are being actively researched. One subset of immunotherapies include therapeutic cancer vaccines, which may be utilised to mobilise a cytotoxic T lymphocyte (CTL) response against cancerous cells. Unfortunately, the response rate remains poor, prompting the need for alternatives.

One hurdle to an effective vaccine is the process of cross presentation in antigen presenting cells. However, cross presentation is still poorly understood, and limited methods are available to improve cross presentation. Delivery of tumour antigen and adjuvants to the cytosol of antigen presenting cells would allow the antigen to be processed by the proteasome and presented on MHC-I as if it were an endogenous antigen. Polyethyleneamine (PEI) has been used successfully for transfection studies, as it has been used to deliver genetic material into the cytosol of cells. To achieve this, PEI uses the 'proton sponge effect' to release contents of endosomes into the cytosol.

Currently, we are exploring the possibility of delivering ovalbumin (a model protein) complexed with PEI to exploit the proton sponge effect. To aid this process, the complexes are encapsulated in liposomes to protect the protein and improve phagocytic uptake. Lastly, the liposomes are embedded with artificial cyclodextrin channels to allow the flow of ions across an otherwise impenetrable membrane.

1341**Targeting of hemagglutinin to MHCII increases antibody responses against highly pathogenic avian influenza (H7N1) in mice**

Andersen, K.¹, Zhou, F.², Cox, R.J.², Grødeland, G.¹, Bogen, B.¹

¹K.G. Jebsen Center for Influenza Vaccine Research, University of Oslo and Oslo University Hospital-Rikshospitalet, Department of Immunology, Oslo, Norway, ²K.G. Jebsen Centre for Influenza Vaccine Research, Influenza Centre, The Gade Institute, University of Bergen, Bergen, Norway

Targeting of influenza hemagglutinin (HA) to major histocompatibility complex class II (MHCII) molecules on antigen presenting cells (APCs) have previously been shown to raise quick and robust antibody responses against H1N1 influenza in mice (Grødeland et al., J. Imm., 2013.). Here, we have used the same strategy to develop a vaccine against H7N1 influenza, which is currently regarded as a potential pandemic strain. The vaccine was delivered as DNA, a format that allows rapid production and deployment in the event of a pandemic emergence.

HA from H7N1(A/chicken/Italy/13474/1999) was inserted into a homodimeric vaccine format, where hemagglutinin and MHCII-specific targeting units are bivalently displayed. A single DNA vaccination in mice demonstrated that MHCII-targeting significantly increased antibodies and T-cell responses against recombinant HA from the H7N1 virus. The antibodies showed neutralizing activity against heterotypic H7 strains of avian influenza.

MHCII-targeting is crucial for the enhanced immune responses observed after DNA immunization. In order to investigate the mechanism behind this effect, we have tracked naïve idiotype-specific B- and T-cells in vitro or in vivo after MHCII-targeted (or non-targeted) vaccine delivery. At low doses, MHCII-targeted vaccines rapidly activated proliferation of idiotype specific B- and T-cells, in contrast to non-targeted controls.

In conclusion, we have demonstrated that targeting of HA to MHCII molecules increases the induced immune responses against H7N1 influenza, and are continuing experiments to investigate the mechanism behind the associated formation of long-lived memory cells.

1342**Iron oxide nanoparticles as vaccine carriers and immune responses against covalently bound protein**

Powles, L.¹, Wilson, K.², Xiang, S.D.², Selomulya, C.¹, Plebanski, M.²

¹Monash University, Department of Chemical Engineering, Clayton, Australia, ²Monash University, Department of Immunology, Melbourne, Australia

It has been demonstrated previously that polystyrene nanoparticles are able to enhance both antibody mediated and cellular immune responses against covalently conjugated protein and peptide. This response depends strongly on the size of the nanoparticles with a hydrodynamic size of 50 nm promoting the strongest responses. As they are not biodegradable, the future applicability of these particles as vaccine vectors is limited and therefore biodegradable

nanoparticles are being investigated as alternatives.

The biodegradation rate of these particles has been suggested to influence the immune response developed. To test this, two iron oxide nanoparticles stabilized with the polysaccharide pullulan are compared as potential antigen delivery vehicles. While the size of the particles, 40-60 nm is similar, their cores are composed of different iron oxide phases. The first is non-magnetic with limited crystallinity while the second is well ordered magnetite/maghemite. These differences manifest themselves in the stability and degradation profiles of the nanoparticles with the magnetically ordered particles exhibiting greater stability in a range of media along with a lower degradation rate as measured by the release of iron *in vitro*. The particles have been successfully conjugated to protein and ongoing work analyzing their capacity to enhance both antibody based and cellular immune responses, as well as their interactions with antigen presenting cells will be presented. The studies outcomes will aid in the design of future nanoparticulate vaccine vectors.

1343**Intranasal administration with a NanoStat™-MOMP vaccine reduces the incidence of oviduct pathology in *Chlamydia*-infected mice**

Trim, L.¹, Fattom, A.², Bitko, V.², Beagley, K.¹

¹Institute of Health and Biomedical Innovation, Brisbane, Australia,

²Nanobio Corporation, Ann Arbor, United States

Vaccination against *Chlamydia trachomatis* is recognized to be the most likely means of reducing the incidence of pelvic inflammatory disease, ectopic pregnancy and infertility in women. Using the mouse model of chlamydial infection, the potential of NanoStat™, an oil-in-water nanoemulsion adjuvant, in combination with the chlamydial major outer membrane protein (MOMP) was investigated. Female BALB/c mice were vaccinated intranasally and then challenged with *C. muridarum* to determine vaccine effectiveness against infection and pathology. Intranasal immunization resulted in high MOMP-specific IgG and IgA antibody titers in serum and vaginal lavage as well as strong splenocyte proliferation as determined by CFSE proliferation. Splenocytes from immunized mice secreted high levels of IFN γ , TNF- α and IL-17A, which are essential for effective immune responses to chlamydial infection. Mice that were immunized with NanoStat™ and 20 μ g MOMP cleared infection faster and had 80% reduced incidence of hydrosalpinx (oviduct occlusion), an indicator of inflammatory pathology, compared to PBS immunized controls. These results demonstrate the effectiveness of NanoStat™ as an intranasal adjuvant targeting infection and pathology associated with genital chlamydial infections.

1344**Genetic background influences the humoral responses to vaccines**

Nouri-Shirazi, M., Zeng, M., Nourishirazi, E., Abu-Nuwar, E.
 Florida Atlantic University, Charles E. Schmidt College of Medicine,
 Boca Raton, United States

Background: The assessment of TLR agonists as promising candidate adjuvants for the induction of effective Th1 immunity continues to rely on the use of inbred mouse. However, the genetic variation among commonly used inbred mice may influence the efficacy of candidate adjuvants and bias the study conclusion. Indeed, we have found significant differences in the recruitment, phenotypes and cytokines production of DCs and NK cells and the generation of effector T cell in lymphoid tissues of two genetically non-identical mouse strains immunized with a protein based vaccine formulated with TLR agonists.

Objective: In this study, we further evaluated the nature and amplitude of humoral immune responses of B6 and BALB/c strains immunized with protein antigen ovalbumin plus Alum, TLR3, TLR4, TLR7/8, or TLR9 agonists.

Results: Our data suggest that compared to the Alum, all other adjuvants induced more effectively the recruitment of B cells and production of OVA-specific antibodies in both strains. We also observed significant differences between two strains. BALB/c strain recruited less B cells but produced significantly higher amounts of IgG2a in response to any of the TLR agonists. In addition, both strains produced similar amounts of IgG1 and IgG2b in response to TLR agonist except for MPLA which induced significantly more of IgG2b production in B6 strain.

Conclusion: Thus, our data suggests that genetic background should be taken into consideration when evaluating and comparing the activities of adjuvants for use in new prophylactic and therapeutic vaccines.

1345**Autoreactive potential of cross-reactive influenza antibodies**

Pillai, M.R., Chang, T.-C., Thomas, P.G., McGargill, M.A.
 St Jude Children's Research Hospital, Memphis, United States

A universal influenza vaccine that protects against multiple strains of influenza virus would be highly beneficial. However, the immune mechanisms that mediate protection to the conserved portions of influenza viruses are not completely understood. Antibodies specific for influenza virus epitopes common to multiple strains have been identified in humans; however, these cross-reactive antibodies are extremely rare despite multiple influenza vaccinations and infections. One possibility is that antibodies cross-reactive against multiple strains of influenza are also autoreactive to self-proteins, and therefore may be deleted during the course of the immune response. Thus, we wanted to examine whether cross-reactive influenza antibodies had a higher potential to be autoreactive. We recently demonstrated that treatment of mice with a low dose of the immunosuppressive drug, rapamycin, during vaccination with a H3N2 strain provided protection from subsequent lethal infections with H5N1, H7N9 and H1N1 strains. This enhanced protection was due to an altered

antibody repertoire with an increase in cross-reactive influenza-specific antibodies. Utilizing this approach, we generated cross-reactive antibodies to influenza, and tested these antibodies for reactivity against a panel of self-antigens that are commonly targeted in autoimmune disorders. Our results indicate that cross-reactive influenza antibodies have a higher potential to also be cross-reactive against specific self-antigens. Further, we are testing if transfer of these cross-reactive antibodies increases autoimmune inflammation.

1346**Cross-protection studies in mice immunized with iron-regulated *Pasteurella multocida* serotype B:3,4 vaccine**

Odugbo, M.
 National Veterinary Research Institute, Bacterial Vaccine
 Department, Vom, Nigeria

Fowl cholera (FC) and Haemorrhagic septicaemia (HS) are specific economic diseases of avian and bovine species caused by certain serotypes of *Pasteurella multocida*. The FC causing serotypes include A:1, A:3, A:4 and A:5 and HS causing serotypes include B:1, B:2, B:3,4 and E:2. The immunological relationship between some of the common strains associated with FC and HS, and a prototype *P. multocida* vaccine strain B:3,4 was evaluated using active mouse protection test. The cross-protective efficacy of the *P. multocida* serotype B:3,4 grown under iron-regulated condition, formalin-inactivated and adjuvanted with sodium alginate was examined in the mouse model by challenging the vaccinates with standardized virulent *P. multocida* serotypes A:1, A:4, B:2, B:3,4 and E:2. With the exception of serotype E:2, cross-protection with the prototype vaccine was observed against the challenge serotypes; and homologous protection was observed against serotype B:3,4 challenge strain. All serotypes invariably produced death of the unvaccinated control mice. Whole cell bacteria proteins of the *P. multocida* B:3,4 vaccine and the challenge serotypes were analyzed by SDS-PAGE and compared. The separation showed more than 12 clearly visible protein bands ranging from 26 to 100 kDa molecular weights. On the basis of stain intensity, the major protein bands occurred between the 30 kDa and 40 kDa of the strains. From this limited study the prospect of a single-strain vaccine that is cost-effective and capable of inducing cross-protection and eliminating antigenic competition may be feasible for use in both poultry and cattle. Further research may be of value toward vaccine development.

1347**Vaccine-induced protection against murine tuberculosis is associated with the development of antigen-specific IFN γ -IL-17+ CD4+ T-cells**

Bhattacharyya, N., Counoupas, C., Feng, C.G.
 The University of Sydney, Infectious Diseases and Immunology,
 Camperdown, Australia

One third of the world's population is infected with *Mycobacterium tuberculosis* (*M.tb*), the pathogen that causes tuberculosis (TB). Although the current TB vaccine *M. bovis*

Bacillus Calmette-Guérin (BCG) is effective at protection against childhood TB, its protective efficacy wanes over time. Therefore, there is an urgent need to develop a new generation of TB vaccines. Whilst some recent vaccine candidates have been shown to be effective in protecting against *M.tb* infection in mice, the correlates of protection remain elusive. To this end, we have developed an adoptive transfer approach using transgenic CD4⁺ T-cells specific for the *M.tb* antigen Early Secretory Antigenic Target 6 (ESAT-6) to characterise the antigen specific immune response generated by novel vaccine candidates. Immunisation of mice with ESAT-6 with the dimethyldioctadecylammonium liposome/monophosphoryl lipid-A (DDA/MPL) adjuvant has been shown to elicit protection against *M.tb*. We demonstrate that the MPL/DDA/ESAT-6 induced protection is associated with the generation of a cell population with a CXCR3⁺CCR6⁺ phenotype in the draining lymph nodes. In addition, the antigen-specific CD4⁺ T-cells co-express both T-bet and ROR γ t and produce both IFN γ and IL-17A. Together, these data highlight that a protective CD4⁺ T-cell response is associated with a Th1 and Th17 signature. This may have important implications on the design and screening method of future TB vaccine strategies.

1348

Lipovaxin, a versatile chelating liposomal vaccine platform for surface-loading of recombinant antigens to generate self-adjuncting immune-stimulatory particles for improved immune responses

MacLennan, N., Price, J., Rusden, A., Gosling, K., Atmosukarto, I. Lipotek Pty Ltd, Canberra, Australia

Lipotek have developed a liposome platform that utilises chelating lipid-based immune-stimulatory nanoparticles for the co-delivery of recombinant antigens and immune potentiating agents. Antigens are attached to the surface of Lipovaxin liposomes by way of the commonly used poly-histidine tag engineered in the recombinant protein, which anchors the protein to a proprietary chelating lipid included in the liposome bilayer. As a result, antigens are all anchored in the same orientation and are displayed as highly ordered array on the surface of the liposomes, a conformation that mimics the display of surface antigens on viral particles. Chelating liposomes can be prepared with various immune-stimulatory properties, by including TLR ligands to achieve disease-relevant vaccine design.

This approach has been tested successfully with a number of antigens, including the model antigen OVA, a fusion of the tuberculosis antigen fusion ESAT6-Ag85C and the malaria antigen MSP2. In combination these studies have confirmed that particle delivered-surface anchored antigens are effectively drained to the lymph node resulting in greater antigen presentation. Furthermore we have demonstrated that the immune-stimulatory content of the particles increases internalisation by antigen presenting cells, the maturation of dendritic cells and the secretion of a range of cytokines. In mouse models humoral and CD4 and CD8 T cell responses have been induced successfully. The data presented will highlight the use of the Lipovaxin as a versatile vaccine platform.

1349

Developing an influenza vaccine using lipid nanoparticle-encapsulated nucleoside-modified mRNA

Pardi, N.¹, Naradikian, M.S.¹, Parkhouse, K.², Hensley, S.E.², Cancro, M.P.¹, Weissman, D.¹

¹University of Pennsylvania, Department of Medicine, Philadelphia, United States, ²Wistar Institute, Philadelphia, United States

Despite significant progress in influenza research, no effective universal vaccine against the virus has been developed, thus requiring yearly revaccination. mRNA has recently emerged as a potential therapeutic agent that effectively generates potent vaccine responses.

We have generated a new vaccine platform using *in vitro* transcribed mRNAs that were optimized for higher levels and extended translation by incorporation of selected UTRs, modified nucleosides, 5' cap, 3' poly(A)-tail, and other modifications and were FPLC-purified to remove dsRNA contaminants. mRNAs were encapsulated into lipid nanoparticles (LNPs) that have recently proved to be safe and efficient tools for *in vivo* nucleic acid delivery. Mice were intradermally vaccinated with a single injection of low dose PR8 hemagglutinin (HA) encoding mRNA-LNPs. At various times post immunization, animals were bled or sacrificed and antigen-specific T and B cell immune responses were evaluated.

Potent antigen-specific CD4⁺ T cells where half of the response was T follicular helper cells was generated. Increased numbers of germinal center and memory B cells was associated with high titers of neutralizing antibodies. Most interestingly, over a third of B cell responses directed at the stalk, which is conserved across groups.

Our results demonstrate that antigen-encoding nucleoside modified mRNA in LNPs induces highly potent and broad influenza-specific immune responses and has great potential for vaccination against infectious diseases.

1350

Immunogenicity of *Mycobacterium tuberculosis* antigens immobilized on bacterially derived polyester beads

Rubio Reyes, P.¹, Parlane, N.A.², Wedlock, N.², Rehm, B.H.A.^{1,3,4}

¹Institute of Fundamental Sciences, Massey University, Palmerston North, New Zealand, ²AgResearch, Hopkirk Research Institute, Palmerston North, New Zealand, ³MacDiarmid Institute for Advanced Materials and Nanotechnology, Wellington, New Zealand, ⁴Polybatics Ltd, Palmerston North, New Zealand

Traditional approaches to vaccine development have failed to identify better vaccines to replace or supplement BCG for the control of tuberculosis (TB). This study evaluates the immunogenicity of bacterially derived polyester beads displaying the reverse vaccinology antigens Rv1626, Rv2032 or Rv1789 from *Mycobacterium tuberculosis*. The beads were formulated in the adjuvant dimethyl dioctadecyl ammonium bromide and used to immunize groups of C57BL/6 mice. Antibody responses were evaluated by Enzyme-Linked Immuno Sorbent Assay (ELISA). Specificity of IgG antibody responses was assessed by immunoblotting cell lysates prepared from the vaccine production strain with antisera from the vaccinated

mice. Mice vaccinated with beads displaying Rv1626 had significantly higher IgG1 responses compared to all the other vaccinated groups ($p < 0.05$). Immunoblotting of antisera from these mice indicated that antibody responses were Rv1626 antigen-specific as there was no detectable immune response to the polyester component of the vaccine. Cytokine responses were evaluated by cytometric bead array (CBA); not showing statistical differences between the beads vaccinated groups. Overall this study suggests that selected TB antigens, derived from a reverse vaccinology approach to antigen identification can be displayed on nano-polyester beads to produce specific immune responses potentially relevant to the prevention of disease.

1351

Assessment of a novel mutated PAP-derived vaccine for the treatment of Prostate Cancer

Le Vu, P., Vadakekolathu, J., Pockley, A.G., Rees, R.C., McArdle, S.E.B. John Van Geest Cancer Research Centre, Nottingham Trent University, School of Science and Technology, Nottingham, United Kingdom

Prostate cancer is the second most frequent cancer in men. Patients are treated with local therapies such as prostatectomy or radiation therapy. However, treatment fails in 1 in 3 cases, thereby leading to an advanced-stage of metastatic disease. The standard treatment for such disease is androgen deprivation therapy, however most patients will develop resistance and progress to metastatic castration-resistant prostate cancer (mCRPC). At this stage, the only treatment has been the chemotherapeutic drug docetaxel, which confers an increased median overall survival benefit. Immunotherapy has demonstrated to be capable of reducing and even curing cancer in some patients. Sipuleucel-T vaccine, which was FDA approved in 2010, provides an additional therapeutic option for mCRPC. Sipuleucel-T has been shown to prolong the overall survival by 4 months, highlighting the feasibility of such an approach. Our laboratory has shown that a PAP-derived vaccine could induce PAP-specific T-cells responses and reduce tumour growth in established heterotopic tumour model of prostate cancer. We have since elongated and mutated the PAP-peptide sequence and shown its ability to induce a stronger immune response. The elongated mutated 42mer PAP-derived sequence was shown to increase the peptides specific Interferon γ response towards the wild-type PAP-derived peptides. In order for any given vaccine to work successfully, the delivery system and the adjuvants needs to be considered in addition to the immunogenicity of the antigen of interest. Different adjuvant strategies and delivery systems were used to boost this response and the results of these experiments will be presented at the conference.

1352

A nanoparticle based Sp17 peptide vaccine exposes immunodominant and species cross-reactive B cell epitopes

Gao, Q.¹, Xiang, S.D.¹, Wilson, K.L.¹, Heyerick, A.², Stephens, A.³, Plebanski, M.¹

¹Monash University, Immunology, Melbourne, Australia, ²PX Biosolutions Pty Ltd, Melbourne, Australia, ³Hudson Institute of Medical Research, Melbourne, Australia

Cancer testis antigen sperm protein antigen 17(Sp17), an immunogenic antigen with highly aberrant expression in ovarian cancer lesions, is a promising antigen candidate for developing ovarian cancer vaccines. Herein we describe the nanovaccine formulation human Sp17(hSp17) sequence derived peptides conjugated to delivery nanoparticles and the new properties of immune responses induced by these nanovaccines. Mapping the T cell and antibody epitopes using such nanovaccine show that the primary T and B cell immunodominant region within Sp17 was within amino acids(aa)111-142, which is the same as mapped by vaccine formulation of hSp17 peptides mixed with conventional proinflammatory CpG adjuvant. However, this nanovaccine formulation can change the dominant antibody isotype from IgG2a to IgG1 and the fine specificity of the B cell epitopes within hSp17111-142, from an immuno-dominant region 134-142 aa for CpG, to region 121-138 aa. Associated with this change in specificity was a substantial increase in antibody crossreactivity between mouse and human Sp17. In addition, unpublished data show the potentially therapeutic antibodies induced by the nanovaccine can be long lasting. These results indicate conjugation of antigen to nanoparticles can have major effects on fine antigen specificity, which could be beneficially used to increase the cross-reactivity of antibody responses.

1353

Ex vivo evaluation of Sendai virus vectors for delivery of CMV IE-1 and pp65

*Kiener, R.¹, Schwegler, C.¹, Wiegand, M.², Asbach, B.¹, Wagner, R.¹
¹University of Regensburg, Molecular Microbiology (Virology), Regensburg, Germany, ²AmVac Research GmbH, Martinsried, Germany*

Human Cytomegalovirus (CMV) remains a major health problem during pregnancy and in immunocompromised patients. For the delivery of CMV IE-1 and pp65 antigens we compared the novel murine Sendai Virus (SeV) platform to the well-established modified Vaccinia Ankara (MVA) vectors in a human *ex vivo* model with regard to their suitability as future vaccine candidates.

BHK-21, Vero cells and monocyte-derived Dendritic Cells (mdDCs) were infected and antigen expression was assessed via Western Blot or intracellular staining and flow cytometry. Maturation of mdDCs was investigated by staining cells with antibodies against CD80/CD86/HLA-DR. Proinflammatory cytokines in cell culture supernatant were quantified in a bead-based multiplex assay. Restimulation of T cell clones after co-culture with infected mdDCs was assessed by intracellular IFN γ staining and flow cytometry.

All viruses induced expression of IE-1 or pp65 in permissive cell lines. In mdDCs, moderate antigen expression was detectable for MVA. Depending on vector modifications, varying amounts of transgene expression were observed for the Sendai vectors at comparable MOIs. None of the tested vectors were capable

of inducing maturation of mdDCs under the applied conditions and MVA infection led to downregulation of HLA-DR and CD86. Depending on the viral vector and vector modifications, varying cytokine profiles were detected. In the restimulation of T cell lines by infected mdDCs, SeV vectors were superior to MVA.

SeV vectors constitute a promising new vector platform since they induce secretion of relevant inflammatory cytokines after infection of mdDCs and show a high capacity for T cell restimulation despite little antigen expression.

1354

Immunogenicity of M13 phage vaccine displaying N-terminal region of amyloid beta peptide: comparison of M13 phage vaccine expressed as g3p fusion and g8p fusion

Miyahara, R.¹, Shimotsu, A.¹, Matsushita, Y.¹, Shinozaki, T.¹, Tsukada, M.¹, Hashimoto, M.¹, Sugimura, K.², Hashiguchi, S.¹

¹Kagoshima University, Graduate School of Science and Engineering, Kagoshima, Japan, ²Kagoshima University, Graduate School of Medical and Dental Sciences, Kagoshima, Japan

Antibodies against amyloid- β peptide (A β) can reduce amyloid deposits and are considered as a potential therapeutic approach for Alzheimer's disease. We have recently shown that M13 phage stimulate an innate immune response and induce a strong primary IgG response in mice without any inflammatory adjuvant materials. Even a single immunization with 10^{11} pfu of phage induced a long-lasting antibody response. To investigate the potential of M13 phage as a vaccine carrier for A β peptide, the sequences of 1-15 region of A β were genetically linked to the N-terminus of M13 gene 3 protein or gene 8 protein, that correspond to A β -g3p phage and A β -g8p phage, respectively. When C57BL/6 mice were immunized subcutaneously with 10^{11} pfu of A β -g3p phage in PBS solution, anti-A β IgG response was induced in two weeks after the secondary immunization. In the case of A β -g8p phage, anti-A β IgG response was induced during a primary response. Anti-A β antibody titer was comparable in the two mice groups. We also observed that A β -g8p phage induced IgG class switch in athymic (nu/nu) BALB/c mice, indicating that there are different immunological mechanisms of phage vaccine between g3p fusion and g8p fusion. Considering safety and habitual presence of an M13 phage, A β 1-15-displaying M13 phage may be promising as a safe AD vaccine.

1355

Generation of recombinant LC3 of *Entamoeba histolytica* as candidate vaccine for intestinal amoebiasis

Martínez-Hernández, S.-L.¹, Cervantes-García, D.¹, Montes de Oca-Luna, R.², Loera-Arias, M.D.J.², Ascacio-Martínez, J.A.I.³, Ventura-Juárez, J.¹

¹Universidad Autónoma de Aguascalientes, Morfología, Aguascalientes, Mexico, ²Universidad Autónoma de Nuevo León, Histología, Monterrey, Mexico, ³Universidad Autónoma de Nuevo León, Bioquímica y Medicina Molecular, Monterrey, Mexico

Entamoeba histolytica (Eh) is a protozoan parasite that causes dysentery and amoebic liver abscess. In Mexico, approximately 8% of the population had suffered amoebiasis. The development

of recombinant proteins is a prophylactic alternative used for generation of safe vaccines against this parasite. In this project we are developing a set of recombinant fusion proteins to generate an effective immune response. The LC3 coding region (52 kDa) of the Gal-GalNAc heavy subunit was codon optimized. This LC3 gen fragment was fused to the exotoxin A gene sequence from *Pseudomonas aeruginosa* deleted in domain III (PEDIII) and to a KDEL sequence. Both Open Read Frames (ORFs) were synthesized by the GenScript company. These constructs PEDIII-LC3-KDEL, PEDIII-LC3, LC3-KDEL and LC3 were subcloned into the expression vector pET6xHN, and used for transformation of *Escherichia coli* BI21 (DE3). After purification of recombinant proteins, immunization tests in male golden hamsters (*Mesocricetus auratus*) will be performed. All animals will be challenged antigenically with *Eh* trophozoites (strain HM-1: IMSS virulent phase V). From the synthesized sequences we derivate the ORFs PEDIII-LC3-KDEL3 (2375 bp), PEDIII-LC3 (2336 bp), LC3-KDEL3 (1232 bp) and LC3 (1193 pb) proteins. These ORFs were subcloned into the expression vector pET6xHN, and characterized by PCR, restriction analyses and sequencing. *Escherichia coli* BI21 (DE3) clones carrying the recombinant plasmids were obtained by electroporation. These clones will be used for the production of the recombinant proteins. Four recombinant plasmids for the expression of LC3 antigen fused or no to PEDIII and/or KDEL were generated.

Gamma-irradiated influenza A virus vaccine: irradiation conditions & vaccine efficacy

David, S., Paton, J., McColl, S., Alsharifi, M.

University of Adelaide, Department of Biological Sciences, Adelaide, Australia

Gamma-irradiation has been used experimentally to inactivate viruses for vaccine purposes, and the cross-protective efficacy of gamma-irradiated Influenza A virus vaccine (Gamma-FLU) has been illustrated previously. While sterility of irradiated vaccines can be achieved using low gamma-radiation doses, 50kGy is recommended to sterilise highly pathogenic viruses such as Avian H5N1. Considering the possible inclusion of highly pathogenic Influenza strains in future clinical development of Gamma-FLU, the irradiation dose required for vaccine inactivation may be increased. Here we examined the effect of different irradiation conditions, including high irradiation doses, on the overall structure of Influenza A virus, the possible damage to surface proteins, and the immunogenicity of Gamma-FLU. Our data illustrate that irradiation at freezing temperatures (using dry ice) is associated with reduced damage to viral structure compared to irradiation at room temperature. Importantly, intranasal vaccination with dry-ice irradiated vaccines at 25kGy (low dose) and 50kGy (high dose) provided 100% protection against lethal Influenza challenge. In addition, use of comparably low vaccine doses shows vaccination with 50kGy Gamma-FLU is associated with reduced virus neutralisation compared to 25kGy Gamma-FLU, despite the induction of equivalent antibody titres. Our data also illustrates this reduction in vaccine efficacy due to use of high radiation doses can be overcome by increasing vaccine dose. Overall, our data highlights the immunogenicity of

50kGy-irradiated materials, which may allow the future clinical development of Gamma-FLU based on highly pathogenic Influenza A viruses.

IgM and IgG dominant LipL32 peptides revealed by leptospirosis patient's sera and therapeutic monoclonal antibodies

Pissawong, T.¹, Maneewatcharangsri, S.², Rithisunthorn, N.², Soonthornworasiri, N.³, Reamtong, O.², Kalambaheti, T.⁴, Adisakwattana, P.⁵, Chaisri, U.⁶, Doungchawee, G.⁷

¹Thammasat University, Chulabhorn International College of Medicine, Pathumthani, Thailand, ²Mahidol University, Department of Molecular Tropical Medicine and Genetic, Faculty of Tropical Medicine, Bangkok, Thailand, ³Mahidol University, Department of Tropical Hygiene, Faculty of Tropical Medicine, Bangkok, Thailand, ⁴Mahidol University, Department of Microbiology and Immunology, Faculty of Tropical Medicine, Bangkok, Thailand, ⁵Mahidol University, Department of Helminthology, Faculty of Tropical Medicine, Bangkok, Thailand, ⁶Mahidol University, Department of Tropical Pathology, Faculty of Tropical Medicine, Bangkok, Thailand, ⁷Mahidol University, Department of Pathobiology, Faculty of Science, Bangkok, Thailand

Leptospirosis is regarded as a globally neglected zoonosis frequently found in tropical countries affects both human and animals. LipL32, an immunodominant outer membrane protein of pathogenic *Leptospira* spp. has been used as diagnostic biomarker, vaccine candidate for a broad spectrum vaccine, and therapeutic target in passive immunotherapy for leptospirosis. This study, LipL32 dominance peptides in middle (LipL32₉₃₋₁₈₄) and carboxy-terminal (LipL32₁₇₁₋₂₇₂) domains have been investigated during acute and convalescence phases of infections by using confirmed leptospirosis patient's paired sera collected from acute febrile illness patients in Thailand (MAT titer \geq 1:400, total no.=58). Equally IgM reactivities specific to middle and C-terminal domains (0.22 \pm 0.11 and 0.21 \pm 0.14) have been investigated. Antigenic specificity of pool acute sera revealed IgM dominance peptides of LipL32₁₄₈₋₁₈₄ and LipL32₁₇₁₋₂₁₄ with OD ELISA at 0.28 \pm 0.17 and 0.28 \pm 0.24, respectively. IgG reactivities of convalescent sera to LipL32₉₃₋₁₈₄ were significant higher than LipL32₁₇₁₋₂₇₂ (0.39 \pm 0.25 and 0.26 \pm 0.09 OD ELISA, respectively) and IgG dominance LipL32 peptide was mapped to LipL32₉₃₋₁₄₇ in middle domain of LipL32 (0.53 \pm 0.26 OD ELISA). IgG dominance of two therapeutic epitopes were located at LipL32₂₄₃₋₂₅₃ of C-terminal b-turn and amphipathic a-helix and LipL32₁₂₂₋₁₃₀ at surface-exposed loop in middle domain of LipL32 structure and have been shown less immunodominant (< 30%) in epitope-blocking ELISA. From this research, LipL32₁₄₈₋₂₁₄ spanning two domains and LipL32₉₃₋₁₄₇ in middle LipL32 are major IgM and IgG antibody responses, respectively during *Leptospira* infections. The IgM/IgG dominant LipL32 peptides revealed by patient's sera and therapeutic antibodies could be further perspectives for LipL32 immunodominance peptide-based serodiagnosis and LipL32 epitope-based vaccine.

Investigating the effect of multiple dosing of an RHDV VLP-based immunotherapeutic vaccine for melanoma

Sadrolodabai, Y.¹, Ward, V.², Young, S.¹

¹University of Otago, Department of Pathology, Dunedin, New Zealand, ²University of Otago, Department of Microbiology and Immunology, Dunedin, New Zealand

Metastatic melanoma has a poor prognosis and continues to be a challenging disease to treat, but recent immunotherapeutic approaches have demonstrated promising results. We have developed a cancer vaccine from virus-like particles (VLPs) derived from *Rabbit hemorrhagic disease virus* (RHDV) which acts as a highly immunogenic scaffold to deliver tumour-associated antigens to the immune system. Previous work has shown that one dose of RHDV VLP carrying gp100₂₅₋₃₃ can specifically activate a potent anti-tumour response and trigger the formation of immunological memory against gp100₂₅₋₃₃ to prevent tumour recurrence. Here we investigated what effect multiple dosing of RHDV VLP coupled to gp100₂₅₋₃₃ would have on the anti-tumour response. *In vivo* cytotoxicity assays carried out in mice showed that administering 3 doses of the vaccine did enhance the specific lysis of target cells compared to a single dose. This observation was also seen in a tumour trial with subcutaneous B16 melanomas. Mice that received 3 doses of the vaccine had improved overall survival and remained tumour free following rechallenge. Administering 6 doses of the vaccine did not significantly enhance the anti-tumour immune response above that achieved by administering 3 doses. An antibody response against the VLP capsid protein was detectable in all vaccinated mice, with mice that received more doses of vaccine producing more antibody. A VLP uptake assay identified that anti-VLP antibodies can enhance the early uptake of VLP by dendritic cells, but whether this has an effect on the anti-tumour immune response is unclear.

1359

Ex vivo generation of mature antigen presenting cells from inflammatory monocytes by oligomannose-coated liposomes

Matsuoka, Y.¹, Kawauchi, Y.¹, Kawauchi, K.², Kojima, N.¹

¹Tokai University, Applied Biochemistry, Hiratsuka, Japan, ²Tokyo Women's Medical University, Medical Center East, Department of Medicine, Tokyo, Japan

Oligomannose-coated liposomes (OMLs), in which the antigens are entrapped, have been shown to serve as effective antigen delivery vehicles and as a novel adjuvant to induce antigen-specific cellular immune response. Here, we demonstrate that inflammatory monocytes in PBMC can differentiate into mature professional antigen presenting cells *ex vivo* in response to uptake of OMLs.

When PBMC obtained from C57BL6 mice was co-cultured with OMLs in the presence mouse serum, OMLs were preferentially and rapidly incorporated into CD11b⁺Ly6C⁺ murine inflammatory monocytes. Interestingly, the expression of CD86, CCR7, CD83, and MHC class II on murine inflammatory monocytes was significantly enhanced within 24 h after OML

uptake. In addition, OML-ingesting inflammatory monocytes can activate T cells from OT-1 mice.

OMLs were also preferentially incorporated into human monocyte-derived DCs *ex vivo*, and in response to OML uptake, expression of CD86 and HLA-DR was upregulated. When, human PBMC were directly co-cultured with OMLs in the presence of human serum, CD14⁺ monocytes significantly ingested OMLs within 1 hour. Furthermore, during 5 day *ex vivo* culture with OMLs, the expression of HLA-DR and CD86 was significantly enhanced, and the expression of CD206, CD209, and CD83, which are not expressed on CD14⁺ monocytes, was induced on OML-ingesting CD11b⁺CD14⁺ cells.

Above results suggest that inflammatory monocytes in PBMC is differentiated into mature APCs, which may be distinguished from monocyte-derived DCs, in response to *ex vivo* OML uptake in both mouse and human models. Thus, use of OMLs may provide a new approach for *ex vivo* professional APC generation.

Inflammation

T cell subsets in regulation of autoimmunity and anti-tumor immunity

Kuchroo, V.K.

Evergrande Center for Immunologic Diseases, Harvard Medical School and Brigham and Women's Hospital

Recently a subset of interleukin (IL)-17-producing T cells (T_H17) distinct from T_H1 or T_H2 cells was described and shown to have a crucial role in the induction of autoimmune tissue injury. Accumulating data suggests that there are three distinct steps in Th17 differentiation: Induction, Amplification and Stabilization mediated by distinct cytokines and loss of any of the cytokines (TGF- β , IL-6, IL-21 or IL-23) in the pathway results in a defect in generation of Th17. However not all Th17 cells are pathogenic and induce autoimmunity, IL-23 is a key cytokine that induces pathogenicity in Th17 cells (Lee et al., 2012). Using expression profiling at very high temporal resolution, novel computational algorithms and innovative nano-wire based "knock-down" approaches, we have developed a regulatory network that governs the development of Th17 cells. In addition to high-density temporal microarray analysis, we have performed single-cell RNA-seq of Th17 cells in order to characterize cellular heterogeneity, identify subpopulations, functional states and learn how gene expression variation affects Th17 effector functions. We have identified novel regulators of Th17 cells both *in vivo* and *in vitro* that do not affect Th17 differentiation but affect pathogenic vs. non-pathogenic functional states of Th17 cells. Some of the genes that are expressed in non-pathogenic Th17 cells are also utilized by CD8⁺ T cells to induce T cell exhaustion. Deletion of some of these novel genes cooperate with known "check-point inhibitors to suppress anti-tumor immunity.

Antibody

Broadly neutralizing antibodies and a new mechanism of diversification

Lanzavecchia, A.

Institute for Research in Biomedicine

We use cell culture-based high-throughput methods to interrogate human memory B cell and plasma cell repertoires and to isolate antibodies selected on the basis of their neutralizing potency and breadth. Relevant examples are antibodies that neutralize all influenza A viruses or even four paramyxoviruses. By targeting conserved structures, these broadly neutralizing antibodies are less prone to select escape mutants and are promising candidates for prophylaxis and therapy of infections, as well as tools for vaccine design. The value of a target-agnostic approach to vaccine design is illustrated by our discovery of extremely potent antibodies that neutralize

human cytomegalovirus, which led to the identification of their viral ligand, a pentameric complex that was then produced and tested as an effective vaccine. By reconstructing the genealogy trees of specific B cell clones, we investigate the role of somatic mutations in affinity maturation and in generation of antibody variants with broader or different specificity. Somatic mutations can also generate autoantibodies, as found in patients with pemphigus and autoimmune pulmonary alveolar proteinosis. Recently, while searching for antibodies that broadly react with malaria variant antigens, we discovered a new mechanism of antibody diversification, which relies on the interchromosomal transposition of genomic DNA sequences into rearranging T cell subsets in regulation of autoimmunity and anti-tumor immunity

Stimulation of camel polyclonal antibody against human T cell immunoglobulin and Mucin-3

Homayouni, V.

Isfahan University of Medical Sciences, Isfahan, Iran, Islamic Republic of

Background: T cell Immunoglobulin and Mucin (TIM)-3 is a type I transmembrane glycoprotein and a member of the TIM family which is identified as a receptor. This receptor expresses on T helper type 1 (Th1) cells and binds to galectin-9 (Gal9). This interaction induces an inhibitory signal, resulting in apoptosis of Th1 cells and cytotoxic CD8 T cells in vitro. Antibody therapy for immune checkpoint blockade has achieved promising results for several types of malignant tumors. Therefore, this immunomodulatory molecule may be used as a novel target for clinical purposes. The production of camel heavy chain antibodies (HCAbs) against TIM-3-expressing cell line was reported in this study.

Methods: A pre-synthesized human TIM-3cDNA was inserted into pcDNA3.1 plasmid and the new construct was transfected in HEK cell. TIM-3 expression was confirmed by qRT-PCR and flow cytometry methods. A 6 months old camel was immunized with the lysate prepared from rTIM-3 expressing HEK cells 4 times. Then, the anti-TIM-3 antibody level was evaluated using ELISA method.

Results and conclusion: TIM-3 was successfully cloned in HEK cells and more than 88% of the cells expressed TIM-3. Hence, using HEK cells was produced a readily obtainable source of TIM-3. It was used for camel immunization. High level of anti-TIM-3 antibody was detected in its serum after the final injection. This antibody may be useful for future diagnostic or therapeutic approaches.

B cell depletion compromises CD8+ T cell response in murine *T. cruzi* infection

Fiocca Vernengo, F., Beccaria, C.G., Araujo Furlán, C., Tosello Boari, J., Gorosito Serrán, M., Montes, C., Acosta Rodriguez, E.V., Gruppi, A.
School of Chemistry, National University of Córdoba, Córdoba, Argentina

Considering CD8+T cells play a major role in *T. cruzi* protective immunity, the signals that promote the generation and maintenance of CD8+T cell responses needs to be identified. Many reports highlight the role of B cells in promoting cellular immunity; however, if B cells affect CD8 responses remain uncharacterized. To assess B-cell function in promoting CD8 responses in Chagas disease, C57BL/6 mice were intraperitoneally injected with anti-CD20, to deplete B cells, or with control antibodies. Eight days after treatment, mice were infected with 5000 trypomastigotes. Flow cytometric analysis using tetramer staining revealed that at day 14 post infection, depleted mice had a lower frequency of parasite-specific CD8+T cells in spleen, blood and liver compared to control mice ($p=0,0003$, $0,0353$ and $0,0447$ respectively). Interestingly, B-cell deficient mice showed higher percentages of naïve CD8+T cells (CD44-CD62L+) and lower frequency of effector memory CD8+T cells (CD44+CD62L-). CD8+T cells from B-cell depleted mice presented a Memory Precursor Effectors Cells phenotype unlike CD8+T cells from B-cell sufficient mice who exhibit a Short Lived Effectors Cells phenotype. Also, we found that depleted mice had lower frequencies of IFN- γ - or TNF-producing CD8+T cells and displayed lower apoptosis and proliferation rate. Unexpectedly CD8+T cells from B-cell depleted mice overexpressed molecules associated to activation/migration than control mice. These results identify

functional defects in CD8+T cells generated in B cell-depleted mice, highlighting B cell influence on CD8+T cell response. Furthermore, our study urges caution during B-cell depletion therapies due to its possible side effects on the immunity against infections.

Transgenic expression of N-acetylglucosaminyltransferase V in T cells accelerates autoimmune diabetes in NOD mice by enhancing pathogenicity of CD8 T cells

Chien, M.-W.¹, Khoo, K.-H.², Sytwu, H.-K.¹

¹National Defense Medical Center, Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan, Republic of China, ²Academia Sinica, Institute of Biological Chemistry, Taipei, Taiwan, Republic of China

β 1,6 N-acetylglucosaminyltransferase V (Mgat5) is a glycosyltransferase that increases N-glycan branching by transferring N-acetylglucosamine (GlcNAc) from UDP-GlcNAc to hydroxyl group on carbon 6 of the α 1,6-linked mannose of N-glycans. Previous studies have shown that deficiency of Mgat5 in mice decreased the T cell activation thresholds and exacerbated the incidence of experimental autoimmune encephalomyelitis (EAE). The non-obese diabetic (NOD) mice, a widely used animal model for human type 1 diabetes (T1D), developed spontaneous autoimmune diabetes and mainly caused by T cell-dependent destruction of pancreatic β -cells. Recently, NOD mouse is reported as an EAE susceptible strain since less N-glycan branching expressed on T cells. However, the relationship between Mgat5-mediated N-glycan branching and diabetogenic processing on T cells in NOD mice is still unknown. Here, we observed that Mgat5 transgenic T cells expressed higher level of N-glycan branching and had attenuated proliferation potential compared to control littermate T cells in NOD mice. Unexpectedly, a significantly higher diabetic incidence was found in both Mgat5 transgenic NOD mice and Mgat5/NY8.3 doubly transgenic mice that express a highly pathogenic transgenic TCR on CD8 T cells. Further, the higher diabetic incidence was also found in NOD/SCID recipients received adoptive transfer of Mgat5-overexpressed CD8 T cells, indicating that Mgat5 overexpression enhances the pathogenic properties of CD8 T cells in an antigen-specific manner. Taken together, our results suggest that upregulated Mgat5-mediated N-glycan branching on CD8 T cells contributes to autoimmune diabetes in NOD mice.

Features of phenotypic structure and functional activity of cord blood immune cells depending a gestational age

Lyapunov, V.¹, Chistyakova, G.¹, Bychkova, S.², Remizova, I.¹, Chereshev, V.³, Ustyantseva, L.²

¹Mother and Child Care Research Institute in Russian Public Health Ministry, Immunology and Clinical Microbiology, Ekaterinburg, Russian Federation, ²Mother and Child Care Research Institute in Russian Public Health Ministry, Pathology of Premature Infants, Ekaterinburg, Russian Federation, ³Institute of Immunology and Physiology UBRAS, Ekaterinburg, Russian Federation

In order to identify genotypic characteristics of the composition and functional activity of immune cells of umbilical cord blood (UCB) as a function of gestational age (GA), studied 102 UCB samples of babies born at 25-28, 29-32 and 33-36 weeks of GA and 31 UCB samples from comparison group (37-41 weeks GA). By the method of flow

cytometry was determined the number of CD3, CD19, CD4, CD8, CD16/56 cells; the level of expression of activation markers on the monocytes and lymphocytes (HLA- DR/CD14, CD71/CD14, CD25/CD4, CD95/CD3); adhesion receptor (CD11b). All premature babies with leukopenia in the background found an increase in the relative number of lymphocytes and decreased ability to absorb opsonized bacteria by granulocytes. Defined a reduction in the percentage of HLA-DR+/CD14+-cells, increasing the number of CD3+CD95+-population in group of children with a GA 25-28 weeks. Decrease at the level of NK-cells in group infants less than 32 weeks of GA was observed. It was determined a reduced percentage of CD3+CD11b+ cells in the 29-32; 33-36 weeks of GA. At the 33-36 weeks of the GA found a reduction in the number CD3+CD95+ lymphocytes and increased expression of the CD25+CD4+ lymphocytes.

Overall, the findings suggest about the features of the immune system, specific to a particular GA preterm infants. A number of the investigated parameters give the opportunity to talk about the partial achievement of the immunological response preparedness for a potential antigen that dictates the need for further research aimed at understanding the functional activity of immune cells.

The importance of serum visfatin levels in Behcet's disease patients

Ozbalkan, Z.¹, Enecik, M.E.¹, Keskin, G.², Karaaslan, Y.¹

¹Ankara Numune Education and Research Hospital, Rheumatology Department, Ankara, Turkey, ²Ankara University School of Medicine, Immunology Department, Ankara, Turkey

Objectives: Adipose tissue is an active endocrine organ and releases adipokines. Visfatin is one of them. Visfatin is related to TNF- α and IL-6, IL-1 beta, co-stimulators like CD40, CD54, CD 80 and endothelial ICAM-1 and ICAM-2. We aimed to search the relation among levels of serum visfatin in BD activity.

Materials and methods: 60BD patients (30 in active state and 30 in remission) diagnosed according to criteria of WGIBD and 20 healthy subjects as controls were involved in to the study. Serum visfatin levels were compared in between three groups.

Results: Visfatin levels were significantly higher in both group of patients compared to the healthy control group (both $p < 0,001$). Serum visfatin levels in active state patients were higher than those in inactive state ($p < 0,001$). The same way in all cases statistically significant correlation between visfatin and CRP ($p < 0,001$) and visfatin and ESR ($p < 0,01$). According to the symptoms of the patients in the active state, patients with genital aphthous ulcers had higher serum visfatin levels than the active patients without genital aphthous ulcers ($p < 0,001$).

Conclusion: Serum visfatin levels in BD patients with active and inactive states are higher than the healthy control group. That could be concluded as visfatin as a proinflammatory cytokines have a role in chronic inflammatory reactions and sustains the cellular expression of the inflammatory cytokines in BD.

Kinetic analysis of type 2 innate lymphoid cells in tissues from IL-25- and IL-33-induced murine models of asthma

Li, Y.¹, Lv, Z.², Wang, J.³, Chi, Y.³, Huang, P.², Corrigan, C.J.⁴, Huang, K.¹, Wang, W.², Ying, S.²

¹Beijing Chao-Yang Hospital, Capital Medical University & Beijing

Institute of Respiratory Medicine, Department of Respiratory and Critical Care Medicine, Beijing, China, ²Capital Medical University, Department of Immunology, School of Basic Medical Sciences, Beijing, China, ³Capital Medical University, Department of Laboratory Animal Sciences, Beijing, China, ⁴King's College London, MRC & Asthma UK Centre in Allergic Mechanisms of Asthma, Division of Asthma, Allergy & Lung Biology, London, United Kingdom

Background: Type-2 innate lymphoid cells (ILC2) play important role in the pathogenesis of asthma through producing large amounts of Th2-type cytokines. The mechanisms of ILC2 chemotaxis into lungs, however, are still unclear.

Methods: To answer these, BALB/c mice were intranasally changed with murine IL-25 or IL-33, while OVA and saline challenged mice were used as positive and negative controls. Bone marrow, spleen, thymus, mesenteric lymph nodes, mediastinal lymph nodes, lung tissue and bronchoalveolar lavage fluid (BALF) were collected from the mice at experimental acute, subacute, chronic and convalescent phases. Flow cytometry, *in vitro* chemotaxis assay and small animal *in vivo* imaging were used to measure the distribution and abundance and chemotaxis of ILC2 *in vitro* and *in vivo*.

Results: Both IL-25 and IL-33 alone induced accumulation of ILC2 into mediastinal lymph nodes, lung tissue and BALF, but with different kinetics. The peak of IL-25 induced ILC2 accumulation into lung tissue and BALF was earlier than that of the IL-33- induced mice. In quantity, the numbers of ILC2 in BALF, lung tissue and mediastinal lymph nodes were significantly higher in IL-33-induced mice compared with IL-25-induced mice. *In vitro* IL-33, but not IL-25 directly induced ILC2 chemotaxis. Small animal *in vivo* imaging further confirmed that single intranasally inhalation of IL-33 was sufficient to induce accumulation of injected ILC2 through tail vein into the lungs.

Conclusion: The data suggest that airways epithelium-derived IL-25 or IL-33 can induce accumulation of ILC2 to the lungs and that IL-33 has direct effect on ILC2 chemotaxis.

Immune responses to oral polio vaccine (OPV) in patients with X-linked agammaglobulinemia (XLA)

Wu, Y.¹, Mao, H.W.², Chan, S.M.¹, Lam, K.T.¹, Tu, W.¹, Lau, Y.L.¹

¹University of Hong Kong, Paediatrics and Adolescent Medicine, Hong Kong, Hong Kong, ²HKU-ShenZhen Hospital, ShenZhen, China

Background: XLA is characterized by impaired antibody response resulting from Bruton's tyrosine kinase (BTK) mutation. Unlike other primary immunodeficiency with no predisposition to extraordinary risk of viral infection, XLA renders a unique susceptibility to enteroviruses infection including poliovirus. OPV can induce paralytic poliomyelitis in XLA patients. Of great public concern is that the attenuated OPV can persist and revert to a virulent form in these patients, which renders a high risk of reintroducing virulent poliovirus into general population. It is known that BTK is involved in toll-like receptor 3 (TLR3) signaling, and TLR3-mediated type I IFN responses play critical roles in host protection against poliovirus. However, whether XLA patients have impaired type I IFN responses to OPV are not clear.

Hypothesis: BTK mutations in XLA impair TLR3-mediated type I IFN response, leading to the unique susceptibility to poliovirus in XLA patients.

Method: To investigate the response of XLA patients to OPV, monocyte derived macrophages (MDM) from XLA patients and healthy controls were infected with OPV Sabin strain 1 (OPV1). Further to examine the role of BTK in OPV infection, MDM from healthy controls were infected with OPV1 in the presence or absence BTK inhibitor.

Result: IFN- α production was measured by ELISA. OPV virus replication and IFN-inducible gene expressions including Mx1, Mx2, OAS1 were detected by qPCR. Results were compared between XLA patients and healthy controls

Conclusion: This study investigated the immune response of XLA patients to OPV and helped to reveal the role of BTK to control OPV infection.

Human placenta-derived multipotent cells (PDMCs) protect against *Klebsiella pneumoniae*- induced pneumonia by enhancing polymorphonuclear granulocytes (PMN) functions

Wang, L.T.^{1,2}, Chao, Y.Y.², Lee, W.¹, Huang, L.Y.³, Liu, K.J.⁴, Siu, L.K.³, Yen, B.L.²

¹Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan, Republic of China, ²Institute of Cellular & System Medicine, National Health Research Institutes (NHRI), Miaoli County, Taiwan, Republic of China, ³National Institute of Infectious Diseases and Vaccinology, NHRI, Miaoli County, Taiwan, Republic of China, ⁴National Institute of Cancer Research, NHRI, Miaoli County, Taiwan, Republic of China

Human mesenchymal stem cells (MSCs) are multilineage somatic progenitors with strong immunomodulatory properties which have been well-demonstrated for T lymphocytes and dendritic cells/macrophages. However, interactions with neutrophils (polymorphonuclear granulocytes or PMNs)—the most abundant population of human leukocytes—are less well understood. Therefore, we investigated the interactions of human placenta-derived multipotent cells (PDMCs), a population of fetal-stage MSCs, with PMNs through *in vitro* studies and a mouse model of *Klebsiella pneumoniae* (KP)-induced pneumonia. KP is a highly virulent gram-negative bacterium and a leading cause of community- and hospital-acquired infections, especially pneumonia. We found that after co-culture with PDMCs, PMN expression of CD11b—a marker of activation—as well as phagocytosis of FITC- labeled KP was significantly increased. Moreover, PMN oxidative metabolism was significantly increased as well, which manifested as increased anti-bacterial activity and improved killing of KP. To ascertain the therapeutic efficacy of PDMCs on bacterial infections, we infected wild type mice with KP by intratracheal inoculation with subsequent intravenous administration of PDMCs. Surprisingly, while injection of PDMCs reduced the influx of PMNs in KP-infected lung tissue, respiratory burst activity was simultaneously enhanced. PDMC treatment also decreased bacterial counts both locally in lung tissue and systemically in the bloodstream. Most importantly, administration of PDMCs significantly increased survival rates in this mouse model of KP pneumonia. Taken together, we found that PDMCs enhance PMN functions *in vitro* and *in vivo* towards KP without increasing overall lung inflammatory damage. Our data strongly implicate a possible therapeutic role for PDMCs towards gram-negative bacterial infections.

PTEN ameliorates autoimmune arthritis through down-regulating STAT3 activation with reciprocal balance of Th17 and Treg

Lee, S.H.¹, Byun, J.-K.¹, Park, J.-S.¹, Jhun, J.Y.¹, Jung, K.², Seo, H.-B.¹, Moon, Y.-M.¹, Park, S.-H.¹, Kim, H.-Y.¹, Cho, M.-L.¹

¹The Catholic University of Korea, Seoul, Korea, Republic of, ²Impact Biotech, Seoul, Korea, Republic of

PTEN is a tyrosine phosphatase that conducts a significant function in an inhibition of STAT3 activation. Recently, inactivation of STAT3 has been demonstrated as a therapeutic candidate for autoimmune arthritis. The expression of PTEN is controlled by p53 which regulates autoimmune arthritis through modulating balance between Th17 and Treg. We hypothesized that PTEN regulated by p53 may reduce CIA severity and inflammatory response via inhibition of STAT3 activation. Here, we reveal that PTEN ameliorates experimental autoimmune arthritis by reducing STAT3 activity and Th17 differentiation. Systemic infusion of PTEN overexpression downregulated CIA severity. Additionally, PTEN overexpression decreased activation of T cells and modulated reciprocal differentiation of Th17 and Treg cells. We observed that p53 deficiency downregulating PTEN expression induces the activation of STAT3. Loss of p53 exacerbates autoimmune arthritis and dysregulated the population of Th17 and Treg. These data suggest that induction of the STAT3-modulatory activity of PTEN may be a therapeutic target for rheumatoid arthritis therapy.

Notch and TCR signaling modulate the effector functions of human gamma delta T cells

Bhat, S., Chiplunkar, S.

ACTREC (Tata Memorial Centre), Chiplunkar Lab, Mumbai, India

Gamma Delta ($\gamma\delta$) T cells account for 5-10% of CD3⁺ peripheral blood T cells. $\gamma\delta$ T cells are activated by phosphoantigens, isopentenyl pyrophosphate (IPP) or 4-hydroxy-3-methyl-but-2-enyl pyrophosphate (HMBPP) which are intermediates of mevalonate/Rohmer pathway. Notch proteins play an important role in cell fate decisions, T cell development and are evolutionary conserved. The present study focuses on understanding how Notch signaling modulates the effector functions of $\gamma\delta$ T cells. Notch receptors (Notch1 and Notch2) were found to be dominantly expressed on $\gamma\delta$ T cells along with Notch ligands Delta- like ligand 1 and Jagged 1. Knockdown of Notch1 and Notch2 genes in $\gamma\delta$ T cells using small interfering RNA inhibited their antitumor cytotoxic potential. A marked decrease in cytotoxic effector function of $\gamma\delta$ T cells was observed with concomitant decrease in the expression of effector molecules like perforin and granzyme B. Altered expression of key transcriptional factors Eomes and Tbet was observed upon inhibition of notch signaling. This further leads to significant changes in the histone modifications, H3K9 acetylation and H3K9 methylation on the promoter region of different effector genes. Inhibition of Notch signaling decreased the expression of IL-2 receptor subunits (CD25, CD122 and CD132) and downstream signaling molecules like pAKT, NF-B and pSTAT5. Further, inhibition of notch signaling in $\gamma\delta$ T cells caused G1-G0 cell cycle arrest. In conclusion, our study demonstrates that notch signaling is indispensable for anti-tumor effector functions of $\gamma\delta$ T cells.

Evaluation of the adjuvant effect of gold nanocages *in vitro*

Yavuz, E.^{1,2}, Sakalak, H.³, Cavusoglu, H.^{1,3}, Uyar, P.^{1,4}, Yavuz, M.S.^{1,3}, Bagriacik, E.U.²

Hepatitis B is a potentially life-threatening disease caused by the hepatitis B virus (HBV). Unfortunately, despite the ongoing vaccine campaigns HBV infection is not completely managed. In order to increase the immune modulation capacities of Hepatitis B vaccines different adjuvant systems have been studied. Especially nanoparticle-based adjuvants are being widely investigated. Biocompatible and bioinert gold nanoparticles have been commonly used *in vitro* and *in vivo* biological research. Recently, gold nanocages (AuNCs), a special design with ultra thin porous walls and hollow interiors, have shown ample potential and have a promising future in the fields of cancer diagnostics and treatment. Our goal is to use AuNCs as an adjuvant in Hepatitis B model *in vitro*.

In this project, synthesized and characterized Au nanocages are used. Following the adsorption of HBsAg protein onto Au nanocages, adsorption efficiency of AuNCs is investigated. The uptake of HBsAg-AuNC by macrophages and its colocalization within the cell are analyzed by flow cytometry and confocal microscopy. The *in vitro* effect of the internalization of only AuNCs or HBsAg-AuNC on macrophage activation, antigen presentation and the cytokine profile are analyzed by flow cytometry and ELISA techniques. Here we aim to study the immunomodulation properties of the porous gold nanoparticles as an adjuvant *in vitro*.

IL-15 activated NK cells overcome DC maturation defects induced by head and neck cancer microenvironment

Upreti, D., Zhang, M., Kung, S.K.P.

University of Manitoba, Winnipeg, Canada

Head and neck squamous cell carcinoma (HNSCC) patients have the lowest 5-year disease-free survival rate. There is need to develop novel therapeutics of HNSCC. Natural Killer (NK) cells play key roles in innate immunity against infections and transformed cells. Through interactions with dendritic cell (DC), NK cells can shape also subsequently induced adaptive T-cell immunity.

Here we used an immunocompetent mouse model (AT-84) to evaluate anti-tumor potential of IL-15 activated NK cells. A direct injection of NK cells at tumor site significantly suppressed AT-84 tumor growth *in vivo*. It induced also protective memory responses against a secondary AT-84 challenge. AT-84 tumor cell was relatively resistant to IL-15 activated NK cells killing *in vitro*, suggesting that direct killing of AT-84 is unlikely the major underlying mechanism. We therefore hypothesized that IL-15 activated NK cells promoted anti-tumor activities via NK-DC crosstalk. Using bone marrow derived DC cultures; we observed that conditioned medium of AT-84 impaired DC maturation induced by TLR ligands *in vitro*. These DC were impaired in inducing T cell activations *in vitro*. Addition of IL-15 NK cells to the AT-84-exposed DC overcame the DC maturation and functional defects *in vitro*. These *in vitro* data was further corroborated by *in vivo* data obtained from the tumor

infiltrating dendritic cells. Collectively, our data demonstrated that IL-15 activated NK cells were able to reverse the immunosuppressed DCs to an immunostimulatory state that correlated well with tumor regressions. It supported future development of IL-15 NK-based immunotherapy of HNSCC.

Plasticity in CD1d-lipid antigen recognition by non-canonical NKT cells

Almeida, C.F.^{1,2}, Sundararaj, S.^{3,4}, Le Nours, J.^{3,4}, Patel, O.³, Cao, B.⁵, Pellicci, D.G.^{1,2}, Williams, S.⁵, Rossjohn, J.^{3,4,6}, Uldrich, A.P.^{1,2}, Godfrey, D.I.^{1,2}

¹The University of Melbourne and The Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ²Australian Research Council Centre of Excellence in Advanced Molecular Imaging, The University of Melbourne, Melbourne, Australia, ³School of Biomedical Sciences, Monash University, Department of Biochemistry and Molecular Biology, Melbourne, Australia, ⁴Australian Research Council Centre of Excellence in Advanced Molecular Imaging, Monash University, Monash, Australia, ⁵School of Chemistry, Bio21 Molecular Science and Biotechnology Institute, The University of Melbourne, Melbourne, Australia, ⁶Institute of Infection and Immunity, Cardiff University, School of Medicine, Heath Park, Cardiff, United Kingdom

Natural Killer T (NKT) cells are specialised lymphocytes that recognise lipid antigens presented by the MHC Class I-like molecule CD1d. Following activation, they rapidly secrete a broad range of immunoregulatory cytokines that can influence other mediators of immune responses and therefore they represent a promising therapeutic target for cancer and other diseases. The most extensively studied are type 1 NKT cells, which recognise a derivative of a marine sponge glycolipid α -galactosylceramide (α -GalCer), express a semi-invariant T cell receptor (TCR) and have a well-established role in the immune system. Much less is known about type 2 NKT cells, which do not recognise α -GalCer and express a diverse TCR repertoire. Using a panel of CD1d mutants, we reveal that different type 2 NKT cell hybridomas can adopt multiple ways to interact with CD1d, and furthermore, we identify a new population of type 2 NKT cells that specifically recognises the microbial derived lipid-antigen α -glucuronosyl-diacylglycerol (α -GlcA-DAG). Single cell sequencing of CD1d- α -GlcA-DAG tetramer⁺ cells reveals a polyclonal TCR repertoire distinct from type 1 NKT cells. Collectively, our results suggest that type 2 NKT cells express highly diverse TCRs and rely on mechanisms different to type 1 NKT cells to recognise distinct antigens. The knowledge obtained from these studies increases the scope of antigens recognized by NKT cells and provides valuable insight in how these cells can be manipulated for therapeutic purposes.

Mucosal route of immunotherapy with transgenic rice seeds expressing hypoallergenic whole T cell epitopes of Cryj1 and Cryj2 - Investigation in murine model of cedar pollinosis

Kawauchi, H.¹, Aoi, N.¹, Yamada, T.², Takagi, H.³, Takaiwa, F.³

¹Shimane University, Faculty of Medicine, Otorhinolaryngology, Izumo, Japan, ²Shimane University, Center for Integrated Research in Science, Department of Experimental Animals, Izumo, Japan, ³National Institute of Agrobiological Sciences, Ministry of Agriculture, Tsukuba, Japan

For the last decade, we have been investigating the therapeutic

effect of mucosal route of administration of transgenic rice (Tg- rice) seeds, which contain T-cell epitopes of Cryj1 and Cryj2, on murine allergic rhinitis models and reported its clinical efficacy to actually attenuate nasal symptoms. However, its mechanism remains to be further investigated and adverse events of this therapeutic approach should be very least with more sophisticated manners.

Results: Therefore, we have examined the effect of natural feeding with protein bodies (PB) of transgenic rice seeds expressing hypoallergenic whole T cell epitopes of Cryj1 and Cryj2 (PB-Tg rice), in comparison with whole Tg-rice, in a murine model of cedar pollinosis. The numbers of sneezing after final intranasal challenge in mice naturally fed with PB Tg-rice powder were significantly decreased in a dose dependent manner, with less doses, in comparison with those of whole Tg-rice powder. Histopathological findings correspondingly demonstrated that the number of eosinophils infiltrating into nasal mucosa decreased and the damage of epithelial cells was less found in each group of mice. Sublingual route of administration is also effective to attenuate nasal symptoms.

Conclusion: Protein body fraction of Tg-rice more efficiently downregulated nasal symptom in murine model of cedar pollinosis with natural feeding or sublingual administration. These result implicates that intake of protein body form of Tg-rice can be more promising strategy and material to be utilized for mucosal route of immunotherapy to attenuate nasal symptoms of patients with cedar pollinosis.

Enhancement of NK cell-mediated cytotoxicity during chronic virus infection

Ha, S.-J., Oh, J.

Yonsei University, Department of Biochemistry, Seoul, Korea, Republic of

NK cells are critical for the clearance of parasites, virus-infected cells and tumors. Recently, several groups reported that NK cells could control virus-specific T cell responses at early stage of chronic infection. However, the physiological role of NK cell in a host infected with chronic virus has not been extensively studied. To identify the role of NK cell in chronic virus infection was studied in the mice persistently infected with LCMV-CL13. In this study, we found that terminally differentiated CD27^{low}KLRG1⁺CD11b^{high} NK cells were more abundant in the chronically infected mice than in naive mice. Furthermore, the NK cells from CL13-infected mice were shown to express higher level of an activating receptor, NKG2D and lower levels of the inhibitory receptors, NKG2A and Ly49C/I than those from naive mice. Such an integrative signal seemed to enhance NK cell activity, elevating expressions of CD69 and Granzyme B. At the functional level, NK cells in the CL13-infected mice display increased *ex vivo* IFN- γ production and increased *in vitro* cytotoxicity. Indeed, the CL13-infected mice, but not naive mice, dramatically delayed tumor formation when various tumor cells such as TC-1 lung adenocarcinoma and B16F10 melanoma were inoculated. The significant decrease of tumor promotion in CL13-infected mice was abrogated by depletion of NK cells, suggesting NK cell-mediated cytolytic activity for tumors. Currently, we are investigating which molecular are able to empower NK cells with enhanced cytolytic activity. Discovery of the key regulator for the enhanced activity of NK cell could be a potent cancer drug.

CD169 identifies an anti-tumor macrophage subpopulation in human hepatocellular carcinoma

Wu, Y., Zhang, Y., Zheng, L.

Sun Yat-sen University, Guangzhou, China

Macrophages are a major component of most solid tumors and can exert both anti- and pro-tumorigenic functions. Although the immunosuppressive/pro-tumor roles of macrophages have been widely examined, significantly less is known about macrophage subpopulations that have potential anti-tumor properties in humans. In the present study, a population of CD169⁺ macrophages with relatively high expression levels of HLA-DR and CD86 was identified in human hepatocellular carcinoma tissues. The frequency of CD169-expressing macrophages within cancer nests was significantly lower compared with that found in paired non-tumor areas. *In vitro* experiments revealed that in the presence of anti-CD3 stimulation, CD169⁺ macrophages could significantly enhance the proliferation, cytotoxicity, and cytokine production capacity of autologous CD8⁺ T cells in a CD169 molecule-dependent manner. Autocrine TGF- β produced by tumor-stimulated macrophages was involved in the down-regulation of CD169 expression on these cells. Moreover, CD169⁺ macrophage accumulation in tumor tissues was negatively associated with disease progression and predicted favorable survival in hepatocellular carcinoma patients, which was in contrast to the trend observed for total CD68⁺ macrophages. Therefore, CD169 may act as a costimulatory molecule for cytotoxic T cell activation, and could define a population of tumor-infiltrating macrophages with potential anti-tumor properties in human hepatocellular carcinoma tissues.

Combination of TLR2 and TLR3 ligands enhances maintenance of CD4 T cells and production of class-switched antibody

Ha, S.-J.¹, Lee, B.R.¹, Jeong, S.K.², Ahn, B.C.², Shin, S.J.³, Yum, J.S.²

¹Yonsei University, Department of Biochemistry, Seoul, Korea, Republic of, ²CHA Vaccine Institute, R&D Center, Seongnam-si, Korea, Republic of, ³Institute for Immunology and Immunological Diseases, Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Department of Microbiology, Seoul, Korea, Republic of

The efficacy of the vaccines in numerous studies including priming or boosting regimens for prophylactic purpose as well as its therapeutic application depends on the type of adjuvant. Thus, a better understanding on the combination of different type adjuvants is essential for optimal immune responses. Here, we investigated the mechanistic actions of a combined adjuvant Pam3csk4 and PolyI:C (hereafter referred to as L-pampo) to improve the adjuvanted-vaccine efficacy. Notably, an administration of ovalbumin (OVA) with L-pampo induced the enhanced production of antibody, correlated to reciprocal expansions of germinal center B cells and multi-functional CD4T cells concomitantly producing IFN- γ and TNF- α in an antigen-specific manner after tertiary immunization with OVA. To dissect the precise mechanism for the synergy by TLR2 and TLR3 ligands in L-pampo, we subdivided courses of the immune responses after primary immunization into three different phases. During 24 hrs after immunization, unlike PolyI:C alone, the levels of type I IFN in serum and spleen selectively decreased

along with an remarkably attenuated IRF3 signaling by L-pampo administration. However, at an effector phase, L-pampo and Pam3 comparably induced expansion of CXCR5⁺PD-1⁺ follicular helper T cells. Interestingly, during the memory phase, L-pampo showed prominent maintenance of antigen-specific CD4 T cells together with a high level of antibody titers when comparing to Poly:I:C or pam3 alone. Collectively, these findings suggest that combination of TLR2 and TLR3 ligands modulates cytokine production and prolong CD4 T cells that may lead to prominent antibody response and expansion of multi-functional CD4 T cells upon boosting.

Adjuvant therapy of chronic uroinfections in colonised patients

Vaskova, S.^{1,2}, Blazickova, S.^{2,3}

¹Laboratoria Piestany, Dept. of Clinical Microbiology, Piestany, Slovakia, ²Trnavian University, Faculty of Health Science and Social Work, Trnava, Slovakia, ³Laboratoria Piestany, Dept. of Clinical Immunology, Piestany, Slovakia

Introduction: Urinary tract infections represent the most commonly acquired bacterial infections. Identical bacterial species permanently isolated from urine of patients with chronic uroinfections are supposed to colonize distal segment of genitourinary tract and to form biofilm on mucous surface. Biofilms are the well-organized microbial communities and decrease the susceptibility to the host immune system and to the antimicrobial agents. Therefore, therapy of chronic infections should be different than therapy of acute ones.

Aim: To compare antibiotic therapy of chronic uroinfections with adjuvant immunomodulatory therapy in colonised patients.

Material and methods: 36 patients with monobacterial chronic uroinfections and bacterial species permanently isolated from urine that produce biofilm *in vitro*. Patients were classed into two groups: group A - patients treated with antibiotics (n = 29), group B - patients treated with antibiotics and adjuvant immunomodulatory therapy (n = 7). Inflammatory and blood elements parameters were analysed in the patients.

Results: We did not observe statistically significant differences between clinical benefits in patients with antibiotic and adjuvant immunomodulatory therapy. Clinical benefit after antibiotic treatment was observed in 9 patients (31 %); clinical benefit after adjuvant immunomodulatory therapy was observed in 4 (57 %) patients. We did not see statistically significant changes in other laboratory parameters.

Conclusion: The present study is a pilot study. Adjuvant therapy seems to have benefit for patients with chronic uroinfections. We would like to focus on analyse changes in immune system in colonised patients with chronic uroinfections and in patients with acute uroinfections.

Keywords: chronic uroinfections, biofilm, immunomodulatory therapy

Strategies for the *in silico* selection of immunogenic epitopes using non-model organisms: use case with *Histoplasma capsulatum*

Rubio C., M.^{1,2}, Cano Restrepo, L.E.^{1,3}, Ochoa Deossa, R.A.⁴

¹Corporación para Investigaciones Biológicas (CIB), Micología Médica Experimental, Medellín, Colombia, ²Universidad de Antioquia, Instituto

de Biología, Medellín, Colombia, ³Universidad de Antioquia, Escuela de Microbiología, Medellín, Colombia, ⁴Universidad de Antioquia, SIU-PECET-CIEMTO, Medellín, Colombia

The dimorphic fungal pathogen *Histoplasma capsulatum* (*Hc*) causes respiratory and systemic diseases. The generation of a protective immune response to the pathogenic fungus *Hc* is critically dependent on the interaction between antigen-reactive T cells and macrophages. Recently, new findings are available about the proteome and secretome of this fungus. Nevertheless, there is a huge gap in knowledge regarding interactions between constituent molecules of the fungus and the host during infection. Therefore, the evaluation of new immunological interfaces will serve us to deepen in the pathogenesis of Histoplasmosis, and then propose possible molecular targets for vaccine or diagnostic tests. Approaches based on bioinformatics tools have contributed to know more about the immunogenicity generated by CD8T cells, optimizing and directing experimental efforts to elucidate the problem. According to the principles of reverse vaccinology, we propose a pipeline that involves: i) search for molecular patterns from immunogenic/antigenic proteins experimentally proven; ii) find the patterns on the complete set of annotated proteins to find unique epitopes; iii) identify whether the proteins are secreted and predict the feasibility of being recognized by CD8T cells. Beta-lactamase, aryl-alcohol-dehydrogenase and GARP complex component are potential new targets in *Hc* related with the adaptive immune response. Functionalities such as the union to penicillin, catalysis of aromatic alcohol and protein transport between Golgi, endosomal, and vacuolar compartments are associated to these targets respectively. The computational protocol was applied and a set of epitopes predicted for further experimental validation. Colciencias grant 221356933526.

Regulation of inflammasome during clinical sepsis: a PCR array study

Esquerdo, K.F.¹, Shama, N.K.¹, Brunialti, M.K.C.¹, Machado, F.R.², Silva, E.³, Rigato, O.⁴, Salomao, R.¹

¹Disciplina de Infectologia, Escola Paulista de Medicina, Hospital São Paulo, Universidade Federal de São Paulo - UNIFESP, Medicine, Sao Paulo, Brazil, ²Disciplina de Anestesiologia, Escola Paulista de Medicina, Hospital São Paulo, Universidade Federal de São Paulo - UNIFESP, Medicine, Sao Paulo, Brazil, ³Hospital Israelita Albert Einstein, Sao Paulo, Brazil, ⁴Hospital Sírio Libanês, Sao Paulo, Brazil

Sepsis is a systemic inflammatory response triggered by an infection. Nod like receptor family (NLR) is involved in this process through inflammasome oligomerization. To study the regulation of inflammasome under sepsis, we analyzed patients (survival n=19, non-survival n=8) at admission and after 7 days of follow-up (survival n=13, non-survival n=5) with healthy volunteers (n=11). In brief, mononuclear cells were separated, cDNA synthesized from isolated RNA from cells and analyzed by real time PCR array (35 genes). Genes were considered differentially modulated when the expression was higher than ± 1.5 and $p \leq 0.05$. The resulted data was processed through Ingenuity Pathway Analysis for functional analysis and interactions. The gene expression study enables us to identify alteration in 8 genes at admission and 7 genes after day 7 in survival, 16 genes at admission and 11 genes after day 7 in non-survival.

Pyroptosis, production of reactive oxygen species and synthesis of nitric oxide, and inflammatory response were activated in survival patients at D0 and D7. Furthermore, bacterial infection inhibition was found in survivals. Interestingly, similar functions were also identified in non-survivals but differences were the activation or inhibition z scores. These results highlight the activation of inflammasome during sepsis, with a different degree of modulation in survivors and non-survivors. Further validation of some genes at protein level is under process.

AS01-adjuvanted vaccine induces a transient innate immune response in humans

Smolen, K.¹, Herve, C.², Brouwer, M.¹, Taton, M.¹, Auquier, P.², Fissette, L.², Marchant, A.¹, Van Belle, P.², Burny, W.², Didierlaurent, A.², Willems, F.²
¹ULB, Institute for Medical Immunology, Gosselies, Belgium, ²GSK, Rixensart, Belgium

AS01 is an Adjuvant System containing 3-O-desacyl-4'-monophosphoryl lipid A (MPL), *Quillaja saponaria* Molina, fraction 21(QS-21) and liposome. AS01 has been selected for the clinical development of several candidate vaccines including the malaria and varicella zoster vaccine. AS01 promotes both humoral and cellular responses. Yet, little is known about the immunological mechanisms in humans by which AS01 induces effective immune responses. Given the fundamental role of the innate immune system in controlling the adaptive immune responses, we have conducted a phase II randomized, single centre, single-blind study (NCT01777295) to characterize the kinetics of the early immune response to immunization with an AS01-adjuvanted vaccine.

60 HBV-naive adults (18-45 years old) received 2 doses of Hepatitis B virus surface antigen (HbsAg) adjuvanted with AS01B (50µg MPL, 50µg QS-21) or aluminium hydroxide at days 0 and 30. All subjects received a saline placebo (baseline) 30 days prior vaccine administration. Whole blood samples were collected at defined time points (0h to 7 days) before and after placebo, dose 1 and dose 2.

Immunization with AS01B-adjuvanted vaccine leads to an early and transient inflammatory response in blood, characterized by changes in some cytokines, innate cell number and activation. Cellular variations were specifically reflected in monocyte subsets-particularly intermediate monocytes- and NK cells, indicative of the stimulation of the innate immune system. Although restricted to HbsAg and a naive population, identification of these early signatures may provide new insights into the mechanisms of AS01-adjuvanted vaccine induced protective immune response.

Analysis of CTLA-4 gene polymorphisms (-319 C/T, +49 A/G, CT60 G/A) in primary Sjögren's syndrome

Carrillo-Ballesteros, F.J.¹, Muñoz-Valle, J.F.¹, Palafox-Sánchez, C.A.¹, Valle, Y.¹, López-Villalobos, E.F.¹, Badial-Hernández, M.F.¹, Hernández-Martínez, M.A.¹, Rodríguez-Machuca, V.U.¹, Vázquez-Villamar, M.¹, Orozco-Barocio, G.², Oregon-Romero, E.¹
¹Universidad de Guadalajara, Instituto de Investigación en Ciencias Biomédicas (IICB), Guadalajara, Mexico, ²Hospital General de Occidente, SSJ., Zapopan, Mexico

Introduction: Primary Sjögren's syndrome (pSS) is an autoimmune disease affecting salivary and lacrimal glands. It is characterized by a progressive lymphocytic infiltration, mainly T cells. Cytotoxic

T-Lymphocyte Antigen 4 (CTLA-4) plays a critical role in the prevention of autoimmune pathology by a critical inhibitory role in T cell responses resulting in diminished proliferation and cytokine production. Polymorphic sites located at -319C/T, +49A/G and CT60G/A in the *CTLA-4* gene have been associated with elevated CTLA-4 serum levels (sCTLA-4) and autoimmunity.

Objective: Determine the frequency of *CTLA-4* polymorphism in pSS.

Methodology: The study included 111 Mexican mestizo patients with pSS, classified according to the American-European Consensus criteria. As control group, 122 clinically healthy subjects were included. The polymorphisms were genotyped by PCR/RFLP technique. Statistical analysis was carried out with *Pasw statistics 18* and *EmHapFre* softwares.

Results: Polymorphisms were in Hardy-Weinberg equilibrium and showed moderate linkage disequilibrium (50%, $p=0.009$). The most frequent haplotypes were: CAG(34%), CAA(26%), CGG(18%), and CGA(17%). Patients that carried CAA haplotype showed high sCTLA-4 levels, lymphocytic infiltrated and autoantibody production without statistic significance. In addition, high levels of sCTLA-4 were observed in pSS patients carriers of -319CT genotype ($p=0.018$ vs CC) and +49AA genotype ($p=0.013$ vs GG).

Conclusion: Our results suggest that *CTLA-4* polymorphisms -319 and +49 could have a role for the development of pSS. However, the low associations of sCTLA-4 with clinical parameters suggest that the potential effect of *CTLA-4* polymorphisms needs to be investigated in subsequent studies in Mexican patients in order to elucidate it.

Simple and effective tumour immunotherapy using intratumoural complete Freund's adjuvant

Fahrer, A.¹, Carroll, C.¹, Andrew, E.¹, Orange, M.², Allavena, R.³

¹The Australian National University, Research School of Biology, Acton, Australia, ²Arlesheim Klinik, Onkologie, Arlesheim, Switzerland, ³University of Queensland, School of Veterinary Science, Gatton, Australia

We demonstrate that intra-tumoural injection of Complete Freund's Adjuvant can result in a potent anti-tumour immune response. In order to test the efficacy of this treatment, we have initiated pre-clinical trials in three species: mice, dogs and horses. Efficacy has been demonstrated in a range of solid tumours, including mastocytoma, mammary tumours and melanoma. Complete tumour regressions have been observed in all three species. Evidence of systemic immune responses (regression of non-injected metastases) have also been observed. We characterise the immune cells infiltrating mouse tumours after treatment. Finally we provide case reports on the treatment of four human cancer patients; suffering from lung cancer, metastatic osteosarcoma, or breast cancer, with one patient having a partial response to treatment with intra-tumoural Complete Freund's Adjuvant.

Taken together, our data demonstrate that our treatment has major anti-tumour effects in a proportion of treated animals, and is safe for use in human cancer patients. Further trials in human cancer patients are therefore strongly warranted. Our novel treatment provides a simple and inexpensive cancer immunotherapy, applicable to a wide range of solid tumours, and of potential benefit to cancer patients around the world, including patients from developing countries.

Preclinical efficacy of Periostin short interfering RNA in pulmonary fibrosis

Hinne, J.¹, D'Alessandro-Gabazza, C.N.¹, Toda, M.¹, Yasuma, T.², Kentaro, F.³, Nishihama, K.², Kobayashi, T.³, Etsuko, H.¹, Gabazza, E.¹, Yazunori, Y.⁴

¹Mie University School of Medicine, Department of Immunology, Tsu, Japan, ²Mie University School of Medicine, Department of Diabetes and Metabolism, Tsu, Japan, ³Mie University School of Medicine, Department Pulmonary and Critical Care Medicine, Tsu, Japan, ⁴Aqua Company, Tsu, Japan

Idiopathic Pulmonary Fibrosis (IPF) is a fatal disease with a mortality rate of 3 years after diagnosis. While pathogenetic mechanisms are incompletely understood, the currently accepted paradigm proposes that injury to the alveolar epithelium is followed by a burst of pro-inflammatory and fibroproliferative mediators that invoke responses associated with normal tissue repair. Recent research in this area has focused on treatment regimen which seems to improve lung function but none has so far been found to increase survival.

Periostin which is a recently characterized matricellular protein belonging to the fasciclin 1 family has been shown to be elevated in IPF patients and in bleomycin (BLM) induced lung fibrosis.

In this study we evaluated the effect of periostin siRNA on BLM-induced lung fibrosis.

The results indicate that periostin is significantly increased on day 3 after BLM treatment and reduced on days 7 and 14 but elevated on day 21. There was increased infiltration of inflammatory cells in the scrambled siRNA treated group as compared to periostin siRNA treated group. The levels of periostin, TGF-beta 1 and collagen were significantly reduced in periostin siRNA treated group as compared to scrambled siRNA treated group. Fibrosis was also significantly reduced as measured by the Ashcroft score. The overall survival was also improved in the periostin siRNA treated group as compared to the control groups. These results show that blockade of periostin with siRNA may be an effective treatment option for the management of pulmonary fibrosis.

The involvement of IL-17A and IL-17F in chronic pulmonary mycobacterial infection

Umemura, M.¹, Fukui, M.¹, Tamura, T.², Nakae, S.³, Iwakura, Y.⁴, Matsuzaki, G.¹

¹Tropical Biosphere Research Center, University of the Ryukyus, Okinawa, Japan, ²Leprosy Research Center, National Institute of Infectious Diseases, Tokyo, Japan, ³Institute of Medical Science, University of Tokyo, Tokyo, Japan, ⁴Research Institute for Biomedical Science, Tokyo University of Science, Chiba, Japan

The interleukin (IL)-17 cytokine family is comprised of six members, namely IL-17A to IL-17F. Recent studies using cytokine- and receptor-deficient mice showed that IL-17A and IL-17F were required for responses to extracellular bacterium *K. pneumoniae* in the lungs and *C. rodentium* in the colon, respectively. However, the involvement of IL-17A and IL-17F in protective immunity was well not clearly demonstrated in mycobacterial infected lung. In this study, we analyzed role of IL-17A and IL-17F in host defense against chronically infected *M. tuberculosis* using IL-17A and IL-17F KO mice. The IL-17A KO mice showed significantly decreased survival rates compared with the wild-type (WT) mice during 250-day observation period. In

contrast, survival rate of the IL-17F KO mice were similar to that of the WT mice. Bacterial burdens of various organs of the IL-17F KO mice on the day 250 were nearly the same as that in the WT mice. In the infected lungs, the IL-17A KO mice produced less IFN- γ , TNF and IL-6 in comparison to those from the WT mice, while cytokine production of the IL-17F KO mice were similar to that of the WT mice. This result indicated that the generation of Th1 cells was impaired in the IL-17A KO mice but not in the IL-17F KO mice infected with *M. tuberculosis*. These data strongly support the notion that the lack of IL-17F neither suppress nor enhances protective immunity in the lung after mycobacterial infection.

Expression of catalytically inactive Lyn tyrosine kinase limits inflammation and autoimmune disease

Maxwell, M.¹, Kong, A.¹, Tsantikos, E.¹, Tarlinton, D.^{1,2}, Hibbs, M.¹

¹Monash University, Dept. of Immunology and Pathology, Melbourne, Australia, ²Walter & Eliza Hall Institute, Melbourne, Australia

Systemic lupus erythematosus (SLE) is characterized by circulating IgG antibodies reactive with nuclear antigens, immune complex deposition in tissues including skin, brain and kidneys with commensurate activation of the complement cascade and myeloid cell activation. Activation of the innate arm of the immune system results in the production of pro-inflammatory cytokines, exacerbating inflammation and the adaptive immune response. The combination of inflammation and antibody causes significant and widespread tissue damage. Lyn-deficient mice with their hyper-responsive B lymphocytes and myeloid cells develop autoimmunity with parallels to SLE, and require both inflammatory factors and B cells to switch the disease to a pathogenic state. To dissect whether the kinase activity of Lyn is critical for maintenance of self-tolerance, we have generated mice carrying a kinase-dead mutation of Lyn. We show that Lyn^{KD/KD} mice share many of the B cell characteristics of Lyn-deficient mice including B cell developmental defects, hyper-responsiveness and enhanced signaling, and they are autoreactive. Unlike older Lyn-deficient animals, aged Lyn^{KD/KD} mice do not develop splenomegaly or an expanded myeloid compartment, yet Lyn^{KD/KD} myeloid cells are intrinsically hyper-responsive to growth factor. Dampened inflammation is not sufficient to drive T cell activation in Lyn^{KD/KD} mice, and while the mice have circulating self-reactive IgG, the levels do not escalate with age and consequently, they have mild renal disease and markedly enhanced survival. These data demonstrate that expression of an inactive form of Lyn is sufficient to restrain development of autoimmune disease through effects on the inflammatory component of the disease.

In vitro generation of tolerogenic DCs using an inhibitor for glycogen synthase kinase 3 beta

Ha, S.-J., Yoo, S.B.

Yonsei University, Department of Biochemistry, Seoul, Korea, Republic of

Although tolerogenic dendritic cells (tolDCs) has come into the spotlight as a promising treatment for autoimmune disease and in transplantation, the optimal protocol for generating tolDCs and their clear identity have not been absolutely defined. Here, using bone marrow-derived DCs (BMDCs), we investigated the effect of various reagents such as cytokines, organic molecules, small chemicals,

and pathogen-derived factors on DCs to find out which reagent can efficiently induce tolDCs. BMDCs were stimulated with those factors and the expressions of co-stimulatory, co-inhibitory, and MHC molecules on BMDCs were observed. In addition, we investigated cytokine profiles of BMDCs by ELISA to further estimate tolerogenic potential of BMDCs. Notably, treatment of inflammatory cytokine, IFN- γ , up-regulated the expression of inhibitory molecules (PD-L1 and PD-L2) on DCs. Another interesting finding was that treatment with one of the inhibitors for glycogen synthase kinase 3 beta (GSK-3 β) slightly up-regulated PD-L1.

Moreover, upon stimulation with lipopolysaccharide (LPS), the GSK-3 β inhibitor-treated DCs showed significantly increased IL-10 production. Finally, we performed functional assay using OT-I and OT-II cells to test the abilities for antigen uptake, processing and T cell priming of induced tolDCs. Through our investigation, we could take another step for searching tolerogenic agent and establishing protocols for generating tolDCs, which can be further applied into clinical trials where immune suppression is needed.

Histamine contributes to the resistance against tick-blood-feeding during the re-infestation

Ohta, T.¹, Yoshikawa, S.¹, Ishiwata, K.², Yamaji, K.², Okayama, N.¹, Yamanishi, Y.¹, Kanuka, H.², Watanabe, N.³, Ohtsu, H.⁴, Karasuyama, H.¹

¹Tokyo Medical and Dental University, Department of Immune Regulation, Tokyo, Japan, ²Jikei University School of Medicine, Department of Tropical Medicine, Tokyo, Japan, ³Jikei University School of Medicine, Department of Allergology, Tokyo, Japan, ⁴Tohoku University, Department of Engineering, Miyagi, Japan

Ticks transmit a variety of pathogens from reservoir host to humans and animals during the tick-blood-feeding, leading to tick-borne infections such as Lyme disease. Some studies have reported that tick-infested animals acquired resistance against tick-blood-feeding and furthermore prevent transmission of pathogens from tick to animals. We previously reported that basophils infiltrate around the tick-bite-sites during the re-infestation but not primary infestation, and basophil-depletion before re-infestation can abolish the resistance against tick-blood-feeding. Moreover, adoptive transfer experiments elucidated the importance of Ig-Fc receptors on basophils for the resistance against tick-blood-feeding. These findings suggested that basophil-activation through the Ig-Fc receptors are important for the resistance against tick-blood-feeding during the re-infestation. Basophils are well known for their release inflammatory molecules such as histamine and protease from their secretory granules in response to IgE/antigen stimulation. We examined whether histamine is involved in resistance against tick-blood-feeding using histamine (*HDC*)-deficient mice. We confirmed that immune reactions such as the levels of tick antigen reactive IgE, basophil-infiltration and their-activation in tick-feeding-site were comparable between wild type and *HDC*-deficient mice during the re-infestation. However, *HDC*-deficient mice failed to develop resistance against tick-blood-feeding. These findings implied that histamine released by basophils upon IgE plus tick antigens is important for the resistance to tick-blood-feeding during the re-infestation.

Blood gene expression profiles from distinct outcomes of infection with *Leishmania infantum*

Gardinassi, L.G.¹, Rocha Garcia, G.¹, Costa Silva, V.², Costa, C.H.N.², de Miranda Santos, I.K.F.¹

¹University of Sao Paulo - Ribeirao Preto Medical School, Biochemistry and Immunology, Ribeirao Preto, Brazil, ²Federal University of Piaui / Natan Portella Tropical Diseases Institute, Teresina, Brazil

Visceral leishmaniasis (VL) can be lethal if left untreated; however, the majority of human infections with the etiological agent *Leishmania infantum*, are asymptomatic. Using Bead Chip microarray technology (Illumina), we investigated the profiles of gene expression from blood of VL patients, patients that received therapy, asymptomatic individuals and controls. Our data demonstrate that each group included in the study presents a unique transcriptional signature. By employing computational analysis based on diverse functional methods as differential gene expression, gene set enrichment analysis, weighted gene co-expression network analysis and immune cell deconvolution, our findings support that VL patients present transcriptional profiles associated to an activation of T lymphocytes via MHC class I. Of interest, VL patients also presented negative associations with transcriptional modules related to cell adhesion and chemotaxis, monocytes, neutrophils and B cells. Treated patients presented with a mixed transcriptional profile, sharing several features of untreated patients or healthy individuals. This group of study presented a positive regulation of cell cycle and proliferation of T cells, as well as transcriptional activity correlated with a modulation of cell adhesion and chemotaxis and the Notch signaling pathway. Asymptomatic and uninfected individuals present similar patterns of gene expression. Nevertheless, asymptomatic individuals present subtle particularities, such as a strong association with type I interferon response. We conclude that VL patients present dysfunctions on several compartments of the immune response and suggest that an efficient global regulation of the immune response is associated with protection to development of clinical symptoms.

A multi-color Natural Killer-cell mediated cytotoxicity detection of tumor cells using fluorescence and direct cell imaging

Sundararaman, S., Roen, D., Karulin, A., Caspell, R., Lehmann, P.

Cellular Technology Ltd, Shaker Heights, United States

The most essential role of effector immune cells such as CD8+ cells and Natural Killer (NK) cells is to identify and lyse target cells. NK Cell- and Antibody Dependent (ADCC) Cell - Cytotoxicity has traditionally been assessed by the release of radioactive Chromium from target cells following lysis. These assays are laborious and require substantial quantities of patient blood to detect minor changes in cell lysis. We have previously shown that we can achieve similar results as the Chromium Release Assay by the direct imaging of fluorescently labelled target cells and visualizing the loss of fluorescence signal upon cytolytic activity. We showed that when performed in a 96-well plate, the % of target cell lysis is inversely proportional to the number of effector cells in each well. In order to further reduce the amount of cell material required and detect the effect of NK cells on different target cell lines we have now developed a multi-color

cytotoxicity detection assay. We stained three different cancer cell lines (one of which had intact MHC receptors) with three different dyes and incubated them in the same well with Effector to Target ratios that match one cell line per well. The results obtained show that we can simultaneously detect the cytolytic effect of NK cells on three different target cell types using only a third of the effector cells as previously required. Also, the data show that control target cells with MHC receptors are not susceptible to NK killing.

Four color T- and B cell ELISPOT assays for simultaneous detection of analytes

Hanson, J., Caspell, R., Sundararaman, S., Karulin, A., Lehmann, P. Cellular Technology Ltd, Shaker Heights, United States

ELISPOT assays are a key research tool for enumerating antigen-specific T and B cells in PBMC. As both T and B cells occur in major classes, immune monitoring has to be concerned with identifying these as well. So far, ELISPOT assays have been primarily done single or double color. We report the development of four color T and B cell ELISPOT assays. We show that the four color assay has the same sensitivity for detecting individual cells secreting analytes as the respective single color assays, and that the four fluorescent colors can be discerned unambiguously, without overlap. Cells secreting any of the four analytes can therefore be identified unambiguously in an automated fashion, without the need for compensation. Cells co-expressing analytes can be identified by superimposing the individual colors. Studying B cells and T cells experimentally has permitted us to verify the accuracy of co-expression measurements. Each B cell secretes only one type of Ig class/subclass. T cells, in contrast, frequently coexpress cytokines. Serial dilution experiments showed that for T cells the numbers of co-expressors linearly decreased with the numbers of cells plated. For B cells, no coexpressors were found.

A positive control for the detection of functional CD4 T cells in human PBMC - CPI protein pool

Schiller, A., Ansari, T., Li, R., Horvath, K., Sundararaman, S., Lehmann, P. Cellular Technology Ltd, Shaker Heights, United States

Testing of PBMC for immune monitoring purposes requires verification of the functionality. This is of particular concern when the PBMC have been shipped or stored for prolonged periods of time. The CEF peptide pool has become the gold standard for testing CD8 cell functionality. A positive control for establishing CD4 cell quality, that also requires intact antigen processing and presentation functionality, is so far lacking. Protein antigens from infectious/environmental organisms have been selected that are ubiquitous. Of an initial selection of 12 antigenic systems, (Varicella, Influenza, Parainfluenza, Mumps, Cytomegalovirus, Streptococcus, Mycoplasma, Lactobacillus, Neisseria, Candida, Rubella, and Measles) three were selected because they A) elicited CD4 cells exclusively, and B) elicited recall responses in the majority of human donors. These were inactivated Cytomegalo, Parainfluenza, and Influenza virions. While individually none of the three antigens triggered recall responses in all of the donors, the pool of these three antigens did. In 100 of 100 human donors (of different demographics) tested so far, the CPI (Cytomegalo, Parainfluenza, and Influenza viruses) protein

pool triggered a positive IFN- γ recall response by CD4 cells. Therefore, the CPI protein pool is suitable as a positive control for CD4 functionality.

Direct detection of T and B memory lymphocytes reveals HCMV exposure that serum antibodies fail to identify

Caspell, R.¹, Terlutter, F.¹, Nowacki, T.², Li, R.¹, Sundararaman, S.¹, Lehmann, P.¹

¹Cellular Technology Ltd, Shaker Heights, United States,

²University hospital of Münster, Munster, Germany

It is essential to identify donors who have not been infected with HCMV in order to avoid transmission to human recipients of transfusion products or of organs. In addition, since HCMV infection has been linked to the pathogenesis of various diseases, it is important to unambiguously establish who has, and who has not been infected. In the present study, we tested the reliability of seronegativity as an indicator for the lack of HCMV exposure of human subjects. Sixty six HCMV seronegative individuals have been identified and their PBMC were tested in ELISPOT assays for the presence of HCMV-specific CD4, CD8 T - and B - memory lymphocytes. Fifty seven percent of the HCMV seronegative subjects displayed CD4 and CD8 T cell memory in addition to HCMV specific memory B cells providing three independent lines of evidence for having developed immunity to HCMV. Fifteen percent of the 66 seronegative donors possessed CD4 and CD8 memory cells to HCMV, however, in the absence of memory B cells, and 16% had CD4 memory cells in isolation. Only 12% of the seronegative donors showed neither T- nor B- cell memory to HCMV qualifying as immunologically naive to the virus. The data suggest that measurements of serum antibodies frequently fail to reveal HCMV exposure of humans, which may be better identified by direct detection of HCMV-specific memory lymphocytes.

Maximizing odds for detecting a positive T cell response by ELISPOT

Roen, D., Karulin, A., Sundararaman, S., Lehmann, P. Cellular Technology Ltd, Shaker Heights, United States

It has been a matter of debate to determine the best cut offs in ELISPOT assay analysis for the unambiguous identification of a positive T cell response. To address this issue we carried out experiments on HLA-A2-0201 positive human subjects who had been infected with HCMV. However, we selected donors whose PBMC, when tested at 100,000 cells per well and challenged with the HLA-A2-0201-restricted HCMV peptide, pp65(495-503) did not display spot counts over medium background. Increasing the number of PBMC plated per well resulted in higher positive to negative count ratio, lower relative experimental error (CV), and higher power for detecting pp65-induced positive responses without causing false positive results from HCMV negative subjects. This decrease of CV and increase in the power of the test was directly proportional to the numbers PBMC plated. We tested the PBMC for pp65 reactivity in 96 replicate wells to establish the distributional properties of these low frequency ELISPOTs. The results were analyzed using diagnostic Q-Q plots and Shapiro-Wilk normality tests which showed that the spot counts in replicate wells follow Normal distribution. We showed that parametric statistics, such as Student *t*-Test can be used and provide

induced proinflammatory signaling, monovalent or divalent targeting with either IgA, IgG, IVIg or with Fab/F(ab')₂ of anti-FcR antibodies can trigger inhibitory signals towards a whole array of cellular functions such as phagocytosis, exocytosis and TLR- or cytokine-mediated responses. At the molecular level, ITAMi is defined by weak phosphorylation of distal ITAM tyrosines, transient recruitment of Syk followed by stable recruitment of the phosphatase SHP-1. This inhibitory effect renders anergic myeloid cells despite of heterologous receptor engagement. *In vivo* ITAMi induction by antibodies or Ig prevents and treats several inflammatory disorders in mice such as nephritis or arthritis. Moreover, *ex-vivo* monovalent or divalent targeting of FcR on synovial cells from untreated rheumatoid arthritis patients reversed the spontaneous ITAMa to an ITAMi anti-inflammatory configuration. Shifting the constitutive ITAMa signals observed in patients to an ITAMi signaling could thus reverse cell activation by inducing a myeloid tolerance state, providing ground for novel treatment options in inflammatory diseases.

Recurrent herpes virus infection: treatment with dendritic cells vaccines

Leplina, O., Tyrinova, T., Starostina, N., Ostanin, A., Chernykh, E.
Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

Chronic recurrent infections caused by herpes simplex virus (HSV) types 1 and 2 are a serious medical and social challenge. Induction of an antigen-specific immune response using dendritic cell (DCs) vaccines, seems to be promising approach for the treatment of HSV infections. 29 patients (14-with labial and 15 - with genital herpes) have been enrolled in this study. DCs were generated in the presence of GM-CSF and IFN- α , loaded with recombinant viral proteins (HSV1gD or HSV2gD) and were utilized as 2 courses of vaccinations conducted during 9 months. Immunotherapy with DCs did not induce serious side effects and was accompanied by two-fold decrease in the relapses rate and increase in the length of remission during the 9 months of treatment. There was a further reduction in the frequency of relapses and a threefold increase in the duration of remissions during the subsequent 6-month follow up. The clinical effect during the treatment and subsequent 6 months follow up was noted in both labial and genital herpes and was associated with the induction of antigen specific proliferative response. Analysis of long-term results based on a survey of patients with followed up more than 24 months has shown that the beneficial effect of immunotherapy manifested as reduction in the relapse rate was maintained in 77.8% of the respondents. At this time, antigen specific proliferative response was maintained in 66.7% of patients. The data obtained suggests that dendritic cell vaccines may be a promising new approach to the treatment of recurrent herpes.

Elucidating the oncogene-driven regulatory T cell responses during melanoma tumorigenesis

Shabaneh, T.B., Steinberg, S.M., Zhang, P., Turk, M.J.
Geisel School of Medicine at Dartmouth, Lebanon, NH, United States

Regulatory T cells (Tregs) are critical mediators of tumor immune suppression. While Tregs are found in established tumors, little is

known about the kinetics and dynamics of Treg accumulation and the factors promoting it during oncogene-driven tumorigenesis. The present studies characterize Treg response kinetics and conversion dynamics during early tumor development in a model of autochthonous, tamoxifen-inducible *Braf*^{F600E} *Pten*^{-/-} melanoma. While microscopic skin dysplasia appeared 16 days following tumor induction, FoxP3⁺ Treg frequency and absolute numbers accumulated by day 26, coinciding with locally-invasive neoplasm development. *Braf*^{F600E} inhibition with PLX4720 prevented Treg accumulation, suggesting that oncogenic *Braf* controls this process. Following adoptive transfer of CD4⁺ T cells specific to TRP-1, antigen-specific FoxP3⁺ Tregs preferentially accumulated in tumor-induced skin and draining lymph nodes (dLNs), as compared to tumor-free counterparts. In contrast, depleting Tregs prior to transfer abrogated the TRP-1-specific Treg response, suggesting a predominant role for natural Tregs.

Furthermore, we observed an increase in chemokine (C-C motif) ligand 17 (Ccl17) and Ccl2 prior to the Treg influx to tumor-induced skin. Oncogenic *Braf* regulated expression of Ccl17 and Ccl2, both of which mediated Treg migration *in vitro*. We are currently investigating the putative role of Ccl17/2-Ccr4 chemotactic axis in Treg recruitment to sites of *Braf*-driven tumorigenesis *in vivo*.

Raf kinase inhibitor protein mediates intestinal epithelial cell apoptosis and promotes IBDs in humans and mice

Lin, W., Fasheng Su, Chunmei Ma, Xiaojian Wang
Zhejiang University, Institute of Immunology, Hangzhou, China

Objective: Raf kinase inhibitor protein (RKIP) appears to control cancer cell metastasis and its expression in colonic tissue is related to colonic cancer development. We sought to identify the roles of RKIP in maintaining homeostasis of gastrointestinal tract. **Design:** The expression of RKIP was determined by immunohistochemistry and western-blot analysis. RKIP knock-out (KO) and wild-type (WT) mice were administered dextran sulfate sodium (DSS) or 2, 4, 6-trinitrobenzenesulfonic acid (TNBS) to induce experimental colitis, and the mice were assessed based on colitis symptoms and biochemical approaches. The mechanism was analyzed using immunoprecipitation and pull-down experiments.

Results: The RKIP expression is positively correlated with the severity of inflammatory bowel disease (IBD). RKIP deficiency protects mice from dextran sulfate sodium (DSS) - or 2, 4, 6-trinitrobenzenesulfonic acid (TNBS)-induced colitis and accelerated recovery from colitis. RKIP deficiency inhibits DSS-induced infiltration of acute-phase immune cells and reduces production of proinflammatory cytokines and chemokines in colon. RKIP deficiency inhibits DSS- or TNBS-induced colonic epithelial barrier damage and intestinal epithelial cell (IEC) apoptosis. RKIP deficiency also inhibits TNF- α induced IEC apoptosis and colitis.

Mechanistically, RKIP enhances the induction of P53-upregulated modulator of apoptosis (PUMA) by interacting with TGF- β -activated kinase 1 (TAK1) and promoting TAK1-mediated NF- κ B activation. This is supported by the observation that TAK1 activation is positively correlated with the expression of RKIP in human clinical samples and the development of IBD. **Conclusions:** RKIP contributes to colitis development by promoting inflammation and mediating IEC apoptosis and might represent a therapeutic target of IBD.

LBP3 enhanced antitumor immune responses partly via releasing the brakes of immunosuppression in the tumor microenvironment of H22 tumor-bearing mice

Deng, X.L.^{1,2}, Hu, M.H.¹, Wang, Y.Y.¹, Ma, F.L.¹, Luo, X.², Zhou, L.²

¹*Infinitus Chinese Herbal Immunity Research Centre, Guangzhou, China,*

²*Guangzhou University of Chinese Medicine, Guangzhou, China*

Recent studies have shown that targeting of immunosuppressive cells and immune checkpoints in the tumor microenvironment is a promising approach to enhance the efficacy for cancer immunotherapy. Polysaccharide from *Lycium barbarum* LBP inhibits tumor growth in vivo at least partly via improving antitumor immunity. However, the mechanisms of how LBP mounts an effective antitumor immune response are not well understood. In the present study, the modulation of a polysaccharide fraction from LBP (LBP3) on the immune system in H22 tumor-bearing mice was investigated. The results showed that LBP3 could effectively inhibit the solid tumor growth of H22 tumor-bearing mice. Thymus indexes, the numbers/percentages of T cells in peripheral blood and tumor tissues, killing activities of natural killer (NK) cells, cytotoxic T lymphocytes (CTL) and peritoneal macrophages against H22 cells were also improved in three LBP3 treated groups. Besides, LBP3 treatment could decrease the secretion of TGF- β , IL-6, IL-2 and IL-10 levels in serum. The percentages of regulatory T cells (Tregs) in tumor-draining lymph nodes (TDLN) and tumor tissues were also significantly decreases in the all LBP3 treated groups. Furthermore, LBP3 treatment could effectively down regulate the PD-1 expression on T cells in TDLN and tumor tissues. Taken together, these findings indicate that LBP3 enhanced antitumor immune responses partly via releasing the brakes of immunosuppression in the tumor microenvironment of H22 tumor-bearing mice.

Interaction between breast cancer cells and microglia in the microenvironment of brain metastasis

Foo, S.L.^{1,2}, Lim, H.K.L.^{1,2}

¹*NUS Graduate School for Integrative Sciences and Engineering, National University of Singapore, Singapore, Singapore,* ²*Inflammation and Cancer Laboratory, Immunology Programme, Yong Loo Lin School of Medicine, National University of Singapore, Physiology, Singapore, Singapore*

The occurrence of breast cancer metastases is preferential to certain organs, and one of it being the brain. As the brain microenvironment is continuously monitored by microglia- a major component of the brain immune system, invasion of metastatic breast cancer cells to the brain should stimulate an immune response in the microglial cells. In this study, we use an in vitro model comprising of microglia and metastatic breast cancer cell lines to investigate microglial reactions to metastatic breast cancer cells, particularly in modulating tumour cell proliferation, cell invasion, immune suppression, and microenvironment modification. In contrast to macrophages, co-cultures and insert-cultures of microglia and breast cancer cells demonstrated that microglia are activated by tumor cell-oriented factors, resulting in priming or sensitization of microglia to adopt an M1 (pro-inflammatory), rather than M2 (anti-inflammatory) phenotype. It is also observed that there are chemoattractant factors secreted by breast cancer cells that induced a significant chemotactic

activity for microglial cells in vitro, and the recruited microglia have further been found to reduce cancer cells growth. The findings of the metastasis-antagonizing role of microglia suggest that there are possibly differences between tumour associated peripheral macrophages and brain intrinsic microglia in terms of their responses towards breast cancer cells and that differences may also exist in microglial reactions toward primary breast cancer cells as compared to cancer cells that have metastasized to the brain. Therefore, it would be of interest to investigate the functional aspects of microglia in invasion, dormancy, and relapse of brain metastatic breast cancer.

Correlation between the metabolome and binder of ST2 receptor in chronic periodontics in elderly

Introduction: High relationship of senescence with the emergence and/or compromise of disease in oral cavity is a triggering factor of disease in this age group including chronic periodontal disease (CPD). Some markers have been associated with disease prognosis, as well as systemic diseases, such as ST2 binder.

Objectives: Evaluate the correlation between metabolites and ST2 receptor binder in crevicular fluid in the elderly. **Methods:** All procedures were approved by the Ethics Committee in Research of the Federal University of Triangulo Mineiro, under number: 017430/2014. Twenty individuals were selected after applying the inclusion and exclusion criteria. They were divided into 2 groups, CPD (N = 10 - Clinical evaluation + probing depth higher or equal to 3 mm, and at least presence of marginal bleeding at a site) without disease - Control (n = 10). To the assessment of metabolites was performed the metabolome (triplicate - GC/MS Agilent -7890B GC; 5977A MS). The ELISA was performed for the detection and quantification of IL-33 (R&D Systems). The Prism software was used for statistical evaluation.

Results: Were identified 969 metabolites, of which 64 were selected to analyze. After analysis 5 metabolic (2,3 dihydroxypropyl icosanoate, glycerol, serine, 5-aminovaleric acid e putrescine) obtained a ratio CPD/Control greater than 2. The elevation was accompanied of increase of the ST2-binder, where was found a positive correlation.

Conclusion/discussion: The data point to a relationship of metabolic activity inducible IL-33/ST2 in CPD in the elderly.

T-bet expressing B cells are required for the development of autoimmunity

Kira Rubtsova^{1,2}, Anatoly V. Rubtsov^{1,2}, John W. Kappler^{1,2,3,5} and Philippa Marrack^{1,2,4,5}

⁴ Department of Pharmacology, University of Colorado School of Medicine, Aurora, CO 80045, USA.

⁵ Department of Medicine, University of Colorado School of Medicine, Aurora, CO 80045, USA.

⁶ Department of Biochemistry and Molecular Genetics, University of Colorado Health Sciences Center, Aurora, CO 80045, USA.

Autoimmune diseases are common, affecting about 8% of the population of the USA. Since there is no cure for autoimmunity, it is extremely important to study the mechanisms that trigger these diseases. The majority of autoimmune diseases affect predominantly females more than males, indicating a strong gender bias.

We have recently identified a subset of B cells that accumulates in aged female mice and can be characterized by the expression of CD11c and the transcription factor, T-bet. A related subset is found in autoimmune mice, appearing at the onset of the disease. T-bet⁺ B cells obtained from autoimmune mice produce high levels of auto-antibodies upon stimulation. Expression of T-bet in B cells is necessary and sufficient for the appearance of these cells.

These data led us to hypothesize that T-bet expressing B cells are major precursors of autoantibody producing B cells during the autoimmune response. Therefore ablation of this subset should lead to the ablation of or significant delay in the onset of autoimmunity. In this study we explored the role of T-bet expressing B cells in the appearance of autoantibodies in SLE1,2,3 mice, a model of lupus. We have generated mice that lack

T-bet expression only in B cells by crossing (SLE1,2,3 x T-bet^{fllox/fllox} x CD19^{CRE}) animals. We followed the appearance of autoantibodies in these mice, comparing them to (SLE1,2,3 x T-bet^{fllox/fllox}) littermate controls. Our data indicate that kidney function and survival is significantly improved in (SLE1,2,3 x T-bet^{fllox/fllox} x CD19^{CRE}) mice. At the same time the titers of autoantibodies were dramatically decreased in the (SLE1,2,3 x T-bet^{fllox/fllox} x CD19^{CRE}) mice when compared to littermate controls. Analysis of the T and B cell compartments revealed a reduction of germinal center B cells, pre-plasmablasts, activated/memory T cells and IFN γ producing T cells. These data indicate that T-bet expression in B cells plays an important role during the onset of lupus-like

autoimmunity. Moreover, T-bet expression in B cells was not required for the development of germinal centers and production of antibodies in response to vaccination, suggesting that T-bet in B cells can serve as a novel target for the treatment of autoimmunity without dramatic impact on the other aspects of immune system.

In conclusion our data suggest that T-bet expression in B cells is required for the generation of autoimmune responses, appearance of pathogenic autoantibodies and destruction of kidney function. Therefore conditional deletion of T-bet from B cells leads to the overall improvement in autoimmune-prone mice.

A high throughput method to characterize monoclonal antibodies and select native antigen specific IgG hybridoma cells

Haolin Liu¹, Janice White¹, Frances Crawford^{1,2}, Gongyi Zhang¹, Philippa Marrack^{1,2} and John W. Kappler^{1,2}

¹ Department of Biomedical Research, National Jewish Health, Denver, CO 80206 and

² Howard Hughes Medical Institute

B cell hybridomas are an important source of monoclonal antibodies. However, the traditional method of using antigen-coated ELISA plate to detect antibody secretion and using limiting dilution to select hybridoma cells is time and labor consuming. Moreover, antigen coated ELISA can't distinguish antibodies against the native and denatured antigen. To solve these problems, we developed a high throughput method to characterize mouse IgG antibodies using Surface Plasmon Resonance (SPR) technology. This assay rapidly determines their sub-isotypes, whether they bind native antigen and their approximate affinities for the antigen with only microliters of hybridoma cell culture supernatant. It could be used to find out pairs of antibodies that can be used as coating and detecting antibodies for commercial ELISA kit and blocking antibodies of virus entry into host. Meanwhile, we found that mouse hybridomas secreting IgG antibodies also have membrane form IgG expression. Based on this surface IgG, we isolated rare γ 2a isotype switched variants from a γ 2b antibody secreting hybridoma cell line. We also used fluorescent antigen to single cell sort native antigen binding hybridoma cells from bulk fusion mixture thus saving time and labor.
